Address Offset	0x0000 0980		
Physical Address	0x4844 A980	**Instance**	IODELAYCONFIG
Description	Delay Select Value in binary coded form for cfg_vin1a_d21_out interface		
Type	RW		

31:18	17:12	11	10	9:0
RESERVED	SIGNATURE	RESERVED	LOCK_BIT	BINARY_DELAY

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0
17:12	SIGNATURE	Write to this register will succeed only if data on these bits carries a signature of 6'h29 (6'b101001)	RW	0x0
11	RESERVED		R	0x0
10	LOCK_BIT	When '1', prevents HW update to this MMR. When '0', allows HW update of this MMR.	RW	0x0
9:0	BINARY_DELAY	Delay Select Value in binary coded form. Indicates the number of coarse (9:5) and fine (4:0) delay elements to be used on the delay line connected to this pad.	RW	0x0

Description	Delay Select Value in binary coded form for cfg_vin2a_d5_in interface		
Type	RW		

31:18	17:12	11	10	9:0
RESERVED	SIGNATURE	RESERVED	LOCK_BIT	BINARY_DELAY

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0
17:12	SIGNATURE	Write to this register will succeed only if data on these bits carries a signature of 6'h29 (6'b101001)	RW	0x0
11	RESERVED		R	0x0
10	LOCK_BIT	When '1', prevents HW update to this MMR. When '0', allows HW update of this MMR.	RW	0x0
9:0	BINARY_DELAY	Delay Select Value in binary coded form. Indicates the number of coarse (9:5) and fine (4:0) delay elements to be used on the delay line connected to this pad.	RW	0x0

Chapter 19
Mailbox

This chapter describes the mailbox module in the device.

19.1 Mailbox Overview........ 5107
19.2 Mailbox Integration........ 5107
19.3 Mailbox Functional Description........ 5115
19.4 Mailbox Programming Guide........ 5121
19.5 Mailbox Register Manual........ 5124

19.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

The device implements the following mailbox types:

- System mailbox:
  - Number of instances: 13
  - Used for communication between: MPU, DSP1, DSP2, IPU1, and IPU2 subsystems
  - Reference name: MAILBOX(1..13)
- IVA mailbox:
  - Number of instances: 1
  - Used for communication between: IVA local user (ICONT1, or ICONT2) and three external users (selected among MPU, DSP1, DSP2, IPU1, and IPU2 subsystems)
  - Reference name: IVA_MBOX
- EVEx mailbox (where x = 1, 2):
  - Number of instances: 3 (per EVE)
  - Used for communication between:
    - EVEx local user (ARP32) and three external users (selected among MPU, DSP1, DSP2, IPU1, and IPU2) - EVEx_MBOX0 and EVEx_MBOX1 are dedicated for this communication
    - EVE1 and EVE2 local users - EVEx_MBOX2 is dedicated for this communication
  - Reference name: EVEx_MBOX(0..2)

Each mailbox module supports the following features:

- Parameters configurable at design time (see Table 19-1):
  - Number of users
  - Number of mailbox message queues
  - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

Table 19-1 shows the configuartion of the mailbox modules in the device.

Table 19-1. Mailbox Configuration in the Device

<table>
<tr><th rowspan="3">Module Parameters</th><th colspan="4">Mailbox Type</th></tr>

<tr><td>Number of users</td><td>3</td><td>4</td><td>4</td><td>4</td></tr>
<tr><td>Number of mailbox message queues</td><td>8</td><td>12</td><td>6</td><td>16</td></tr>
<tr><td>Number of messages (FIFO depth) for each message queue</td><td colspan="2">4</td><td>4</td><td>4</td></tr>
</table>

19.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

19.2.1 System MAILBOX Integration

The integration of MAILBOX1 in the device differs from the integration of the rest of the system mailboxes (MAILBOX2..13). Figure 19-1 and Figure 19-2 show the MAILBOX1 and MAILBOX2..13 integration, respectively.

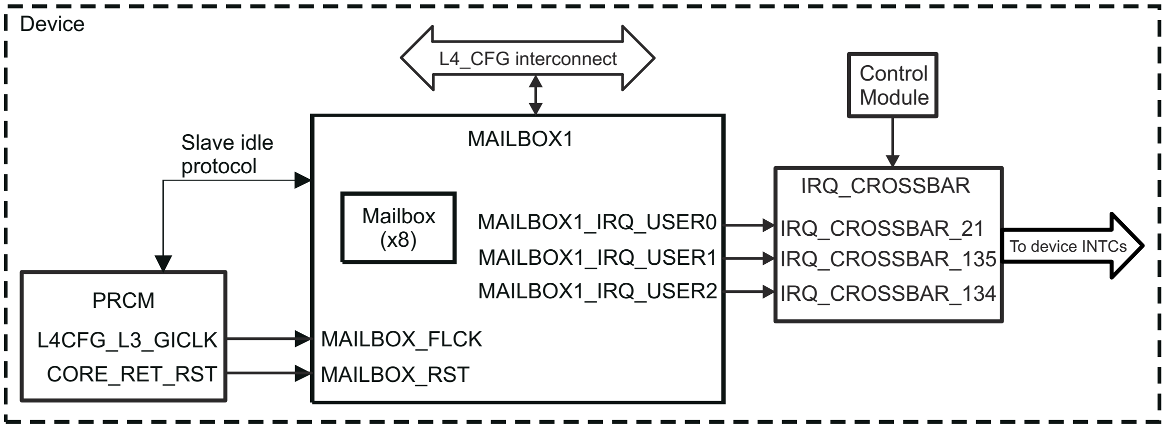

Figure 19-1. MAILBOX1 Integration

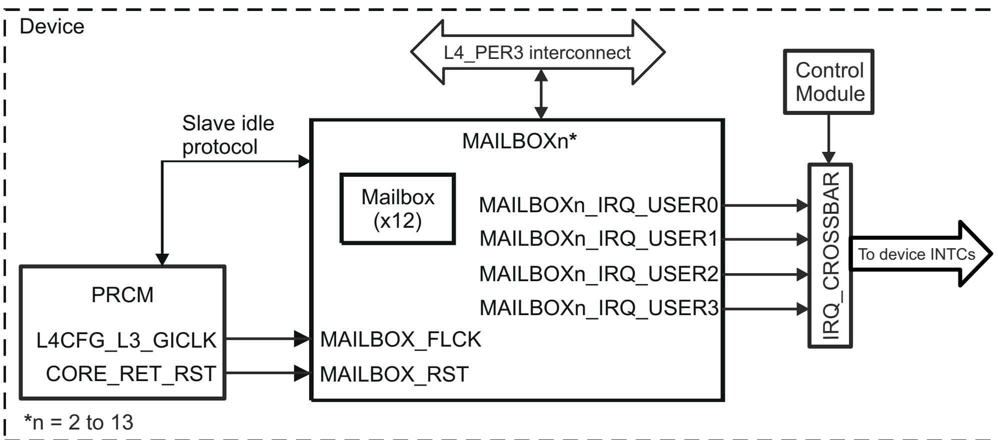

Figure 19-2. MAILBOX2..13 Integration

Note

For more information about the Slave idle protocol, see *Module-Level Clock Management* in *Power, Reset, and Clock Management*.

Table 19-2 through Table 19-4 summarize the MAILBOX(1..13) integration in the device.

Table 19-2. MAILBOX Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
MAILBOX1	PD_COREAON	N/A	L4_CFG
MAILBOX2..13	PD_COREAON	N/A	L4_PER3

Table 19-3. MAILBOX Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

Table 19-3. MAILBOX Clocks and Resets (continued)

MAILBOX	MAILBOX_FCLK	L4CFG_L3_GICLK	PRCM	MAILBOX interface clock. This clock is used for all interface and functional operations.

Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
MAILBOX	MAILBOX_RST	CORE_RET_RST	PRCM	MAILBOX hardware reset. This reset is asynchronously applied to the MAILBOX registers.

Table 19-4. MAILBOX Hardware Requests

Interrupt Requests

Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
MAILBOX1	MAILBOX1_IRQ_USER0	IRQ_CROSSBAR_21	MPU_IRQ_26; DSP1_IRQ_52; DSP2_IRQ_52;	MAILBOX1 user 0 interrupt request.
	MAILBOX1_IRQ_USER1	IRQ_CROSSBAR_135	–	MAILBOX1 user 1 interrupt request.
	MAILBOX1_IRQ_USER2	IRQ_CROSSBAR_134	IPU1_IRQ_50; IPU2_IRQ_50;	MAILBOX1 user 2 interrupt request.
MAILBOX2	MAILBOX2_IRQ_USER0	IRQ_CROSSBAR_237	–	MAILBOX2 user 0 interrupt request.
	MAILBOX2_IRQ_USER1	IRQ_CROSSBAR_238	–	MAILBOX2 user 1 interrupt request.
	MAILBOX2_IRQ_USER2	IRQ_CROSSBAR_239	–	MAILBOX2 user 2 interrupt request.
	MAILBOX2_IRQ_USER3	IRQ_CROSSBAR_240	–	MAILBOX2 user 3 interrupt request.
MAILBOX3	MAILBOX3_IRQ_USER0	IRQ_CROSSBAR_241	–	MAILBOX3 user 0 interrupt request.
	MAILBOX3_IRQ_USER1	IRQ_CROSSBAR_242	–	MAILBOX3 user 1 interrupt request.
	MAILBOX3_IRQ_USER2	IRQ_CROSSBAR_243	–	MAILBOX3 user 2 interrupt request.
	MAILBOX3_IRQ_USER3	IRQ_CROSSBAR_244	–	MAILBOX3 user 3 interrupt request.
MAILBOX4	MAILBOX4_IRQ_USER0	IRQ_CROSSBAR_245	–	MAILBOX4 user 0 interrupt request.
	MAILBOX4_IRQ_USER1	IRQ_CROSSBAR_246	–	MAILBOX4 user 1 interrupt request.
	MAILBOX4_IRQ_USER2	IRQ_CROSSBAR_247	–	MAILBOX4 user 2 interrupt request.
	MAILBOX4_IRQ_USER3	IRQ_CROSSBAR_248	–	MAILBOX4 user 3 interrupt request.
MAILBOX5	MAILBOX5_IRQ_USER0	IRQ_CROSSBAR_249	–	MAILBOX5 user 0 interrupt request.
	MAILBOX5_IRQ_USER1	IRQ_CROSSBAR_250	–	MAILBOX5 user 1 interrupt request.
	MAILBOX5_IRQ_USER2	IRQ_CROSSBAR_251	–	MAILBOX5 user 2 interrupt request.

	MAILBOX13_IRQ_USER1	IRQ_CROSSBAR_380	–	MAILBOX13 user 1 interrupt request.
	MAILBOX13_IRQ_USER2	IRQ_CROSSBAR_381	–	MAILBOX13 user 2 interrupt request.
	MAILBOX13_IRQ_USER3	IRQ_CROSSBAR_382	–	MAILBOX13 user 3 interrupt request.
		No DMA Requests		

Note

The "**Default Mapping**" column in Table 19-4, Table 19-7 , and Table 19-10 shows the default mapping of module interrupts. These interrupts can also be mapped to other input lines of each device interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For information about interrupt source description, see *Mailbox Interrupt Requests*.

19.2.2 IVA Mailbox Integration

Figure 19-3 shows the IVA mailbox integration.

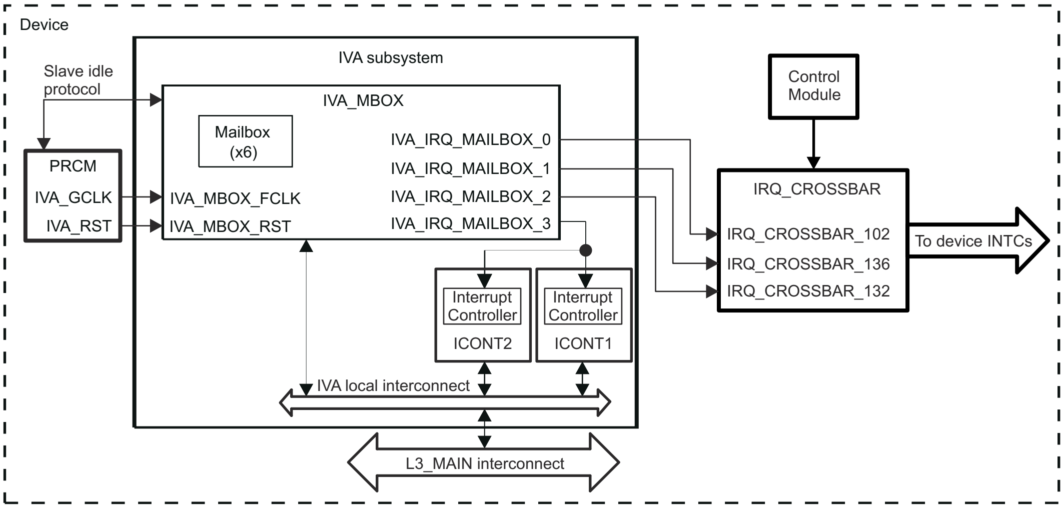

Figure 19-3. IVA Mailbox Integration

Note

The IVA_IRQ_MAILBOX_3 interrupt is mapped on both ICONT1 and ICONT2 interrupt controllers. It is recommended that this interrupt is unmasked at only one one interrupt controller at a time. For more information, see *IVA Imaging Controller*.

Table 19-5 through Table 19-7 summarize the IVA_MBOX integration in the device.

Table 19-5. IVA_MBOX Integration Attributes

	EVE2_IRQ_MBX1_USER3	IRQ_CROSSBAR_298	–	EVE2_MBOX1 user 3 interrupt request.
EVE2_MBOX2	EVE2_IRQ_MBX2_USER0	–	EVE2_IRQ_28	EVE2_MBOX2 user 0 interrupt request.
	EVE2_IRQ_MBX2_USER1	–	EVE1_IRQ_17	EVE2_MBOX2 user 1 interrupt request.
	EVE2_IRQ_MBX2_USER2	–	Not connected	EVE2_MBOX2 user 2 interrupt request.
	EVE2_IRQ_MBX2_USER3	–	Not connected	EVE2_MBOX2 user 3 interrupt request.
		No DMA Requests		

19.3 Mailbox Functional Description

Note

The functionality of all mailbox instances in the device is the same and is described in this section.

Note

In this chapter, *u* is the user number and *m* is the mailbox number as follows:

- For MAILBOX1: *u* = 0 to 2 and *m* = 0 to 7;
- For MAILBOX2..13: *u* = 0 to 3 and *m* = 0 to 11;
- For IVA_MBOX: *u* = 0 to 3 and *m* = 0 to 5;
- For EVEx_MBOX: *u* = 0 to 3 and *m* = 0 to 15;

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQENABLE_SET_u (or MAILBOX_IRQENABLE_CLR_u) register.

Table 19-11 shows the potential users of the mailbox modules in the device.

Table 19-11. Mailbox Users in the Device

<table>
<tr><th colspan="3" rowspan="2">Mailbox Type</th><th colspan="4">Users</th></tr>
<tr><th>User 0</th><th>User 1</th><th>User 2</th><th>User 3</th></tr>
<tr><td rowspan="2">System Mailbox</td><td colspan="2">MAILBOX1</td><td colspan="3">Any of: MPU, DSP1, DSP2, IPU1, IPU2</td><td>–</td></tr>
<tr><td colspan="2">MAILBOX2..13</td><td colspan="4">Any of: MPU, DSP1, DSP2, IPU1, IPU2</td></tr>
<tr><td colspan="3">IVA Mailbox</td><td colspan="3">Any of: MPU, DSP1, DSP2, IPU1, IPU2</td><td>IVA local - ICONT, or ICONT2</td></tr>
<tr><td rowspan="3">EVEx Mailbox</td><td colspan="2">EVEx_MBOX0, EVEx_MBOX1</td><td>TBD</td><td colspan="3">Any of: MPU, DSP1, DSP2, IPU1, IPU2</td></tr>
<tr><td rowspan="2">EVEx_ MBOX2</td><td>EVE1_MBOX2</td><td>ARP32 of EVE1</td><td>ARP32 of EVE2</td><td colspan="2">–</td></tr>
<tr><td>EVE2_MBOX2</td><td>ARP32 of EVE2</td><td>ARP32 of EVE1</td><td colspan="2">–</td></tr>
</table>

Note

It is software responsibility to select a user by mapping (via IRQ_CROSSBAR) the corresponding mailbox interrupt to the interrupt controller of the appropriate processor subsystem.

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.
Each MAILBOX_IRQSTATUS_RAW_u/MAILBOX_IRQSTATUS_CLR_u interrupt status register corresponds to a particular user.

19.3.1 Mailbox Block Diagram

19.3.1.1

Figure 19-6 shows the mailbox block diagram.

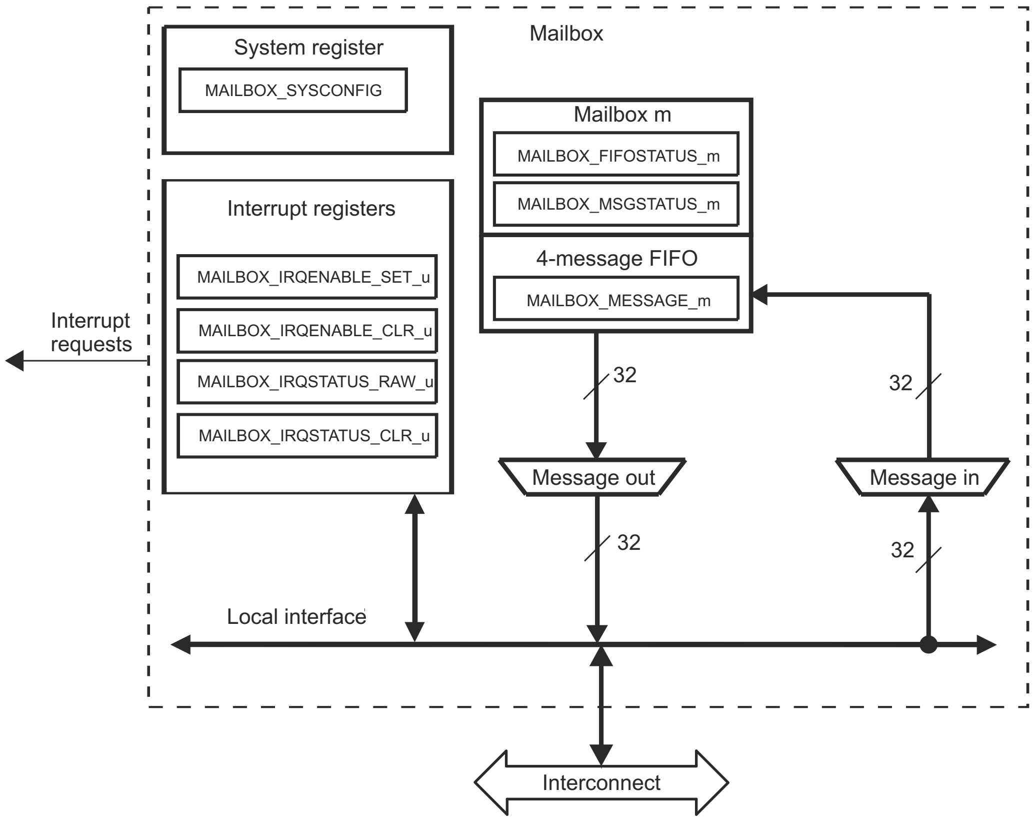

Figure 19-6. Mailbox Block Diagram

19.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

19.3.3 Mailbox Power Management

Table 19-12 describes power-management features available for the mailbox module.

Table 19-12. Local Power Management Features

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

The mailbox module can be configured using the MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

19.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

Table 19-13 lists the event flags, and their mask, that can cause module interrupts.

Table 19-13. Interrupt Events

Non-Maskable Event Flag[(1)]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[0+m*2] NEWMSGSTATUSUUMBm	Mailbox *m* receives a new message.
MAILBOX_IRQSTATUS_RAW_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[1+m*2] NOTFULLSTATUSUUMBm	Mailbox *m* message queue is not full.

(1) MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

> **CAUTION**
>
> Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQSTATUS_CLR_u register.
>
> Writing a logical 1 in a bit of the MAILBOX_IRQSTATUS_CLR_u register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQENABLE_SET_u register. Events are reported in the appropriate MAILBOX_IRQSTATUS_CLR_u and MAILBOX_IRQSTATUS_RAW_u registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQENABLE_CLR_u register. Events are only reported in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

In case of the MAILBOX_IRQSTATUS_RAW_u register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

19.3.5 Mailbox Assignment

19.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQENABLE_SET_u register. The receiver reads the MAILBOX_MESSAGE_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFOSTATUS_m and/or MAILBOX_MSGSTATUS_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQENABLE_SET_u register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFOSTATUS_m or MAILBOX_MSGSTATUS_m registers
- Write the message to the corresponding MAILBOX_MESSAGE_m register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQENABLE_SET_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQSTATUS_CLR_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQSTATUS_CLR_u register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

19.3.6 Sending and Receiving Messages

19.3.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the MAILBOX_FIFOSTATUS_m register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX_MESSAGE_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_m register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSGSTATUS_m register.

19.3.7 16-Bit Register Access

19.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the MAILBOX_MESSAGE_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX_MESSAGE_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

When using 16-bit accesses to the MAILBOX_MESSAGE_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the MAILBOX_MSGSTATUS_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX_MESSAGE_m are accessed.

19.3.8 Example of Communication

Figure 19-7 shows an example of communication between MPU and DSP1 subsystems.

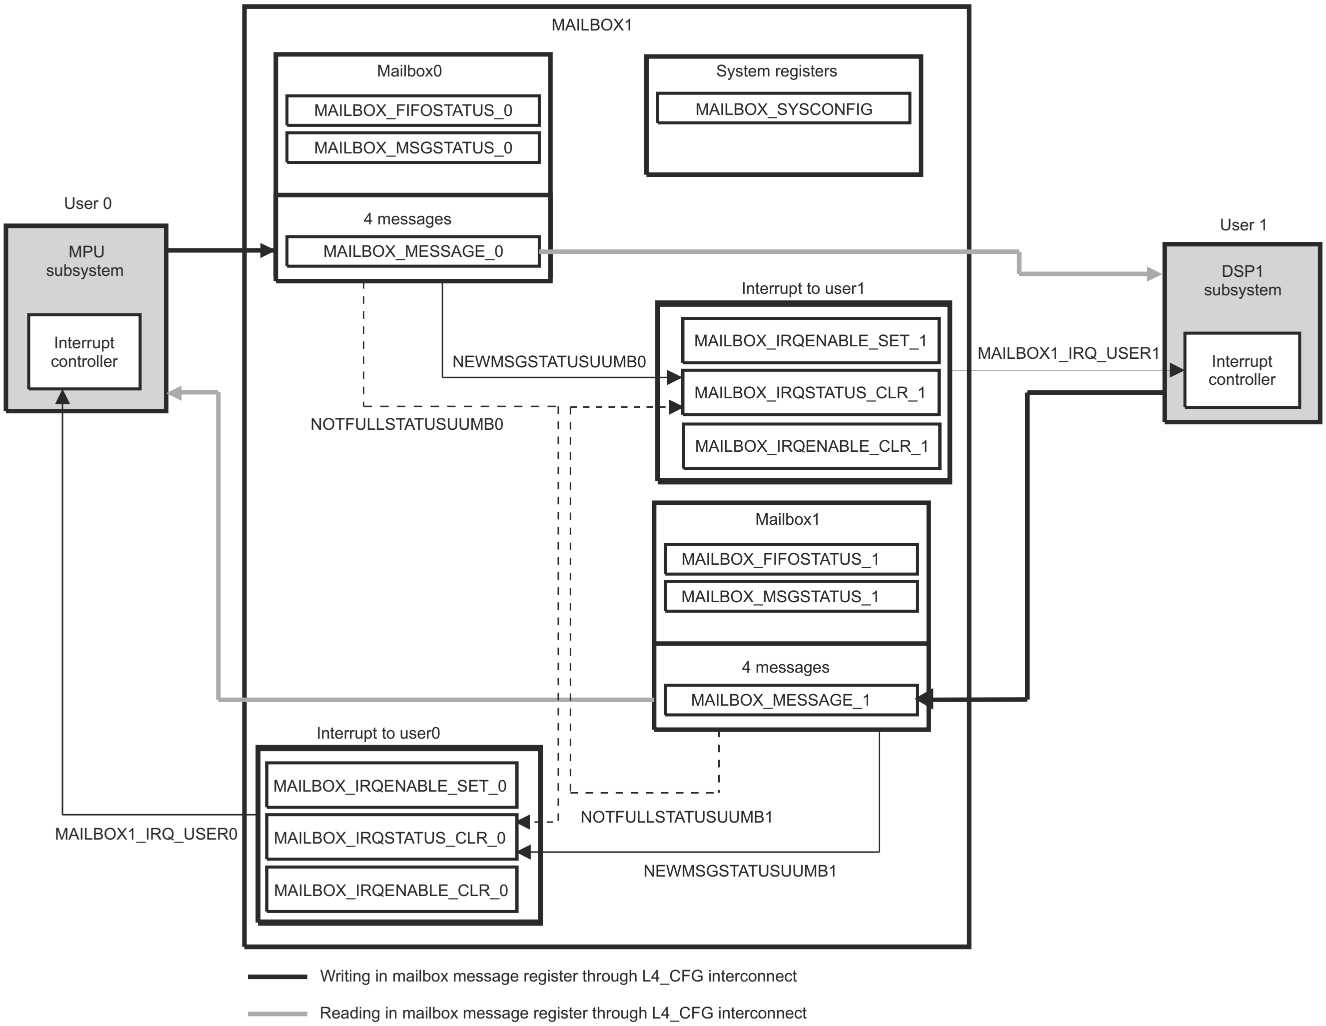

Figure 19-7. Example of Communication

19.4 Mailbox Programming Guide

19.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

19.4.1.1 Global Initialization

19.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See Section 19.2, *Mailbox Integration*, for further information.

Table 19-14. Global Initialization of Surrounding Modules for MAILBOX

Surrounding Modules	Comments
PRCM	MAILBOX functional/interface clock must be enabled.
Interrupt Controllers	MPU, or IPU1, or IPU2, or DSP1, or DSP2 interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

Table 19-15. Global Initialization of Surrounding Modules for IVA_MBOX

Surrounding Modules	Comments
PRCM	IVA_MBOX functional/interface clock must be enabled.
Interrupt Controllers	MPU, or IPU1, or IPU2, or DSP1, or DSP2, or IVA ICONT1/ICONT2 interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

Table 19-16. Global Initialization of Surrounding Modules for EVEx_MBOX

Surrounding Modules	Comments
PRCM	EVEx_MBOX functional/interface clock must be enabled.
Interrupt Controllers	MPU, or IPU1, or IPU2, or DSP1, or DSP2, or EVE interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

19.4.1.1.2 Mailbox Global Initialization

19.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 19-17. Mailbox Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG[0] SOFTRESET	= 0x0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2] SIDLEMODE	0x-

19.4.1.2 Mailbox Operational Modes Configuration

19.4.1.2.1 Mailbox Processing modes

19.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

Table 19-18. Sending a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x0
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

19.4.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

Table 19-19. Sending a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 19.4.1.3.1 for interrupt handling in sending mode		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

19.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

Table 19-20. Receiving a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

19.4.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

Table 19-21. Receiving a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 19.4.1.3.2 for interrupt handling in receiving mode		

19.4.1.3 Mailbox Events Servicing

19.4.1.3.1 Events Servicing in Sending Mode

Table 19-22 describes the events servicing in sending mode.

Table 19-22. Events Servicing in Sending Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1

Table 19-22. Events Servicing in Sending Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1

19.4.1.3.2 Events Servicing in Receiving Mode

Table 19-23 describes the events servicing in receiving mode.

Table 19-23. Events Servicing in Receiving Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0

Chapter 20

Memory Management Units

This chapter describes the memory management units (MMUs) in the device.

20.1 MMU Overview 5148
20.2 MMU Integration 5151
20.3 MMU Functional Description 5153
20.4 MMU Low-level Programming Models 5165
20.5 MMU Register Manual 5168

20.1 MMU Overview

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit, DMA controller, or other bus requestor. MMU functions include:

- Translation of initiator internal (virtual) addresses to physical addresses (that is, virtual memory management)
- Preventing an initiator from making accesses to unmapped pages of the system memory

This device includes the following MMUs:

- Two top-level (system) MMUs:
  - MMU1 dedicated to EDMA Transfer Controller 0 (TC0), and EDMA Transfer Controller 1 (TC1)
  - MMU2 dedicated to PCIe_SS1, and PCIeSS2
- One MMU inside the MPU (dual Cortex®-A15) subsystem – MPU_MMU. This MMU is integrated in the Cortex-A15 processor.
- Two MMUs inside each of the DSP1, and DSP2 subsystems:
  - DSP1 subsystem: DSP1_MMU0, and DSP1_MMU1
  - DSP2 subsystem: DSP2_MMU0, and DSP2_MMU1
- Two MMUs inside each of the EVE1, and EVE2 subsystems:
  - EVE1 subsystem: EVE1_MMU0, and EVE1_MMU1
  - EVE2 subsystem: EVE2_MMU0, and EVE2_MMU1
- Two MMUs inside each of the IPU1, and IPU2 subsystems:
  - L1 unicache MMU – IPU1_UNICACHE_MMU, and IPU2_UNICACHE_MMU
  - L2 MMU – IPU1_MMU, and IPU2_MMU
- One MMU inside the 3D GPU (dual SGX544 core) subsystem
- One MMU inside the BB2D subsystem

Note

There is a Physical Address Translator (PAT) module in the Dynamic Memory Manager (DMM), which has similar to the MMU functionality. For more information about this module, see Section 15.2, *Dynamic Memory Manager*.

Note

This chapter provides a detailed description of the following MMUs:

- System MMUs
- DSP MMUs
- EVE MMUs
- IPU L2 MMU

System MMUs, DSP MMUs and EVE MMUs are fully identical from functional perspective. IPU L2 MMU is different in that it does not support “bypass” functionality.

For more information about:

- Cortex-A15 MMU, see the Arm® *Cortex®-A15 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).
- IPU unicache MMU, see Chapter 7, *Dual Cortex-M4 IPU Subsystem*.

Figure 20-1 and Figure 20-2 show an overview of system MMU1 and MMU2, respectively. In summary, requests initiated by a given requestor (EDMA TC0 and TC1 [both read and write ports] for system MMU1; PCIe_SS1 and PCIe_SS2 for system MMU2) can optionally be routed through the corresponding system MMU. Each requestor’s use (or not) of the MMU is independently controllable via the Control Module CTRL_CORE_SMA_SW_7 register bitfields. It is recommended that this register is set during system initialization and remain static.

If the MMU loopback path is enabled for a given requestor, requests will be routed via the L3_MAIN interconnect to the MMU and will again go through the L3 interconnect to the requested physical address. If the MMU loopback path is disabled for a given requestor, those bus requests go directly through the L3_MAIN interconnect to the requested physical address, thus minimizing bus request latency.

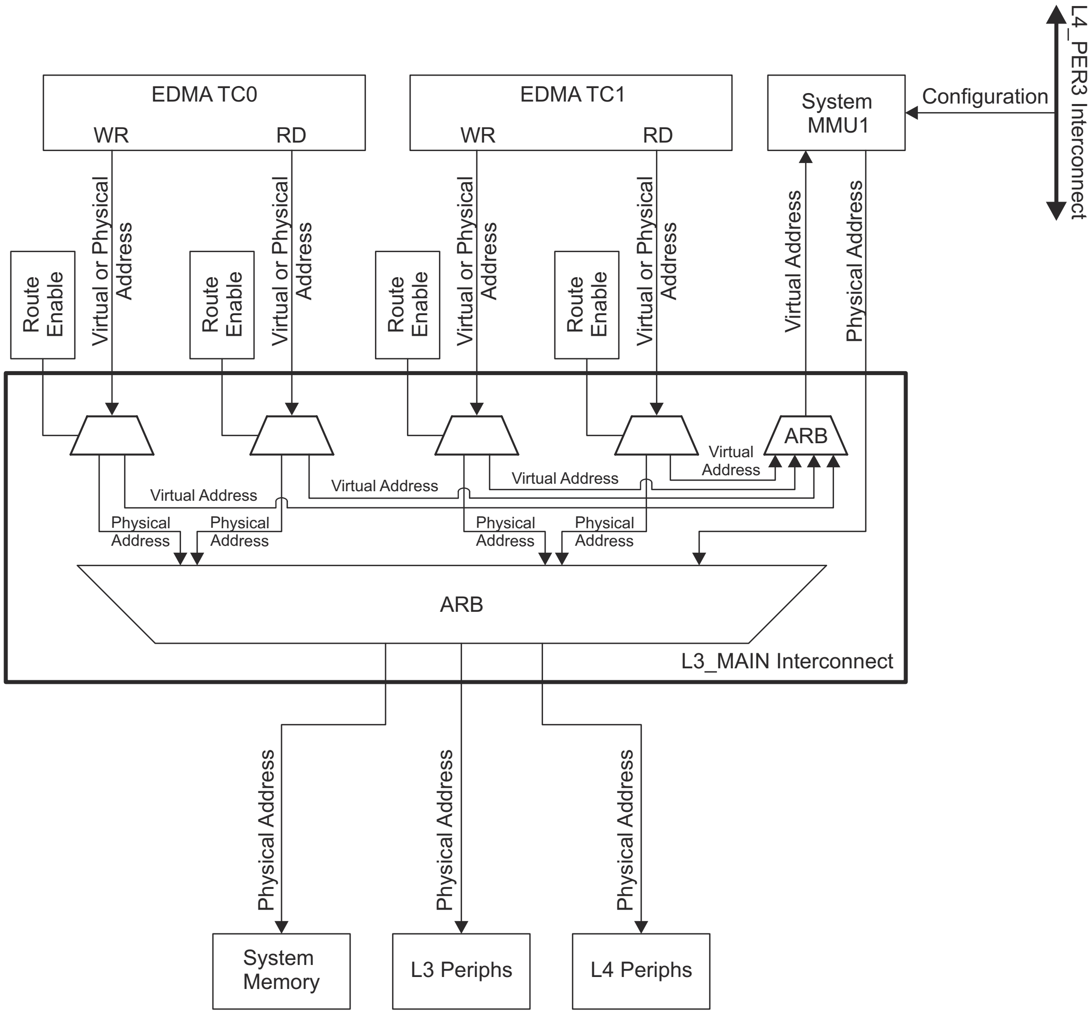

Figure 20-1. System MMU1 Overview

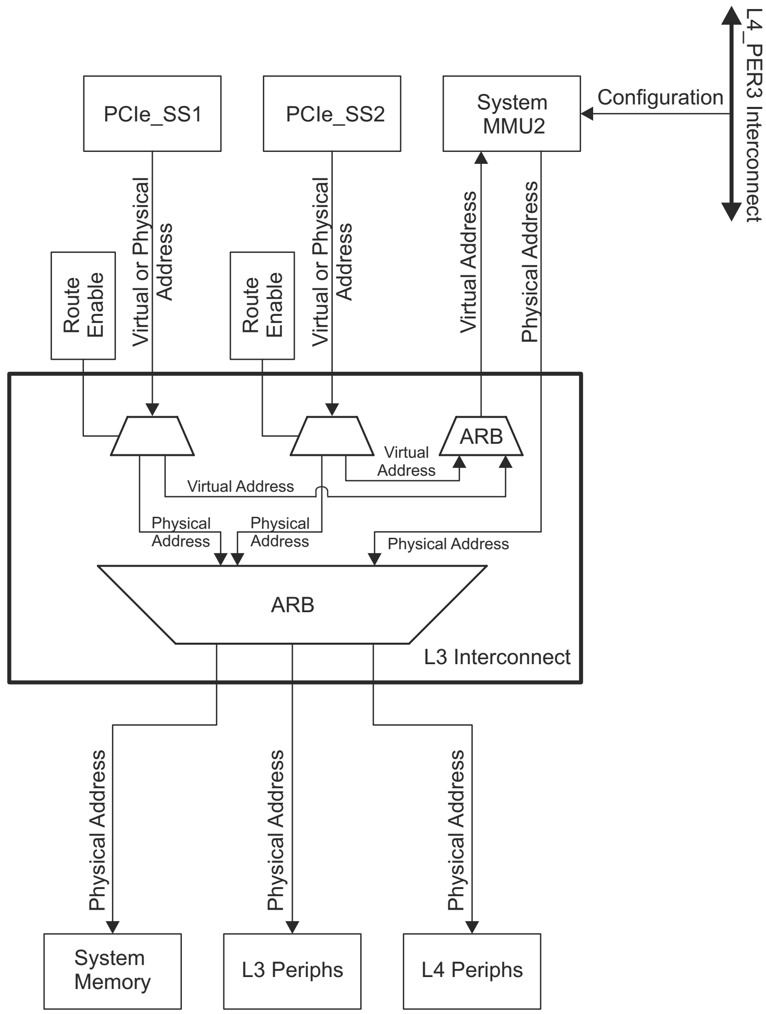

Figure 20-2. System MMU2 Overview

20.2 MMU Integration

This section describes the system MMUs integration in the device, including information about clocks, resets, and hardware requests. For more information about DSP, EVE, and IPU MMUs integration, refer to their respective chapters.

Figure 20-3 and Figure 20-4 show system MMU1, and MMU2 integration, respectively.

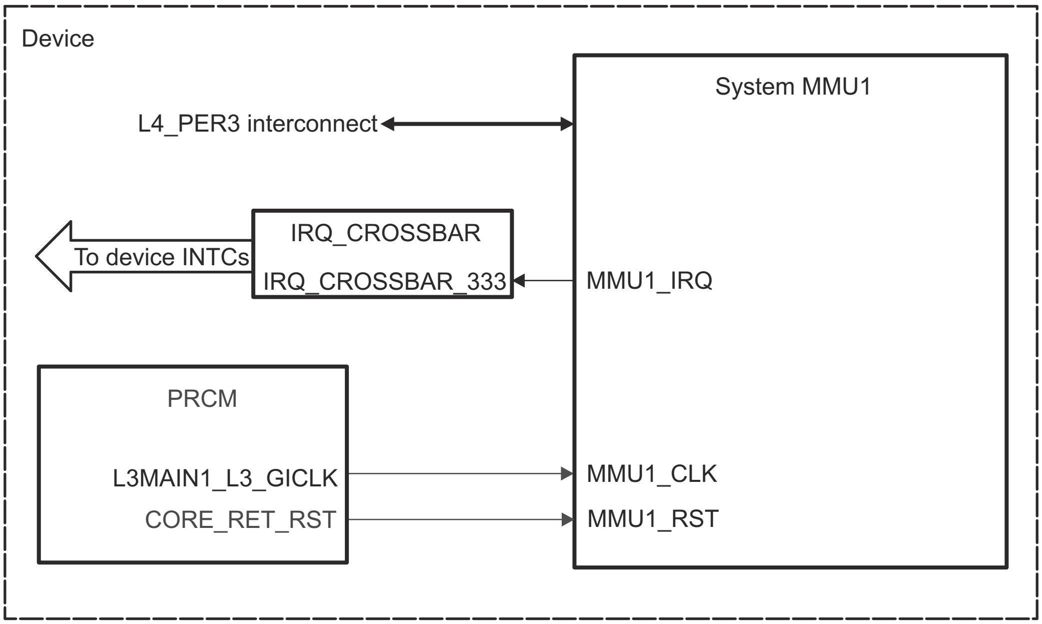

Figure 20-3. System MMU1 Integration

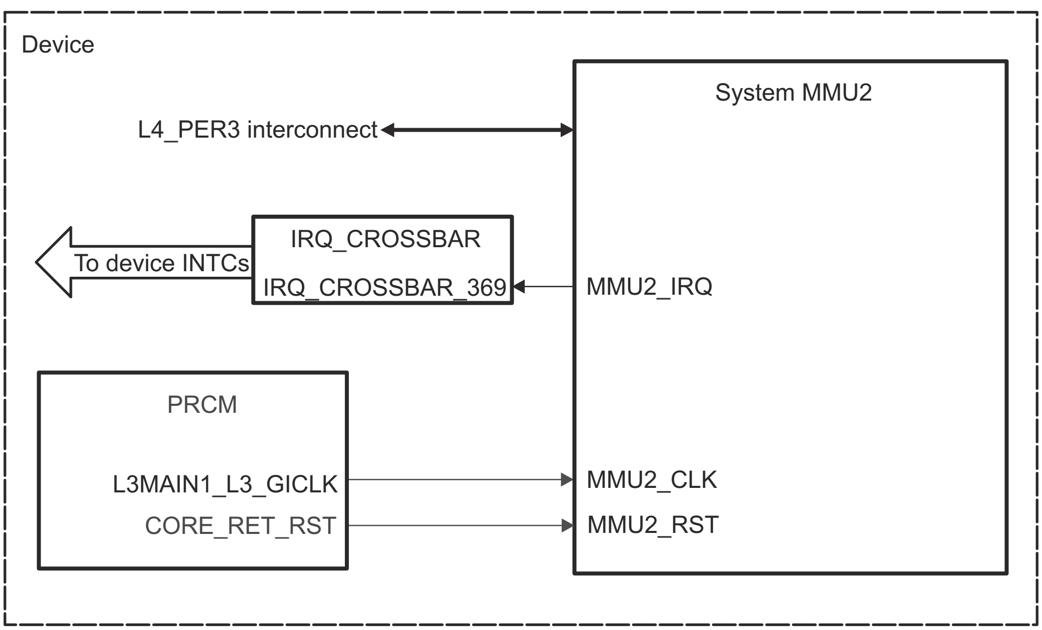

Figure 20-4. System MMU2 Integration

Table 20-1 through Table 20-3 summarize the system MMUs integration.

Table 20-1. MMU Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
System MMU1	PD_COREAON	L4_PER3
System MMU2	PD_COREAON	L4_PER3

Table 20-2. MMU Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
System MMU1	MMU1_CLK	L3MAIN1_L3_GICLK	PRCM	System MMU1 interface/functional clock. This clock is used for all interface and functional operations.
System MMU2	MMU2_CLK	L3MAIN1_L3_GICLK	PRCM	System MMU2 interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
System MMU1	MMU1_RST	CORE_RET_RST	PRCM	System MMU1 hardware reset. This reset is asynchronously applied to the MMU1 internal registers.
System MMU2	MMU2_RST	CORE_RET_RST	PRCM	System MMU2 hardware reset. This reset is asynchronously applied to the MMU2 internal registers.

Table 20-3. MMU Hardware Requests

Interrupt Requests				
Module Instance	**Interrupt Name (Source)**	**IRQ_CROSSBAR Input (Destination)**	**Default Mapping**	**Description**
System MMU1	MMU1_IRQ	IRQ_CROSSBAR_333	–	System MMU1 interrupt.
System MMU2	MMU2_IRQ	IRQ_CROSSBAR_369	–	System MMU2 interrupt.
No DMA Requests				

Note

For a description of the interrupt sources, see Section 20.3.4, *MMU Interrupt Requests*.

20.3 MMU Functional Description

20.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses. Figure 20-5 shows the MMU block diagram.

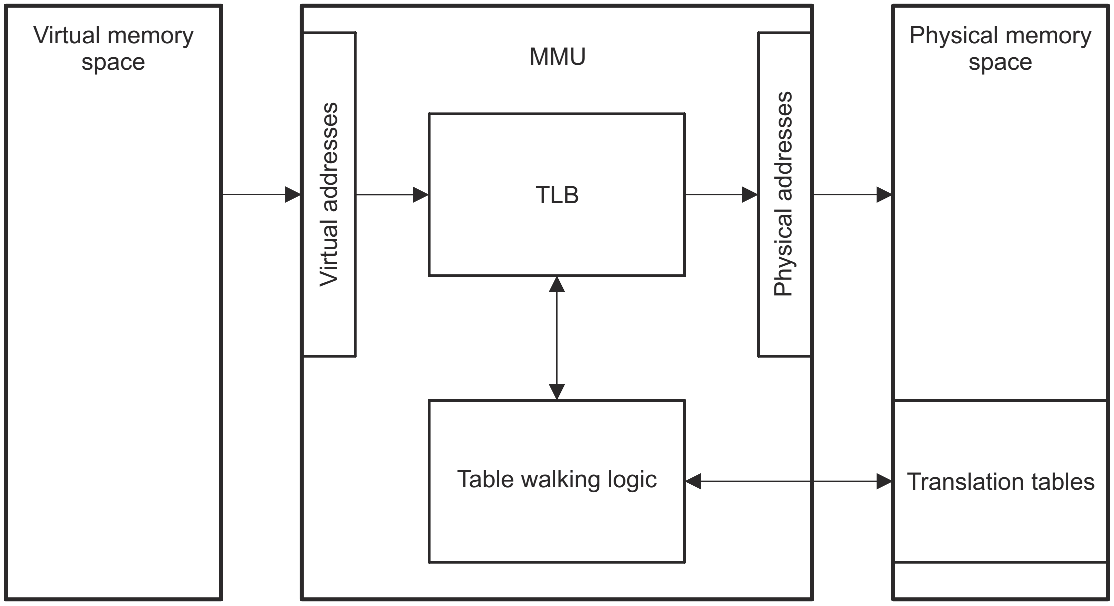

Figure 20-5. MMU Block Diagram

Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see Section 20.3.1.2, *Translation Tables*.

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

20.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. Figure 20-6 summarizes the process.

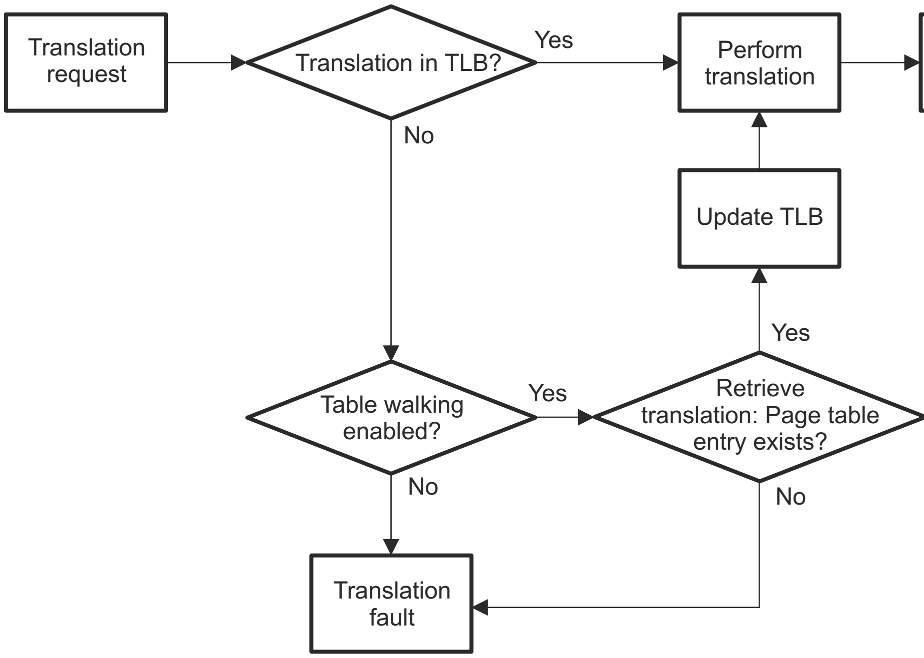

Figure 20-6. Translation Process

20.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

20.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4-KiB and 64-KiB pages, a 1-MiB section, and a 16-MiB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4 KiB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4 KiB memory pages with one translation table would require one million entries to span the entire 4-GiB address range. The table itself would be 32 MiB, a size that is not feasible.

However, using bigger pages reduces the flexibility of typical OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1 MiB memory regions.

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1 MiB (section) or 16 MiB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.
- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1-MiB page of memory. These pages can be either 64 KiB (large page) or 4 KiB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. Figure 20-7 shows the hierarchy.

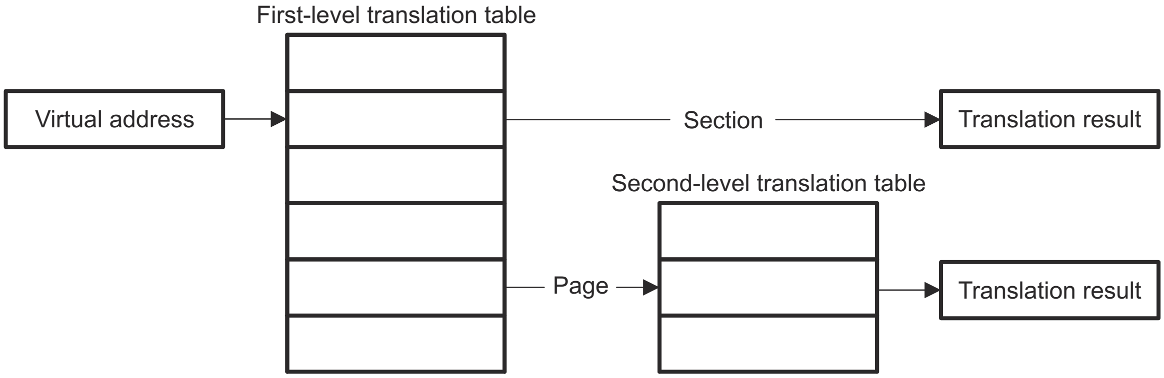

Figure 20-7. Translation Hierarchy

The structure of the first and second-level translation tables and their entries are described in more detail in Section 20.3.1.2.2, *First-Level Translation Table*, and Section 20.3.1.2.3, *Two-Level Translation*.

20.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1-MiB sections. To describe a 4-GiB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. Figure 20-8 shows this mechanism.

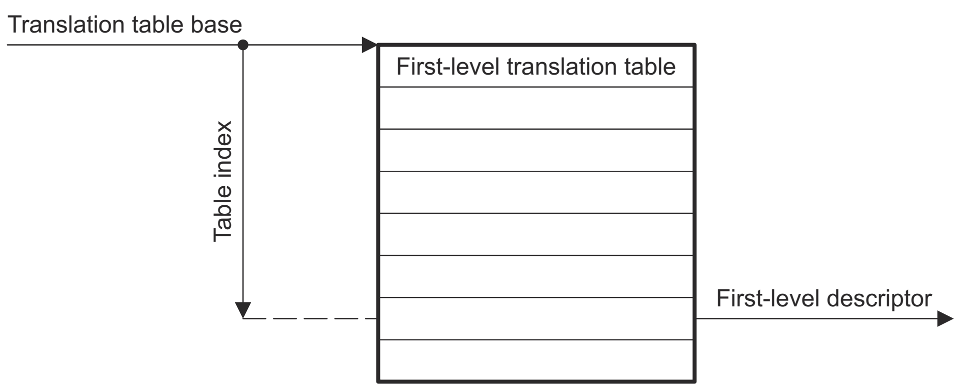

Figure 20-8. First-level Descriptor Address Calculation

To summarize, the translation table base and the translation table index together define the first-level descriptor address. Figure 20-9 outlines the precise mechanism used to calculate this address.

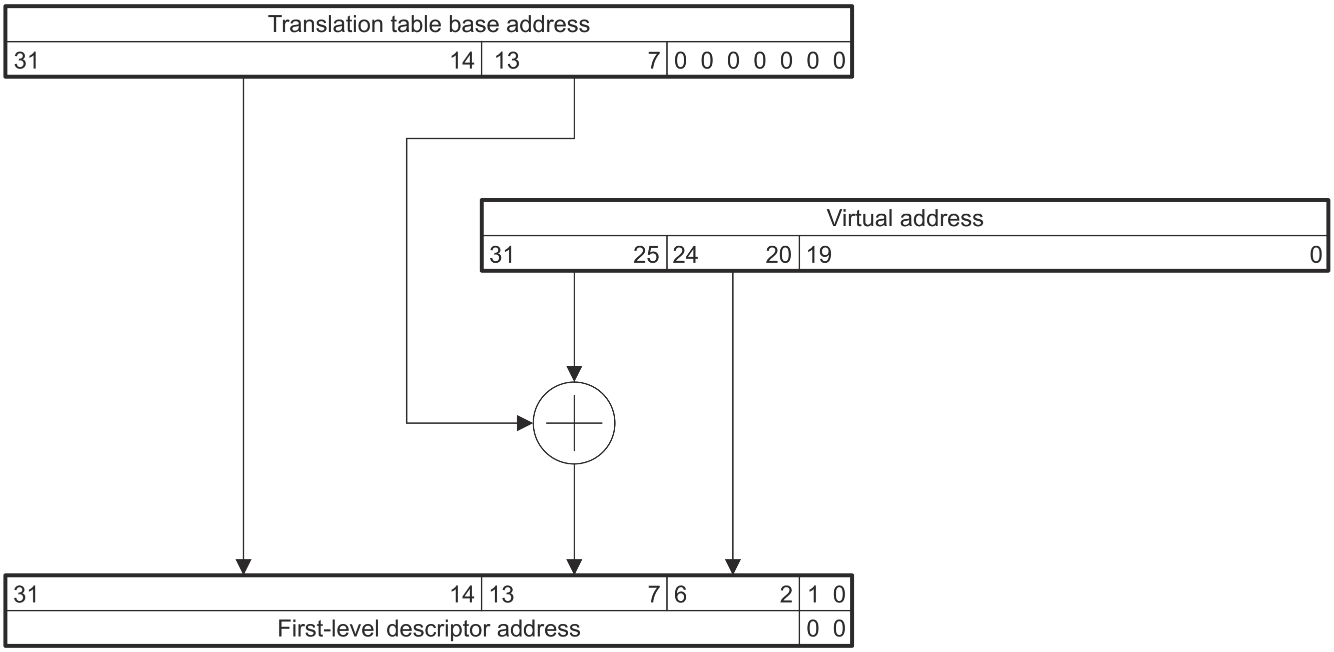

Figure 20-9. Detailed First-Level Descriptor Address Calculation

As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is 0x8000:0000 + (0x123 << 2) = 0x8000:048C.

20.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1-MiB or 16-MiB sections or provides a pointer to a second-level translation table for 4 KiB or 64 KiB pages. Table 20-4 shows the first-level descriptor format.

Table 20-4. First-Level Descriptor Format

First-Level Descriptor Format								
31:24	23:20	19	18	17:10	9:2	1	0	
X						0	0	Fault
Second-Level Translation Table Base Address					X	0	1	Page
Section Base Address		X	0	X		1	0	Section
Supersection Base Address	X		1	X		1	0	Supersection
X						1	1	Fault

X = Don't care. Set to 0 for future compatibility.

20.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1 MiB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

20.3.1.2.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1-MiB section or a 16-MiB supersection.

Note

Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1 MiB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

20.3.1.2.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. Figure 20-10 summarizes the address translation process for a section.

Figure 20-10. Section Translation Summary

20.3.1.2.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

Figure 20-11 shows the translation mechanism for a supersection.

Figure 20-11. Supersection Translation Summary

20.3.1.2.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1 MiB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. Figure 20-12 shows this indexing mechanism.

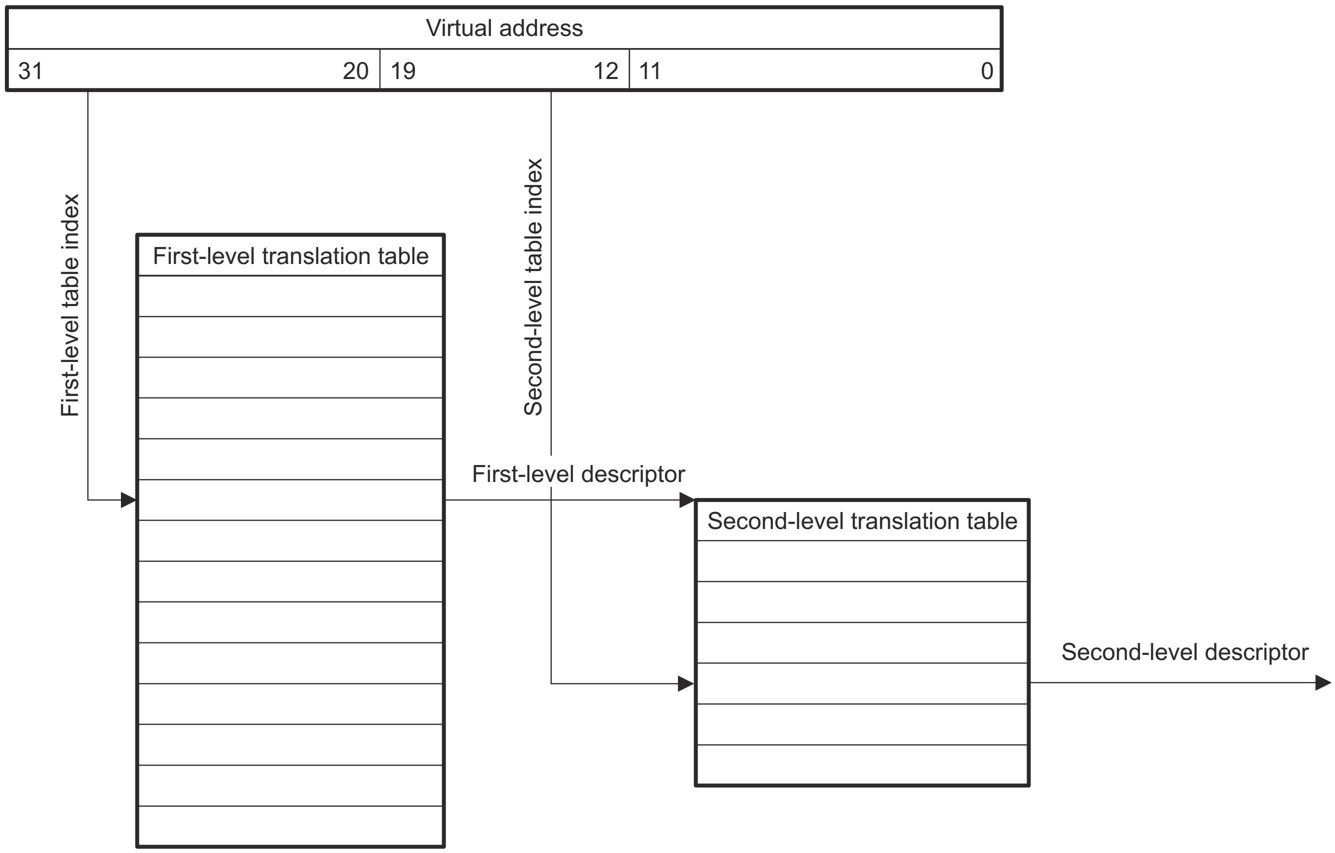

Figure 20-12. Two-Level Translation

Each second-level translation table describes the translation of 1 MiB of address space in pages of 64 KiB (large page) or 4 KiB (small page). It consists of 256 second-level descriptors describing 4 KiB each.

Note

In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

20.3.1.2.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. Table 20-5 shows the format of second-level descriptors.

Table 20-5. Second-Level Descriptor Format

Second-Level Descriptor Format					
31:16	15:12	11:2	1	0	
X			0	0	Fault
Large Page Base Address	X		0	1	Large Page
Small Page Base Address		X	1	X	Small Page

X = Don't care. Set to 0 for future compatibility.

20.3.1.2.3.2 Small Page Translation Summary

Figure 20-13 summarizes the translation process for small pages.

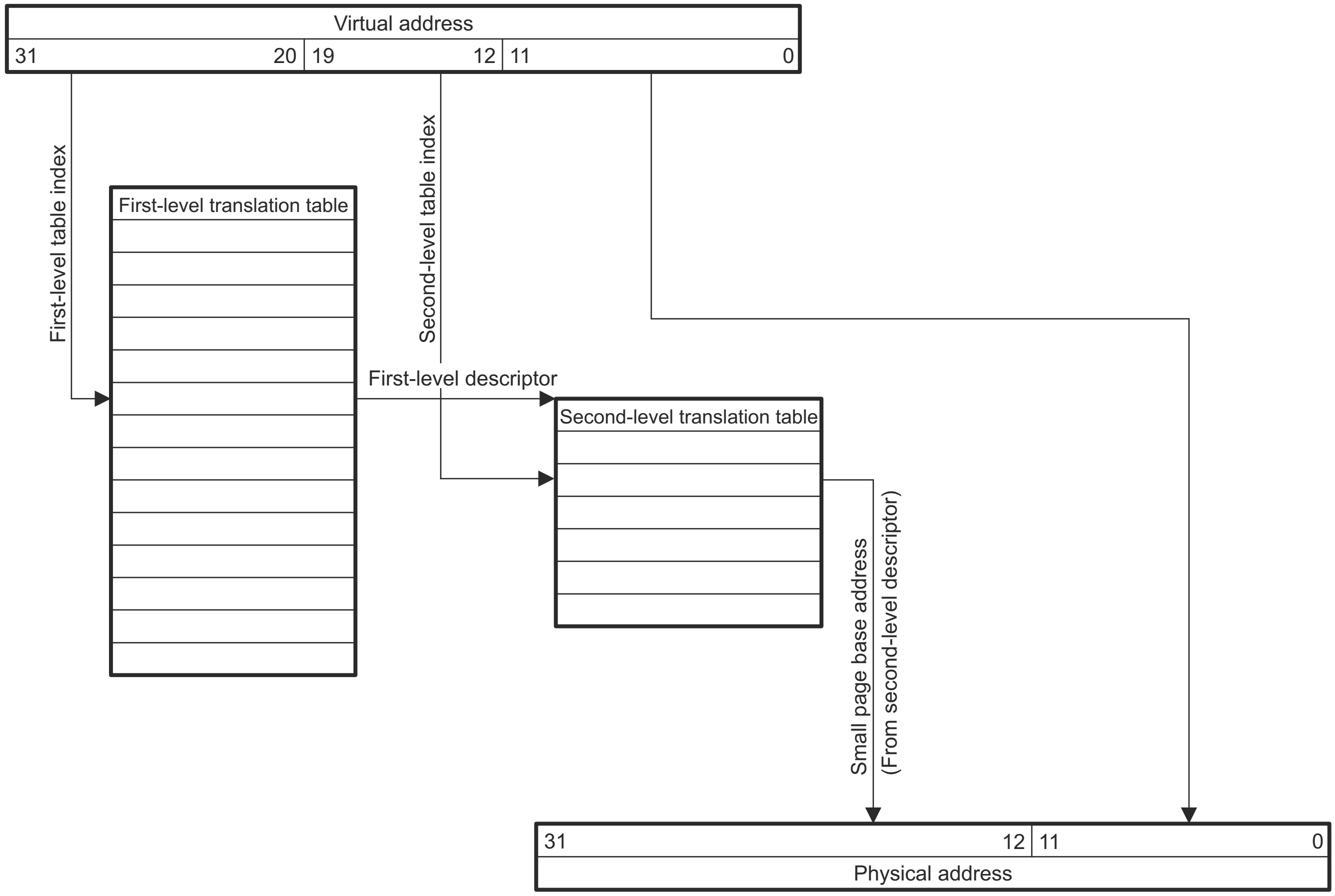

Figure 20-13. Small Page Translation Summary

20.3.1.2.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 20-14.

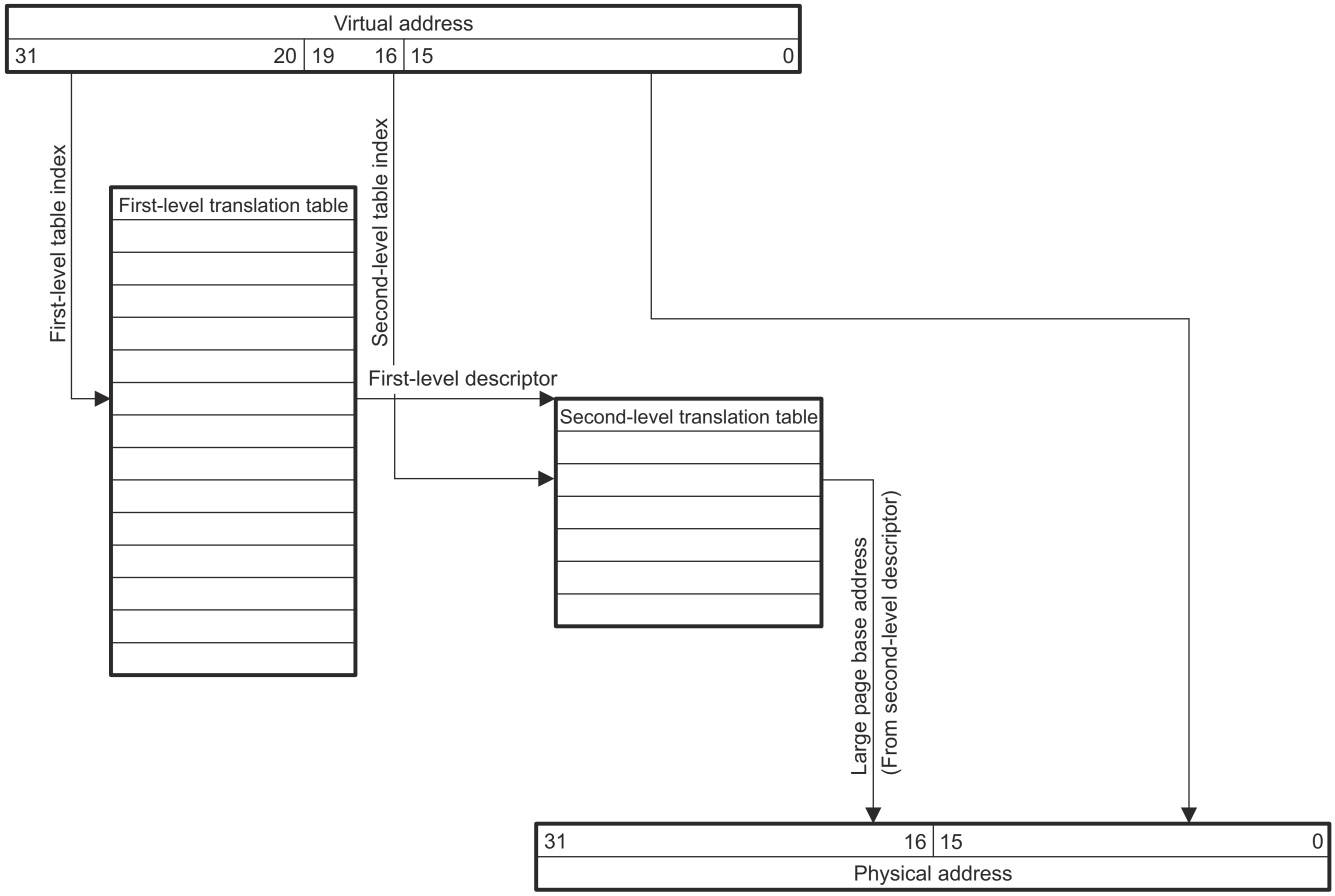

Figure 20-14. Large Page Translation Summary

20.3.1.3 Translation Lookaside Buffer

Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first *n* TLB entries, where *n* < *Total Number N of TLB Entries*, can be protected (locked) against being overwritten by setting the TLB base pointer to *n*. When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 20-15 shows an example of the TLB with N TLB entries (ranging from 0 to N-1). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

Note

The last TLB entry (Entry N-1) always remains unprotected.

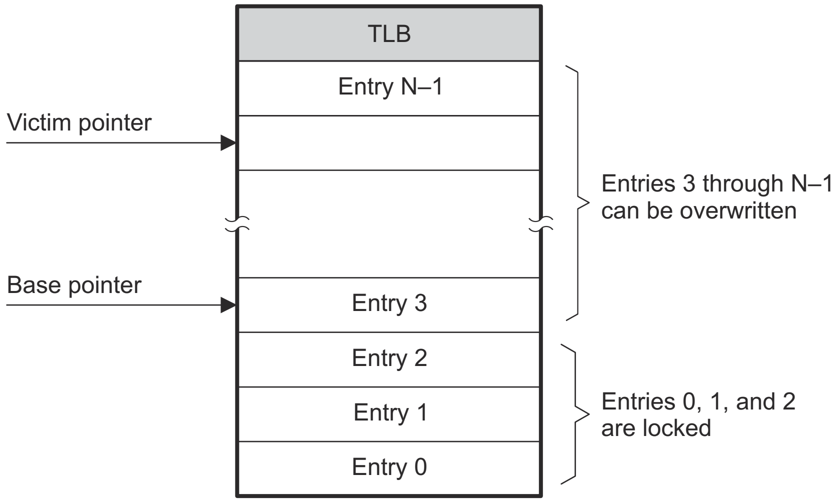

Figure 20-15. TLB Entry Lock Mechanism

The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

20.3.1.3.1 TLB Entry Format

TLB entries consist of two parts:

- The Content Addressable Memory (CAM) part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the MMU_CAM register table for more details.
- The Random Addressable Memory (RAM) part contains the address translation that belongs to the virtual address tag. See the MMU_RAM register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when MMU_GFLUSH[0] GLOBALFLUSH is set to 1. Preserved entries must be deleted manually. Section 20.3.1.2.2, *First-Level Translation Table* describes the procedure to delete TLB entries.

Figure 20-17 shows the TLB entry structure.

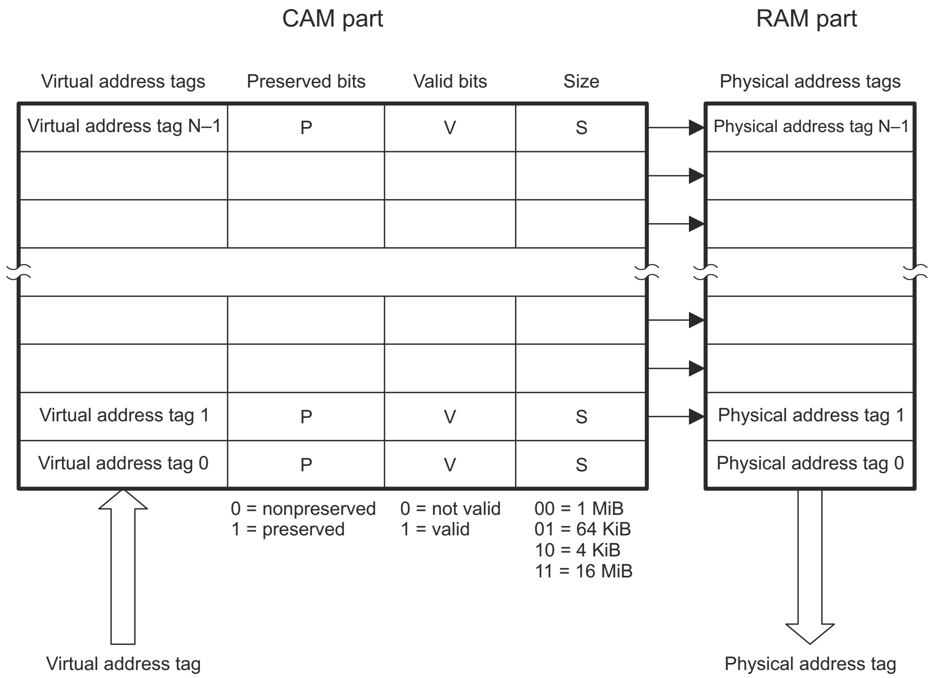

Figure 20-16. TLB Entry Structure

20.3.1.4 No Translation (Bypass) Regions

The MMU provides support for up to four user programmable regions where there is no address translation. Any access to a region specified by the MMU_BYPASS_REGIONx_ADDR and MMU_BYPASS_REGIONx_SIZE registers (where x = 1 to 4) will have no virtual to physical address translation.

20.3.2 MMU Software Reset

To perform a software reset, write 1 in the MMU_SYSCONFIG[1] SOFTRESET bit. The MMU_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the MMU_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

20.3.3 MMU Power Management

Table 20-6 describes the power-management features available for the MMU modules.

Table 20-6. MMU Local Power Management Features

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

Note

The MMU_SYSCONFIG[9:8] CLOCKACTIVITY bit field is read only.

20.3.4 MMU Interrupt Requests

Table 20-7. MMU Events

Event Flag	Event Mask	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Error due to multiple matches in the TLB

Table 20-7. MMU Events (continued)

Event Flag	Event Mask	Description
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Error due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS	Error due to unrecoverable TLB miss during debug (hardware TWL disabled)
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Error due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Error due to unrecoverable TLB miss (hardware TWL disabled)

20.3.5 MMU Error Handling

Table 20-8 summarizes the intended operation for real and potential error conditions.

Table 20-8. Error Handling

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU. Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU. This condition should be avoided by ensuring that no accesses are pending.
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.
7	Interrupt is not enabled and a fault/miss happens during translation.	If MMU_GPR[0] FAULT_INTR_DIS = 1 : Error response is sent back. If MMU_GPR[0] FAULT_INTR_DIS = 0 : • Mreqdebug = 1 (debug access) : Error response is sent back • Mreqdebug = 0 (application access) : Error response is not sent. MMU is waiting for TLB to be updated through config port. But since the interrupt is not asserted, system does not know there was a fault. This results in deadlock. Software must take care of this by enabling interrupts.

20.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

20.4.1 Global Initialization

20.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see Section 20.2, *MMU Module Integration* .

Table 20-9. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Enable MMU interface/functional clock.
(optional) Interrupt controller(s)	Configure device interrupt controller(s) to enable the interrupts from MMU.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

20.4.1.2 MMU Global Initialization

20.4.1.2.1 Main Sequence - MMU Global Initialization

Figure 20-17 shows the procedure to initialize the MMU after a power-on or software reset.

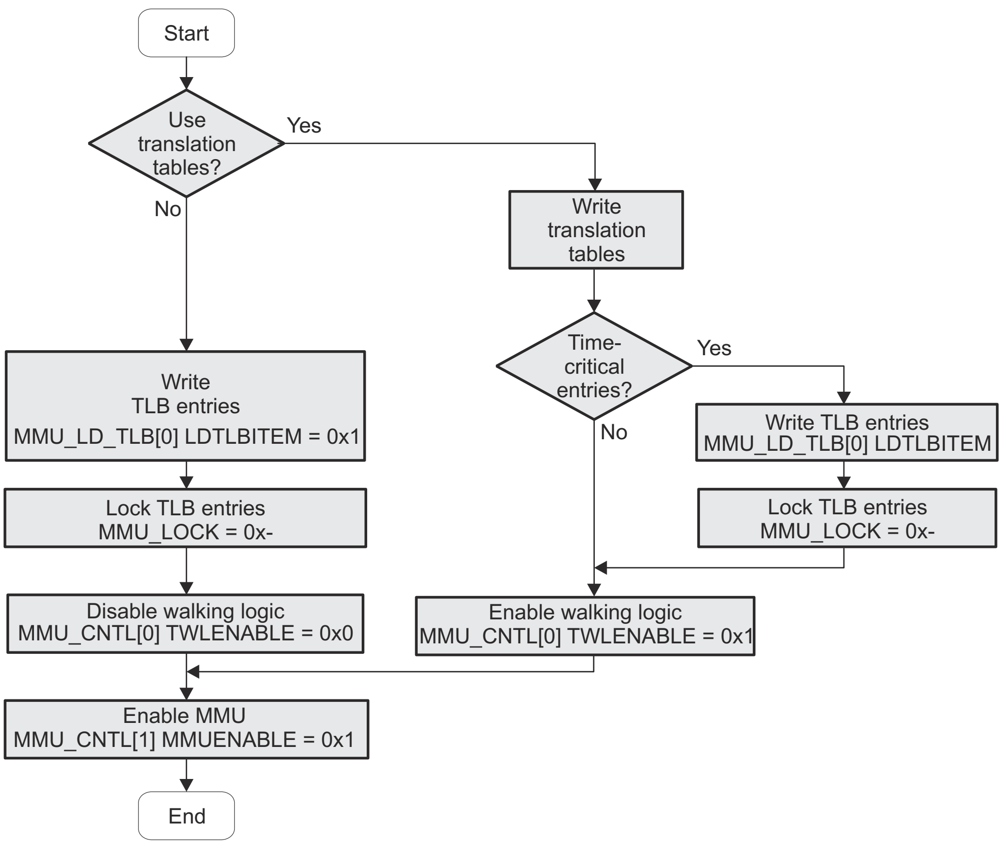

Figure 20-17. MMU Global Initialization

20.4.1.2.2 Subsequence - Configure a TLB entry

Table 20-10. Configure a TLB Entry

Step	Register / Bit Field / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

20.4.1.3 Operational Modes Configuration

20.4.1.3.1 Main Sequence - Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Table 20-11. MMU Writing TLB Entries Statically

Step	Register/ Bit Field / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	See Table 20-10	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

20.4.1.3.2 Main Sequence - Protecting TLB Entries

The first *n* TLB entries (with *n* < total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 20-12. Protecting TLB Entries

Step	Registe/Bit Field/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

20.4.1.3.3 Main Sequence - Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 20-13. Deleting TLB Entries

Step	Registet / Bit Field / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

20.4.1.3.4 Main Sequence - Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 20-14. Read TLB Entries

Step	Register / Bit Field / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	
Read CAM parts of the TLB entry	MMU_READ_CAM	

20.5 MMU Register Manual

20.5.1 MMU Instance Summary

Table 20-15. MMU Instance Summary

Module Name	Base Address (L3/L4 Access)	Base Address (CPU Private Access)	Size

20.5.2.2 MMU Register Description

Table 20-22. MMU_REVISION

Address Offset	0x0000 0000		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register contains the IP revision code		
Type	R		

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="32">REVISION</td></tr>
</table>

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision	R	See [1]

(1) TI internal data

Table 20-23. MMU_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register controls the various parameters of the OCP interface		
Type	RW		

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
</table>

RESERVED	CLOCKACTIVITY	RESERVED	IDLEMODE	RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x000000
9:8	CLOCKACTIVITY	Clock activity during wake-up mode 0x0: Functional and OCP clocks can be switched off	R	0x0
7:5	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
4:3	IDLEMODE	Idle mode 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module 0x3: Reserved. Do not use	RW	0x0
2	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always return 0 Write 0x0: No functional effect Write 0x1: The module is reset	W	0x0
0	AUTOIDLE	Internal OCP clock gating strategy 0x0: OCP clock is free-running 0x1: Automatic interconnect clock gating strategy is applied, based on the interconnect interface activity	RW	0x0

Table 20-24. MMU_SYSSTATUS

Address Offset	0x0000 0014		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register provides status information about the module, excluding the interrupt status information		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															RESETDONE

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reads returns 0	R	0x000000
0	RESETDONE	Internal reset monitoring Read 0x0: Internal module reset in on-going Read 0x1: Reset completed	R	-

Table 20-25. MMU_IRQSTATUS

Address Offset	0x0000 0018		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											MULTIHITFAULT	TABLEWALKFAULT	EMUMISS	TRANSLATIONFAULT	TLBMISS

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0's for future compatibility. Read returns 0	R	0x0000000
4	MULTIHITFAULT	Error due to multiple matches in the TLB Read 0x0: MultiHitFault false Write 0x0: MultiHitFault status bit unchanged Write 0x1: MultiHitFault status bit is reset Read 0x1: MultiHitFault is true ('pending')	RW (W1toClr)	0x0
3	TABLEWALKFAULT	Error response received during a Table Walk Read 0x0: TableWalkFault false Write 0x0: TableWalkFault status bit unchanged Write 0x1: TableWalkFault status bit is reset Read 0x1: TableWalkFault is true ('pending')	RW (W1toClr)	0x0
2	EMUMISS	Unrecoverable TLB miss during debug (hardware TWL disabled) Read 0x0: EMUMiss false Write 0x0: EMUMiss status bit unchanged Write 0x1: EMUMiss status bit is reset Read 0x1: EMUMiss is true ('pending')	RW (W1toClr)	0x0
1	TRANSLATIONFAULT	Invalid descriptor in translation tables (translation fault) Read 0x0: TranslationFault false Write 0x0: TranslationFault status bit unchanged Write 0x1: TranslationFault status bit is reset Read 0x1: TranslationFault is true ('pending')	RW (W1toClr)	0x0
0	TLBMISS	Unrecoverable TLB miss (hardware TWL disabled) Read 0x0: TLBMiss false Write 0x0: TLBMiss status bit unchanged Write 0x1: TLBMiss status bit is reset Read 0x1: TLBMiss is true ('pending')	RW (W1toClr)	0x0

Table 20-26. MMU_IRQENABLE

Address Offset	0x0000 001C		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED	MULTIHITFAULT	TABLEWALKFAULT	EMUMISS	TRANSLATIONFAULT	TLBMISS

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0's for future compatibility Read returns 0	R	0x0000000
4	MULTIHITFAULT	Error due to multiple matches in the TLB 0x0: MultiHitFault is masked 0x1: MultiHitFault event generates an interrupt if occurs	RW	0x0
3	TABLEWALKFAULT	Error response received during a Table Walk 0x0: TableWalkFault is masked 0x1: TableWalkFault event generates an interrupt if occurs	RW	0x0
2	EMUMISS	Unrecoverable TLB miss during debug (hardware TWL disabled) 0x0: EMUMiss interrupt is masked 0x1: EMUMiss event generates an interrupt when it occurs	RW	0x0
1	TRANSLATIONFAULT	Invalid descriptor in translation tables (translation fault) 0x0: TranslationFault is masked 0x1: TranslationFault event generates an interrupt if occurs	RW	0x0
0	TLBMISS	Unrecoverable TLB miss (hardware TWL disabled) 0x0: TLBMiss interrupt is masked 0x1: TLBMiss event generates an interrupt when if occurs	RW	0x0

Table 20-27. MMU_WALKING_ST

Address Offset	0x0000 0040		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register provides status information about the table walking logic		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															TWLRUNNING

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reads return 0	R	0x0000 0000
0	TWLRUNNING	Table Walking Logic is running Read 0x0: TWL Completed Read 0x1: TWL Running	R	0x0

Table 20-28. MMU_CNTL

Address Offset	0x0000 0044		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register programs the MMU features		
Type	RW		

31–4	3	2	1	0
RESERVED	EMUTLBUPDATE	TWLENABLE	MMUENABLE	RESERVED

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x0000000
3	EMUTLBUPDATE	Enable TLB update on emulator table walk 0x0: Emulator TLB update disabled 0x1: Emulator TLB update enabled	RW	0x0
2	TWLENABLE	Table Walking Logic enable 0x0: TWL disabled 0x1: TWL enabled	RW	0x0
1	MMUENABLE	MMU enable 0x0: MMU disabled 0x1: MMU enabled	RW	0x0
0	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x0

Table 20-29. MMU_FAULT_AD

Address Offset	0x0000 0048		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register contains the virtual address that generated the interrupt		
Type	R		

31–0
FAULTADDRESS

Bits	Field Name	Description	Type	Reset
31:0	FAULTADDRESS	Virtual address of the access that generated a fault	R	0x0000 0000

Table 20-30. MMU_TTB

Address Offset	0x0000 004C		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register contains the Translation Table Base address		
Type	RW		

31–7	6–0
TTBADDRESS	RESERVED

Bits	Field Name	Description	Type	Reset
31:7	TTBADDRESS	Translation Table Base Address	RW	0x0000000
6:0	RESERVED	Write 0's for future compatibility. Reads retiurn 0	R	0x00

Table 20-31. MMU_LOCK

Address Offset	0x0000 0050		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register locks some of the TLB entries		
Type	RW		

31:15	14:10	9	8:4	3:0
RESERVED	BASEVALUE	RESERVED	CURRENTVICTIM	RESERVED

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x00000
14:10	BASEVALUE	Locked entries base value.	RW	0x00
9	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x0
8:4	CURRENTVICTIM	Current entry to be updated either by the TWL or by the software. Write value : TLB entry to be updated by software Read value : TLB entry that will be updated by table walk logic. This will be same as BASEVALUE when there are no tablewalks.	RW	0x00
3:0	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x0

Table 20-32. MMU_LD_TLB

Address Offset	0x0000 0054		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register loads a TLB entry (CAM+RAM)		
Type	RW		

31:1	0
RESERVED	LDTLBITEM

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x0000 0000
0	LDTLBITEM	Write (load) data in the TLB. Reads return 0. Write 0x0: No functional effect Write 0x1: Load TLB data	W	0x0

Table 20-33. MMU_CAM

Address Offset	0x0000 0058		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register holds a CAM entry		
Type	RW		

31:12	11:4	3	2	1:0
VATAG	RESERVED	P	V	PAGESIZE

Bits	Field Name	Description	Type	Reset
31:12	VATAG	Virtual address tag	RW	0x00000
11:4	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x00
3	P	Preserved bit 0x0: TLB entry may be flushed 0x1: TLB entry is protected against flush	RW	0x0
2	V	Valid bit 0x0: TLB entry is invalid 0x1: TLB entry is valid	RW	0x0
1:0	PAGESIZE	Page size 0x0: Section (1 MiB) 0x1: Large page (64 KiB) 0x2: Small page (4 KiB) 0x3: Supersection (16 MiB)	RW	0x0

Table 20-34. MMU_RAM

Address Offset	0x0000 005C		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register contains bits [31:12] of the physical address to be written to a TLB entry pointed to by CURRENTVICTIM field of MMU_LOCK register.		
Type	RW		

31:12	11:0
PHYSICALADDRESS	RESERVED

Bits	Field Name	Description	Type	Reset
31:12	PHYSICALADDRESS	Physical address of the page	RW	0x00000
11:0	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x0

Table 20-35. MMU_GFLUSH

Address Offset	0x0000 0060		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register flushes all the non-protected TLB entries		
Type	RW		

31:1	0
RESERVED	GLOBALFLUSH

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x0000 0000
0	GLOBALFLUSH	Flush all the non-protected TLB entries when set. Reads return 0. Write 0x0: No functional effect Write 0x1: Flush all the non-protected TLB entries	W	0x0

Table 20-36. MMU_FLUSH_ENTRY

Address Offset	0x0000 0064

Table 20-36. MMU_FLUSH_ENTRY (continued)

Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register flushes the entry pointed to by the CAM virtual address		
Type	RW		

31:1	0
RESERVED	FLUSHENTRY

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x0000 0000
0	FLUSHENTRY	Flush the TLB entry pointed by the virtual address (VATag) in MMU_CAM register, even if this entry is set protected. Reads return 0. Write 0x0: No functional effect Write 0x1: Flush all the TLB entries specified by the CAM register	W	0x0

Table 20-37. MMU_READ_CAM

Address Offset	0x0000 0068		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register reads CAM data from a CAM entry		
Type	R		

31:12	11:4	3	2	1:0
VATAG	RESERVED	P	V	PAGESIZE

Bits	Field Name	Description	Type	Reset
31:12	VATAG	Virtual address tag	R	0x00000
11:4	RESERVED	Reads return 0	R	0x00
3	P	Preserved bit Read 0x0: TLB entry may be flushed Read 0x1: TLB entry is protected against flush	R	0x0
2	V	Valid bit Read 0x0: TLB entry is invalid Read 0x1: TLB entry is valid	R	0x0
1:0	PAGESIZE	Page size Read 0x0: Section (1 MiB) Read 0x1: Large page (64 KiB) Read 0x2: Small page (4 KiB) Read 0x3: Supersection (16 MiB)	R	0x0

Table 20-38. MMU_READ_RAM

Address Offset	0x0000 006C		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register reads bits [31:12] of the physical address from the TLB entry pointed to by CURRENTVICTIM field of the MMU_LOCK register.		
Type	R		

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="20">PHYSICALADDRESS</td><td colspan="12">RESERVED</td></tr>
</table>

Bits	Field Name	Description	Type	Reset
31:12	PHYSICALADDRESS	Physical address of the page	R	0x00000
11:0	RESERVED	Reads return 0	R	0x0

Table 20-39. MMU_EMU_FAULT_AD

Address Offset	0x0000 0070		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	This register contains the last virtual address of a fault caused by the debugger		
Type	R		

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="32">EMUFAULTADDRESS</td></tr>
</table>

Bits	Field Name	Description	Type	Reset
31:0	EMUFAULTADDRESS	Virtual address of the last emulator access that generated a fault	R	0x0000 0000

Table 20-40. MMU_FAULT_PC

Address Offset	0x0000 0080		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	Typically CPU program counter value of instruction generating MMU fault. The address value is captured at MMU_EMU_FAULT_AD[31:0] EMUFAULTADDRESS. Data-Read-access : corresponding PC. Data-write-access : not perfect accuracy due to posted-write.		
Type	R		

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="32">PC</td></tr>
</table>

Bits	Field Name	Description	Type	Reset
31:0	PC	Typically CPU program counter value of instruction generating MMU fault	R	0x0000 0000

Table 20-41. MMU_FAULT_STATUS

Address Offset	0x0000 0084		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	Fault status register		
Type	RW		

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="23">RESERVED</td><td colspan="5">MMU_FAULT_TRANS_ID</td><td>RD_WR</td><td colspan="2">MMU_FAULT_TYPE</td><td>FAULTINDICATION</td></tr>
</table>

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000

Bits	Field Name	Description	Type	Reset
8:4	MMU_FAULT_TRANS_ID	MtagID of the transaction that caused fault	R	0x0
3	RD_WR	Indicates read or write 0x0: Write 0x1: Read	R	0x0
2:1	MMU_FAULT_TYPE	MReqInfo[1:0] is captured as fault type	R	0x0
0	FAULTINDICATION	Indicates an MMU fault	RW (W1toClr)	0x0

Table 20-42. MMU_GPR

Address Offset	0x0000 0088		
Physical Address	See Section 20.5.2.1	**Instance**	See Table 20-15
Description	General purpose register

Chapter 21
Spinlock

This chapter describes the Spinlock module of the device.

21.1 Spinlock Overview 5188
21.2 Spinlock Integration 5189
21.3 Spinlock Functional Description 5190
21.4 Spinlock Programming Guide 5192
21.5 Spinlock Register Manual 5194

21.1 Spinlock Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Dual Cortex®-A15 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystems – DSP1 and DSP2
- Dual Cortex-M4 image processing unit (IPU) subsystems – IPU1 and IPU2

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 21-1 shows an overview of the Spinlock module.

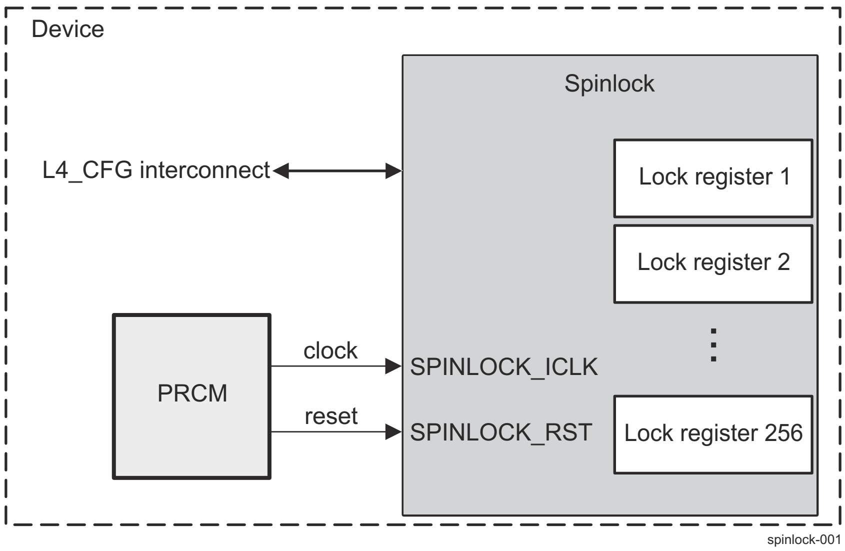

Figure 21-1. Spinlock Overview

21.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 21-2 shows the Spinlock integration.

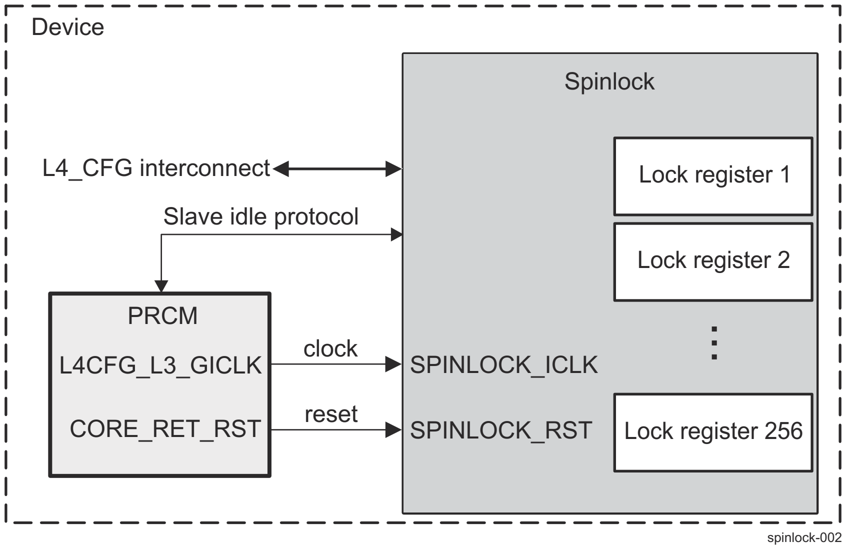

Figure 21-2. Spinlock Integration

Note

For more information about the Slave idle protocol and the wake-up request, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

Table 21-1 and Table 21-2 summarize the integration of the module in the device.

Table 21-1. Spinlock Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_COREAON	L4_CFG

Table 21-2. Spinlock Clocks and Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
Clocks				
SPINLOCK	SPINLOCK_ICLK	L4CFG_L3_GICLK	PRCM	Spinlock interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SPINLOCK	SPINLOCK_RST	CORE_RET_RST	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers.

Note

The Spinlock module does not support any interrupt and DMA requests.

21.3 Spinlock Functional Description

21.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The SPINLOCK_SYSTATUS[0] RESETDONE bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

21.3.2 Spinlock Power Management

Table 21-3 describes power-management features available to the Spinlock module.

Table 21-3. Spinlock Local Power Management Features

Feature	Registers	Description
Clock auto gating	SPINLOCK_SYSCONFIG[0] AUTOGATING bit	This bit indicates that the Spinlock module uses an automatic internal interface clock gating strategy, based on interface activity.
Global wake-up enable	SPINLOCK_SYSCONFIG[2] ENAWAKEUP bit	This bit indicates that the wake-up generation feature (at Spinlock module level) is disabled.
Slave idle modes	SPINLOCK_SYSCONFIG[4:3] SIDLEMODE bit field	This bit field indicates that the Spinlock module uses smart-idle mode.

Note

All Spinlock local power management features are non-configurable – that is, their respective bit fields are read-only and only show the actual hardware implementation.

For information about source clock gating and sleep/wake-up transitions description, see *Clock Domain-Level Clock Management*, in *Power, Reset, and Clock Management*. For descriptions of EnaWakeUp, and IdleMode features, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

21.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

21.3.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 0).

When the status of lock *i* (where i = 0 to 255) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_i register returns 0 and sets the lock to Taken (locked). When the status of lock *i* is Taken, a read returns 1 and does not change the state of the lock.

A write to the SPINLOCK_LOCK_REG_i register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

CAUTION

Only 32-bit reads and writes are supported.

Figure 21-3 shows the SPINLOCK_LOCK_REG_i register state diagram.

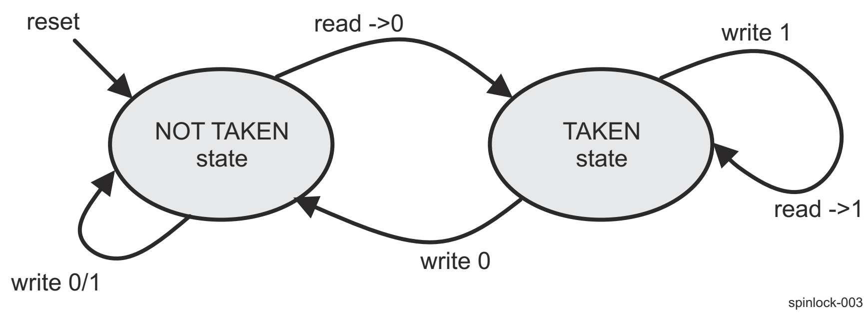

Figure 21-3. Lock Register State Diagram

Note

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

21.4 Spinlock Programming Guide

21.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

21.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 21-4. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, see *CD_L4_CFG Clock Domain*, in *Power, Reset, and Clock Management*.
Interconnect	For more information about the L4_CFG interconnect configuration, see *L4 Interconnects*.

21.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

21.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_i registers at system startup to insure that all locks are initialized to Not Taken.

Table 21-5. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = = 1?	SPINLOCK_SYSTATUS[0] IU0	
Free the 256 locks	SPINLOCK_LOCK_REG_i[0] TAKEN (i = 0 to 255)	0x0
END		

21.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the SPINLOCK_LOCK_REG_i[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. Figure 21-4 shows the described above procedure.

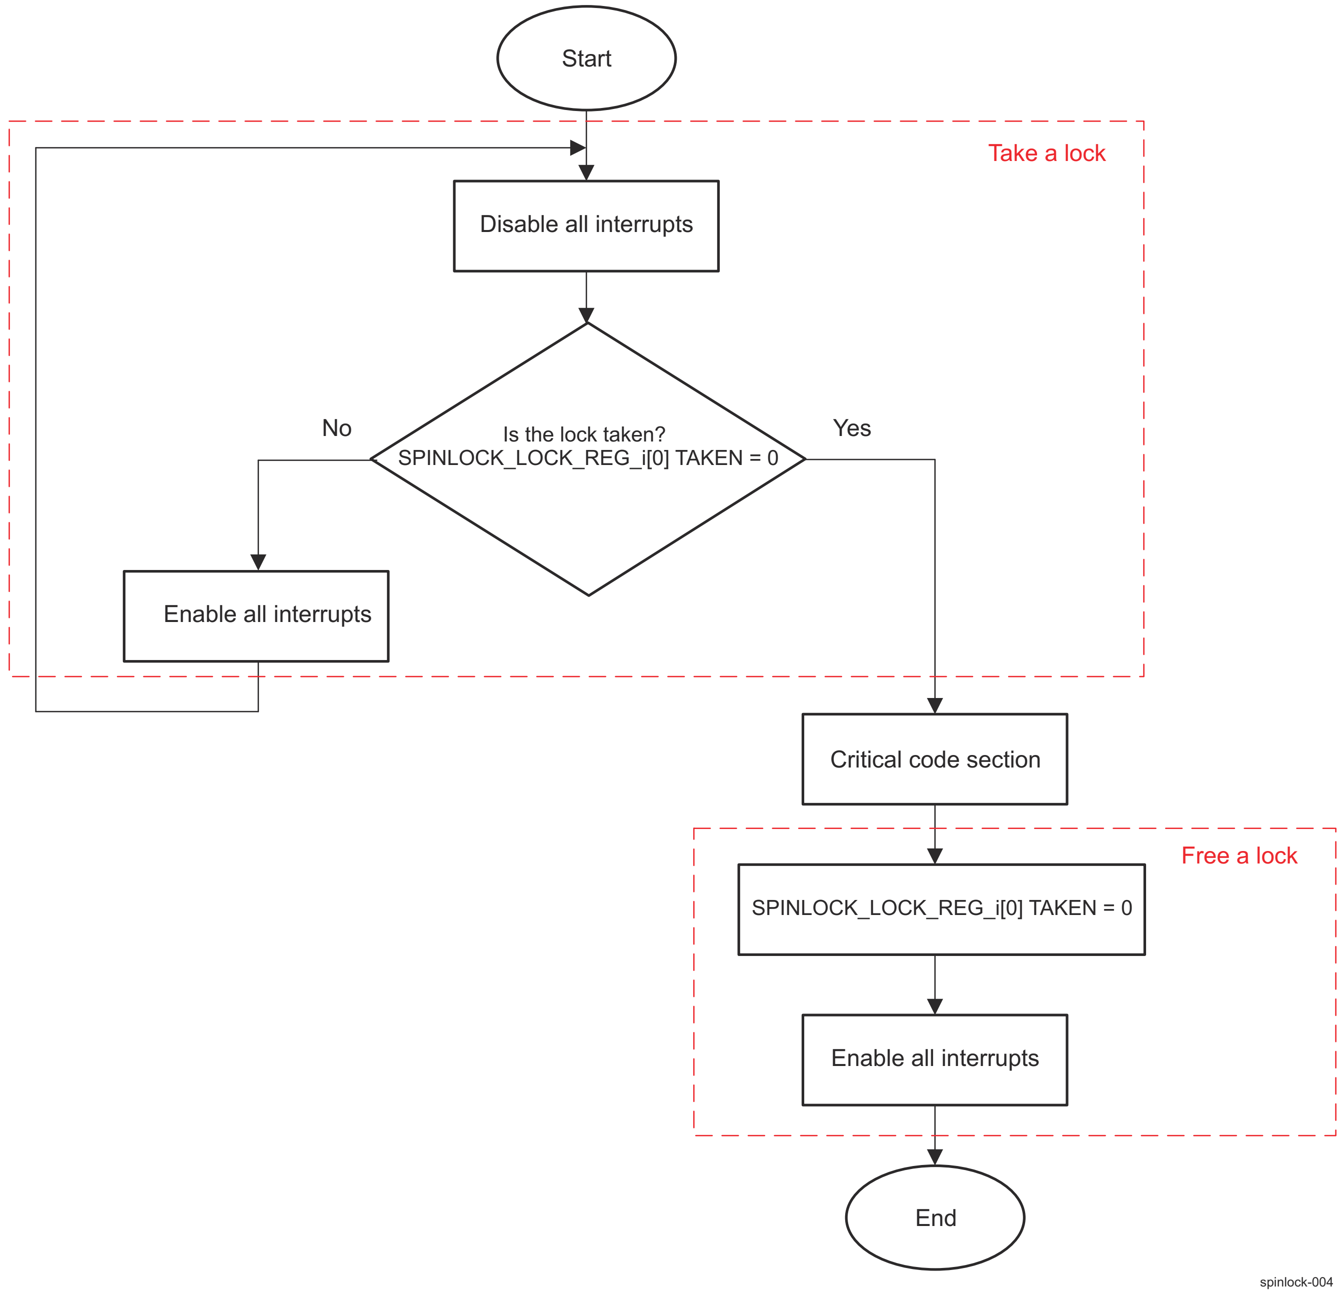

Figure 21-4. Take and Release Spinlock

Chapter 22

Timers

This chapter describes the timer modules for the device.

22.1 Timers Overview 5199
22.2 General-Purpose Timers 5200
22.3 32-kHz Synchronized Timer (COUNTER_32K) 5249
22.4 Watchdog Timer 5256

22.1 Timers Overview

The device includes several types of timers used by the system software, including 16 general-purpose (GP) timers, one watchdog timer, and a 32-kHz synchronized timer (COUNTER_32K). Figure 22-1 is a high-level block diagram of the device timers.

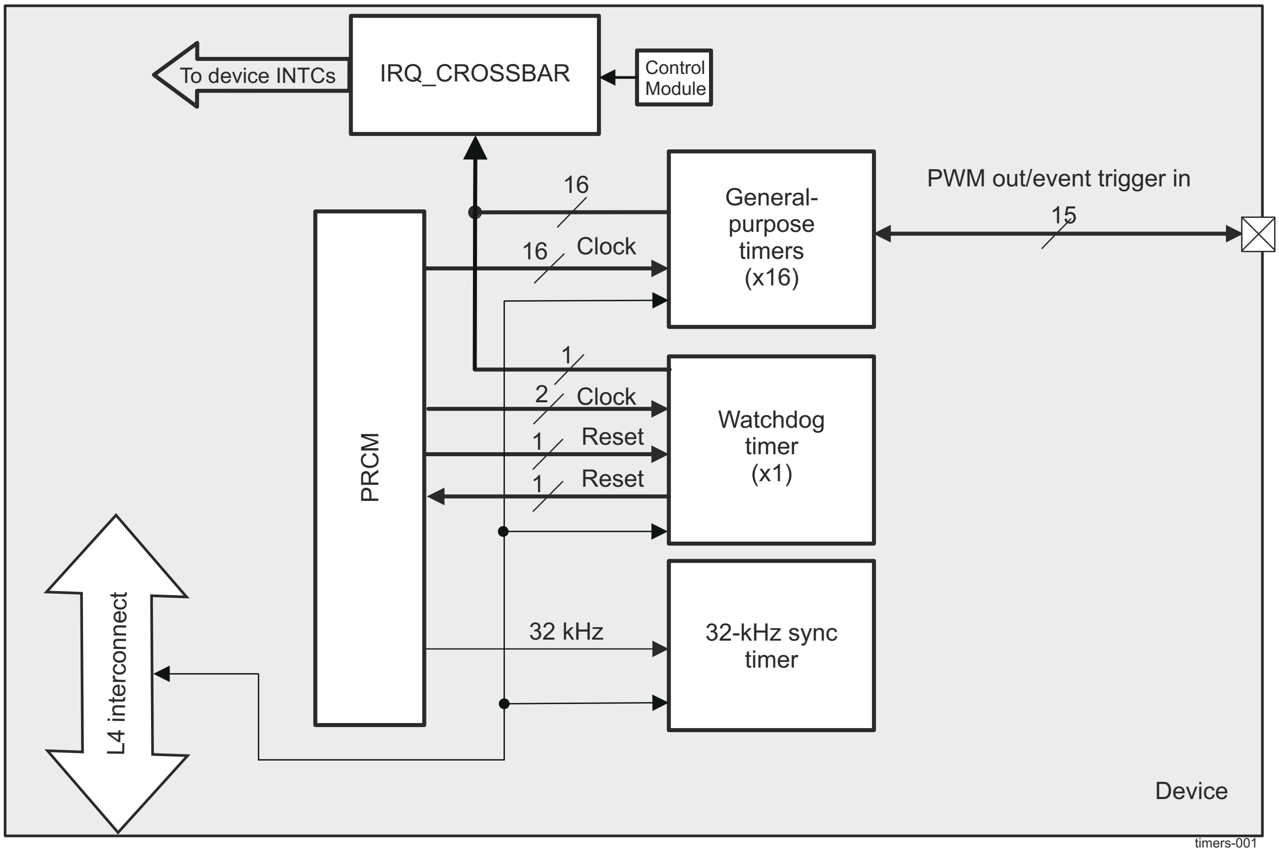

Figure 22-1. Timers Overview

The watchdog timer is clocked with 32-kHz clocks. The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. The fifteen GP timers, which are useful as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

22.2 General-Purpose Timers

22.2.1 General-Purpose Timers Overview

The device has 16 GP timers: TIMER1 through TIMER16.

- TIMER1(1ms tick): has its event capture pin tied to 32KHz clock and can be used to gauge the system clock input and detects its frequency among 19.2, 20, or 27 MHz. It includes specific functions to generate accurate tick interrupts to the operating system
- TIMER2 and TIMER10: (1ms tick timers): they include specific functions to generate accurate tick interrupts to the operating system

Each timer (except TIMER12) can be clocked from the system clock (19.2, 20, or 27 MHz) or the 32-kHz clock. The selection of clock source is made at the power, reset, and clock management (PRCM) module level. TIMER12 can be clocked only from the internal oscillator (on-die oscillator). For more information, see *PRM Clock Source*.

Each timer provides an interrupt via the device IRQ_CROSSBAR.

Each timer is connected to external pin by its PWM output or its event capture input pin (for external timer triggering). Figure 22-2 is an overview of the GP timers.

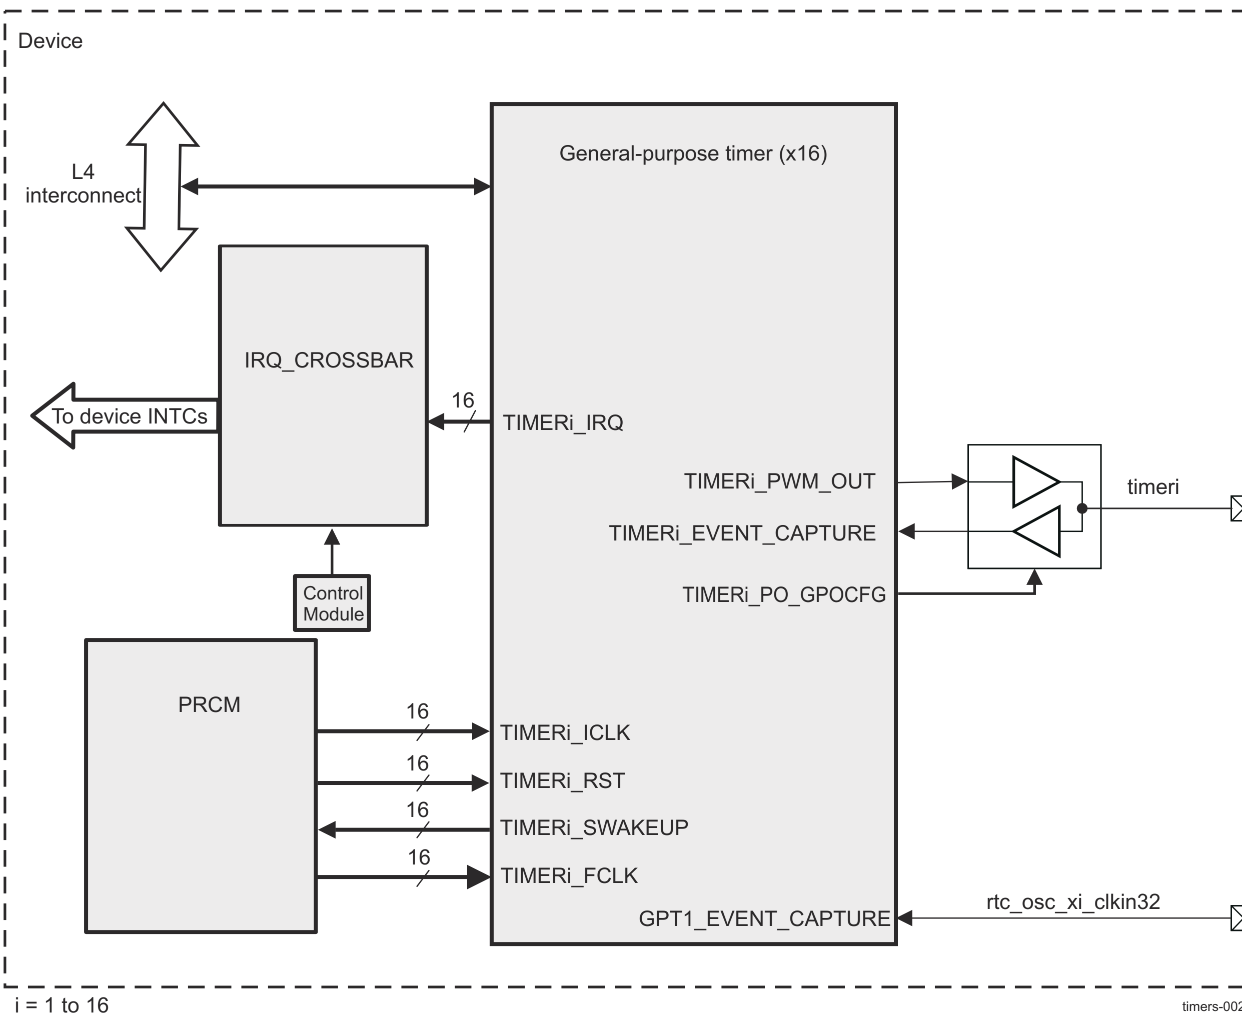

Figure 22-2. GP Timers Overview

22.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- Level 4 (L4) slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 10-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n, where n = [0:8])
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated GP output signal for using the TIMERi_GPO_CFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32.768-Hz functional clock generated (only TIMER1, TIMER2, and TIMER10)

22.2.2 GP Timer Environment

22.2.2.1 GP Timer External System Interface

Each timer can send or receive stimulus to/from the external (off-chip) system. In the device all timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. TIMER1 is also configured to receive an event trigger input (GPT1_EVENT_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input, detecting its frequency among 19.2, 20, or 27 MHz.

Figure 22-3 shows the external system interface for the GP timers, and Table 22-1 describes the GP timer inputs and outputs.

Note

Software control must ensure that MUX mode is configured to select the timeri (where i = 1 to 16) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the timeri I/O pads, see *Pad Configuration Registers*.

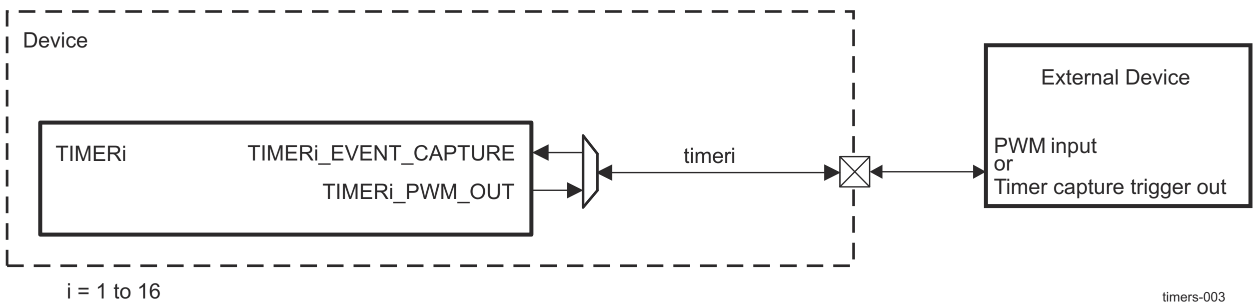

Figure 22-3. GP Timers External System Interface

Table 22-1. Input/Output Description

Pin Name	Type [(1)]	Reset Value	Signal Name	Description
timer1	I/O	0	TIMER1_PI_EVENT_CAPTURE TIMER1_PWM_OUT	TIMER1 trigger input/ PWM output
timer2	I/O	0	TIMER2_PI_EVENT_CAPTURE TIMER2_PWM_OUT	TIMER2 trigger input/ PWM output
timer3	I/O	0	TIMER3_PI_EVENT_CAPTURE TIMER3_PWM_OUT	TIMER3 trigger input/ PWM output
timer4	I/O	0	TIMER4_PI_EVENT_CAPTURE TIMER4_PWM_OUT	TIMER4 trigger input/ PWM output
timer5	I/O	0	TIMER5_PI_EVENT_CAPTURE TIMER5_PWM_OUT	TIMER5 trigger input/ PWM output
timer6	I/O	0	TIMER6_PI_EVENT_CAPTURE TIMER6_PWM_OUT	TIMER6 trigger input/ PWM output
timer7	I/O	0	TIMER7_PI_EVENT_CAPTURE TIMER7_PWM_OUT	TIMER7 trigger input/ PWM output
timer8	I/O	0	TIMER8_PI_EVENT_CAPTURE TIMER8_PWM_OUT	TIMER8 trigger input/ PWM output
timer9	I/O	0	TIMER9_PI_EVENT_CAPTURE TIMER9_PWM_OUT	TIMER9 trigger input/ PWM output
timer10	I/O	0	TIMER10_PI_EVENT_CAPTURE TIMER10_PWM_OUT	TIMER10 trigger input/ PWM output
timer11	I/O	0	TIMER11_PI_EVENT_CAPTURE TIMER11_PWM_OUT	TIMER11 trigger input/ PWM output

Table 22-1. Input/Output Description (continued)

Pin Name	Type [(1)]	Reset Value	Signal Name	Description
timer12	I/O	0	TIMER12_PI_EVENT_CAPTURE TIMER12_PWM_OUT	TIMER11 trigger input/ PWM output
timer13	I/O	0	TIMER13_PI_EVENT_CAPTURE TIMER13_PWM_OUT	TIMER13 trigger input/ PWM output
timer14	I/O	0	TIMER14_PI_EVENT_CAPTURE TIMER14_PWM_OUT	TIMER14 trigger input/ PWM output
timer15	I/O	0	TIMER15_PI_EVENT_CAPTURE TIMER15_PWM_OUT	TIMER15 trigger input/ PWM output
timer16	I/O	0	TIMER16_PI_EVENT_CAPTURE TIMER16_PWM_OUT	TIMER16 trigger input/ PWM output

(1) When configured for that function; I = Input, O = Output

Note

Each TIMERi_PO_GPOCFG signal is used to as an output enable to control the function of the TIMERi pin (where i = 1 to 16) as the PWM output (PO_GPOCFG =0) or capture input (PO_GPOCFG = 1).

22.2.3 GP Timer Integration

Figure 22-4 shows the integration of the GP timer in the device.

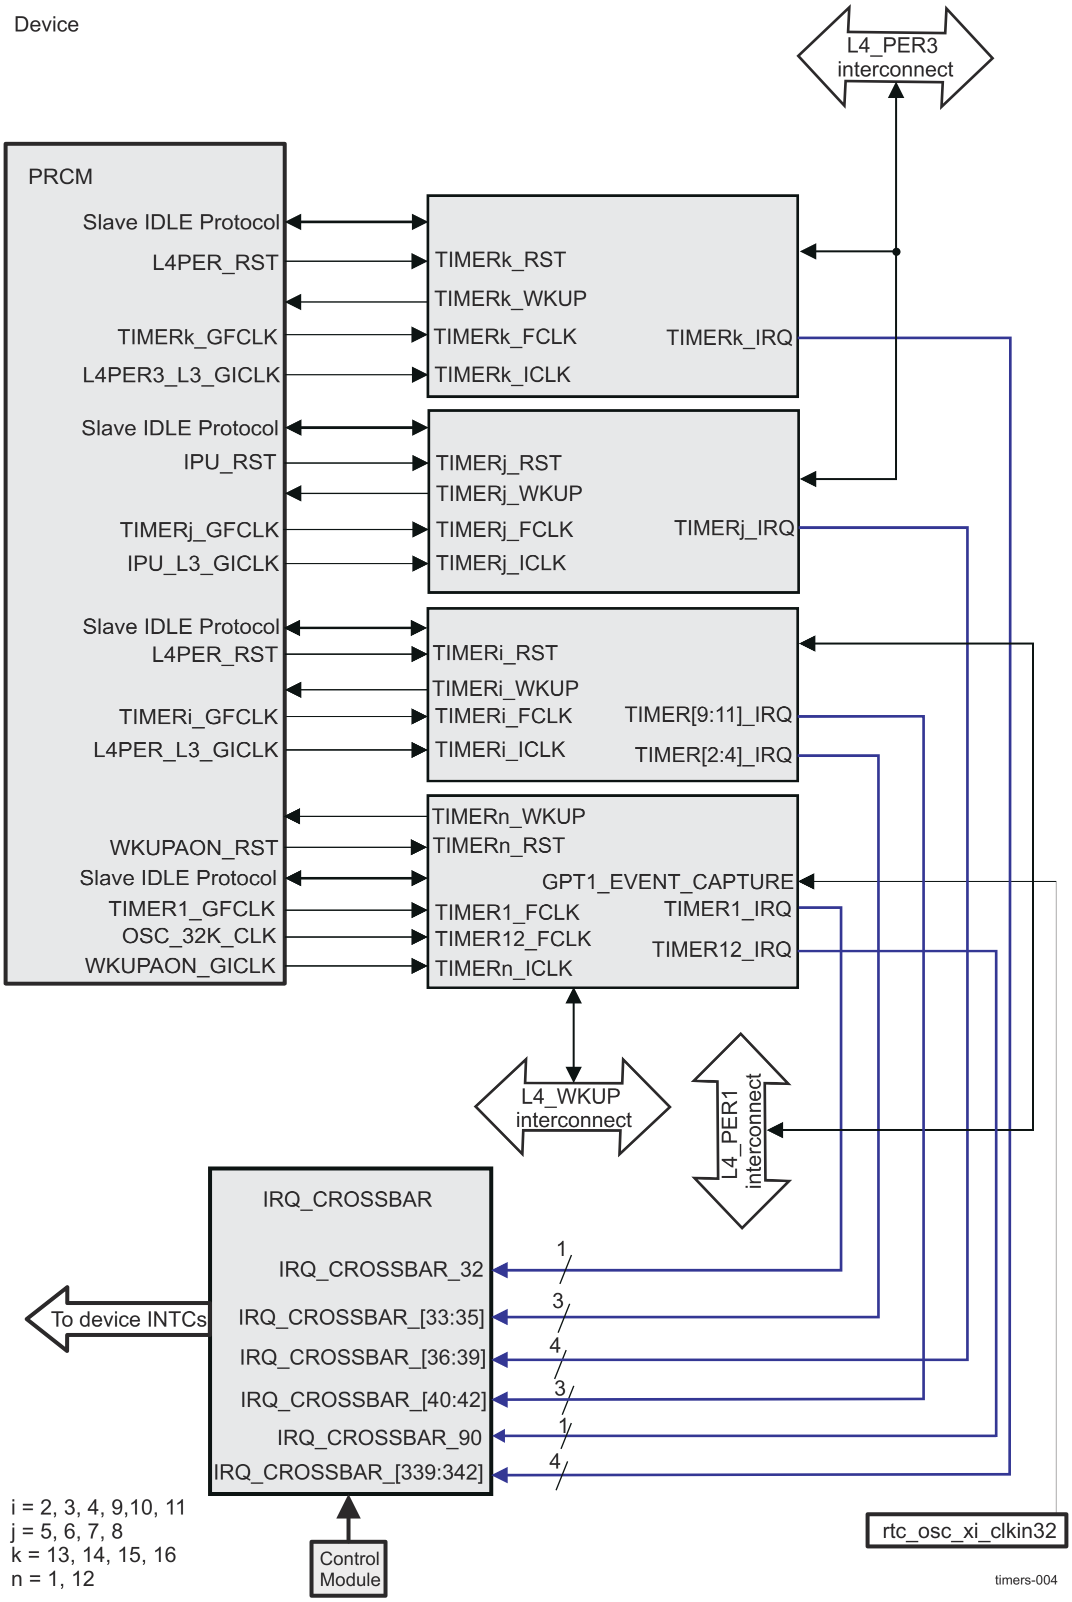

Figure 22-4. GP Timer Integration

Table 22-2 through Table 22-4 summarize the integration of the module in the device.

Table 22-2. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
TIMER1	PD_WKUPAON	Yes	L4_WKUP
TIMER2	PD_COREAON	Yes	L4_PER1
TIMER3	PD_COREAON	Yes	L4_PER1
TIMER4	PD_COREAON	Yes	L4_PER1
TIMER5	PD_COREAON	Yes	L4_PER3
TIMER6	PD_COREAON	Yes	L4_PER3
TIMER7	PD_COREAON	Yes	L4_PER3
TIMER8	PD_COREAON	Yes	L4_PER3
TIMER9	PD_COREAON	Yes	L4_PER1
TIMER10	PD_COREAON	Yes	L4_PER1
TIMER11	PD_COREAON	Yes	L4_PER1
TIMER12	PD_WKUPAON	Yes	L4_WKUP
TIMER13	PD_COREAON	Yes	L4_PER3
TIMER14	PD_COREAON	Yes	L4_PER3
TIMER15	PD_COREAON	Yes	L4_PER3
TIMER16	PD_COREAON	Yes	L4_PER3

Table 22-3. Clocks and Resets

Clocks

TIMER12	TIMER12_IRQ	IRQ_CROSSBAR_90	MPU_IRQ_95	TIMER12 interrupt
TIMER13	TIMER13_IRQ	IRQ_CROSSBAR_339	-	TIMER13 interrupt. This IRQ source signal is not mapped by default to any device INTC
TIMER14	TIMER14_IRQ	IRQ_CROSSBAR_340	-	TIMER14 interrupt. This IRQ source signal is not mapped by default to any device INTC
TIMER15	TIMER15_IRQ	IRQ_CROSSBAR_341	-	TIMER15 interrupt. This IRQ source signal is not mapped by default to any device INTC
TIMER16	TIMER16_IRQ	IRQ_CROSSBAR_342	-	TIMER16 interrupt. This IRQ source signal is not mapped by default to any device INTC
No DMA Requests				

Note

The “**Default Mapping**” column in Table 22-4 *GP Timers Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For the description of the interrupt source, see Section 22.2.4.5, *GP Timer Interrupt*.

22.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the IRQSTATUS_SET and IRQSTATUS_CLR register for the interrupt features, and a dedicated bit of the IRQWAKEEN register for the wake-up of TIMER1, TIMER2, and TIMER10. In addition, these timers have a mechanism implemented to generate an accurate tick interrupt.

For all other internal interrupt source can be independently enabled and disabled through the IRQENABLE_SET and IRQENABLE_CLR registers.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see Section 22.2.1, *GP Timer Overview*).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

22.2.4.1 GP Timer Block Diagram

Figure 22-5 is a block diagram of the common GP timers, and Figure 22-6 is a block diagram of the GP timers with a 1-ms tick generation module.

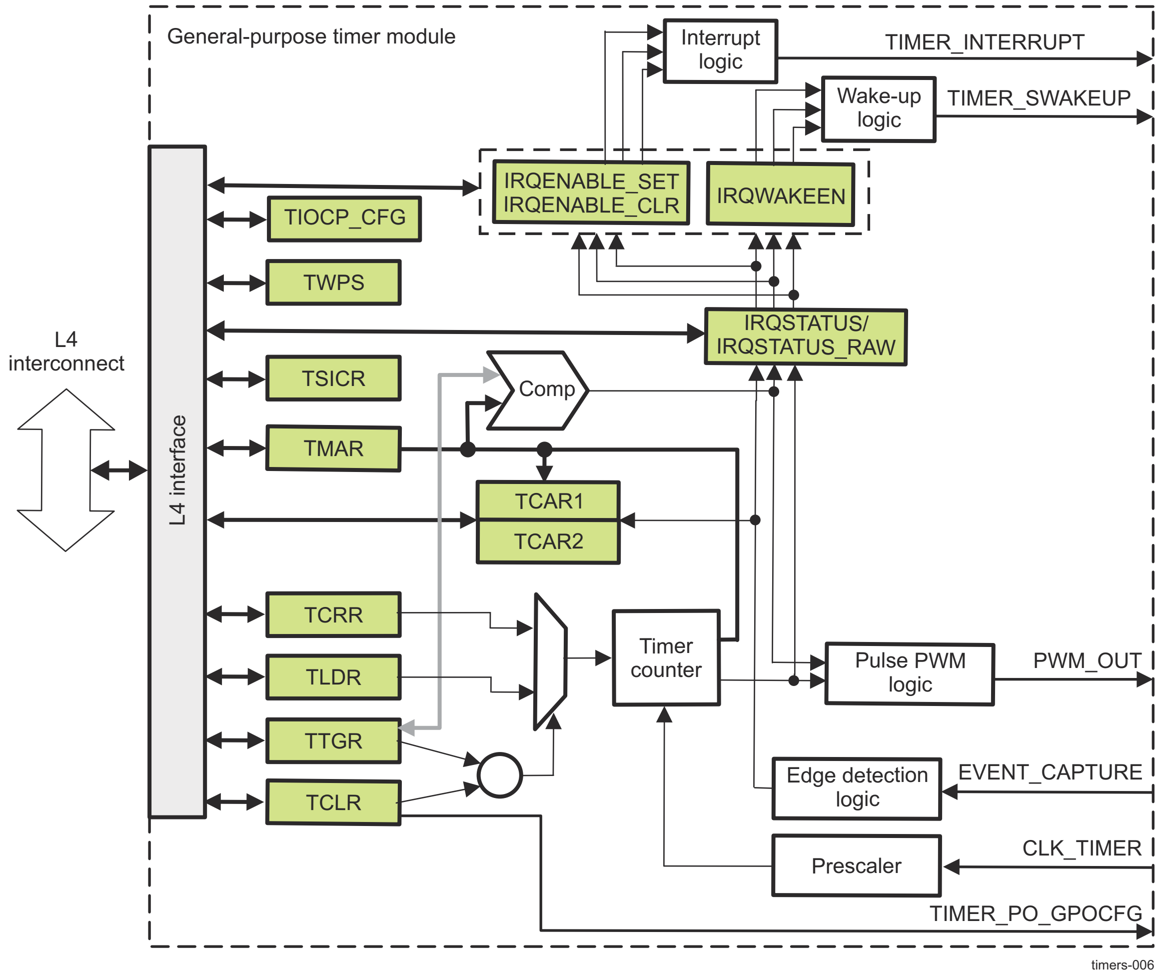

Figure 22-5. Block Diagram of TIMER3 Through TIMER9 and TIMER11 Through TIMER16

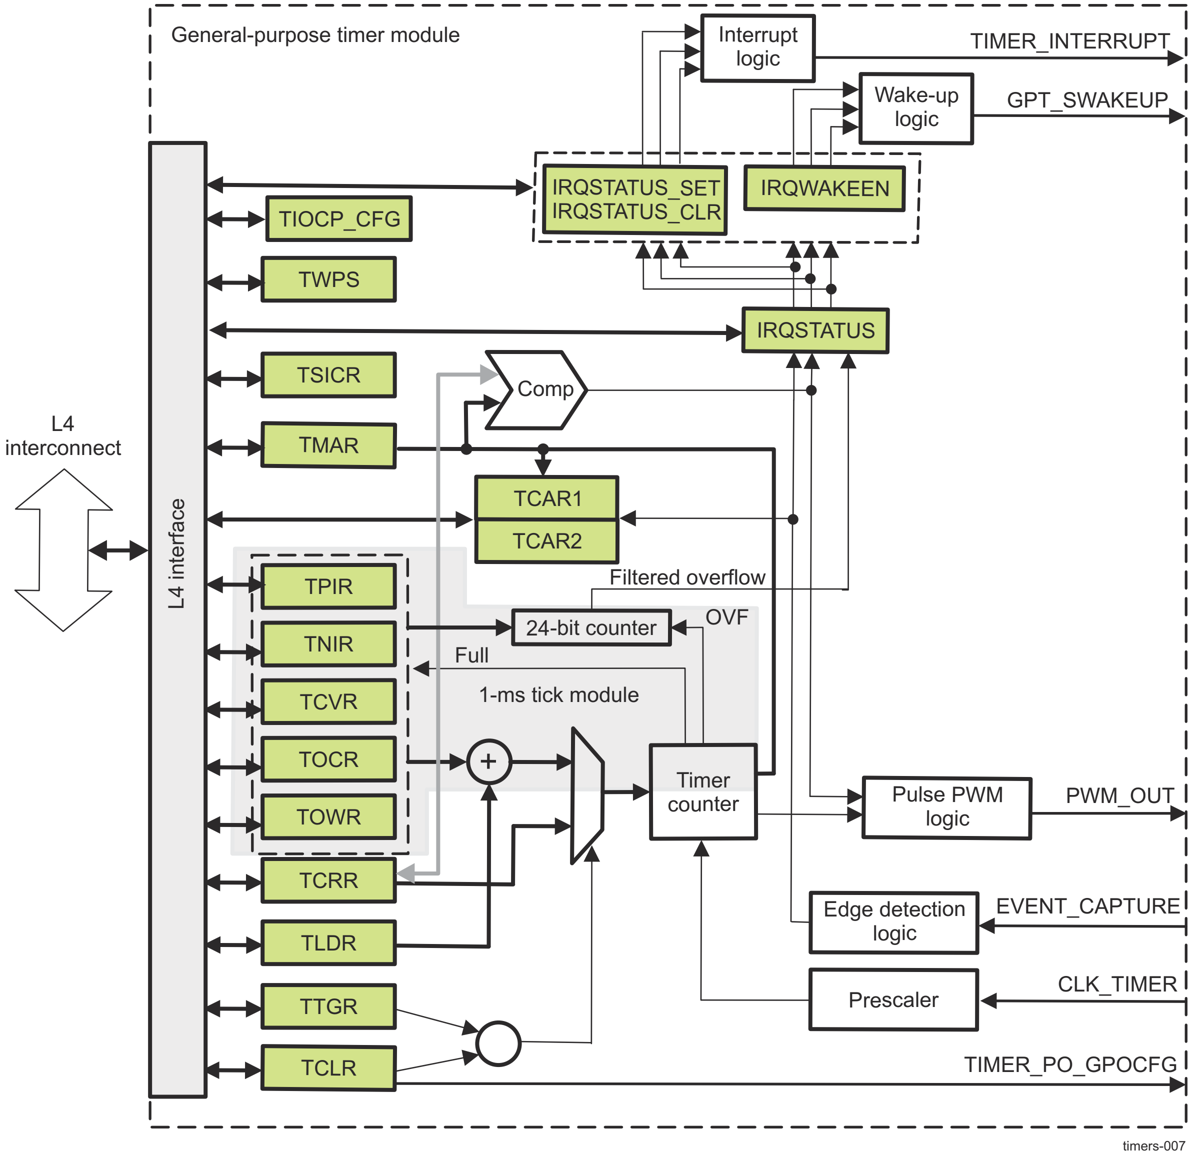

Figure 22-6. Block Diagram of TIMER1, TIMER2 and TIMER10

22.2.4.2 TIMER1, TIMER2 and TIMER10 Power Management

At the PRCM module level, when all conditions to shut off the functional or interface output clocks in the PRCM module are met (see *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the TIOCP_CFG[3:2] IDLEMODE bit field.

Table 22-5 lists the IDLEMODE settings and the related acknowledgment modes.

Table 22-5. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

22.2.4.2.1 Wake-Up Capability

If the TIOCP_CFG[3:2] IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode.

Figure 22-7 shows the wake-up request generation. For more information about the GP timer clock control, *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.

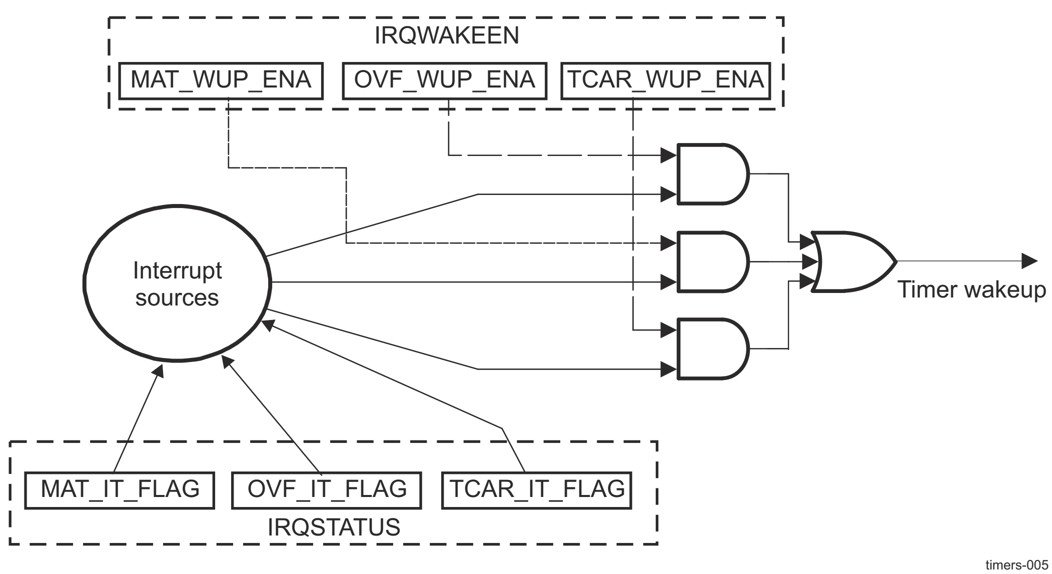

Figure 22-7. Wake-Up Request Generation

For TIMER1, TIMER2 and TIMER10, the timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (TCRR), a timer match (the compare result of TCRR and TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER_EVENT_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

Note

The status bit must be reset to re-enter idle mode.

22.2.4.3 Power Management of Other GP Timers

At the PRCM module level, when all conditions to shut off the functional or interface output clocks of the PRCM module are met (see *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the TIOCP_CFG[3:2] IDLEMODE bit field.

Table 22-6 lists the IDLEMODE settings and the related acknowledgment modes.

Table 22-6. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

22.2.4.3.1 Wake-Up Capability

If the TIOCP_CFG[3:2] IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode. This wake-up request is sent only if the IRQWAKEEN[2:0] bit field enables the timer wake-up capability.

Figure 22-8 shows the wake-up request generation. For more information about the GP timer clock control, see *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.

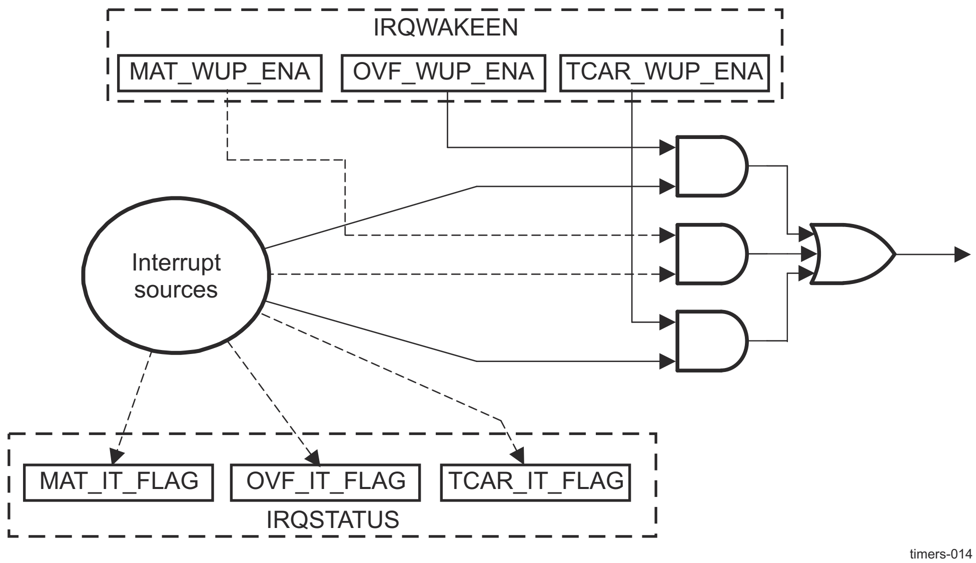

Figure 22-8. Wake-Up Request Generation

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

Note

The status bit must be reset to re-enter idle mode.

22.2.4.4 Software Reset

Two bits can generate a software reset of the GP timer:

- TIOCP_CFG[0] SOFTRESET
- TSICR[1] SFT

For both bits, all read accesses return 0.

The TIOCP_CFG[0] SOFTRESET bit allows resetting of the functional and interface domains. The TSICR[1] SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the TIOCP_CFG[0] SOFTRESET bit. This bit monitors the internal reset status.

22.2.4.5 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (IRQSTATUS_SET for TIMER1/2/10 and IRQENABLE_SET for other timers) and disabled in the interrupt-disable register (IRQSTATUS_CLR for TIMER1/2/10 and IRQENABLE_CLR for other timers). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS).

22.2.4.6 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the TCLR[0] ST bit). The timer counter register (TCRR) can be loaded when stopped or on-the-fly (while counting). TCRR can be loaded directly by a TCRR write access with a new timer value. TCRR can also be loaded with the value held in the timer load register (TLDR) by a trigger register (TTGR) write access. The loading of TCRR is done regardless of the written value of TTGR. The value of TCRR can be read when stopped or captured on-the-fly by a TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the TCLR[1] AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the TCLR[1] AR bit is set to 1), TCRR is reloaded with the value of TLDR after a counting overflow occurs.

CAUTION

Do not put the overflow value (0xFFFF FFFF) in the TLDR register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the IRQSTATUS_SET[1] OVF_EN_FLAG bit is set to 1 for TIMER1/2/10 and the IRQENABLE_SET[1]OVF_EN_FLAG bit is set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in the TCLR[12] PT bit through the TCLR[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The TCLR[12] PT bit selects pulse/toggle modulation (the TCLR[11:10] TRG bit field selects trigger mode).

Figure 22-9 shows the TCRR timing value.

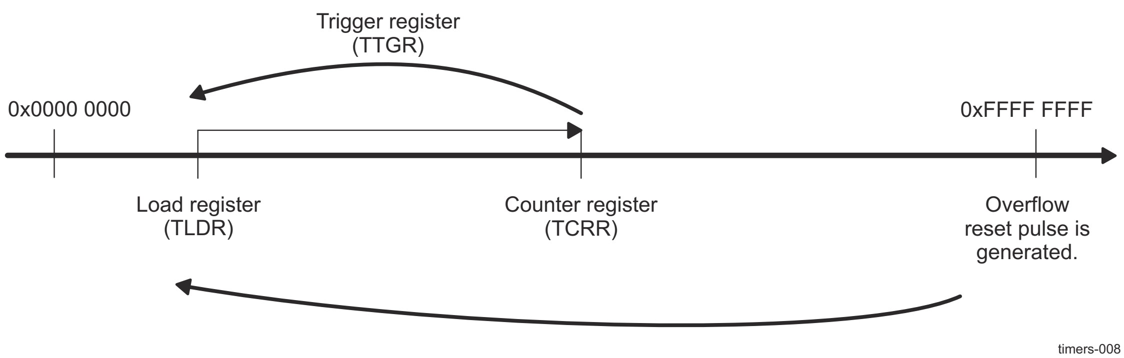

Figure 22-9. TCRR Timing Value

22.2.4.6.1 1-ms Tick Generation (Only TIMER1, TIMER2 and TIMER10)

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See Figure 22-10.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the TPIR[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (the TNIR[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

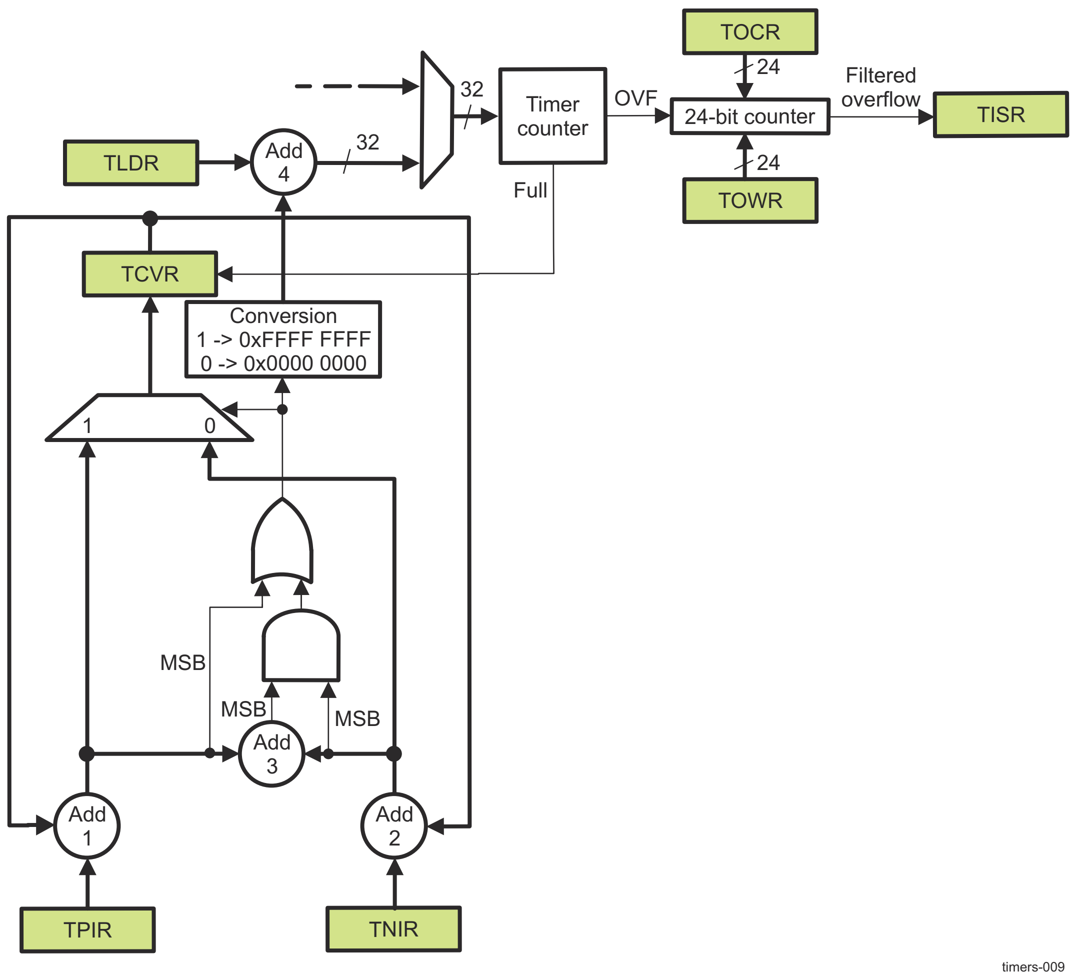

Figure 22-10. Block Diagram of the 1-ms Tick Module

The TPIR, TNIR, and TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (the TCRR[31:0] TIMER_COUNTER bit field) is the value of the TLDR[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of TLDR[31:0] LOAD_VALUE –1 (period greater than 1 ms).

Table 22-7 lists the value loaded in the TCRR according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value; MSB = 1: Negative value

Table 22-7. Value Loaded in TCRR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of TCRR Register
0	0	0	TLDR[31:0] LOAD_VALUE bit field
0	0	1	TLDR[31:0] LOAD_VALUE bit field
0	1	0	TLDR[31:0] LOAD_VALUE bit field
0	1	1	TLDR[31:0] LOAD_VALUE –1
1	0	0	N/A
1	0	1	N/A
1	1	0	TLDR[31:0] LOAD_VALUE –1
1	1	1	TLDR[31:0] LOAD_VALUE –1

The values of the TPIR and TNIR registers are calculated using the following formulas:

- Positive increment value = ((INTEGER[F_{clk} × T_{tick}] + 1) × 1e6) – (F_{clk} × T_{tick} × 1e6)
- Negative increment value = (INTEGER[F_{clk} × T_{tick}] × 1e6) – (F_{clk} × T_{tick} × 1e6)

Note

F_{clk} clock frequency (kHz)

T_{tick} tick period (ms)

The timer overflow counter register (TOCR) and the timer overflow wrapping register (TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TOCR. When the values in the 24-bit TOCR match the values in the 24-bit TOWR and the timer overflow is asserted, the TOCR is reset and an interrupt is generated to the IRQSTATUS register.

Note

TOWR has to be set to requested value. For example, if no interrupt needs to be masked TOWR must be set ot 0, if one interrupt needs to TOWR must be set to 1, if two interrupt need to be masked TOWR must be set to 2 and so on.

It is important to have in mind that the case when FFFFFF interrupt need to be masked is not possible.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of TIMER1, TIMER2, and TIMER10 remain unchanged.

For 1-ms tick with a 32.768-Hz clock:

- TPIR[31:0] POSITIVE_INC_VALUE = 232,000
- TNIR[31:0] NEGATIVE_INC_VALUE = –768,000
- TLDR[31:0] LOAD_VALUE = 0xFFFF FFE0

Note

Any value of the tick period can be generated with the appropriate value of the TPIR, TNIR, and TLDR.

By default, the TPIR, TNIR, TCVR, TOCR, and TOWR and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

22.2.4.7 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the TCRR can be captured and saved in the TCAR1 or TCAR2 register function of the mode selected in the TCLR[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

The rising edge, falling edge, or both, can be selected in the TCLR[9:8] TCM bit field to trigger the timer counter capture. The module sets the IRQSTATUS[2] TCAR_IT_FLAG bit when an active edge is detected, and at the same time, the counter value TCRR is stored in timer capture register TCAR1 or TCAR2, as follows:

- If the TCLR[13] CAPT_MODE bit is 0, on the first enabled capture event, the value of the counter register is saved in the TCAR1 register, and the next events are ignored (no update on the TCAR1 register and no interrupt triggering) until the detection logic is reset or the IRQSTATUS[2] TCAR_IT_FLAG is cleared by writing 1 to it.
- If the TCLR[13] CAPT_MODE bit is 1, on the first enabled capture event, the value of the counter register is saved in the TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on TCAR1/TCAR2 and no interrupt triggering) until the

detection logic is reset or the IRQSTATUS[2] TCAR_IT_FLAG bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The IRQSTATUS[2] TCAR_IT_FLAG bit is cleared by writing 1 to it or when the edge detection mode bits (the TCLR[9:8] TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT_CAPTURE). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the IRQSTATUS_SET[2] TCAR_EN_FLAG bit (for TIMER1/2/10) or in the IRQENABLE_SET[2] TCAR_EN_FLAG bit (for other timers). See the examples in Figure 22-11 and Figure 22-12.

In Figure 22-11, the value of the TCLR[9:8] TCM bit field is 0b01, and the TCLR[13] CAPT_MODE bit is 0. Only the rising edge of EVENT_CAPTURE triggers a capture in the TCAR1 and TCAR2 registers, and only the TCAR1 register updates.

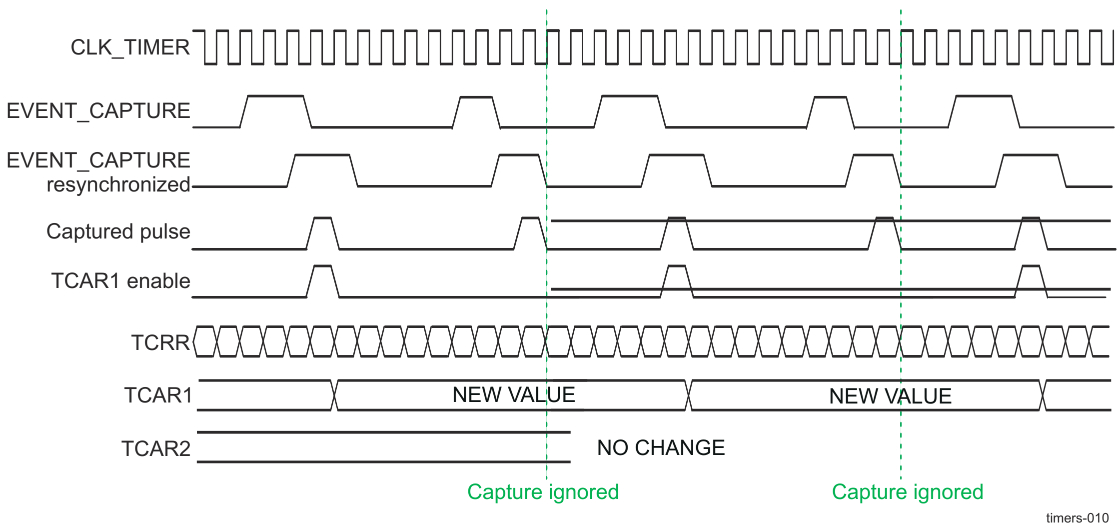

Figure 22-11. Capture Wave Example for TCLR[13] CAPT_MODE = 0

In Figure 22-12, the value of the TCLR[9:8] TCM bit field is 0b01, and the TCLR[13] CAPT_MODE bit is 1. Only the rising edge of EVENT_CAPTURE triggers a capture in the TCAR1 register on the first enabled event, and the TCAR2 register updates on the second enabled event.

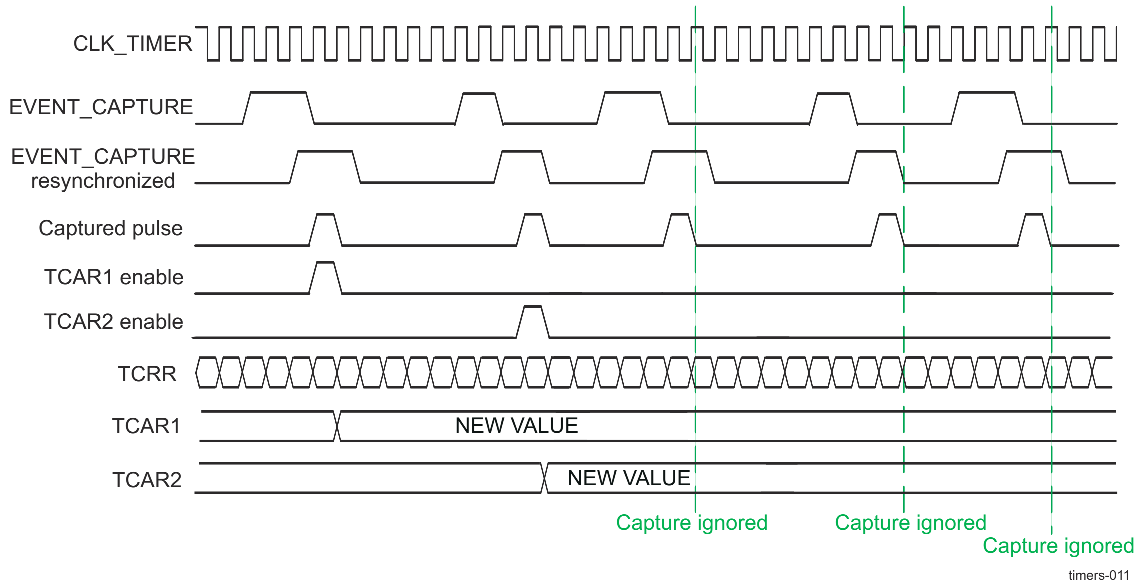

Figure 22-12. Capture Wave Example for TCLR[13] CAPT_MODE = 1

22.2.4.8 Compare Mode Functionality

When the compare-enable register TCLR[6] CE bit is set to 1, the timer value (the TCRR[31:0] TIMER_COUNTER bit field) is continuously compared to the value held in the timer match register (TMAR). The value of the TMAR[31:0] COMPARE_VALUE bit field can be loaded at any time (timer counting or stopped). When the TCRR and the TMAR values match, an interrupt is issued, if the IRQSTATUS_SET[0] MAT_EN_FLAG bit (for TIMER1, TIMER2, and TIMER10), or the IRQENABLE_SET[0] MAT_EN_FLAG bit (for other timers) is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the TMAR before setting the TCLR[6] CE bit.

The dedicated output pin (timer PWM) can be programmed in the TCLR[12] PT bit through the TCLR[11:10] TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

22.2.4.9 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the TCLR[5] PRE bit is set. The TCLR[4:2] PTV bit field sets the 2^n division ratio (prescaler value is $2^{(PTV + 1)}$. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 22-8 lists the prescaler/timer reload values versus contexts.

Table 22-8. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	TLDR[31:0]
TCRR write	Reset	TCRR[31:0]
TTGR write	Reset	TLDR[31:0]
Stop	Reset	Frozen

22.2.4.10 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The TCLR[11:10] TRG bit field determines on which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

Note

In toggle mode, when TCLR[11:10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first, it does not toggle the PWM line (see Figure 22-14).

The TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the TCLR[11:10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 22-13, the internal overflow pulse is set each time the (0xFFFF FFFF – TLDR[31:0] LOAD_VALUE + 1) value is reached, and the internal match pulse is set when the counter reaches the value of TMAR. Depending on the value of the TCLR[12] PT bit and TCLR[11:10] TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

The TLDR and TMAR must keep values below the overflow value (0xFFFF FFFF) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the TMAR and the value in the TLDR must be at least two units. When match event is used, the compare mode TCLR[6] CE bit must be set.

In Figure 22-13, the TCLR[7] SCPWM bit is set to 0. In Figure 22-14, the TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (TCLR[7] SCPWM bit).

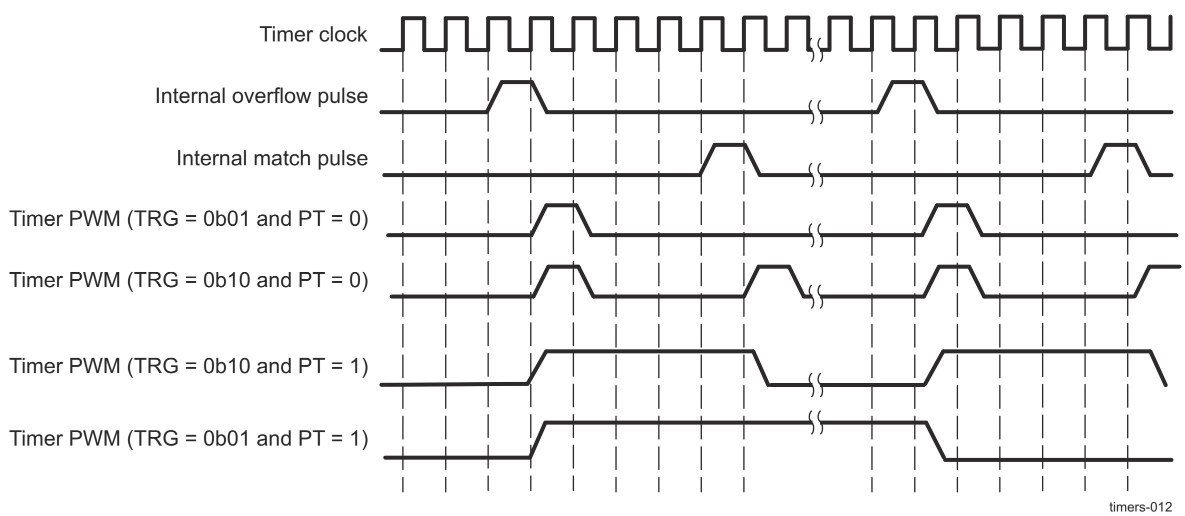

Figure 22-13. Timing Diagram of PWM With TCLR[7] SCPWM Bit = 0

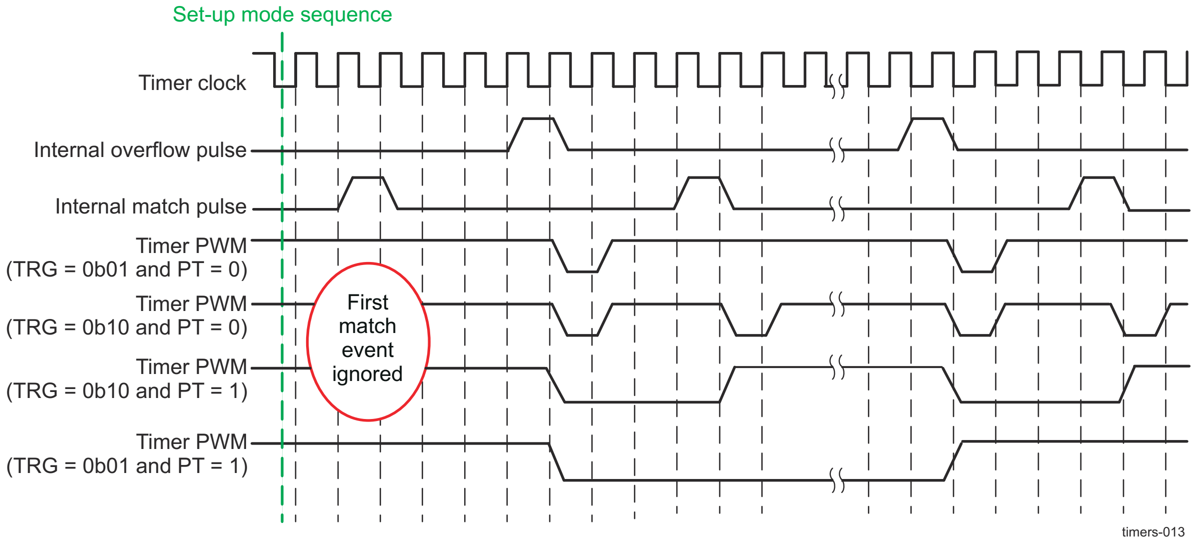

Figure 22-14. Timing Diagram of PWM With TCLR[7] SCPWM Bit = 1

22.2.4.11 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the TCLR[5] PRE bit and TCLR[4:2] PTV bit field)
- Value loaded into the TLDR

Table 22-9 lists the prescaler clock ratio values.

Table 22-9. Prescaler Clock Ratio Values

TCLR[5] PRE	TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

OVF_Rate = (0xFFFF FFFF – TLDR + 1) × (timer-functional clock period) × PS

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS = $2^{(PTV + 1)}$ if prescaler is enabled, or PS = 1 if prescaler is disabled.

CAUTION

Internal resynchronization causes any write to the TCLR[1] ST bit to have some latency before the register is updated:

2.5 × functional clock cycles write_TIMER_TCLR_latency 3.5 × functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the TCLR[1] ST bit.

CAUTION

- In non-PWM mode, TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, TLDR must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and the TCLR[5] PRE bit set to 0, the timer output period is as listed in Table 22-10.

Table 22-10. Value and Corresponding Interrupt Period

TLDR[31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 µs
0xFFFF FFFE	62.5 µs

22.2.4.12 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the TIOCP_ CFG[1] EMUFREE bit.

If the TIOCP_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the TIOCP_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (timerx_pwm_evt, where x = [8:11]) is internally synchronized on two timer-clock rising edges.

22.2.4.13 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration. All registers are 32 bits wide, accessible through the OCP interface with 16- or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB) first. Write operations to the following GP timer registers can skip the MSB access if it is not necessary to update the 16 MSBs of the register:

- TIDR (all GP timers)
- TIOCP_CFG (all GP timers)
- IRQSTATUS_SET (GP timers 1, 2, 10)
- IRQSTATUS_RAW (all GP timers)
- IRQSTATUS (all GP timers)
- IRQENABLE_SET(all GP timers except 1,2,10)
- IRQENABLE_CLR(all GP timers except 1,2,10)
- IRQSTATUS_SET (GP timers 1, 2, 10)
- IRQSTATUS_CLR (GP timers 1, 2, 10)
- IRQWAKEEN (all GP timers)
- TSICR (all GP timers)

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- TCLR (all GP timers)
- TCRR (all GP timers)
- TLDR (all GP timers)
- TTGR (all GP timers)
- TMAR (all GP timers)
- TPIR (GP timers 1, 2, 10)
- TNIR (GP timers 1, 2, 10)
- TCVR (GP timers 1, 2, 10)
- TOCR (GP timers 1, 2, 10)

- TOWR (GP timers1, 2, 10)

The following L4 synchronous registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one L4 clock cycle from command assertion:

- TIDR
- TIOCP_CFG
- IRQSTATUS
- IRQSTATUS_RAW
- IRQENABLE_SET
- IRQENABLE_CLR
- IRQSTATUS_SET
- IRQSTATUS_CLR
- IRQWAKEEN
- TWPS
- TSICR

22.2.4.13.1 Writing to Timer Registers

The host uses the OCP interface to write to the following registers synchronously with the timer interface clock:

- TLDR
- TCRR
- TCLR
- TIOCP_CFG
- IRQSTATUS
- IRQENABLE_SET
- IRQENABLE_CLR
- IRQWAKEEN
- TTGR
- TSICR
- TMAR

TIMER1, TIMER2, and TIMER10 also have the following registers:

- IRQSTATUS_SET
- IRQSTATUS_CLR
- TPIR
- TNIR
- TCVR
- TOCR
- TOWR

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

22.2.4.13.1.1 Write Posting Synchronization Mode

This mode is used if the TSICR[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (TCLR, TCRR, TLDR, TTGR, TMAR, and TPIR, TNIR, TCVR, TOCR, and TOWR for TIMER1, TIMER2, and TIMER10). Therefore, the write transaction is immediately acknowledged on the open-core protocol (OCP) interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status (TWPS) register. In this mode, it is mandatory that software check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the OCP clock. Consequently, any read access to TCRR does not add any resynchronization latency; the current value is always available.

Note

Because the overflow IRQ is generated when the value of TCRR reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of (1 × PS × timer functional clock period) before any read access to TCRR to ensure a correct reading of its content.

Note

If TTGR register is written during posted write to TCRR, the value to be written to TCRR will be discarded.

If a posted write to TCVR is started, the user must not write to TPIR or TNIR before the TCVR write is finished, because the value of TCVR is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range: freq(timer clock) < freq(OCP interface clock) / 4.

22.2.4.13.1.2 Write Nonposting Synchronization Mode

This mode is used if the TSICR[2] POSTED bit is set to 0 (default value). It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the OCP interface frequency and the timer clock frequency.

22.2.4.13.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (TCRR, TCAR1, and TCAR2) captures the current timer counter value. This must be followed by reading the 16 MSBs. The synchronization schemes for read posted and read non-posted transactions are the same as the corresponded write transactions described before.

Note

LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

The TCRR is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. This capture scheme is also performed for the TCAR1 and TCAR2 registers as they can be changed due to internal processes too. DSP 16 bit accesses can be interleaved with MCU 32 bit accesses.

Note

Reading of counter value of GPTimer5 through GPTimer8 should be done with delay of 10 L4_PER clock cycles when the functional clock source is 32kHz and the IPU CD is in the hardware AUTO state.

Note

Reading of counter value of GPTimer5 through GPTimer8 can be done without any delay when the functional clock source is 32kHz and the IPU CD is in software wakeup mode, or the static dependency between IPU and MPU is enabled.

22.2.4.13.2.1 Read Posted

This mode is functional whatever the ratio between the OCP interface frequency and the functional clock frequency are. The recommended functional frequency range is freq(timer) < freq(OCP) / 4.

Read posted mode is used if TSICR[2] POSTED = 0x1 or TSICR[3] READ_MODE is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the OCP interface, and the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to TCRR, TCAR1, TCAR2, TCVR, and TOWR, which need resynchronization from functional to OCP clock domains.

22.2.4.13.2.2 Read Non-Posted

This mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is freq(timer) >= freq(OCP) / 4.

Read non-posted mode is used if TSICR[2] POSTED = 0x0 and TSICR[3] READ_MODE = 0x1. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the OCP interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to TCRR, TCAR1, TCAR2, TCVR, and TOWR, which need resynchronization from functional to OCP clock domains.

22.2.4.14 Posted Mode Selection

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are TCLR, TLDR, TCRR, TTGR, TMAR, TPIR, TNIR, TCVR, TOCR, and TOWR. For read operation, the registers affected by this selection are: TCRR, TCAR1, TCAR2, TCVR, and TOWR.

The OCP clock domain synchronous registers TIDR, TIOCP_CFG, IRQSTATUS, IRQSTATUS_SET, IRQWAKEEN, TWPS, and TSICR are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one OCP clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in TSICR[2] POSTED bit. The TSICR[3] READ_MODE defines how the read operation is performed when the module is configured in non-posted mode (see TSICR). The following cases are possible:

- TSICR[2] POSTED = 0x1 and TSICR[3] READ_MODE = x (don't care): read and write operations are expected in posted mode.
- TSICR[2] POSTED = 0x0 and TSICR[3] READ_MODE = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.

- TSICR[2]POSTED = 0x0 and TSICR[3] READ_MODE = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

22.2.5 GP Timer Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

22.2.5.1 Global Initialization

22.2.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the GP timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the GP timer. For more information, see Section 22.2.3, *GP Timers Integration*, and Section 22.2.2, *GP Timers Environment*. Table 22-11 summarizes the surrounding modules.

Table 22-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.
Control module	The module-specific pad muxing must be set in the control module. For more information about the module configuration, see *Pad Configuration Registers,* in *Control Module*.
IRQ_CROSSBAR	The IRQ_CROSSBAR configuration must be done to enable the interrupts from the GP timer module. See *IRQ_CROSSBAR Module Functional Description*.

22.2.5.1.2 GP Timer Module Global Initialization

22.2.5.1.2.1 Main Sequence – GP Timer Module Global Initialization

Table 22-12 identifies the main steps for initializing the GP timer module when the module is to be used for the first time.

Table 22-12. GP Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	TIOCP_CFG[0] SOFTRESET	0x1
Wait until reset release?	TIOCP_CFG[0] SOFTRESET	0x0
Configure idle mode.	TIOCP_CFG[3:2] IDLEMODE	0x-
Enable wake-up interrupt events.	IRQWAKEEN[2:0]	0x-
Select posted mode.	TSICR[2] POSTED	0x-

22.2.5.2 Operational Mode Configuration

22.2.5.2.1 GP Timer Mode

22.2.5.2.1.1 Main Sequence – GP Timer Mode Configuration

Table 22-13 lists the steps in the GP timer mode configuration.

Table 22-13. GP Timer Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Enable overflow interrupt.	IRQSTATUS_SET[1] OVF_EN_FLAG[(1)] or IRQENABLE_SET[1] OVF_EN_FLAG[(2)]	0x1
Load timer counter value.	TCRR	0x-
Load timer load value.	TLDR	0x-
Start the timer.	TCLR[0] ST	0x1

(1) Applies only to TIMER1, TIMER2, and TIMER10.
(2) Applies to TIMER3 through TIMER 9 and TIMER11 through TIMER16.

22.2.5.2.2 GP Timer Compare Mode

22.2.5.2.2.1 Main Sequence – GP Timer Compare Mode Configuration

Table 22-14 lists the steps in the GP timer compare mode configuration.

Table 22-14. GP Timer Compare Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Enable match interrupt.	IRQSTATUS_SET[0] MAT_EN_FLAG(1) or IRQENABLE_SET[0] MAT_EN_FLAG(2)	0x1
Load timer counter value.	TCRR	0x-
Load timer compare value.	TMAR	0x-
Enable compare mode.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

(1) Applies only to TIMER1, TIMER2, and TIMER10.
(2) Applies to TIMER3 through TIMER9 and TIMER11 through TIMER16.

22.2.5.2.3 GP Timer Capture Mode

22.2.5.2.3.1 Main Sequence – GP Timer Capture Mode Configuration

Table 22-15 lists the steps in the GP timer capture mode configuration.

Table 22-15. GP Timer Capture Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See Section 22.2.5.2.3.2.	
Enable capture interrupt.	IRQENABLE_SET[2] TCAR_EN_FLAG (2) or IRQSTATUS_SET[2] TCAR_EN_FLAG (1)	0x1
Start the timer.	TCLR[0] ST	0x1
Detect event.	See Section 22.2.5.2.3.3.	

(1) Applies only to TIMER1, TIMER2, and TIMER10.
(2) Applies only to TIMER3 through TIMER9 and TIMER11 through TIMER16.

22.2.5.2.3.2 Subsequence – Initialize Capture Mode

Table 22-16 lists the steps to initialize capture mode.

Table 22-16. Initialize Capture Mode

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select TIMERi (where i = 2 to 11 and 13 to 16). Capture input at device pin timeri.	TCLR[14] GPO_CFG	0x1
Select single or second event capture.	TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	TCLR[9:8] TCM	0x-

22.2.5.2.3.3 Subsequence – Detect Event

Table 22-17 lists the steps in detecting an event.

Table 22-17. Detect Event

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	IRQSTATUS[2] TCAR_IT_FLAG	= 0x1

Table 22-17. Detect Event (continued)

Step	Register/Bit Field/Programming Model	Value
Read timer capture value.	TCAR1 and/or TCAR2	
Clear capture interrupt request.	IRQSTATUS[2] TCAR_IT_FLAG	0x1

22.2.5.2.4 GP Timer PWM Mode

22.2.5.2.4.1 Main Sequence – GP Timer PWM Mode Configuration

Table 22-18 lists the steps in the GP timer PWM mode configuration.

Table 22-18. GP Timer PWM Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select trigger output mode.	TCLR[11:10] TRG	0x-
Select pulse or toggle modulation PWM mode.	TCLR[12] PT	0x-
Select TIMERi (where i = 2 to 11 and 13 to 16) PWM output at device pin timeri.	TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	TCLR[7] SCPWM	0x-
Load timer load value.	TLDR	0x-
Load timer compare value.	TMAR	0x-
Enable compare.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

22.2.6 GP Timer Register Manual

22.2.6.1 GP Timer Instance Summary

Table 22-19 lists the base address and block size for the GP timer module instances.

Table 22-19. GP Timer Instance Summary

Module Name	Base Address L4_PER1 Interconnect	Base Address L4_PER3 Interconnect	Base Address L4_WKUP Interconnect	Size
TIMER2	0x4803 2000	–	–	112 Bytes
TIMER3	0x4803 4000	–	–	92 Bytes
TIMER4	0x4803 6000	–	–	92 Bytes
TIMER9	0x4803 E000	–	–	92 Bytes

22.2.6.2 GP Timer Registers

22.2.6.2.1 GP Timer Register Summary

CAUTION

The GP timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 22-20 through Table 22-25 provide the register summary and associated offset addresses for the 15 GP timer internal registers.

Table 22-20. TIMER1, TIMER2, and TIMER10 Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	TIMER1 Physical Address L4_WKUP Interconnect	TIMER2 Physical Address L4_PER1 Interconnect	TIMER10 Physical Address L4_PER1 Interconnect
TIDR	RO	32	0x0000 0000	0x4AE1 8000	0x4803 2000	0x4808 6000

Description	This register controls the various parameters of the L4 interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE		EMUFREE	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x0000000

Bits	Field Name	Description	Type	Reset
3:2	IDLEMODE	Power management, req/ack control 0x0: Force-idle mode: local target idle state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Back-up mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Back-up mode, for debug only. 0x2: Smart-idle mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module *swake-up* output(s) is (are) implemented.	RW	0x0
1	EMUFREE	Emulation mode 0x0: The timer is frozen in emulation mode (PINSUSPENDN signal active). 0x1: The timer runs free, regardless of PINSUSPENDN value.	RW	0
0	SOFTRESET	Software reset 0x0: Read 0: reset done, no pending action Write 0: No action 0x1: Read 1: initiate software reset Write 1: Reset ongoing	RW	0

RESERVED																	GPO_CFG	CAPT_MODE	PT	TRG		TCM		SCPWM	CE	PRE	PTV			AR	ST

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	GPO_CFG	General-purpose output - this register directly drives the PO_GPOCFG output. For specific use of the GPO_CFG bit, see *GP Timer External System Interface*. 0x0: PO_GPOCFG drives 0. 0x1: PO_GPOCFG drives 1.	RW	0
13	CAPT_MODE	Capture mode select bit (first/second) 0x0: Single capture: Capture the first enabled capture event in TCAR1. 0x1: Capture on second event: Capture the second enabled capture event in TCAR1 and the second enabled capture event in TCAR2.	RW	0
12	PT	Pulse or toggle mode on TIMERi_PWM_out output pin 0x0: Pulse modulation 0x1: Toggle modulation	RW	0

Bits	Field Name	Description	Type	Reset
11:10	TRG	Trigger output mode on TIMERi_PWM_out output pin 0x0: No trigger 0x1: Trigger on overflow. 0x2: Trigger on overflow and match. 0x3: Reserved	RW	0x0
9:8	TCM	Transition capture mode on TIMERi_EVENT_CAPTURE input pin (When the TCM field passed from (00) to any other combination, the TCAR_IT_FLAG and the edge detection logic are cleared.) 0x0: No capture 0x1: Capture on rising edges of TIMERi_EVENT_CAPTURE pin 0x2: Capture on falling edges of TIMERi_EVENT_CAPTURE pin 0x3: Capture on both edges of TIMERi_EVENT_CAPTURE pin	RW	0x0
7	SCPWM	Pulse width modulation output pin default setting This bit must be set or clear while the timer is stopped or the trigger is off. 0x0: Clear the TIMERi_PWM_out output pin and select positive pulse for pulse mode. 0x1: Set the TIMERi_PWM_out output pin and select negative pulse for pulse mode.	RW	0
6	CE	Compare enable 0x0: Compare mode is disable. 0x1: Compare mode is enable.	RW	0
5	PRE	Prescaler enable 0x0: The TIMER clock input pin clocks the counter. 0x1: The divided input pin clocks the counter.	RW	0
4:2	PTV	Prescale clock timer value The timer counter is prescaled with the value $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode 0x0: One shot timer 0x1: Autoreload timer	RW	0
0	ST	Start/stop timer control 0x0: Stop timer: Only the counter is frozen. If one-shot mode selected (AR =0), this bit is automatically reset by internal logic when the counter is overflowed. 0x1: Start timer	RW	0

22.3 32-kHz Synchronized Timer (COUNTER_32K)

22.3.1 32-kHz Synchronized Timer Overview

The 32-kHz synchronized timer (COUNTER_32K) is a 32-bit counter clocked by the falling edge of the 32-kHz system clock.

Figure 22-15 is the block diagram of the 32-kHz synchronized timer.

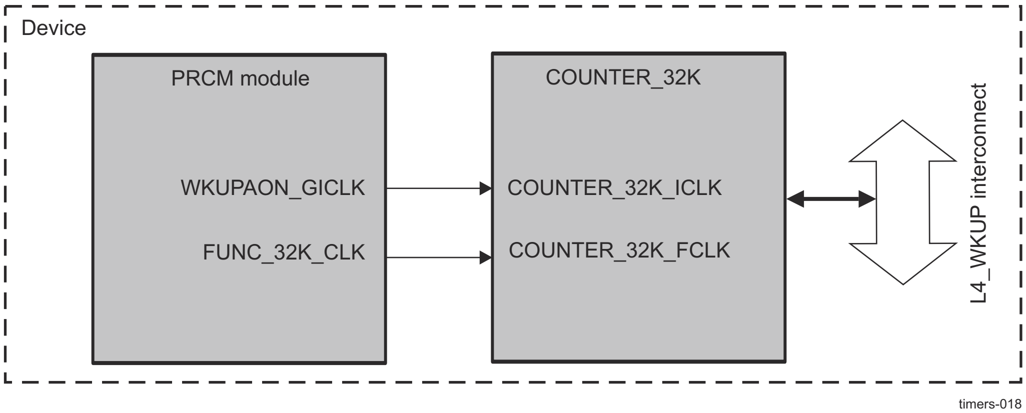

Figure 22-15. 32-kHz Synchronized Timer Block Diagram

22.3.1.1 32-kHz Synchronized Timer Features

The main features of the 32-kHz synchronized timer controller are:

- L4 slave interface (OCP) support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 16-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0; highest value reached: 0xFFFF FFFF
- On-the-fly read (while counting)

22.3.2 32-kHz Synchronized Timer Integration

The synchronized timer is accessible only through the L4_WKUP interface.

Table 22-50 through Table 22-52 summarize the integration of the module in the device.

Table 22-52. COUNTER_32K Hardware Requests

No Interrupt Requests
No DMA Requests

22.3.3 32-kHz Synchronized Timer Functional Description

The synchronized timer is a counter that starts on the rising edge of an external asynchronous signal (COUNTER_32K_NRESPWRON). When COUNTER_32K_NRESPWRON is released (on the rising edge of COUNTER_32K_FCLK), the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz COUNTER_32K_FCLK clock after three inverted 32-kHz clock periods. After reaching its highest value, the counter wraps back to 0 and starts counting again with no additional delay.

Figure 22-16 shows the reset synchronization timing diagram.

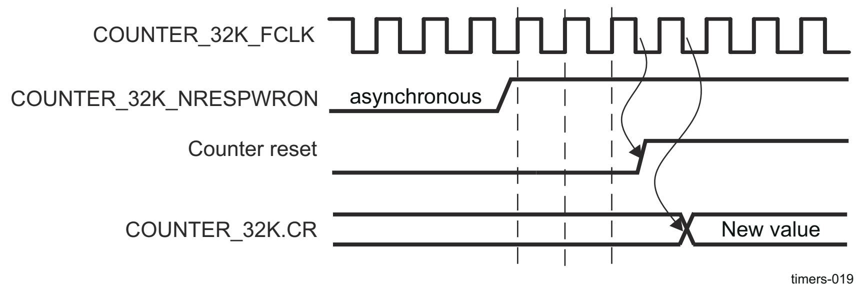

Figure 22-16. Reset Resynchronization Timing Diagram

Figure 22-17 is the block diagram of the synchronized timer.

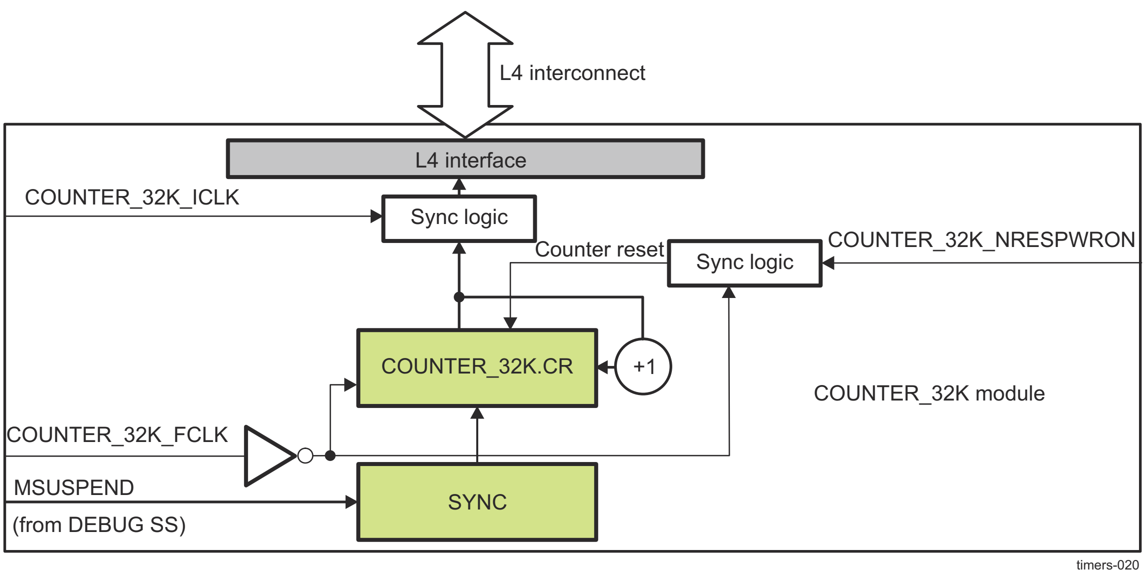

Figure 22-17. CONTER_32K Block Diagram

The sync logic ensures the correctness of the read transaction by synchronizing the counter register read access on COUNTER_32K_ICLK, because the COUNTER_32K_ICLK clock signal is completely asynchronous with COUNTER_32K_FCLK. The COUNTER_32K_NRESPWRON input resets the counter register (CR). The inverted COUNTER_32K_FCLK clocks the counter register CR.

The counting is temporally stopped when MSUSPEND control signal (coming from DEBUG SS) is asserted.

22.3.3.1 Reading the 32-kHz Synchronized Timer

The counter register (CR) is 32 bits wide. For correct count capture, it must be accessed as 16-bit LSB access first and 16-bit MSB access next. The value of the counter is read through the L4 interconnect slave interface. Internal synchronization logic allows the reading of the counter value with COUNTER_32K_ICLK while the counter is running. The time latency to read the synchronized counter register is one COUNTER_32K_ICLK clock period.

The user can select between two syncronization schemes by setting SYSCONFIG[0]SYNCMODE bit.

- SYSCONFIG[0]SYSCMODE = 0x0 - default. In this mode COUNTER_32K timer uses Gray encode/decode scheme. When the L4 interface sends a LSB16 read request command, the 32 bit coded value is registered directly to the interface domain. Due to the characteristics of this encoding if a read command arrives during a count up event either the old or the new value of CR is captured, not a transient value. The captured value will be decoded and send on the SDATA bus. The MSB16 read command reads upper 16 bits of the 32 bit value of counter register captured during the last LSB16 read access.
- SYSCONFIG[0]SYNCMODE = 0x1 - legacy synchronization scheme. In this mode the value of the CR is synchronized to the OCP domain at every count up event. This synchronization is possible because the COUNTER_32K_ICLK is much faster that the 32KHz clock (COUNTER_32K_FCLK). The drawback of this method is that if the interface clock is switched back after wake up from idle mode, the syncronized value will be updated only at the next count up event, until then it will be incorrect.

22.3.4 COUNTER_32K Timer Register Manual

Table 22-53 lists the base address and block size for the 32-kHz synchronized timer. It is memory-mapped to the L4 peripheral bus memory space.

Table 22-53. COUNTER_32K Timer Instance Summary

Module Name	Module Base Address	Size
L4_WKUP_COUNTER_32K	0x4AE0 4000	52 Bytes

22.3.4.1 COUNTER_32K Timer Register Mapping Summary

CAUTION

The 32-kHz synchronized timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 22-54 lists the 32-kHz synchronized timer registers. Table 22-55 through Table 22-59 describe the register bits.

22.4 Watchdog Timer

22.4.1 Watchdog Timer Overview

The device includes one instance of the 32-bit watchdog timer: WD_TIMER2. Figure 22-18 shows how the timer is connected in the device.

The watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The WD_TIMER2 timer serves resets to the PRCM module (its interrupt outputs are unused).

WD_TIMER2 is located in the PD_WKUPAON power domain, and can run when the device is in lowest power state above RTC mode (all power domains are off except always-on (AON), WKUP, and RTC domains).

The watchdog timer can be accessed, loaded, and cleared by registers through the L4_WKUP interface. The watchdog timer has the 32-kHz clock for its timer clock input. WD_TIMER2 directly generates a warm reset condition on overflow.

WD_TIMER2 connects to a single target agent port on the L4_WKUP interconnect.

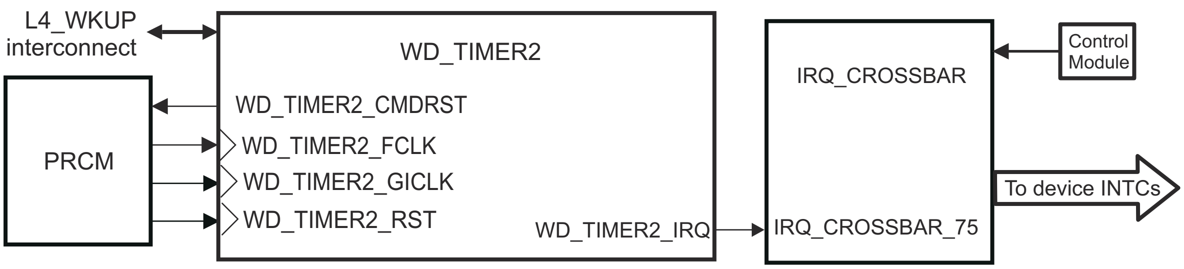

Figure 22-18. Watchdog Timer Block Diagram

Table 22-61 lists the default state of the watchdog timer in the device.

Table 22-61. Watchdog Timer Default State

Timer	Default State	
WD_TIMER2	Enabled	Not running

Note

The default state of the watchdog timer described in Table 22-61 is considered to be its state immediately after ROM code execution. For more information, see *Initialization*.

22.4.1.1 Watchdog Timer Features

The main features of the watchdog timer controllers are:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 11-bit address bus width
  - Burst mode not supported
  - Write nonposted mode supported
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n where n = [0:7])
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- The watchdog timer is reset either on power on or after a warm reset before it starts counting.
- Reset or interrupt actions when a timer overflow condition occurs

- The watchdog timer generates a reset or an interrupt in its hardware integration.

22.4.2 Watchdog Timer Integration

Figure 22-19 shows the integration of the watchdog timers in the device.

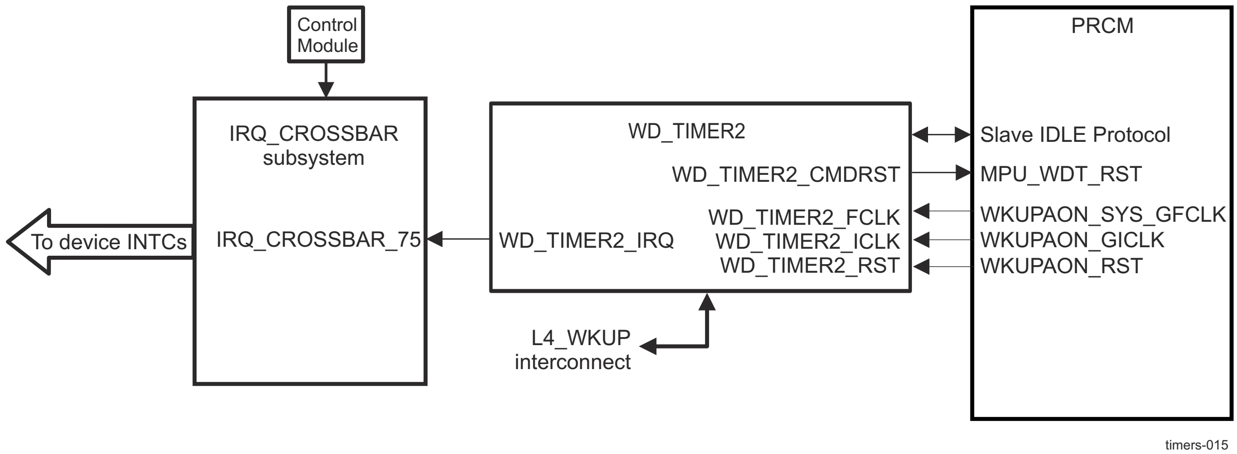

Figure 22-19. Watchdog Timer Integration

Table 22-62 through Table 22-64 summarize the integration of the module in the device.

Note

The "**Default Mapping**" column in Table 22-64 *Watchdog Timer Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

22.4.3 Watchdog Timer Functional Description

22.4.3.1 Power Management

There are two clock domains in the watchdog timer:

- Functional clock domain: WD_TIMER2_FCLK is the watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WD_TIMER2_ICLK is the watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WD_TIMER2_ICLK.

Table 22-63 lists the source clocks for the watchdog timer in the device. For more information about clock control and domains, see *Clock Management Functional Description,* in *Power, Reset, and Clock Management*.

From a global system power-management perspective, when the watchdog timer clocks is no longer required, the watchdog timer can be deactivated at the PRCM module level in the corresponding registers.

At the PRCM module level, when the conditions to shut off the PRCM module functional or interface output clocks are met (for more information, see *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the watchdog timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the watchdog timer.

Although this handshake is a hardware function and out of software control, the way on which the watchdog timer acknowledges the PRCM IDLE request is configurable through the WDSC[4:3] IDLEMODE bit field. Table 22-65 lists the settings and related acknowledgment modes of the IDLEMODE bit field.

Table 22-65. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The watchdog timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off.
01	No-idle	The watchdog timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM module output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management.
11	Smart-idle wakeup-capable mode	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The timer generates (IRQ-request-related) wake-up events when in IDLE state if the WIRQWAKEEN[1:0] bit field is set to 1.

22.4.3.1.1 Wake-Up Capability

If the WDSC[4:3] IDLEMODE bit field sets smart-idle wakeup-capable mode (= 0 × 3), the timer evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the WIRQWAKEEN[0] OVF_WK_ENA and/or the WIRQWAKEEN[1] DLY_WK_ENA bits enable the overflow and/or the delay wake-up capability.

22.4.3.2 Interrupts

Table 22-66 list the event flags, and their masks that cause module interrupts.

Table 22-66. Watchdog Timer Events

Event Flag	Event Mask	Mapping	Comments
WIRQSTAT[0] EVENT_OVF	WIRQENSET/WIRQENCLR[0] OVF_IT_ENA	WD_TIMER2_IRQ	Watchdog timer overflow

Table 22-66. Watchdog Timer Events (continued)

Event Flag	Event Mask	Mapping	Comments
WIRQSTAT[1] EVENT_DLY	WIRQENSET/WIRQENCLR[1] DLY_IT_ENA	WD_TIMER2_IRQ	Watchdog delay value reached

22.4.3.3 General Watchdog Timer Operation

The watchdog timer is based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see Figure 22-18. The interrupt generation mechanism is controlled through the WIRQENSET/WIRQENCLR and WIRQSTAT registers.

The prescaler ratio can be set from 1 to 128 by accessing the WCLR[4:2] PTV bit field and the WCLR[5] PRE bit of the watchdog control register (WCLR).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register (WCRR), modified by accessing the watchdog timer load register (WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the watchdog timer trigger register (WTGR). A start/stop sequence applied to the watchdog timer start/stop register (WSPR) can start and stop the watchdog timers.

Figure 22-20 is a functional block diagram of the watchdog timer.

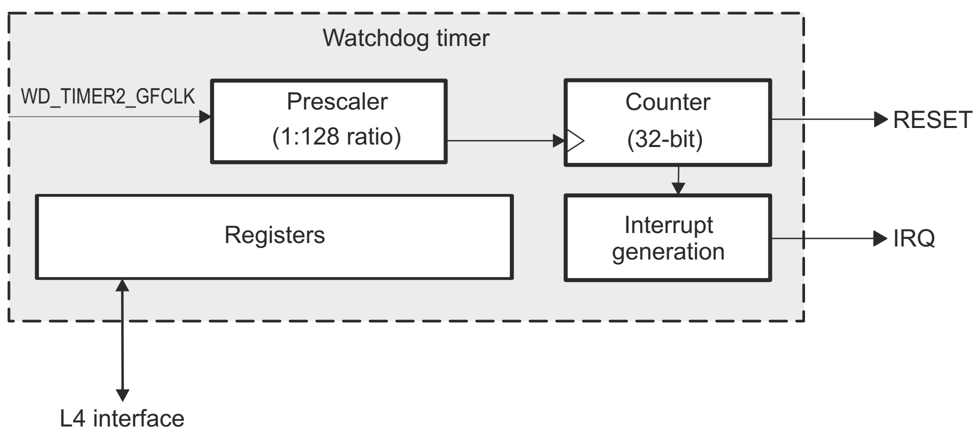

Figure 22-20. 32-Bit Watchdog Timer Functional Block Diagram

22.4.3.4 Reset Context

The watchdog timer is enabled after reset. Table 22-67 lists the default reset values of the two watchdog timer load registers (WLDR) and prescaler ratios (the WCLR[4:2] PTV bit field). To get these values, software must read the corresponding WCLR[4:2] PTV bit field and the 32-bit register to retrieve the static configuration of the module.

Table 22-67. Count and Prescaler Default Reset Values

Timer	WLDR Reset Value	PTV Reset Value
WD_TIMER2	0xFFFB 0000	0

22.4.3.5 Overflow/Reset Generation

When the WCRR overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the WLDR and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 22-21 shows a general functional view of the watchdog timers.

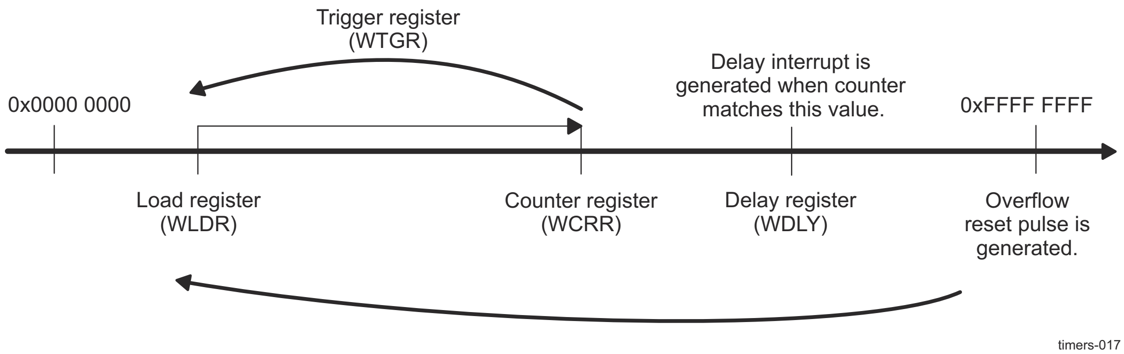

Figure 22-21. Watchdog Timers General Functional View

22.4.3.6 Prescaler Value/Timer Reset Frequency

The watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WCLR[5] PRE bit and the WCLR[4:2] PTV bit field)
- Value loaded into WLDR

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WCLR [4:2] PTV bit field) and is enabled with the WCLR[5] PRE bit.

Table 22-68 lists the prescaler clock ratio values.

Table 22-68. Prescaler Clock Ratio Values

WCLR[5] PRE	WCLR[4:2] PTV	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

Thus the watchdog timer overflow rate is expressed as:

OVF_Rate = (0xFFFF FFFF – WLDR + 1) × (timer clock period) × PS

where wd-functional clock period = 1 / (timer clock frequency) and PS = $2^{(PTV)}$

CAUTION

Internal resynchronization causes some latency in any software write to WSPR before WSPR is updated with the programmed value:

1.5 × functional clock cycles ≤ write_WD_TIMER_WSPR_latency ≤ 2.5 × functional clock cycles

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and WCLR[5] PRE = 1 (clock divider enabled), the reset period is as listed in Table 22-69.

Table 22-69. Reset Period Examples

WLDR Value	Reset Period
0x0000 0000	74 h 56 min
0xFFFF 0000	4 s
0xFFFF FFF0	1 ms
0xFFFF FFFF	62.5 µs

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the WLDR[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WLDR[31:0] = 0xFFFF FFFF is a special case, although such value of WLDR is meaningless. When WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

Table 22-70 lists the default reset periods for the watchdog timer.

Table 22-70. Default Watchdog Timer Reset Periods

Watchdog Timers	Clock Source	Default Reset Period
WD_TIMER2	32 kHz	10 s

22.4.3.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the WTGR using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WTGR differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

The timer counter is loaded with the value of the watchdog timer load register (the WLDR[31:0] TIMER_LOAD bit field), and the prescaler is reset.

22.4.3.8 Start/Stop Sequence for Watchdog Timer (Using the WSPR Register)

To start and stop a watchdog timer, access must be made through the WSPR using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xXXXX AAAA in the WSPR.
2. Write 0xXXXX 5555 in the WSPR.

To enable the timer, follow this sequence:

1. Write 0xXXXX BBBB in the WSPR.
2. Write 0xXXXX 4444 in the WSPR.

All other write sequences on the WSPR have no effect on the start/stop feature of the module.

22.4.3.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the WCRR), the prescaler ratio (the WCLR[4:2] PTV bit field), delay configuration value (the WDLY[31:0] DLY_VALUE bit field), or the load value (the WLDR[31:0] TIMER_LOAD bit field), the watchdog timer must be disabled by using the start/stop sequence (the WSPR).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the WTGR).

22.4.3.10 Watchdog Counter Register Access Restriction (WCRR)

A 32-bit shadow register is implemented to read a coherent value of the WCRR because the WCRR is directly related to the timer counter value and is updated on the timer clock (WD_TIMER_FCLK). The shadow register is updated by a 16-bit LSB read command.

Note

Although the L4 clock (WD_TIMER_ICLK) is completely asynchronous with the timer clock (WD_TIMER_FCLK), some synchronization is performed to ensure that the value of the WCRR is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

To ensure that a coherent value is read inside the WCRR, the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

22.4.3.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the WISR[0] OVF_IT_FLAG or WISR[1] DLY_IT_FLAG bit) is set to 1. The output interrupt line (WD_TIMER_IRQ) is asserted (active high) when status (the EVENT_xxx bit) and enable (the xxx_IT_ENA bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WISR. Reading the WISR and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt-enable register (WIER[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WISR[0] OVF_IT_FLAG bit) is set to 1. The output interrupt line (WD_TIMER_IRQ) is asserted (active high) when status (OVF_IT_FLAG) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the WIER [0] OVF_IT_ENA bit to 1.

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt-enable register (WIER[1] DLY_IT_ENA = 1). When the counter is running and the counter value matches the value stored in the delay configuration register (WDLY), the corresponding interrupt status bit is set in the watchdog status register (WISR) and the output interrupt line is asserted (active high) when the flag (DLY_IT_FLAG) and enable (DLY_IT_ENA) bits are set to 1 in the WISR and WIER registers, respectively; the order (normally enable, then flag) is not relevant. This interrupt can be disabled by setting the WIER[1] DLY_IT_ENA bit to 1.

Note

Writing 0 to the WISR[0] OVF_IT_FLAG or WISR[1] DLY_IT_FLAG bit has no effect.

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain (WD_TIMERi_FCLK) during the updating of the interrupt status register.

The WDLY register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register (WLDR) and the programmed value in this register (WDLY).

Use the following formula to estimate the delay time:

Delay time period = (WDLY – WLDR + 1) × Timer clock period × Clock divider

Where:

- Timer clock period = 1 / (Timer clock frequency)
- Clock divider = 2PTV

If the counter value (WCRR) reaches the programmed value (WDLY), the status bit (EVENT_DLY) is set in the interrupt status register (WIRQSTAT), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register (WIRQENSET).

CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value (the WDLY[31:0] WDLY_VALUE bit field), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the WDLY register is less than the value stored in the WLDR.

22.4.3.12 Watchdog Timer Under Emulation

During emulation mode, the watchdog timer can or cannot continue to run, according to the value of the WDSC[5] EMUFREE bit of the system configuration register (WDSC).

- When EMUFREE is 1, watchdog timer execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting emulation mode.

22.4.3.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain (WD_TIMER2_FCLK). For write/read operation, the following registers are affected:

- WCLR
- WCRR
- WLDR
- WTGR
- WDLY
- WSPR

The timer interface clock domain synchronous registers are not affected by the posted/nonposted selection; the write/read operation is effective and acknowledged (command accepted) after one WD_TIMER_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- WIDR
- WDSC
- WDST
- WISR
- WIER
- WWER
- WWPS

Note

Accesses to WD_TIMER2 is posted.

22.4.4 Watchdog Timer Low-Level Programming Model

This section covers the low-level hardware programming sequences for the configuration and use of the module.

22.4.4.1 Global Initialization

22.4.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see Table 22-71). For more information, see Section 22.4.2, *Watchdog Timer Integration.*

Table 22-71. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing must be set in the control module. For more information about the module configuration, see *Pad Configuration Registers* in *Control Module*.
IRQ_CROSSBAR	The IRQ_CROSSBAR configuration must be performed to enable the interrupts from the watchdog timer. See *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

22.4.4.1.2 Watchdog Timer Module Global Initialization

22.4.4.1.2.1 Main Sequence – Watchdog Timer Module Global Initialization

Table 22-72 lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

Table 22-72. Watchdog Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	WDSC[1] SOFTRESET	0x1
Wait until reset release?	WDSC[1] SOFTRESET	0x0
Configure idle mode.	WDSC[4:3] IDLEMODE	0x-
Enable delay wakeup.	WIRQWAKEEN[1] DLY_WK_ENA	0x1
Enable overflow wakeup.	WIRQWAKEEN[0] OVF_WK_ENA	0x1
Enable delay interrupt.	WIRQENSET[1] ENABLE_DLY	0x1
Enable overflow interrupt.	WIRQENSET[0] ENABLE_OVF	0x1

22.4.4.2 Operational Mode Configuration

22.4.4.2.1 Watchdog Timer Basic Configuration

22.4.4.2.1.1 Main Sequence – Watchdog Timer Basic Configuration

Table 22-73 lists the steps for the basic configuration of the watchdog timer.

Table 22-73. Watchdog Timer Basic Configuration

Step	Register/Bit Field/Programming Model	Value
Disable the watchdog timer.	See Section 22.4.4.2.1.2.	
Set prescaler value.	WCLR[4:2] PTV	0x-
Enable prescaler.	WCLR[5] PRE	0x1
Load delay configuration value.	WDLY	0x-
Load timer counter value.	WCRR	0x-
Enable the watchdog timer.	See Section 22.4.4.2.1.3.	

22.4.4.2.1.2 Subsequence – Disable the Watchdog Timer

Table 22-74 lists the steps to disable the watchdog timer.

Table 22-74. Disable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write disable sequence Data1.	WSPR	0xXXXX AAAA
Write disable sequence Data2.	WSPR	0xXXXX 5555

22.4.4.2.1.3 Subsequence – Enable the Watchdog Timer

Table 22-75 lists the steps to enable the watchdog timer.

Table 22-75. Enable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write enable sequence Data1.	WSPR	0xXXXX BBBB
Write enable sequence Data2.	WSPR	0xXXXX 4444

22.4.5 Watchdog Timer Register Manual

22.4.5.1 Watchdog Timer Instance Summary

Table 22-76 lists the base address and address space for the watchdog timer module instances.

Table 22-76. Watchdog Timer Instance Summary

Module Name	Module Base Address L4_WKUP Interconnect	Size
WD_TIMER2	0x4AE1 4000	104 Bytes

Note

Private access is access that does not use the L4 interconnect.

22.4.5.2 Watchdog Timer Registers

22.4.5.2.1 Watchdog Timer Register Summary

CAUTION

The watchdog timers registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 22-77 lists the WD_TIMER2 registers.

Table 22-77. WD_TIMER2 Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	WD_TIMER2 Physical Address L4_WKUP Interconnect

Chapter 23

Real-Time Clock (RTC)

This chapter provides a functional presentation of the Real-Time Clock (RTC) module.

23.1 RTC Overview 5280
23.2 RTC Environment 5282
23.3 RTC Integration 5283
23.4 RTC Functional Description 5285
23.5 RTC Low-Level Programming Guide 5293
23.6 RTC Register Manual 5294

23.1 RTC Overview

The real-time clock is a precise timer which can generate interrupts on intervals specified by the user. Interrupts can occur every second, minute, hour, or day. The clock can track the passage of real time for durations of several years, provided it has a sufficient power source the entire time.

The basic purpose of the RTC is to keep time of day. The other equally important purpose of the RTC is for Digital Rights management. Some degree of tamper proofing is needed to ensure that simply stopping, resetting, or corrupting the RTC does not go unnoticed so that if this occurs, the application can re-acquire the time of day from a trusted source. Another purpose of the RTC is to wake up the rest of the chip from a power-down state.

Alarms are available to interrupt the host processor at a particular time, or at periodic intervals, such as once per minute or once per day. In addition, the RTC can interrupt the CPU every time the calendar and time registers are updated, or at programmable periodic intervals.

Figure 23-1 shows the RTC functional block diagram.

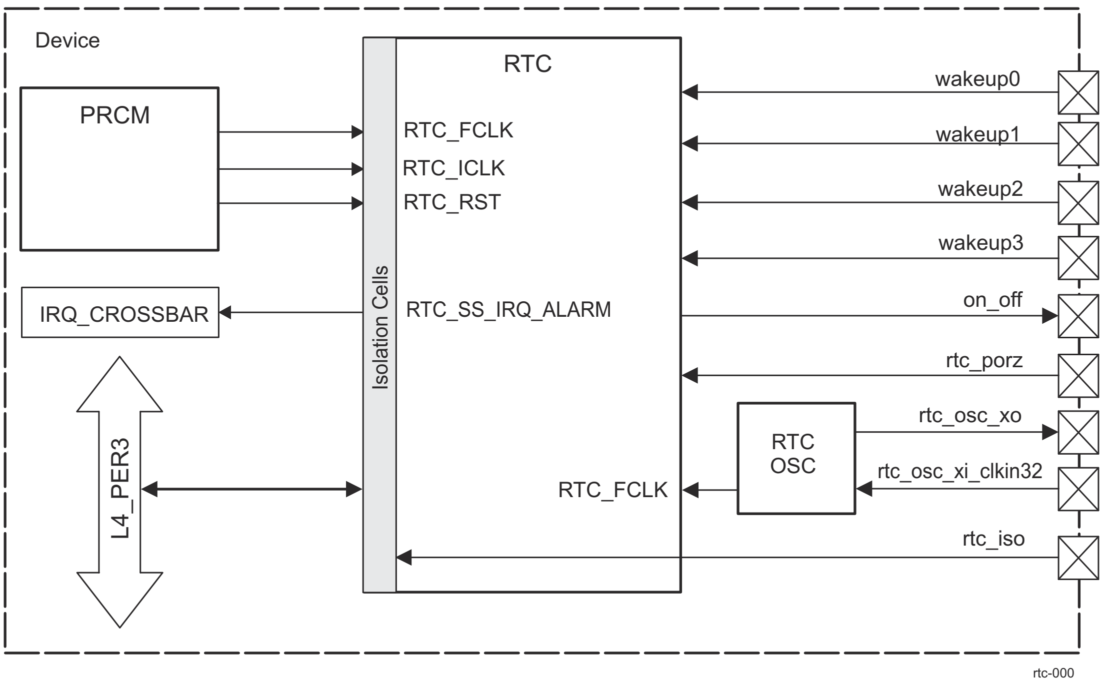

Figure 23-1. RTC Block Diagram

23.1.1 RTC Features

The main features of the RTC are:

- 100-year calendar
- Counts seconds, minutes, hours, day of the week, date, month, and year with leap year compensation
- Binary-coded decimal (BCD) representation of time, calendar and alarm
- Alarm interrupt
- Periodic interrupt
- Single interrupt to the host processor
- External 32-kHz clock
- Isolated RTC voltage domain which remains powered during standby (RTC) mode while the rest of chip supplies are turned off
- RTC voltage domain has 3 × 32-bit read/write scratch registers retained in RTC modes
- RTC supports four wakeup input pins:
  - Each input has a filter to detect high or low transition with pulse duration.

  - Each pin has the following controls retained in standby mode and modified and read by control module in ON mode.
    - Enable bit (decides if the pin causes wakeup or not)
    - Edge sensitivity (rising, falling, or both causing wakeup)
    - Wake-up flag (sticky bits indicating wake-up source)
  - Allow paths for optional input to GPIO if not used for wakeup.
- PMIC enable output pin to indicate external switched MAIN domain supplies to turn on or off based on wakeup state

23.2 RTC Environment

23.2.1 RTC External Interface

The RTC is connected to four external system wake-up signals. The RTC also can operate on external 32-kHz clock and has dedicated power-on reset pin. An external control of the RTC isolation cells is available to isolate RTC from other power domains when the PD_RTC is the only powered domain.

The RTC module can be configured to produce a power-up/down control signal for the power-management chip (PMIC, if present).

Table 23-1 summarizes the external signals received and produced by the RTC module.

Table 23-1. RTC External Signals

Device-Level Pin	Module-Level Signal	I/O	Description
rtc_osc_xi_clkin32	RTC_32K_CLK	I	RTC clock input
rtc_osc_xo	—(1)	O	32k oscillator crystal driver output. Unused if clock is provided from external source (crystal not connected)
wakeup0	EXT_WAKEUP0	I	External wake-up signal
wakeup1	EXT_WAKEUP1	I	External wake-up signal
wakeup2	EXT_WAKEUP2	I	External wake-up signal
wakeup3	EXT_WAKEUP3	I	External wake-up signal
on_off	PMIC_PWR_ENABLE	O	Companion PMIC control output (on/off) (optional)
rtc_porz	RTC_POR_ARST	I	External power-on-reset input (optional)
rtc_iso	—(2)	I	External control of isolation cells. This signal must be kept low (0) during RTC mode and high (1) after the device power supplies ramped-up. This can typically be achieved by connecting rtc_iso to the porz (not rtc_porz) with appropriate voltage level translation if necessary.

(1) Not a RTC module's signal. Crystal driver output from oscillator.
(2) Not a RTC module's signal. Controls isolation cells.

Figure 23-2 shows the described signals.

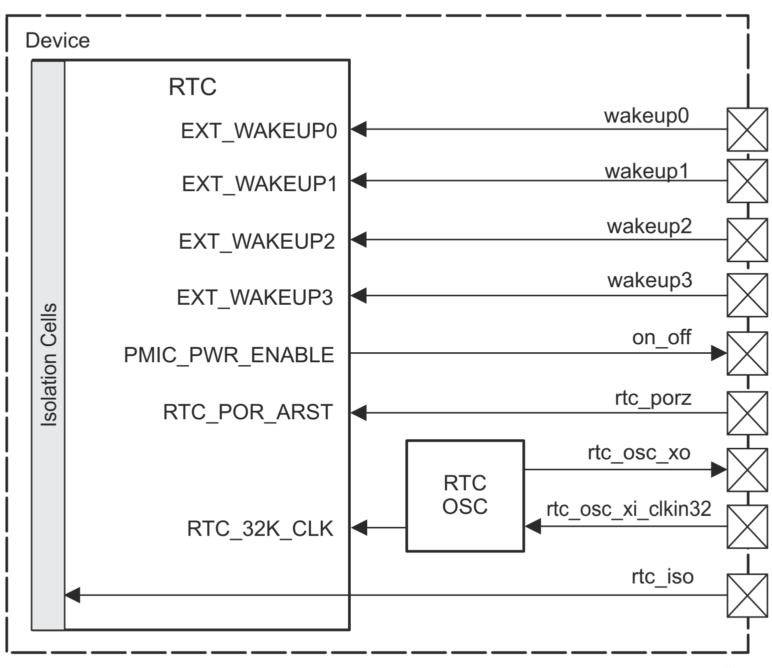

Figure 23-2. RTC External Signals

23.3 RTC Integration

Figure 23-3 shows the integration of the Real-time clock subsystem inside the device.

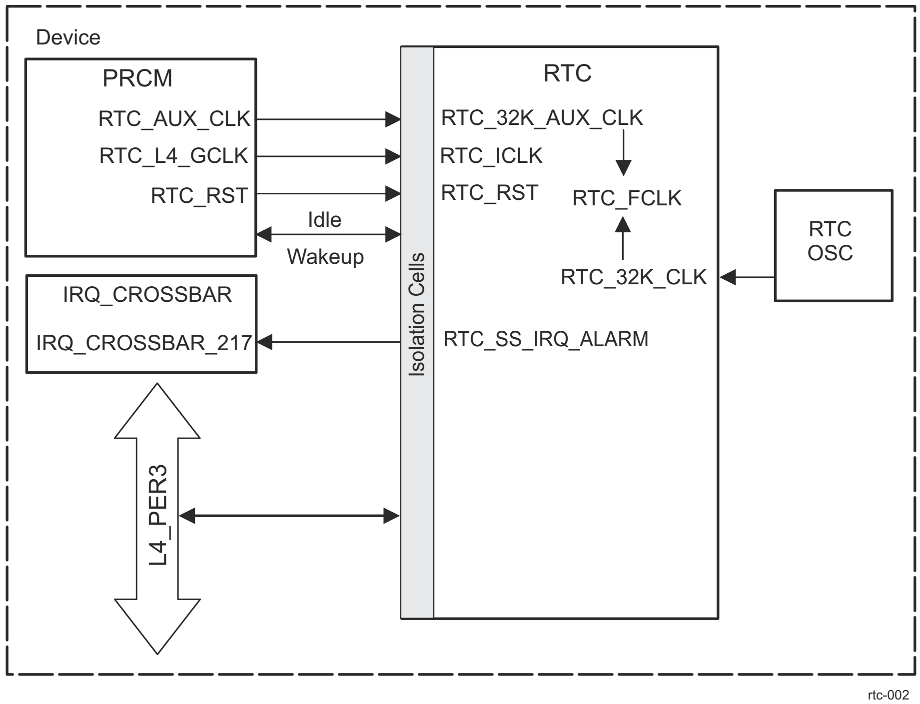

Figure 23-3. RTC Module Integration

Table 23-4. RTC Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**IRQ_CROSSBAR**	**Default Mapping**	**Description**
RTC	RTC_SS_IRQ_ALARM	IRQ_CROSSBAR_217	-	Alarm interrupt going to device IRQ_CROSSBAR.
No DMA Requests				

Note

The **Default Mapping** column in Table 23-4, *RTC Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other inputs of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

23.4 RTC Functional Description

This section defines the module interrupt capabilities and requirements.

Figure 23-4 shows the functional block diagram of the RTC module.

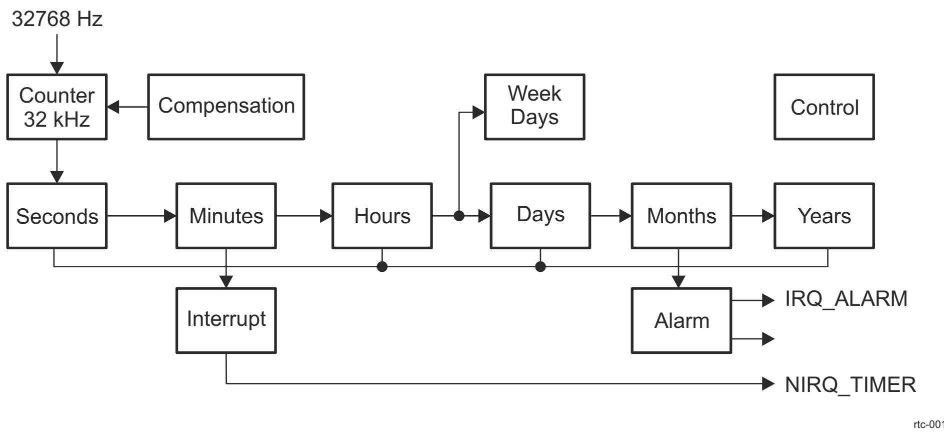

Figure 23-4. RTC Functional Block Diagram

23.4.1 Clock Source

The clock reference for the RTC is an internal 32-kHz clock signal (RTC_AUX_CLK from PRCM) or an external clock source of the 32.768 Hz frequency on the RTC_32K_CLK pin.

The RTC_DISABLE bit in the control register (RTC_CTRL_REG) can be set to save power; however, the RTC_DISABLE bit is not to be cleared once it has been set. If the application requires the RTC module to stop and continue, the STOP_RTC bit in RTC_CTRL_REG is used instead.

The selection between external and internal clock is done through the RTC_OSC_REG register. Setting the RTC_OSC_REG[3] K32CLK_SEL = 1 selects the 32-kHz external/oscillator clock (RTC_32K_CLK), setting it to 0 selects the PRCM clock (RTC_AUX_CLK). RTC_OSC_REG[2] RES_SELECT enables the internal feedback resistor. By modifying the RTC_OSC_REG[4] OSC32K_GZ bit, software enables or disables the 32-kHz oscillator.

If the RTC module or RTC oscillator is not used, the rtc_osc_xi_clkin32 device pin should be held low and rtc_osc_xo should be left unconnected. For more information about rtc pin connection if RTC is not used in the design, see the device-specific data manual.

23.4.2 Interrupt Support

23.4.2.1 CPU Interrupts

The RTC generates two interrupt outputs:

- timer_intr is a timer interrupt.
- alarm_intr is an alarm interrupt.

These two interrupts are OR-ed inside the RTC subsystem and a single interrupt (RTC_SS_IRQ_ALARM) is passed to the IRQ_CROSSBAR module.

Note

Both interrupt outputs support high-level and high-pulse.

23.4.2.2 Interrupt Description

23.4.2.2.1 Timer Interrupt (timer_intr)

The timer interrupt can be generated periodically: every second, every minute, every hour, or every day (see RTC_INTERRUPTS_REG[1:0] for a description of how to set this up). The IT_TIMER bit of RTC_INTERRUPTS_REG enables this interrupt. The timer interrupt is active-low.

The RTC_STATUS_REG bits are only updated at each new interrupt and occur according to Table 23-5. For example, bit 2 (SEC) is set every time one second has passed. Bit 2 is also set when 1 minute has passed, because the completion of 1 minute also marks the completion of 1 second (from 59 seconds to 60 seconds). The same holds true for hours and days: each of them also corresponds to the passing of a second.

Conversely, bit 5 (DAY) is always set when a day has passed. It might also be set when an hour, minute, or second has passed. However, this only occurs when the elapsed hour, minute, or second corresponds to the start of a new day.

Table 23-5. Interrupt Trigger Events

STATUS_REG Bit	One Day Has Passed	One Hour Has Passed	One Minute Has Passed	One Second Has Passed
[5] (DAY)	1	0/1[(1)]	0/1[(1)]	0/1[(1)]
[4] (HOUR)	1	1	0/1[(1)]	0/1[(1)]
[3] (MIN)	1	1	1	0/1[(1)]
[2] (SEC)	1	1	1	1

(1) This event is triggered only when the elapsed time unit (for example, Day) corresponds to the passage of another unit (for example, Seconds). For example, when the clock ticks from 00:23:59:59 (days : hours : minutes : seconds) to 01:00:00:00.

23.4.2.2.2 Alarm Interrupt (alarm_intr)

The alarm interrupt can be generated when the time set into the Timer/Calendar (TC) ALARM registers (see Section 23.4.3.2) is exactly the same as in the TC registers. This interrupt is then generated, if the IT_ALARM bit in the interrupt register (RTC_INTERRUPTS_REG) is set. This interrupt is low-level sensitive. The RTC_STATUS_REG[6] ALARM bit indicates that alarm interrupt has occurred. This interrupt is disabled by setting the RTC_STATUS_REG[6] ALARM bit to 1.

To set up an alarm:

- Modify the RTC_ALARM_SECONDS_REG, RTC_ALARM_MINUTES_REG, RTC_ALARM_HOURS_REG, RTC_ALARM_DAYS_REG, RTC_ALARM_MONTHS_REG, and RTC_ALARM_YEARS_REG registers to the exact time an alarm is to be generated.
- Set the IT_ALARM bit in RTC_INTERRUPTS_REG to enable the alarm interrupt.

When the RTC_PMIC_REG[3:0] EXT_WAKEUP_EN and RTC_PMIC_REG[16] PWR_ENABLE_EN bits are set to 0x1, the PMIC_PWR_ENABLE is controlled by EXT_WAKEUP[3:0] ALARM and ALARM2.

The ALARM2 is set by writing the exact time and date to generate an alarm in RTC_ALARM2_SECONDS_REG, RTC_ALARM2_MINUTES_REG, RTC_ALARM2_HOURS_REG, RTC_ALARM2_DAYS_REG, RTC_ALARM2_MONTHS_REG, and RTC_ALARM2_YEARS_REG registers.

23.4.3 RTC Programming/Usage Guide

23.4.3.1 Time/Calendar Data Format

The time and calendar data in the RTC is stored in BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. Four bits are assigned to each BCD digit in most time/calendar registers; however, some of the register fields are shorter, because the range of valid numbers may be limited. For example, only three bits are required to represent the day of the week (RTC_WEEKS_REG), because only BCD numbers 1 through 7 are required. The following time and calendar registers are supported (BCD Format):

- RTC_SECONDS_REG — Second Count (00–59)
- RTC_MINUTES_REG — Minute Count (00–59)
- RTC_HOURS_REG — Hour Count (12HR: 01–12; 24HR: 00–23)
- RTC_DAYS_REG — Day of the Month Count (01–31)

- RTC_WEEKS_REG — Day of the Week (0–6: SUN = 0)
- RTC_MONTHS_REG — Month Count (01–12; JAN = 1)
- RTC_YEARS_REG — Year Count (00–99)

23.4.3.2 Register Access

The three register types are as follows and each has its own access constraints:

- TC registers and TC alarm registers
  – TC registers (see Section 23.4.3.1)
  – TC alarm registers:
    - RTC_ALARM_SECONDS_REG
    - RTC_ALARM_MINUTES_REG
    - RTC_ALARM_HOURS_REG
    - RTC_ALARM_DAYS_REG
    - RTC_ALARM_MONTHS_REG
    - RTC_ALARM_YEARS_REG
    - RTC_ALARM2_SECONDS_REG
    - RTC_ALARM2_MINUTES_REG
    - RTC_ALARM2_HOURS_REG
    - RTC_ALARM2_DAYS_REG
    - RTC_ALARM2_MONTHS_REG
    - RTC_ALARM2_YEARS_REG
- General registers:
  – RTC_CTRL_REG
  – RTC_STATUS_REG
  – RTC_INTERRUPTS_REG
  – RTC_SCRATCH0_REG
  – RTC_SCRATCH1_REG
  – RTC_SCRATCH2_REG
  – RTC_KICK0_REG
  – RTC_KICK1_REG
  – RTC_REVISION_REG
  – RTC_SYSCONFIG_REG
  – RTC_IRQWAKEEN
  – RTC_PMIC_REG
  – RTC_RTL_DEBOUNCE_REG
  – RTC_OSC_REG
- Compensation registers:
  – RTC_COMP_LSB_REG
  – RTC_COMP_MSB_REG

23.4.3.3 Register Spurious Write Protection

The module also contains a kicker mechanism (see Figure 23-5) to prevent any spurious writes from changing the register values.

Note

This mechanism requires two register writes to the KICK0 and KICK1 registers with exact data values before the kicker lock mechanism is released. Once released, the registers are writeable. The KICK0 data is 83E7 0B13h; the KICK1 data is 95A4 F1E0h. The mechanism remains in an unlocked state until a reset or invalid data pattern is written to one of the RTC_KICK0_REG or RTC_KICK1_REG registers.

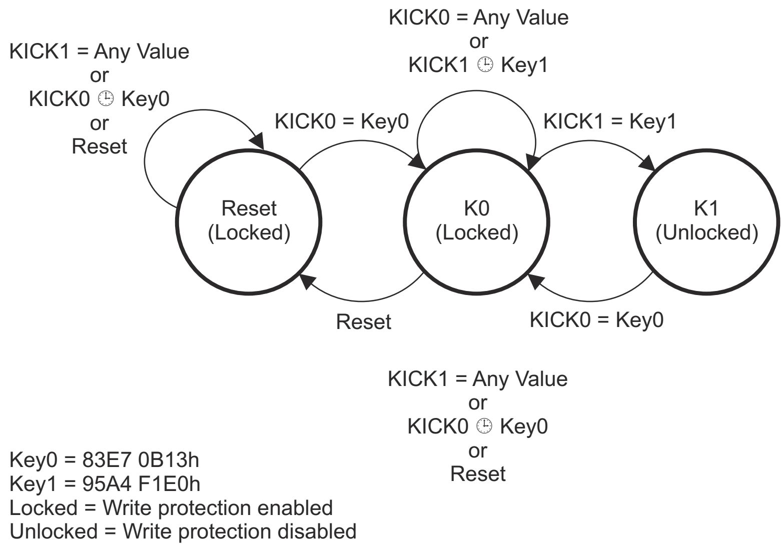

Figure 23-5. Kick Register State Machine Diagram

- S0 is the Reset/Idle state
- S1 is an write cycle of 83E7 0B13h at KICK0 completed state
- S2 is the UNLOCK register WRT state
- S0 → S1 when write cycle of 83E7 0B13h at KICK0
- S1 → S2 when write cycle of 95A4 F1E0h at KICK1
- S1 → S0 when reset event
- S2 → S0 when reset event or write cycle of NOT 83E7 0B13h at KICK0 or write cycle at KICK1
- S2 → S1 when write cycle of 83E7 0B13h at KICK0

23.4.3.4 Reading the Timer/Calendar (TC) Registers

The TC registers have a read-show register. The reading of the SECONDS register updates all TC registers. For example, the Year is updated only on a reading of the SECONDS register. The TC registers are updated every second as the time changes. During a read of the SECONDS register, the RTC copies the current values of the time/date registers into shadow read registers. This isolation assures that the CPU can capture all the time/date values when the SECONDS read request occurs and is not subject to changing register values from time updates.

If desired, the RTC also provides a one-time-triggered minute-rounding feature to round the MINUTE:SECOND registers to the nearest minute (with zero seconds). This feature is enabled by setting the ROUND_30S bit in the control register (RTC_CTRL_REG). The RTC automatically rounds the time values to the nearest minute the next time the SECONDS register is read.

Note

Software should always read the SECONDS register first. However, software does not have to poll any status bit to determine when to read the TC registers. Table 23-6 defines the TC set that gets shadowed.

Table 23-6. RTC Register Names and Values

Time Unit	Range	Remarks
Year	00 to 99	
Month	01 to 12	

Table 23-6. RTC Register Names and Values (continued)

Time Unit	Range	Remarks
Day	01 to 31	Months 1, 3, 5, 7, 8, 10, 12
	01 to 30	Months 4, 6, 9, 11
	01 to 29	Month 2 (leap year)
	01 to 28	Month 2 (common year)
Week	00 to 06	Day of week
Hour	00 to 23	24-hour mode
	01 to 12	AM/PM mode
Minute	00 to 59	
Seconds	00 to 59	

23.4.3.4.1 Rounding Seconds

Time can be rounded to the closest minute, by setting the ROUND_30S bit of the control register (RTC_CTRL_REG). When this bit is set, TC values are set to the closest minute value at the next second. The ROUND_30S bit is automatically cleared when rounding time is performed.

Example:

- If current time is 10H59M45S, round operation changes time to 11H00M00S.
- If current time is 10H59M29S, round operation changes time to 10H59M00S.

23.4.3.5 Modifying the TC Registers

To write correct data from and to the TC and TC alarm registers and read the TC alarm registers, the MPU must first read the BUSY bit of the status register (RTC_STATUS_REG) until BUSY is equal to zero. Once the BUSY flag is zero, there is a 15-μs access period in which the MPU can program the TC and TC alarm registers. Once the 15-μs access period passes, the BUSY flag must again be read from the STATUS register as previously described. If the MPU accesses the TC registers outside of the access period, then the access is not assured.

The MPU can access the RTC_STATUS_REG and the RTC_CTRL_REG registers at any time, with the exception of the RTC_CTRL_REG[5] bit, which can only be changed when the RTC is stopped. The MPU can stop the RTC by clearing the STOP_RTC bit of RTC_CTRL_REG. After clearing this bit, the RUN bit in RTC_STATUS_REG must be checked to verify the RTC has stopped. Once this is confirmed, the TC values can be updated. After the values have been updated, the RTC can be restarted by resetting the STOP_RTC bit.

Note

After writing to a TC register, software must wait four clock cycles before reading the value from the register. If this wait time is not observed and the TC register is accessed, then old data will be read from the register.

CAUTION

To remove any possibility of interrupting the register read process, which introduces a risk of violating the authorized 15-μs access period, TI recommends disabling all incoming interrupts during the register read process.

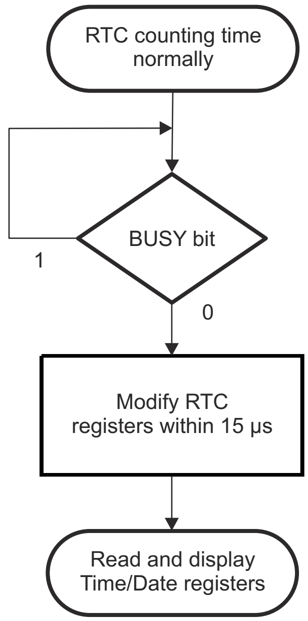

Figure 23-6. Flow Control for Updating RTC Registers

23.4.3.5.1 General Registers

The MPU can access the RTC_STATUS_REG and the RTC_CTRL_REG registers at any time (except the CTRL_REG[5] bit, which must be changed only when the RTC is stopped). For the RTC_INTERRUPTS_REG register, the MPU should respect the available access period to prevent spurious interrupt.

The RTC_DISABLE bit of the RTC_CTRL_REG register must only be used to completely disable the RTC function. When this bit is set, the 32-kHz clock is gated, and the RTC is frozen. From this point, resetting the RTC_DISABLE bit to zero can lead to unexpected behavior. To save power, this bit should only be used if the RTC function is unwanted in the application.

23.4.3.6 Crystal Compensation

To compensate for any inaccuracy of the 32-kHz oscillator the MPU can perform a calibration of the oscillator frequency, calculate the drift compensation versus a 1-hour period, and load the compensation registers with the drift compensation value. Auto compensation is enabled by the AUTO_COMP bit in the RTC_CTRL_REG register. If the value of the COMP_REG registers (RTC_COMP_LSB_REG and RTC_COMP_MSB_REG) is positive, compensation occurs after the second change event. COMP_REG cycles are removed from the next second. If the COMP_REG value is negative, compensation occurs before the second change event. COMP_REG cycles are added to the current second. This enables compensation with a 1 32-kHz period accuracy each hour. The waveform in Figure 23-7 summarizes positive and negative compensation effect.

Access to the RTC_COMP_MSB_REG and RTC_COMP_LSB_REG registers must respect the available access period. These registers should not be updated during compensation (the first second of each hour), but it is alright to update them during the second preceding a compensation event. For example, the MPU could load the compensation value into these registers after each hour event, during an available access period.

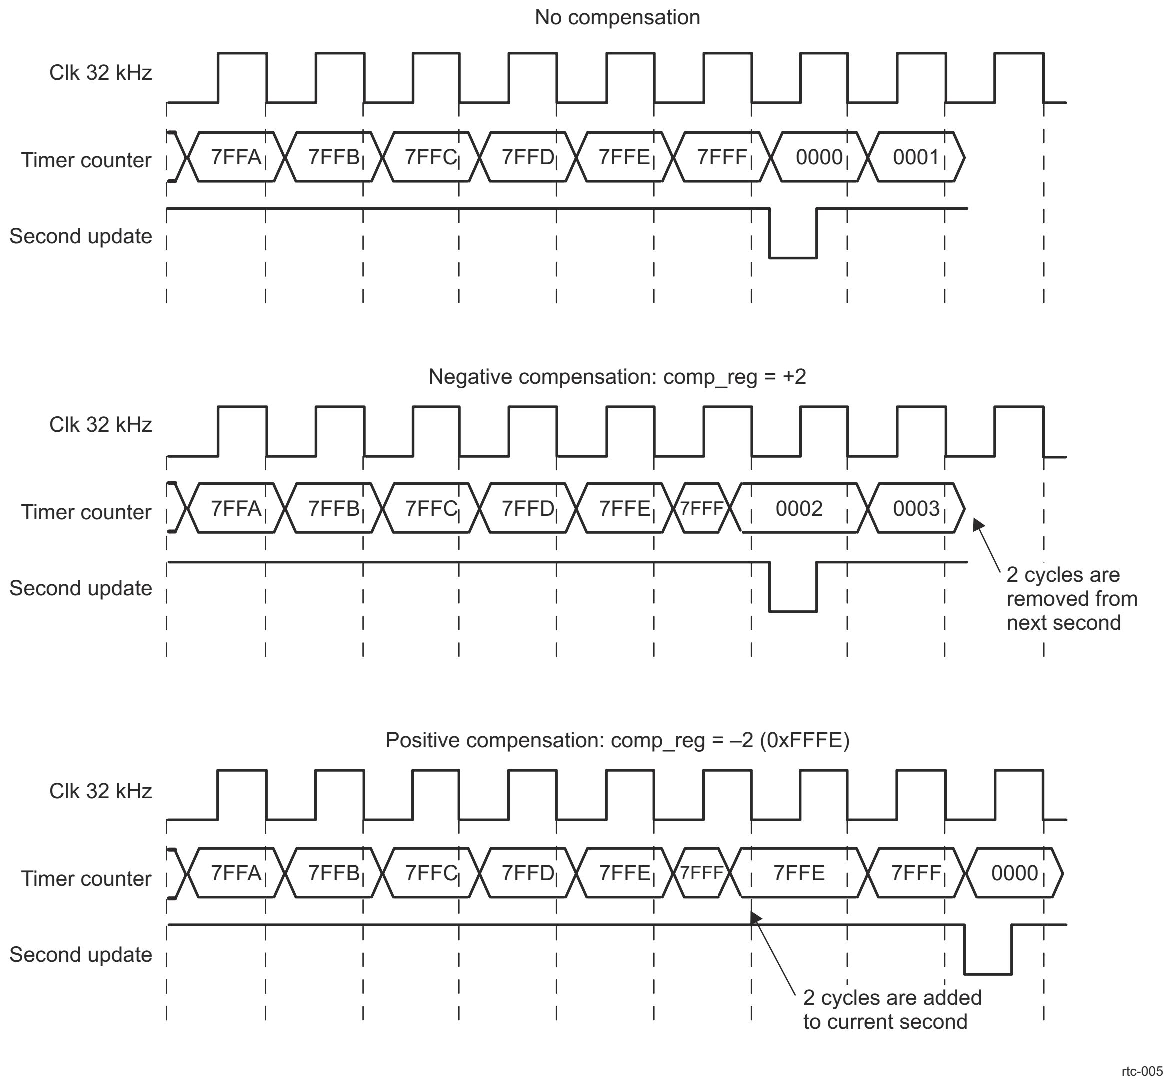

Figure 23-7. Compensation Illustration

23.4.4 Scratch Registers

The RTC provides three general-purpose registers (RTC_SCRATCHx_REG) that can be used to store 32-bit words -- these registers have no functional purpose for the RTC. Software using the RTC may find the SCRATCHx_REG registers to be useful in indicating RTC states. For example, the RTC_SCRATCHx_REG (RTC_SCRATCH0_REG, RTC_SCRATCH1_REG, RTC_SCRATCH2_REG) registers may be used to indicate write-protection lock status or unintentional power downs. To indicate write-protection, the software should write a unique value to one of the RTC_SCRATCHx_REG registers when write-protection is disabled and another unique value when write-protection is enabled again. In this way, the lock-status of the registers can be determined quickly by reading the RTC_SCRATCHx_REG register. To indicate unintentional power downs, the software should write a unique value to one of the RTC_SCRATCHx_REG registers when RTC is configured and enabled. If the RTC is unintentionally powered down, the value written to the RTC_SCRATCHx_REG register is cleared.

23.4.5 Debouncing

The debounce timer uses the 32768-Hz clock or the clock coming from the external oscillator, depending on the SW configurations for the RTC. It allows choosing the timing or accuracy of the "debouncing".

A register receives a bit from the reference pin. Software then chooses the timing if it uses the debouncing feature like a timer, or it chooses the accuracy if it uses the debouncing like a real debouncing. The debouncing is finished when the reference pin stays the same value, defined in RTC_RTL_DEBOUNCE_REG[7:0] DEBOUNCE_REG, for a defined time.

If the RTC module uses the internal 32-kHz clock then setting the RTC_RTL_DEBOUNCE_REG[7:0] DEBOUNCE_REG to 0x0 results in a debounce time of 30.52us. Otherwise (DEBOUNCE_REG = n) the debounce time is 30.52μs × (n + 1). The debounce time may be different, depending on, whether the module uses the internal 32 kHz clock, or an external clock source.

23.4.6 Power Management

23.4.6.1 Device-Level Power Management

The RTC supports the power idle protocol. The RTC has two SWakeup ports: one for the alarm event and one for a timer event.

When the RTC is in IDLE mode, the clock is turned off and the 32 kHz clock remains on. The time and calendar continue to count in IDLE mode. When the RTC is placed back in FUNCTIONAL mode, the TC registers can be read. The RTC idle mode configuration is done through the RTC_SYSCONFIG_REG[1:0] IDLEMODE bit (see Table 23-7).

Table 23-7. RTC Idle Configuration

IDLEMODE	Description
0x0	Force IDLE: idle state of the local target follows (acknowledges) the system IDLE request unconditionally
0x1	No-idle mode: RTC never enters idle state
0x2	Smart-idle mode: RTC subsystem waits for all interrupts/events to be serviced before entering in IDLE mode.
0x3	Smart-idle wakeup-capable mode: RTC eventually acknowledges the system IDLE requests, depending on its internal requirements, RTC can generate wakeup events when in idle state.

The Alarm SWakeup event can be used to wake up the RTC when it is in idle state. To do so, the alarm must be set and enabled before RTC enters idle state. Also the wakeup generation for alarm/timer event must be set (bits [1:0] in the RTC_IRQWAKEEN register). Once this is done, the SWakeup event occurs when the alarm event triggers.

Note

SWakeup is not periodic, using Timer SWakeup event to wake up the RTC when in idle state is not recommended. Use Alarm SWakeup instead.

There are two idle modes: smart-idle mode and smart-idle wakeup-capable mode. The RTC should be configured to smart-idle wakeup-capable mode in order to use the SWakeup events.

23.4.6.2 Subsystem-Level Power Management — PMIC Mode

The RTC generates PMIC_PWR_ENABLE control, which can be used to control an external PMIC. The control of the associated PMIC wakeups and alarms is done through the RTC_PMIC_REG[22:0] bits.

23.5 RTC Low-Level Programming Guide

23.5.1 Global Initialization

23.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the real time clock is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the RTC.

Table 23-8. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. for more information about the module configuration. For more information about the module configuration, see *Module Level Clock Management*, in *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing must be set in the control module. For more information about the module configuration, see *Pad Configuration Registers* in *Control Module*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

23.5.1.2 RTC Module Global Initialization

23.5.1.2.1 Main Sequence – RTC Module Global Initialization

Table 23-9 lists the steps for initializing the RTC module when the module is to be used for the first time.

Table 23-9. RTC Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Write 0x83E7 0B13 to the Kick0 Register to unlock register writes	RTC_KICK0_REG	0x83E70B13
Write 0x95A4 F1E0 to the Kick1 Register to unlock register writes	RTC_KICK1_REG	0x95A4F1E0
Select the clock source (internal or external 32-kHz clock)	RTC_OSC_REG[3] 32KCLK_SEL	-
If external clock is selected, start the oscillator. Wait for oscillator to stabilize.	RTC_OSC_REG[4] OSC32K_GZ	0
Enable the 32-kHz clock	RTC_OSC_REG[6] 32KCLK_EN	1
Configure slave idle mode	RTC_SYSCONFIG_REG [1:0] IDLEMODE	0x-
Enable interrupts, if needed	RTC_INTERRUPTS_REG[4:0]	0x-
Enable wakeup interrupts, if needed	RTC_IRQWAKEEN[1:0]	0x-
Set current time	RTC_SECONDS_REG[6:0]	BCD
	RTC_MINUTES_REG[6:0]	BCD
	RTC_HOURS_REG[5:0]	BCD
Set current date	RTC_DAYS_REG[5:0]	BCD
	RTC_MONTHS_REG[4:0]	BCD
	RTC_YEARS_REG[7:0]	BCD
	RTC_WEEKS_REG[2:0]	BCD
Run the real-time clock	RTC_CTRL_REG[0] STOP_RTC	1

Table 23-40. RTC_STATUS_REG

Address Offset	0x0000 0044		
Physical Address	0x4883 8044	**Instance**	RTC_SS
Description	RTC STATUS_REG contains bits that signal the status of interrupts, events to the processor. Status for the alarm interrupt and timer events are notified by the register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								ALARM2	ALARM	EVENT_1D	EVENT_1H	EVENT_1M	EVENT_1S	RUN	BUSY

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved	R	0x0
7	ALARM2	Indicates that an alarm2 interrupt has been generated. Software must wait 31 µs before it clears this status to allow PMIC_PWR_ENABLE 1 - 0 transmission.	RW	0x0
6	ALARM	Indicates that an alarm interrupt has been generated. Writing 1 to the bit clears the interrupt.	RW	0x0
5	EVENT_1D	One day has occurred.	R	0x0
4	EVENT_1H	One hour has occurred.	R	0x0
3	EVENT_1M	One minute has occurred.	R	0x0
2	EVENT_1S	One second has occurred.	R	0x0
1	RUN	0: RTC is frozen. 1: RTC is running.	R	0x0

Bits	Field Name	Description	Type	Reset
0	BUSY	0: Updating event in more than 15 µs. 1: Updating event. This bit will give the status of RTC module. The time and alarm registers can be modified only when this bit is 0.	R	0x0

Table 23-44. RTC_COMP_LSB_REG

Address Offset	0x0000 004C		
Physical Address	0x4883 804C	**Instance**	RTC_SS
Description	COMP_LSB_REG is used to program the LSB value of the 32-kHz periods to be added to the 32-kHz counter every hour. This is used to compensate the oscillator drift. The COMP_LSB_REG works with the compensation (MSB) register (COMP_MSB_REG). The AUTOCOMP bit in the control register (CTRL_REG) must be enabled for compensation to OCCUR.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

24.1 Multimaster High-Speed I^{2}C Controller

This section describes the high-speed inter-integrated circuit (I^{2}C) controller modules in the device.

Note

Not all I^{2}C instances support HS-mode operation. See the Device Data Manual for details.

24.1.1 HS I^{2}C Overview

The device contains five multimaster high-speed (HS) inter-integrated circuit (I^{2}C) controllers (I2C*i* modules, where *i* = 1, 2 ,3, 4, 5) each of which provides an interface between a local host (LH), such as a digital signal processor (DSP), and any I^{2}C-bus-compatible device that connects through the I^{2}C serial bus. External components attached to the I^{2}C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I^{2}C interface.

Each multimaster HS I^{2}C controller can be configured to act like a slave or master I^{2}C-compatible device.

I2C1 and I2C2 controllers have dedicated I2C compliant open drain buffers, and support Fast mode (up to 400Kbps). I2C3, I2C4 and I2C5 controllers are multiplexed with standard LVCMOS IO and connected to emulate open drain. I^{2}C emulation is achieved by configuring the LVCMOS buffers to output Hi-Z instead of driving high when transmitting logic 1. These controllers support HS mode (up to 3.4Mbps). For the specific IO timing characteristics of the different I^{2}C instances, see the device data manual.

Figure 24-1 shows the I^{2}C.

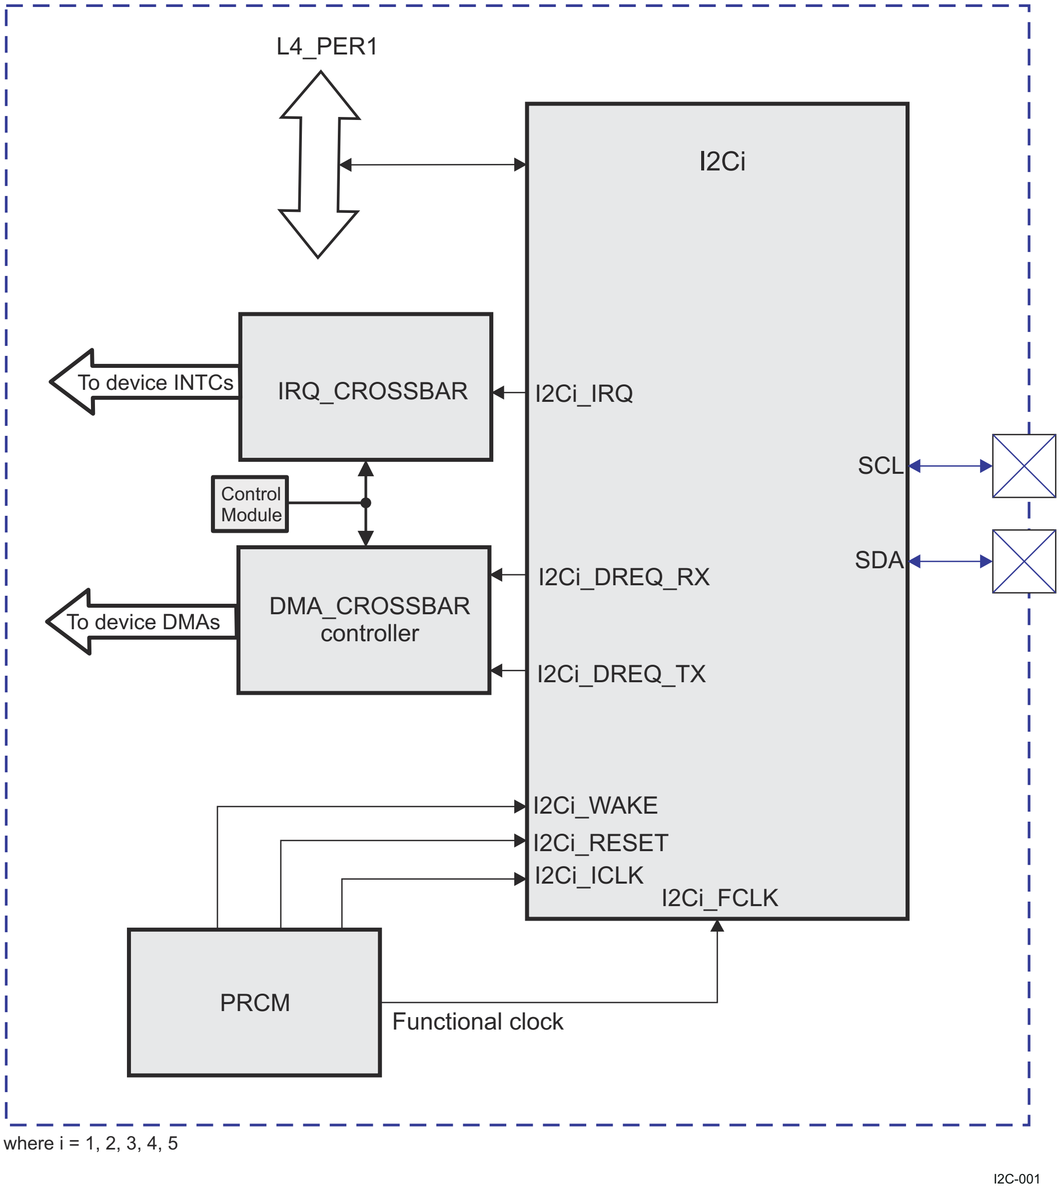

Figure 24-1. HS I²C Controllers

The multimaster HS I²C controllers have the following features:

- Compliant with Philips I²C specification version 2.1
- Supports a standard mode (up to 100 kbps) and fast mode (up to 400 kbps)
- Supports HS mode for transfer up to 3.4 Mbps (only for I2C3, I2C4 and I2C5)
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFOs (16 bytes) for buffered read or write
- Module enable/disable capability
- Programmable multislave channel (responds to four separate addresses)
- Programmable clock generation

- 8-bit-wide data access
- Designed for low power consumption
- Implement Auto Idle mechanism
- Implement Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Two direct memory access (DMA) channels
- Wide interrupt capability

24.1.2 HS I²C Environment

This section describes the HS I²C application fields from an environment point of view (external connections). It describes HS I²C connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

24.1.2.1 HS I²C Typical Application

Figure 24-2 shows the multimaster HS I²C controllers and their related connections with I²C-compliant devices.

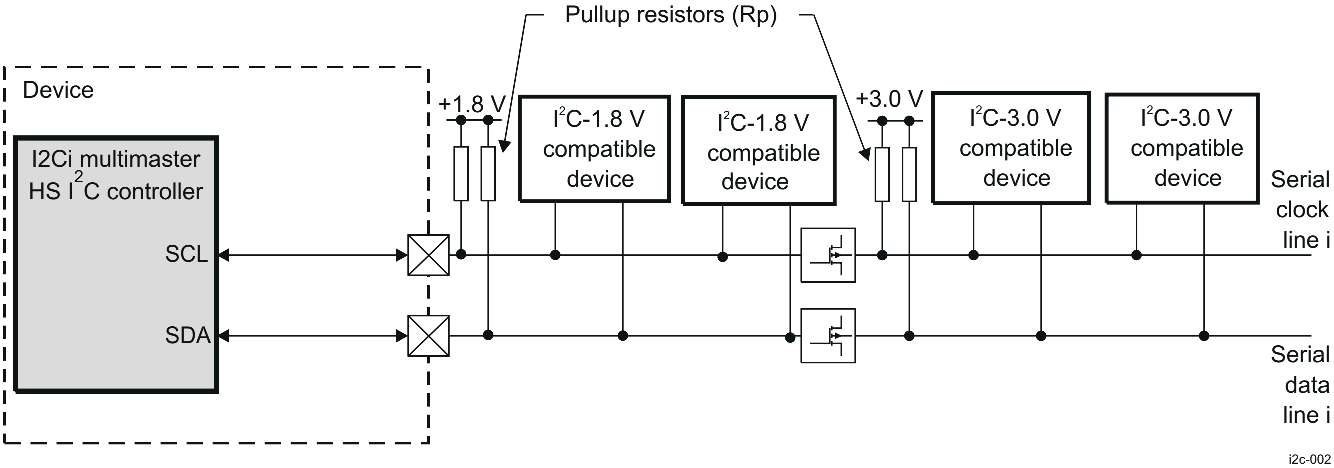

Figure 24-2. HS I²C and Typical Connections to I²C Devices

24.1.2.1.1 HS I²C Pins for Typical Connections in I²C Mode

Figure 24-3 shows the multimaster HS I²C controller pins used for typical connections with I²C devices.

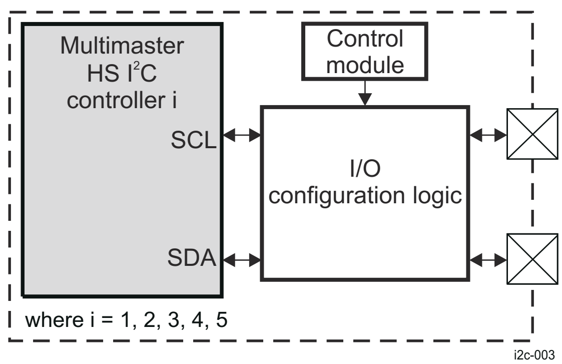

Figure 24-3. HS I²C Interface Signals

24.1.2.1.2 HS I²C Interface Typical Connections

Table 24-1 lists the pins associated with the I²C interface.

Table 24-1. HS I²C Input/Output

Signal	Device Level Signal	I/O(1)	Description	Reset Value
SCL	i2c*j*_scl(2)	I/O	I²C serial clock line. Open-drain output buffer.	1
SDA	i2c*j*_sda(2)	I/O	I²C serial data line. Open-drain output buffer.	1
SCL	i2c*i*_scl(3)	I/O	I²C serial clock line. Emulated open-drain output buffer.	1
SDA	i2c*i*_sda(3)	I/O	I²C serial data line. Emulated open-drain output buffer.	1

(1) I = Input; O = Output
(2) j= 1 and 2
(3) i= 3 to 5

Note

For the i2c*j*_scl and i2c*i*_scl signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. Refer to the sections *Pad Functional Multiplexing* of the chapter *Control Module*, for more information.

24.1.2.2 HS I^{2}C Typical Connection Protocol and Data Format

24.1.2.2.1 HS I^{2}C Serial Data Format

The I^{2}C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I^{2}C. Figure 24-4 shows a typical I^{2}C communication format.

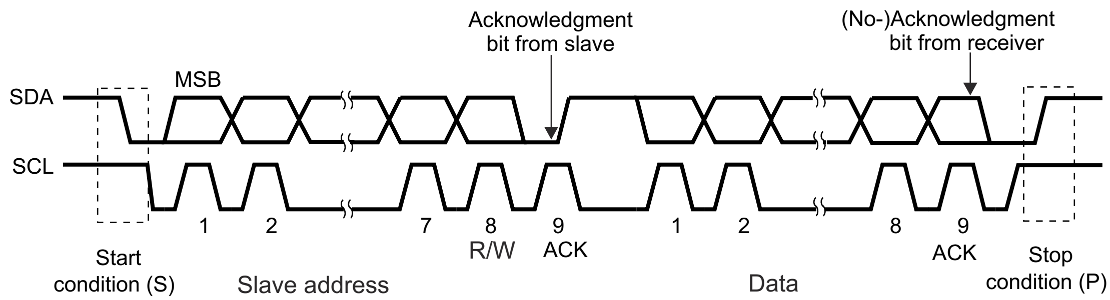

Figure 24-4. HS I^{2}C Data Transfer

24.1.2.2.2 HS I^{2}C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

Figure 24-5 is an example of data validity requirements.

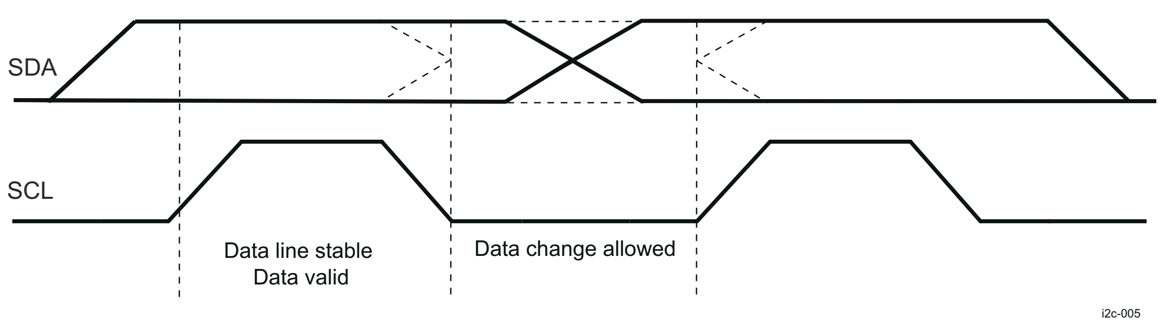

Figure 24-5. HS I^{2}C Bit Transfer on the I^{2}C Bus

24.1.2.2.3 HS I^{2}C Start and Stop Conditions

The I^{2}C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2C*i*. [12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2C*i*.I2C_IRQSTATUS_RAW [12] BB bit is 0 to indicate that the bus is free).

Figure 24-6 shows the waveforms that occur during an S and a P condition.

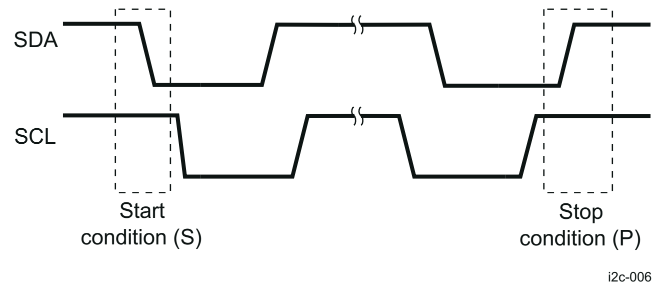

Figure 24-6. HS I²C S and P Condition Events

Note

I²C controller does not support messages non-compliant with I2C standard. Void messages are non-standard I²C messages and will lockup the controller. A void message is a START condition followed by a STOP condition, in other words, while the bus is free the SDA line is pulled low (START) and then released (STOP). This would result in a timeout (software) of the next master transfer which would never complete. A soft reset of the controller is recommended for recovery.

24.1.2.2.4 HS I²C Addressing

The I²C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

24.1.2.2.4.1 Data Transfer Formats in F/S Mode

Figure 24-7 shows the I²C data transfer formats in F/S mode.

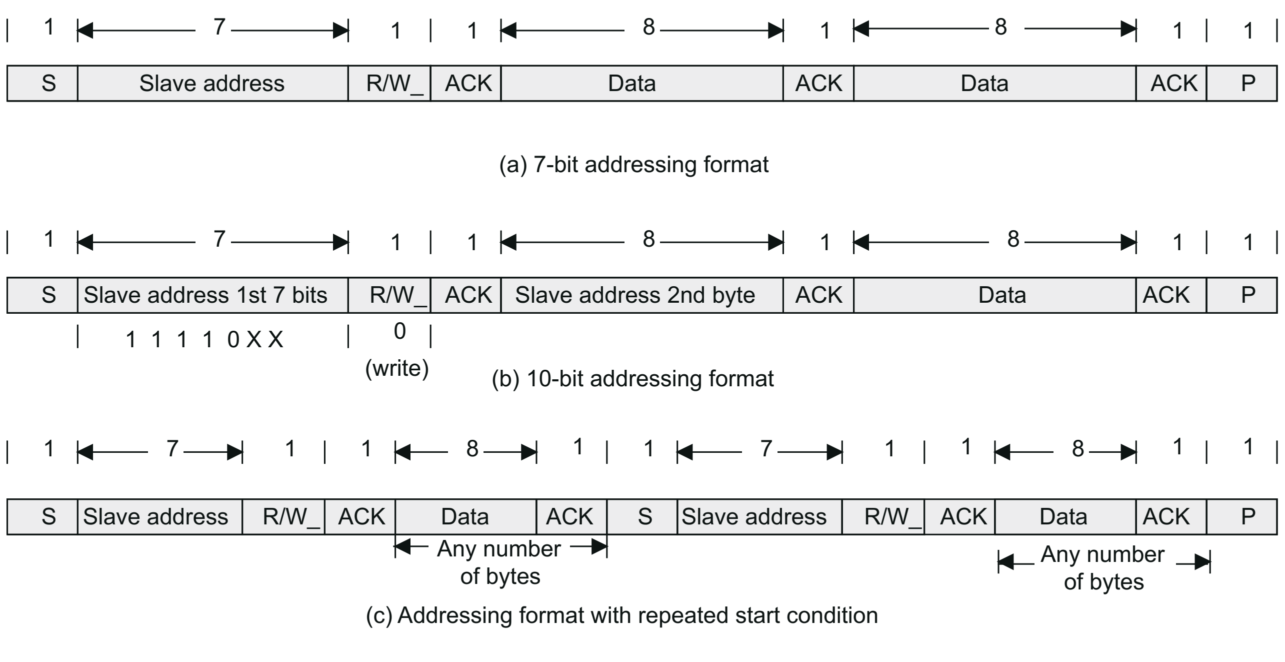

Figure 24-7. HS I²C Data Transfer Formats in F/S Mode

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

24.1.2.2.4.2 Data Transfer Format in HS Mode

Figure 24-8 shows the I^2C data transfer format in HS mode.

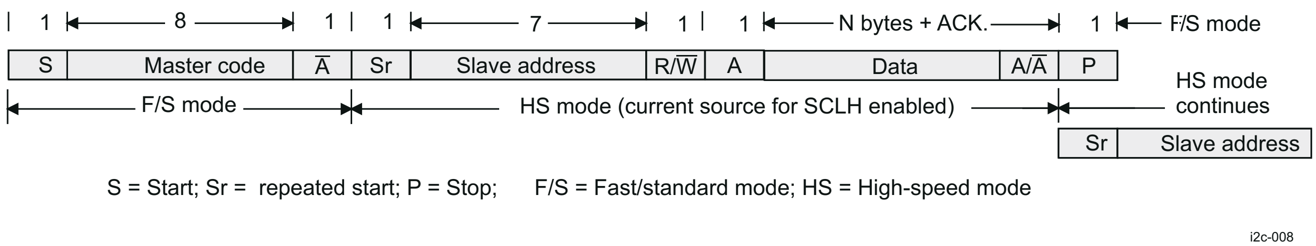

Figure 24-8. HS I^2C Data Transfer in HS Mode

Each multimaster HS I^2C controller can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 24-8.

24.1.2.2.5 HS I^2C Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

24.1.2.2.6 HS I^2C Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 24-7), if R/W_ is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line SDAI are shifted in synchronization with the self-generated clock pulses on SCLI.

24.1.2.2.7 HS I^2C Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 24-7), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W_ is transmitted, if R/W_ is high. The slave transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

24.1.2.2.8 HS I^2C Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

24.1.2.2.9 HS I²C Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 24-9 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

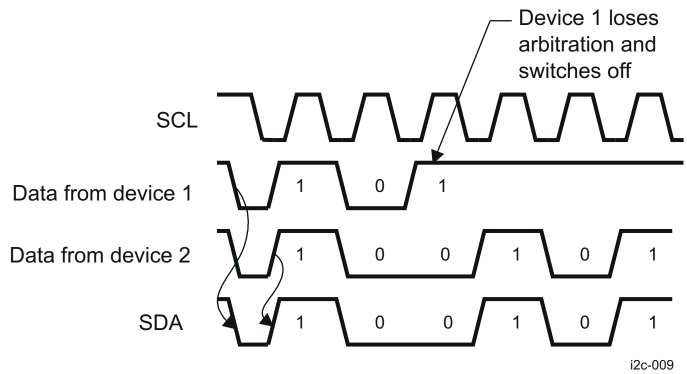

Figure 24-9. HS I²C Arbitration Between Master Transmitters

24.1.2.2.10 HS I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. However, there are two or more master devices during the arbitration procedure, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (clock stretching).

Note

In case the SCL or SDA lines are stuck low, a bus clearing operation is supported:

- If the clock line (SCL) is stuck low, the preferential procedure is to reset the bus using the hardware reset signal if your I²C devices have hardware reset inputs. If the I²C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.
- If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 24-10 shows clock synchronization.

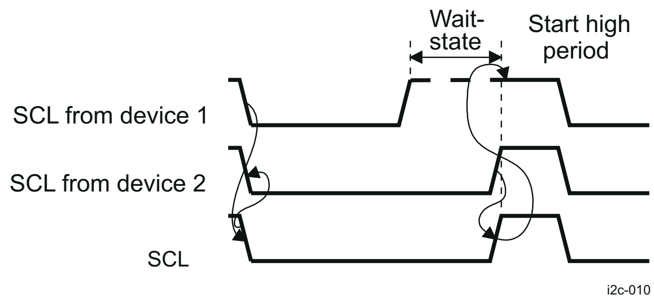

Figure 24-10. HS I^{2}C Clock Generators Synchronization

24.1.3 HS I²C Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-11 shows the integration of the five HS I²C controllers in the device.

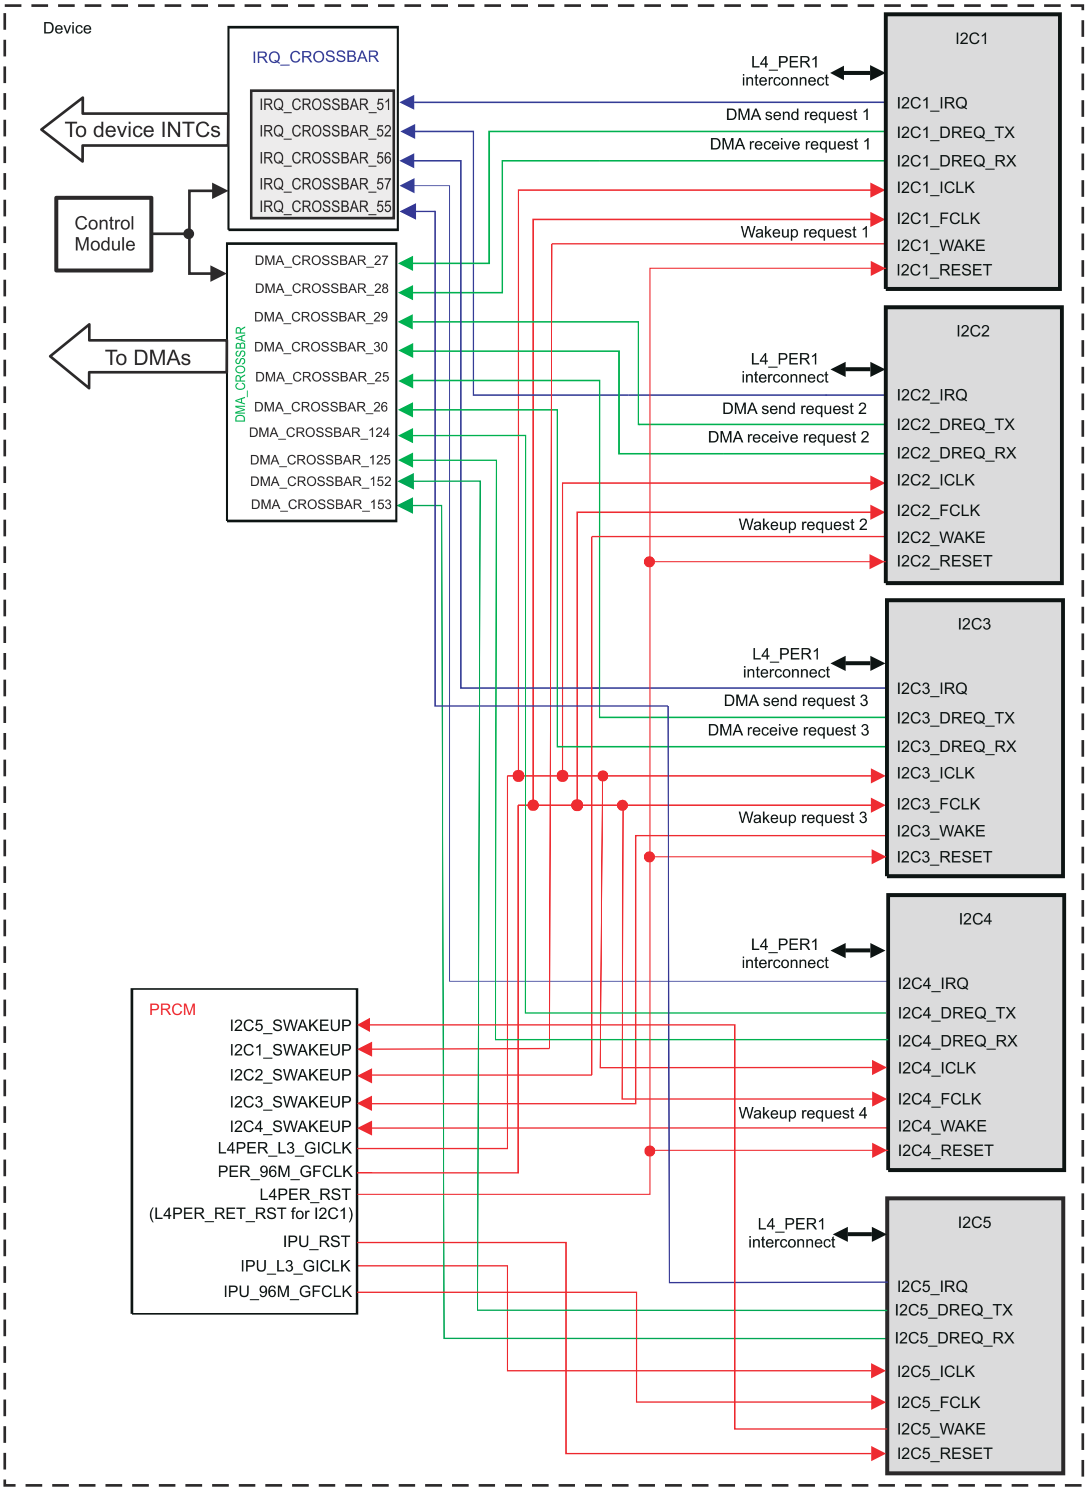

Figure 24-11. HS I²C Integration

Note

For more information about the slave idle protocol and the wake-up request, see *Power Management Functional Description*, in *Power, Reset, and Clock Management*.

Table 24-2 through Table 24-4 summarize the integration of the module in the device.

Table 24-2. HS I²C Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
I2C1	PD_COREAON	L4_PER1

	I2C5_DREQ_RX	DMA_CROSSBAR_153	-	I2C5 DMA receive request

Note

The **Default Mapping** column in Table 24-4 *HS I^2C Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.
For more information about the device DMA_SYSTEM module, see *System DMA*.
For more information about the device EDMA module, see *Enhanced DMA*.

Note

- For a description of interrupt source, see Table 24-10.
- For a description of DMA source, see Table 24-11.

24.1.4 HS I²C Functional Description

24.1.4.1 HS I²C Block Diagram

Figure 24-12 is the multimaster I²C HS controller block diagram.

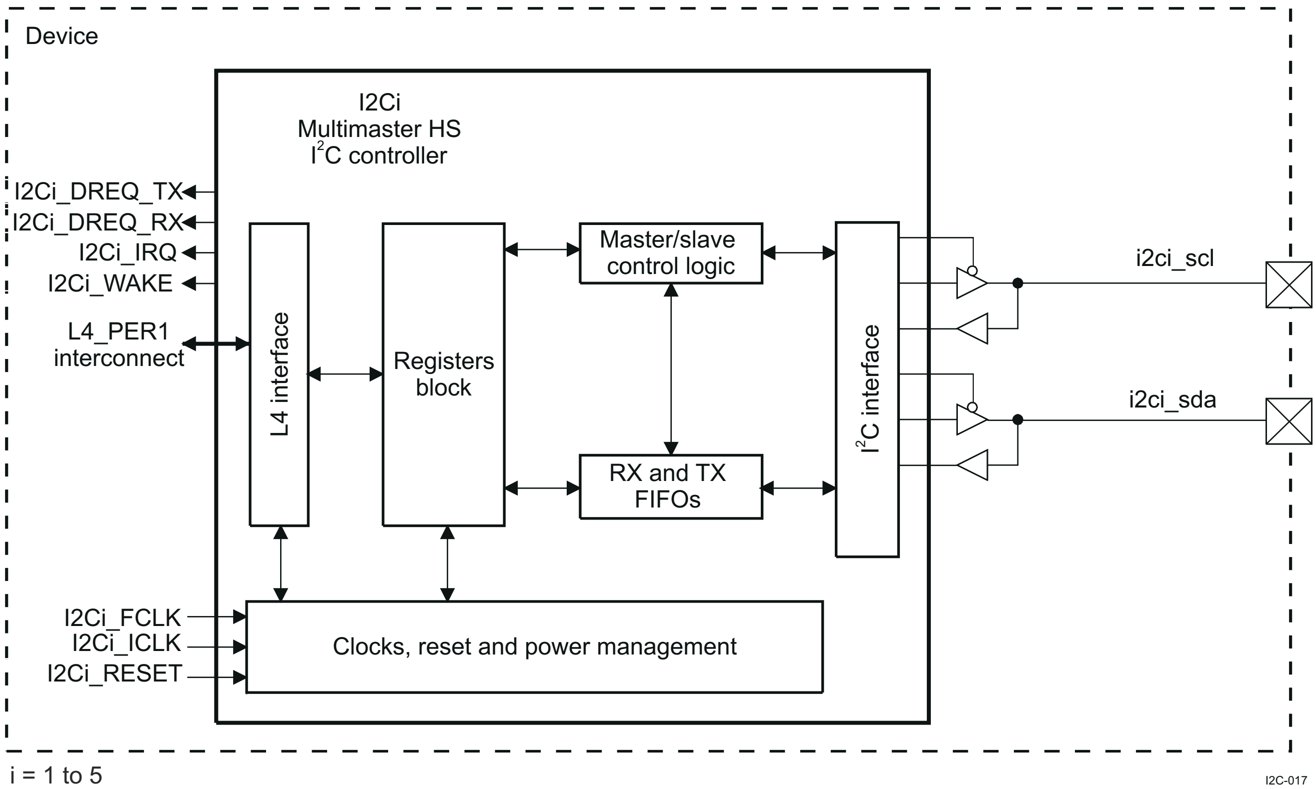

Figure 24-12. HS I²C Block Diagram

The five multimaster HS I²C controllers can be configured in F/S I²C mode or HS I²C mode. The operation mode is selected by configuring the I2C*i*.I2C_CON[13:12] OPMODE bit field. Table 24-5 lists the available operation modes.

Table 24-5. HS I²C Operation Mode Selection

Operation Mode	Value of I2C*i*.I2C_CON[13:12] OPMODE
F/S I²C	0x0
HS I²C	0x1
Reserved	0x2
Reserved (not used)	0x3

24.1.4.2 HS I²C Clocks

24.1.4.2.1 HS I²C Clocking

Figure 24-13 shows the I²C clock generation of the HS I²C controllers.

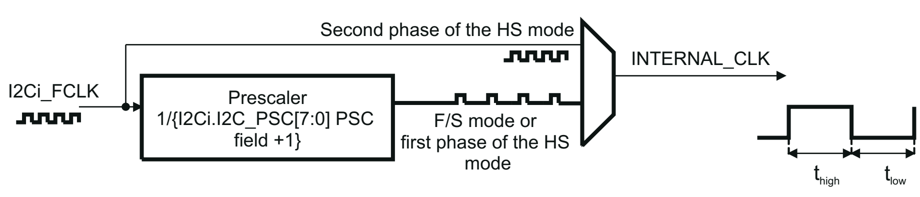

Figure 24-13. HS I²C Clock Generation

Each multimaster HS I^2C controller uses the I2C*i*_FCLK functional clock in the PRCM module. The internal sampling clock I2C*i*_INTERNAL_CLK is generated by dividing the functional clock by the I2C*i*.I2C_PSC[7:0] PSC bit field value + 1 in F/S mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2C*i*_SCLL signal is determined by the I2C*i*.I2C_SCLL[7:0] SCLL bit field in F/S mode and in the first phase of HS mode; or by the I2C*i*.I2C_SCLL[15:8] HSSCLL bit field in the second phase of HS mode.

The high time of the I2C*i*_SCLL signal is determined by the I2C*i*.I2C_SCLH[7:0] SCLH bit field in F/S mode and in the first phase of HS mode; or by the I2C*i*.I2C_SCLH[15:8] HSSCLH bit field in the second phase of HS mode.

Table 24-6 lists the t_{LOW} and t_{high} values in master mode only (in slave mode, the I^2C controller does not generate the I^2C clock).

Table 24-6. HS I^2C t_{LOW} and t_{high} Values of the I^2C Clock

Mode	I2C*i* Clock	t_{LOW}	t_{high}
F/S or HS first phase	I2C*i*_INTERNAL_CLK = I2C*i*_FCLK / (I2C*i*.I2C_PSC[7:0] PSC bit field + 1)	(I2C*i*.I2C_SCLL[7:0] SCLL bit field value + 7) x I2C*i*_INTERNAL_CLK period	(I2Ci.I2C_SCLH [7:0] SCLH bit filed value + 5) x I2Ci_INTERNAL_CLK period
HS second phase	I2C*i*_FCLK	(I2C*i*.I2C_SCLL[15:8] HSSCLL bit field value + 7) x I2C*i*_FCLK period	(I2Ci.I2CSCLL [15:8] HSSCLH bit field value + 5) x I2Ci_FCLK period

Note

For HS mode, the I2C*i*.I2C_SCLL[15:8] HSSCLL and I2C*i*.I2C_SCLL[7:0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2C*i*.I2C_SCLH[15:8] HSSCLH and I2C*i*.I2C_SCLH[7:0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

Note

The equations in Table 24-6 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I^2C controller outputs. Actual tlow and thigh periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

CAUTION

During active mode (the I2C*i*.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2C*i*.I2C_SCLL and I2C*i*.I2C_SCLH registers. Changes may result in unpredictable behavior.

Table 24-7 lists the register values for obtaining the maximum I^2C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

Table 24-7. HS I^2C Register Values for Maximum I^2C Bit Rates in I^2C F/S, I^2C HS Modes

[1]	I^2C Mode for I2C*i*,			Description
	Standard Mode	Fast Mode	High-Speed Mode[2]	
I2C*i*_FCLK frequency (MHz)	96			

Table 24-7. HS I²C Register Values for Maximum I²C Bit Rates in I²C F/S, I²C HS Modes (continued)

[1]	I²C Mode for I2C*i*,			Description
I2C *i* .I2C_PSC[7:0] PSC	**23**	**9**	**1**	Prescaler value for F/S and HS modes
I2C*i*_INTERNAL_CLK frequency (MHz)	4	9.6	96	
I2C *i* .I2C_SCLL[7:0] SCLL	**13**	**5**	**115**	Value for F/S mode and first phase of HS mode
I2C *i* .I2C_SCLH[7:0] SCLH	**15**	**7**	**113**	Value for F/S mode and first phase of HS mode
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate
Maximum filter period (ns)	250	104.2	10	
I2C *i* .I2C_SCLL[15:8] HSSCLL			**12**	Values for second phase of HS mode
I2C *i* .I2C_SCLH[15:8] HSSCLH			**5**	Values for second phase of HS mode
HS mode maximum bit rate (Mbps)			3.31	HS mode maximum bit rate
Maximum filter period (ns)			10	

(1) Programmable fields are in bold.
(2) Supported only on I2C3, I2C4 and I2C5.

Note

This table presents informative values only for the configuration parameters and the I²C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

Note

For I2Ci (where i=1, 2, 3, 4, 5)

I2Ci_INTERNAL_CLK freq = I2Ci_FCLK / (PSC +1)

F/S filter period = 1 / I2Ci_INTERNAL_CLK

HS filter period = 1 / I2Ci_FCLK freq

HS bit rate = I2Ci_FCLK freq / (HSSCLL+ 7 + HSSCLH + 5)

FS bit rate = I2Ci_INTERNAL_CLK / (SCLL+ 7 + SCLH + 5)

24.1.4.2.2 HS I²C Automatic Blocking of the I²C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock can be performed independently for each Own Address (I2C*i*.I2C_OA, and I2C*i*.I2C_OAx registers, where *i* = 1 to 5, x = 1, 2, 3) by deasserting the corresponding bit in the I2C*i*.I2C_SBLOCK register.

24.1.4.3 HS I²C Software Reset

Each multimaster HS I²C controller supports the software reset by accessing the I2C*i*.I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2C*i*.I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2C*i*.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2C*i*.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2C*i*.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2C*i*.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

Note

The I2C*i*.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster HS I^{2}C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I^{2}C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2C*i*.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I^{2}C controller.

The I2C*i*.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2C*i*.I2C_CON[15] I2C_EN bit to 1.

24.1.4.4 HS I^{2}C Power Management

Table 24-8 describes power-management features available for the multimaster HS I^{2}C controllers.

Note

- For information about source clock gating and sleep/wake-up transitions description, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

Table 24-8. HS I^{2}C Local Power-Management Features

Feature	Registers	Description
Clock auto gating	I2C*i*.I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2C*i*.I2C_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2C*i*.I2C_SYSC[9:8] CLOCKACTIVITY	For configuration details, see Table 24-9.
Global wake-up enable	I2C*i*.I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

Note

The voltage controllers, in which the HS I^{2}C controller is implemented, have no idle request/ acknowledge mechanism. The idle modes for the voltage controllers are directly managed by the PRCM module.

Table 24-9. HS I^{2}C Clock Activity Settings

I2C*i*.I2C_SYSC[9:8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	I2C*i*_ICLK	I2C*i*_ FCLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; functional clock is enabled
01	ON	OFF	Functional clock is disabled; interface clock is enabled
11	ON	ON	Both clocks are enabled.

CAUTION

The PRCM module has no hardware means of reading the settings of CLOCKACTIVITY. Thus, software must ensure consistent programming between the I2C CLOCKACTIVITY and I2C clock PRCM control bits. For a description of the ClockActivity feature, see *Module-Level Clock Management* in *Power, Reset, and Clock Management*.

24.1.4.5 HS I2C Interrupt Requests

Table 24-10 lists the event flags, and their mask, that can cause module interrupts.

Table 24-10. HS I2C Events

Event Flag	Event Unmask	Event Mask	Description
I2C*i*.I2C_IRQSTATUS[0] AL	I2C*i*.I2C_IRQENABLE_SET[0] AL_IE	I2C*i*.I2C_IRQENABLE_CLR [0] AL_IE	Arbitration lost. This bit is automatically set by the hardware when it loses the arbitration in master transmit mode, an interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[1] NACK	I2C*i*.I2C_IRQENABLE_SET[1] NACK_IE	I2C*i*.I2C_IRQENABLE_CLR [1] NACK_IE	No acknowledgement. Bit is set when No Acknowledge is received, an interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[2] ARDY	I2C*i*.I2C_IRQENABLE_SET[2] ARDY_IE	I2C*i*.I2C_IRQENABLE_CLR [2] ARDY_IE	Register access ready. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[3] RRDY	I2C*i*.I2C_IRQENABLE_SET[3] RRDY_IE	I2C*i*.I2C_IRQENABLE_CLR [3] RRDY_IE	Receive data ready. Set to 1 by core when in receiver mode, a new data can be read. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[4] XRDY	I2C*i*.I2C_IRQENABLE_SET[4] XRDY_IE	I2C*i*.I2C_IRQENABLE_CLR [4] XRDY_IE	Transmit data ready. Set to 1 by core when transmitter is ready for new data. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[5] GC	I2C*i*.I2C_IRQENABLE_SET[5] GC_IE	I2C*i*.I2C_IRQENABLE_CLR [5] GC_IE	General call. Set to 1 by core when General Call address was detected. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[6] STC	I2C*i*.I2C_IRQENABLE_SET[6] STC_IE	I2C*i*.I2C_IRQENABLE_CLR [6] STC_IE	Start condition detected. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[7] AERR	I2C*i*.I2C_IRQENABLE_SET[7] AERR_IE	I2C*i*.I2C_IRQENABLE_CLR [7] AERR_IE	Bus Access Error. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[8] BF	I2C*i*.I2C_IRQENABLE_SET[8] BF_IE	I2C*i*.I2C_IRQENABLE_CLR [8] BF_IE	Bus free. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[9] AAS	I2C*i*.I2C_IRQENABLE_SET[9] AAS_IE	I2C*i*.I2C_IRQENABLE_CLR [9] AAS_IE	Address recognized as slave. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[10] XUDF	I2C*i*.I2C_IRQENABLE_SET [10] XUDF_IE	I2C*i*.I2C_IRQENABLE_CLR [10] XUDF_IE	Transmit underflow. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[11] ROVR	I2C*i*.I2C_IRQENABLE_SET [11] ROVR_IE	I2C*i*.I2C_IRQENABLE_CLR [11] ROVR_IE	Receive overrun. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[12] BB	N/A	N/A	Bus busy indicator
I2C*i*.I2C_IRQSTATUS[13] RDR	I2C*i*.I2C_IRQENABLE_SET [13] RDR_IE	I2C*i*.I2C_IRQENABLE_CLR [13] RDR_IE	Receive draining. An interrupt is signaled to the host.
I2C*i*.I2C_IRQSTATUS[14] XDR	I2C*i*.I2C_IRQENABLE_SET [14] XDR_IE	I2C*i*.I2C_IRQENABLE_CLR [14] XDR_IE	Transmit draining. An interrupt is signaled to the host.

24.1.4.6 HS I2C DMA Requests

Each multimaster HS I2C controller can generate two DMA requests to the device DMA controllers through the DMA_CROSSBAR module. Table 24-11 lists the DMA requests. For information about DMA generation, see Section 24.1.4.8.3, *HS I2C FIFO DMA Mode (I2C Mode Only)*.

Table 24-11. HS I2C DMA Requests

Name	Source	Description
I2C1_DREQ_TX	I2C1	I2C1 DMA write request to inform the DMAs to write new data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C1_DREQ_RX	I2C1	I2C1 DMA read request to inform the DMAs to read the data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_TX	I2C2	I2C2 DMA write request to inform the DMAs to write new data in the I2C2.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_RX	I2C2	I2C2 DMA read request to inform the DMAs to read the data in the I2C2.I2C_DATA[7:0] DATA bit field
I2C3_DREQ_TX	I2C3	I2C3 DMA write request to inform the DMAs to write new data in the I2C3.I2C_DATA[7:0] DATA bit field
I2C3_DREQ_RX	I2C3	I2C3 DMA read request to inform the DMAs to read the data in the I2C3.I2C_DATA[7:0] DATA bit field
I2C4_DREQ_TX	I2C4	I2C4 DMA write request to inform the DMAs to write new data in the I2C4.I2C_DATA[7:0] DATA bit field
I2C4_DREQ_RX	I2C4	I2C4 DMA read request to inform the DMAs to read the data in the I2C4.I2C_DATA[7:0] DATA bit field
I2C5_DREQ_TX	I2C5	I2C5 DMA write request to inform the DMAs to write new data in the I2C5.I2C_DATA[7:0] DATA bit field
I2C5_DREQ_RX	I2C5	I2C5 DMA read request to inform the DMAs to read the data in the I2C5.I2C_DATA[7:0] DATA bit field

Note

For more information about I2C*i*_DREQ_TX and I2C*i*_DREQ_RX (where *i* = 1 to 5)signals mapping to DMA_CROSSBAR, see Section 16.1.3.2 Section 16.1.3.2, *Mapping of DMA Requests to DMA_CROSSBAR Inputs*, in Table 24-4, *HS I2C Hardware Requests*.

24.1.4.7 HS I2C Programmable Multislave Channel Feature

This feature allows each multimaster HS I2C controller to be addressed using four separate Own Addresses configured in the I2C*i*.I2C_OA and I2C*i*.I2C_OAx registers (where = 1 to 5, x = 1, 2, 3). An additional register (I2C*i*.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I2C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2C*i*.I2C_CON[7] XOA0, I2C*i*.I2C_CON[6] XOA1, I2C*i*.I2C_CON[5] XOA2, or I2C*i*.I2C_CON[4] XOA3).

24.1.4.8 HS I2C FIFO Management

Each multimaster HS I2C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

The depth of the RX and TX FIFOs can be checked by reading the I2C*i*.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

24.1.4.8.1 HS I2C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2C*i*.I2C_IRQENABLE_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX FIFO or the I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the

LH to transfer data to the destination (from the I²C controller in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

Figure 24-14 and Figure 24-15 show receive and transmit operations, respectively, from a FIFO management point of view.

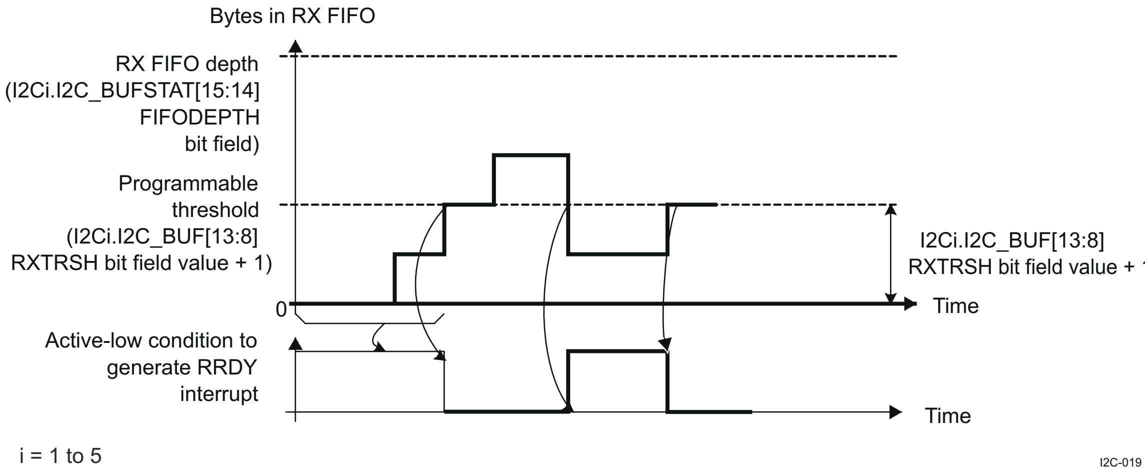

Figure 24-14. HS I²C Receive FIFO Interrupt Request Generation

In Figure 24-14 , the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

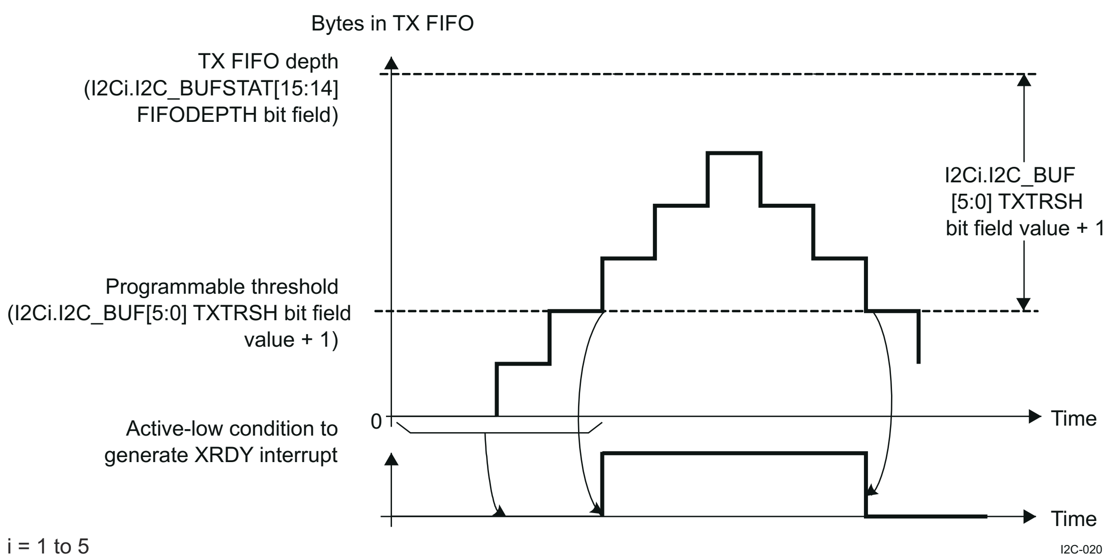

Figure 24-15. HS I²C Transmit FIFO Interrupt Request Generation

In Figure 24-15 , the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2C*i*.I2C_IRQENABLE_CLR [4] XRDY_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF[5:0] TXTRSH + 1 or I2C_BUF[5:0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 24.1.4.8.4, *Draining Feature [I²C Mode Only]*).

Note

In slave transmit mode (the I2C*i*.I2C_CON[10] MST bit is cleared and the I2C*i*.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2C*i*.I2C_BUF[6] TXFIFO_CLR bit.

24.1.4.8.2 HS I²C FIFO Polling Mode

In FIFO polling mode (the I2C*i*.I2C_IRQENABLE_SET [4] XRDY_IE and I2C*i*.I2C_IRQENABLE_SET [3] RRDY_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY and the I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bits (the I2C*i*.I2C_IRQSTATUS_RAW [13] RDR and I2C*i*.I2C_IRQSTATUS_RAW [14] XDR bits can also be polled if the draining feature is enabled). The I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY and I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

24.1.4.8.3 HS I²C FIFO DMA Mode

In receive mode, a DMA request is generated by the I2C*i*_DREQ_RX signal as soon as the RX FIFO exceeds its threshold level (the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the DMA controller.

Figure 24-16 shows the DMA request generation in receive mode.

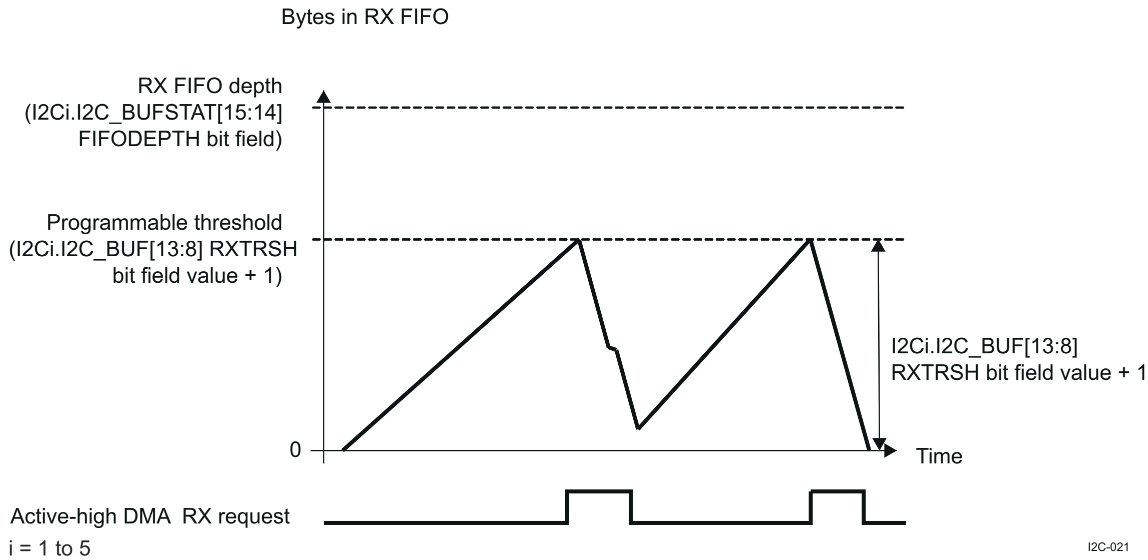

Figure 24-16. HS I²C Receive FIFO DMA Request Generation

In transmit mode, a DMA request is automatically asserted by the I2C*i*_DREQ_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1) is written in the FIFO by the DMA controller. If an insufficient number of bytes is written, the DMA request remains active. Figure 24-17 and Figure 24-18 show the DMA TX transfers with different values for the I2C*i*.I2C_BUF[5:0] TXTRSH bit field.

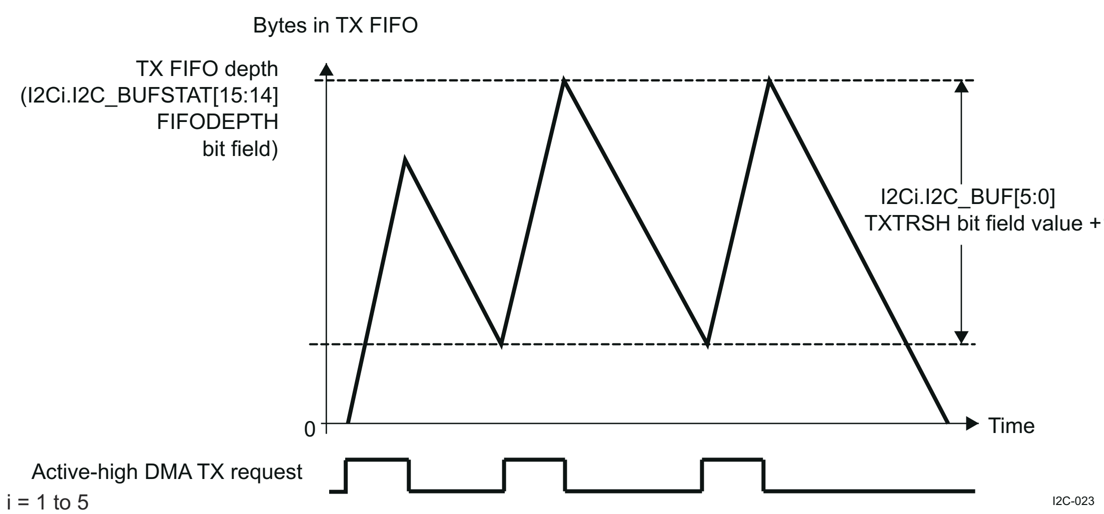

Figure 24-17. HS I²C Transmit FIFO Request Generation (High Threshold)

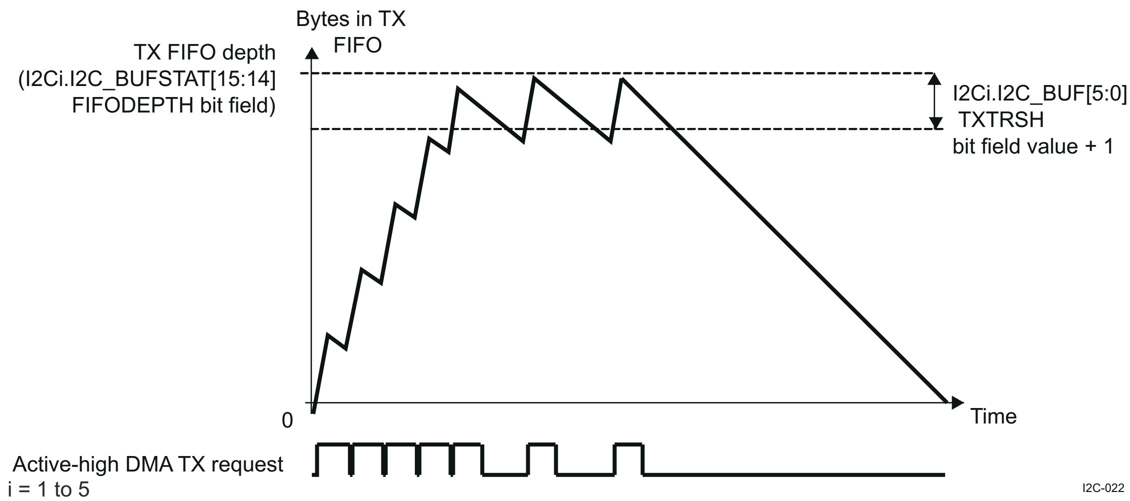

Figure 24-18. HS I²C Transmit FIFO Request Generation (Low Threshold)

The I2C module provides the possibility to the user to clear the RX or TX FIFO, by setting the I2Ci.I2C_BUF[14]RXFIFO_CLR and I2Ci.I2C_BUF[6]TXFIFO_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the following conditions are met:

1. The module is configured as a transmitter
2. The external receiver responds with a NACK in the middle of the transfer
3. There is still data in TX FIFO waiting to be transferred

24.1.4.8.4 HS I²C Draining Feature

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold and the I2C*i*.I2C_BUF[5:0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2C*i*.I2C_IRQSTATUS_RAW [7] AERR bit.

The draining mechanism generates an interrupt using the I2C*i*.I2C_IRQSTATUS_RAW [13] RDR or I2C*i*.I2C_IRQSTATUS_RAW [14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2C*i*.I2C_BUFSTAT[13:8] RXSTAT or I2C*i*.I2C_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I²C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2C*i*.I2C_IRQSTATUS_RAW [13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2C*i*.I2C_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2C*i*.I2C_BUFSTAT[13:8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (the I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2C*i*.I2C_IRQSTATUS_RAW [14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2C*i*.I2C_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2C*i*.I2C_BUFSTAT[5:0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately not check the values of the I2C*i*.I2C_BUFSTAT[5:0] TXSTAT and I2C*i*.I2C_BUFSTAT[13:8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2C*i*.I2C_CNT[15:0] DATACOUNT bit field value modulo I2C*i*.I2C_BUF[13:8] RXTRSH or I2C*i*.I2C_BUF[5:0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2C*i*.I2C_IRQENABLE_SET [14] XDR_IE or I2C*i*.I2C_IRQENABLE_SET [13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX threshold or the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold).

24.1.4.9 HS I^{2}C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2C*i*_INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For standard mode (for example, the I2C*i*.I2C_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the 2C*i*.I2C_PSC[7:0] PSC bit field.

24.1.4.10 HS I^{2}C System Test Mode

A system test mode is available for multimaster HS I^{2}C controller module testing. This mode is enabled by setting the I2C*i*.I2C_SYSTEST[15] ST_EN bit to 1. When this bit is cleared to 0, the I^{2}C controller is configured in normal operation mode.

In system test mode, the I2C*i*.I2C_SYSTEST [13:12] TMODE bit field selects the type of test. Table 24-12 lists the tests available for the multimaster HS I^{2}C controllers.

Table 24-12. HS I^{2}C List of Tests

I2C*i*.I2C_SYSTEST[13:12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of i2c*i*_scl serial clock line	The i2c*i*_scl line is driven with a permanent clock as if mastered with the parameters set in the I2C*i*.I2C_PSC, I2C*i*.I2C_SCLL, and I2C*i*.I2C_SCLH registers.
11	Loop-back mode + i2c*i*_scl/ i2c*i*_sda I/O	In master transmit mode only, data transmitted out of the I2C*i*.I2C_DATA register (write action) is received in the same I2C*i*.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2c*i*_scl and i2c*i*_sda are controlled with the I2C*i*.I2C_SYSTEST[3:0] bits.

Note

When the I2C*i*.I2C_SYSTEST[13:12] TMODE bit field is set to 11, the I^{2}C controller must be configured in I^{2}C F/S (I2C*i*.I2C_CON[13:12] OPMODE set to 00) or I^{2}C HS mode (I2C*i*.I2C_CON[13:12] OPMODE set to 01).

Note

In normal operation mode (the I2C*i*.I2C_SYSTEST[15] ST_EN bit cleared to 0), the I2C*i*.I2C_SYSTEST[3:0] bits that control the i2c*i*_scl, i2c*i*_sda lines in system test mode are read-only bits.

In system test mode (the I2C*i*.I2C_SYSTEST[15] ST_EN bit set to 1), the I2C*i*.I2C_IRQSTATUS_RAW.XRDY, I2C_IRQSTATUS_RAW.RRDY, I2C_IRQSTATUS_RAW.XUDF, I2C_IRQSTATUS_RAW.ROVR, I2C_IRQSTATUS_RAW.ARDY and I2C_IRQSTATUS_RAW.NACK status bits can be set to 1 when the I2C*i*.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2C*i*.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2C*i*.I2C_IRQSTATUS_RAW bits to 0. The I2C*i*.I2C_IRQSTATUS_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

24.1.5 HS I²C Programming Guide

24.1.5.1 HS I²C Low-Level Programming Models

24.1.5.1.1 HS I²C Programming Model

This section describes the programming model of the multimaster HS I²C controllers configured in I²C mode.

24.1.5.1.1.1 Main Program

24.1.5.1.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see Table 24-3).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2C*i*.I2C_PSC[7:0] PSC bit field. This value depends on the frequency of the functional clock (I2C*i*_FCLK).
3. Program the I2C*i*.I2C_SCLL[7:0] SCLL and I2C*i*.I2C_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 kbps or 400 kbps. These values depend on the internal sampling clock frequency (see Table 24-6).
4. (Optional) Program the I2C*i*.I2C_SCLL[15:8] HSSCLL and I2C*i*.I2C_SCLH[15:8] HSSCLH bit fields to obtain a bit rate of 400 kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see Table 24-6).
5. Configure the Own Address of the I²C controller by storing it in the I2C*i*.I2C_OA register. Up to four Own Addresses can be programmed in the I2C*i*.I2C_OA and I2C*i*.I2C_OAx registers (where x = 1, 2, 3) for each I²C controller.

Note

For a 10-bit address, set the corresponding expand Own Address bit in the I2C*i*.I2C_CON register.

6. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2C*i*.I2C_BUF[5:0] TXTRSH bit field to (TX threshold – 1) and the I2C*i*.I2C_BUF[13:8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
7. Take the I²C controller out of reset by setting the I2C*i*.I2C_CON[15] I2C_EN bit to 1.

24.1.5.1.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2C*i*.I2C_CON register:
   - For master or slave mode, set the I2C*i*.I2C_CON[10] MST bit (0: slave; 1: master).
   - For transmitter or receiver mode, set the I2C*i*.I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2C*i*.I2C_IRQENABLE_SET register to 1 (the I2C*i*.I2C_IRQENABLE_SET [4] XRDY_IE bit for the transmit interrupt, the I2C*i*.I2C_IRQENABLE_SET [3] RRDY bit for the receive interrupt).
3. If using DMA to receive and transmit data, set the corresponding bit in the I2C*i*.I2C_BUF register to 1 (the I2C*i*.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2C*i*.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

24.1.5.1.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2C*i*.I2C_SA[9:0] SA bit field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2C*i*.I2C_CNT[15:0] DCOUNT bit field.

Note

For a 10-bit address, set the I2C*i*.I2C_CON[8] XSA bit to 1.

24.1.5.1.1.1.4 Initiate a Transfer

Poll the I2C*i*.I2C_IRQSTATUS_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2C*i*.I2C_CON[0] STT and I2C*i*.I2C_CON[1] STP bits. To initiate a transfer, the I2C*i*.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2C*i*.I2C_CON[1] STP bit to 1.

24.1.5.1.1.1.5 Receive Data

Poll the I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bit, or use the RRDY interrupt (the I2C*i*.I2C_IRQENABLE_SET [3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2C*i*.I2C_BUF[15] RDMA_EN bit must be set to 1 together with I2C_DMARXENABLE_SET) to read the receive data in the I2C*i*.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2C*i*.I2C_BUF[13:8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2C*i*.I2C_IRQENABLE_SET [13] RDR_IE bit to 1).

Note

In receive mode only, the I2C*i*.I2C_IRQSTATUS_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I^{2}C controller simply holds i2c*i*_scl to low to prevent other bytes from being received.

The I2C*i*.I2C_IRQSTATUS_RAW[7] AERR bit is set to 1 when a read access is performed in the I2C*i*.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2C*i*.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

24.1.5.1.1.1.6 Transmit Data

Poll the I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY bit, or use the XRDY interrupt (the I2C*i*.I2C_IRQENABLE_SET [4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2C*i*.I2C_BUF[7] XDMA_EN bit must be set to 1 together with I2C_DMATXENABLE_SET) to write data to the I2C*i*.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2C*i*.I2C_BUF[5:0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2C*i*.I2C_IRQENABLE_SET [14] XDR_IE bit to 1).

Note

In transmit mode only, the I2C*i*.I2C_IRQSTATUS_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2C*i*.I2C_CNT[15:0] DCOUNT bit field is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I^{2}C master device still requests data bytes to be read.

The I2C*i*.I2C_IRQSTATUS_RAW [7] AERR bit is set to 1 when a write access is performed in the I2C*i*.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2C*i*.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

24.1.5.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2C*i*.I2C_IRQSTATUS_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2C*i*.I2C_IRQSTATUS_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2C*i*.I2C_IRQSTATUS_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2C*i*.I2C_IRQSTATUS_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2C*i*.I2C_IRQSTATUS_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2C*i*.I2C_IRQSTATUS_RAW [7] AERR bit) and resolve accordingly.

9. Test for bus free (the I2C*i*.I2C_IRQSTATUS_RAW [8] BF bit) and resolve accordingly.

24.1.5.1.1.3 Programming Flow-Diagrams

Figure 24-19 through Figure 24-27 are procedure flow charts for programming the F/S and HS I^{2}C modes.

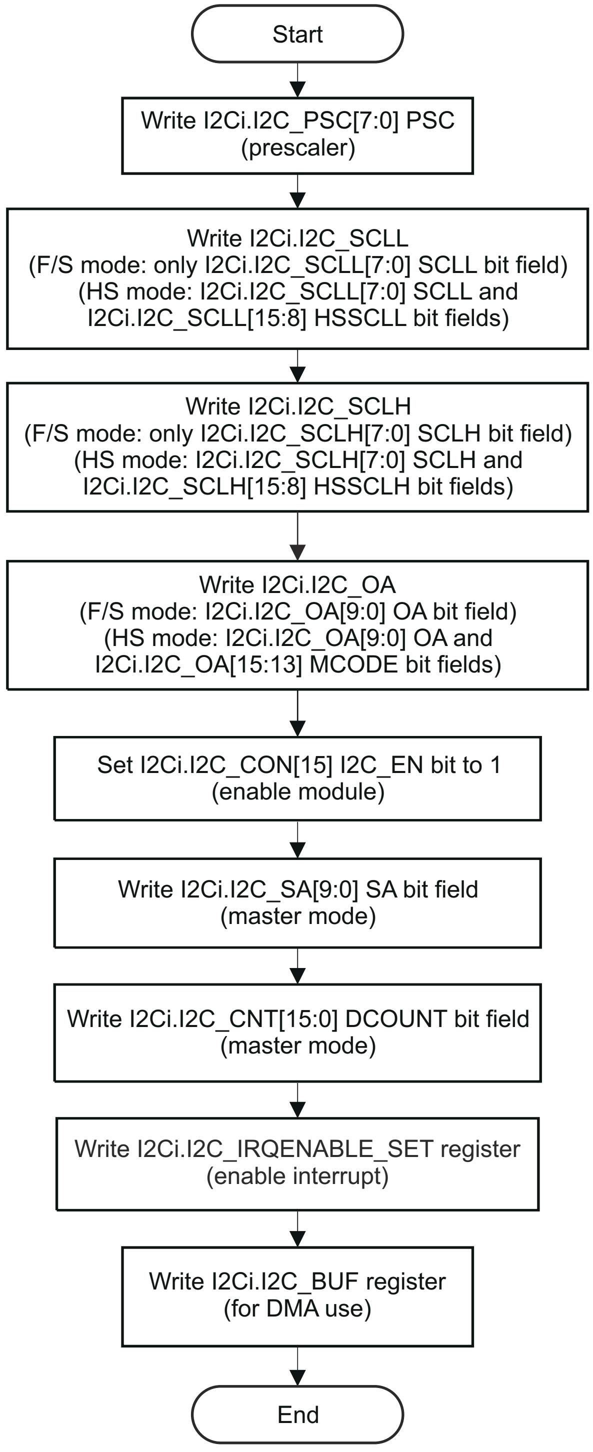

Figure 24-19. HS I^{2}C Setup Procedure

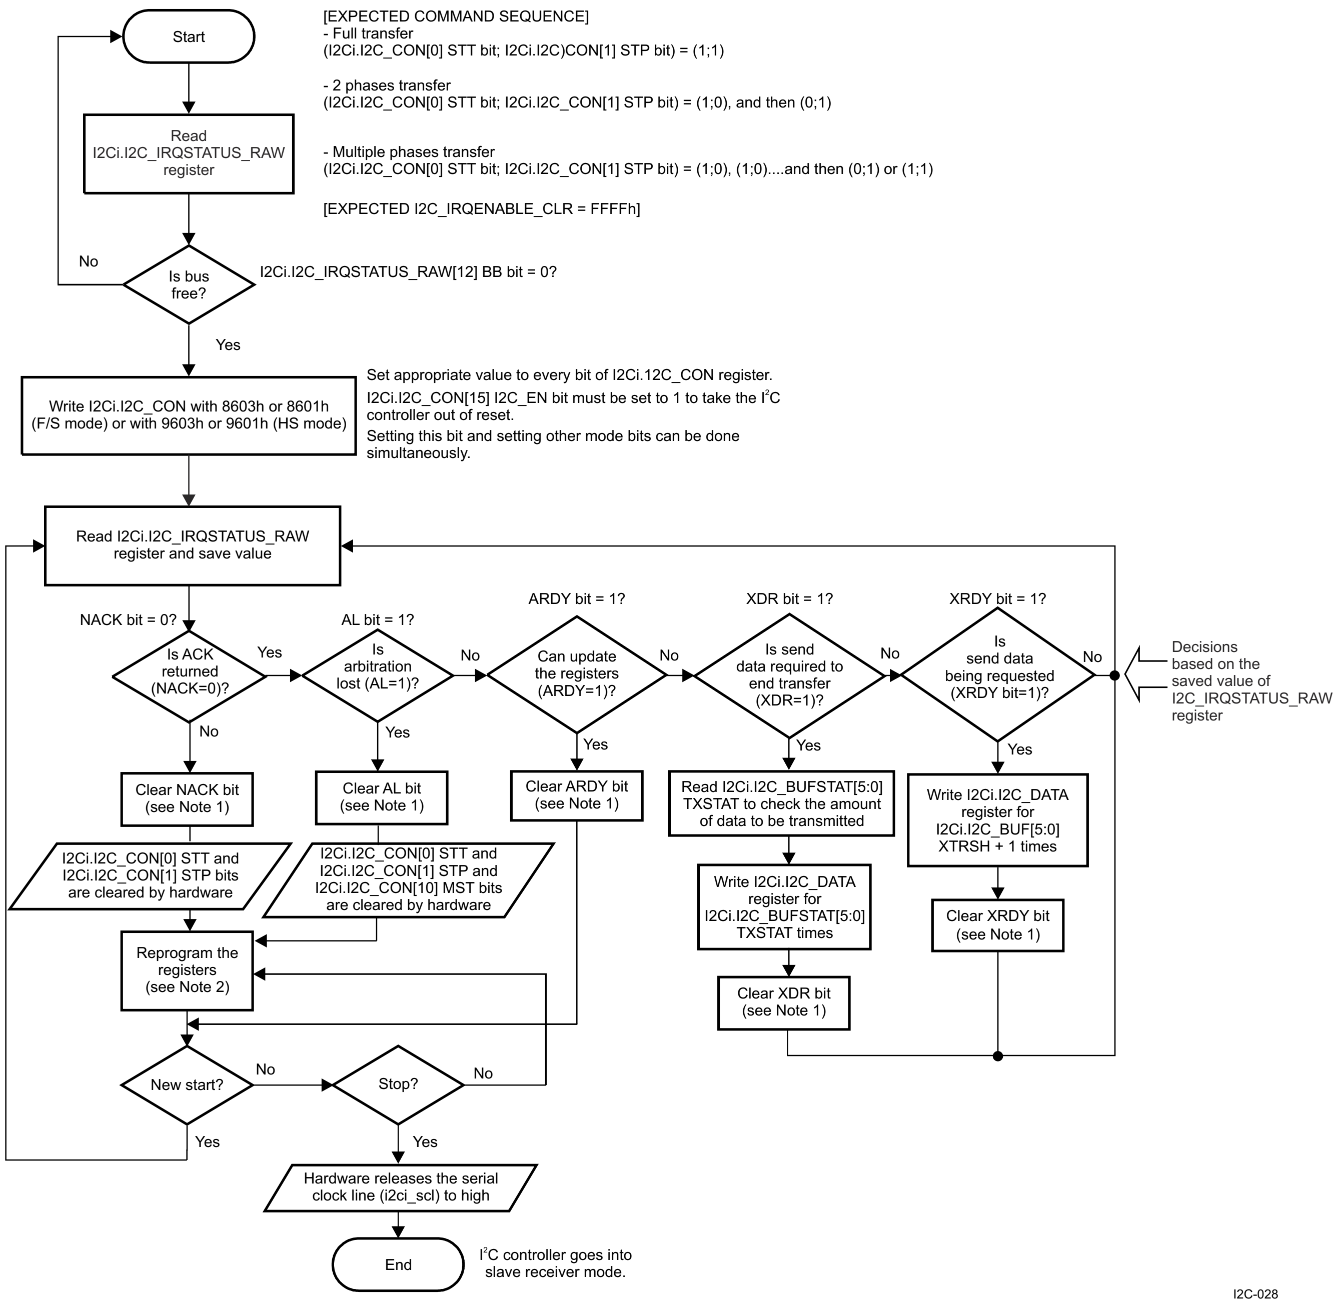
Table 24-13. Subprocess Call Summary for Sequence – I²C Setup Procedure

Subprocess Name	Cross-Reference
Pad configuration	See *PAD Configuration Registers* in *Control Module*

Table 24-14. HS I²C Register Call Summary for Sequence – Setup Procedure

Register Name	Register Name	Register Name
I2C*i*.I2C_PSC (1)	I2C*i*.I2C_CON (1)	I2C*i*.I2C_BUF (1)
I2C*i*.I2C_SCLL (1)	I2C*i*.I2C_SA (1)	I2C*i*.I2C_IRQENABLE_SET (1)
I2C*i*.I2C_SCLH (1)	I2C*i*.I2C_CNT (1)	I2C*i*.I2C_OA (1)

(1) *i* = 1 to 5



A. The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C*i*.I2C_IRQSTATUS register.

B. Reprogram the registers means: I2C*i*.I2C_CON[11] STB and/or I2C*i*.I2C_CON[10] MST bit and/or I2C*i*.I2C_SA[9:0] SA register and/or I2C*i*.I2C_CNT[15:0] DCOUNT register and/or I2C*i*.I2C_CON[0] STT bit and/or I2C*i*.I2C_CON[1] STP bit.

Figure 24-20. HS I^{2}C Master Transmitter Mode, Polling Method, in F/S and HS Modes

Note

The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

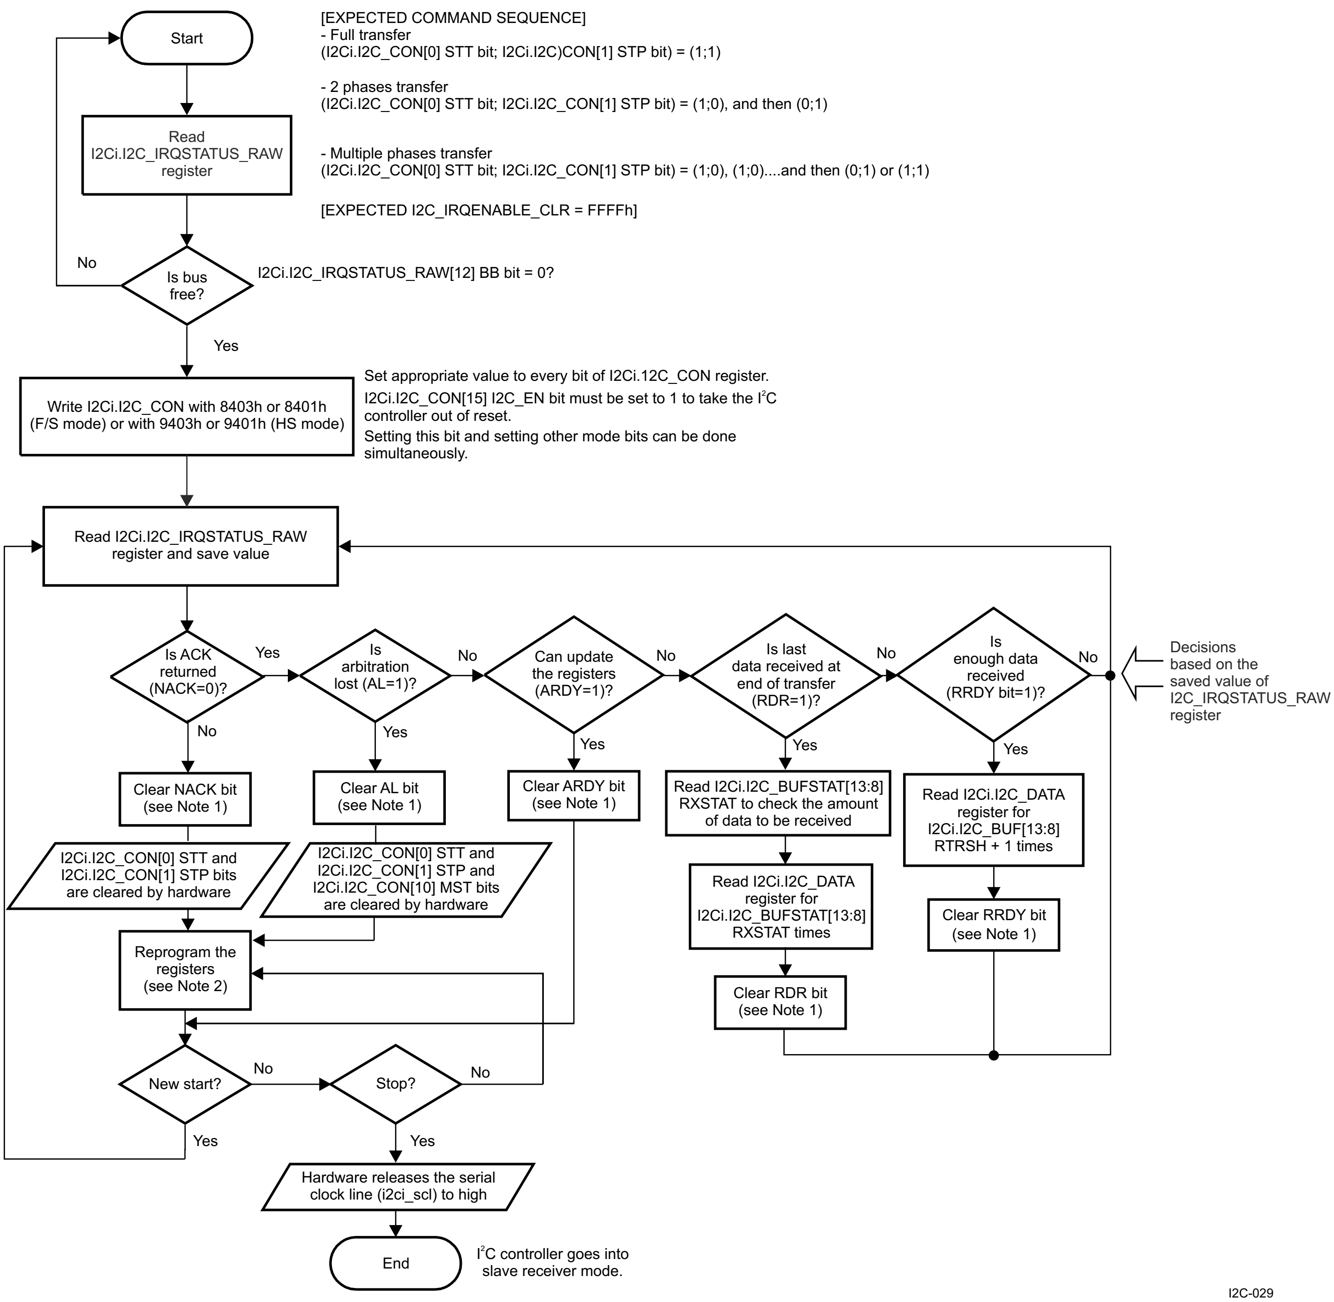
Note

In HS mode, the Sr condition and clock frequency switching are automatically generated by the multimaster HS I^{2}C controller.

Table 24-15. HS I^{2}C Register Call Summary for Sequence – Master Transmitter Mode, Polling Method, in F/S and HS Modes

Register Name	Register Name	Register Name
I2C*i*.I2C_IRQSTATUS_RAW [(1)]	I2C*i*.I2C_DATA [(1)]	I2C*i*.I2C_CON [(1)]
I2C*i*.I2C_BUFSTAT [(1)]	I2C*i*.I2C_CON [(1)]	I2C*i*.I2C_BUF [(1)]

(1) *i* = 1 to 5



A. The NACK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2C*i*.I2C_IRQSTATUS register.

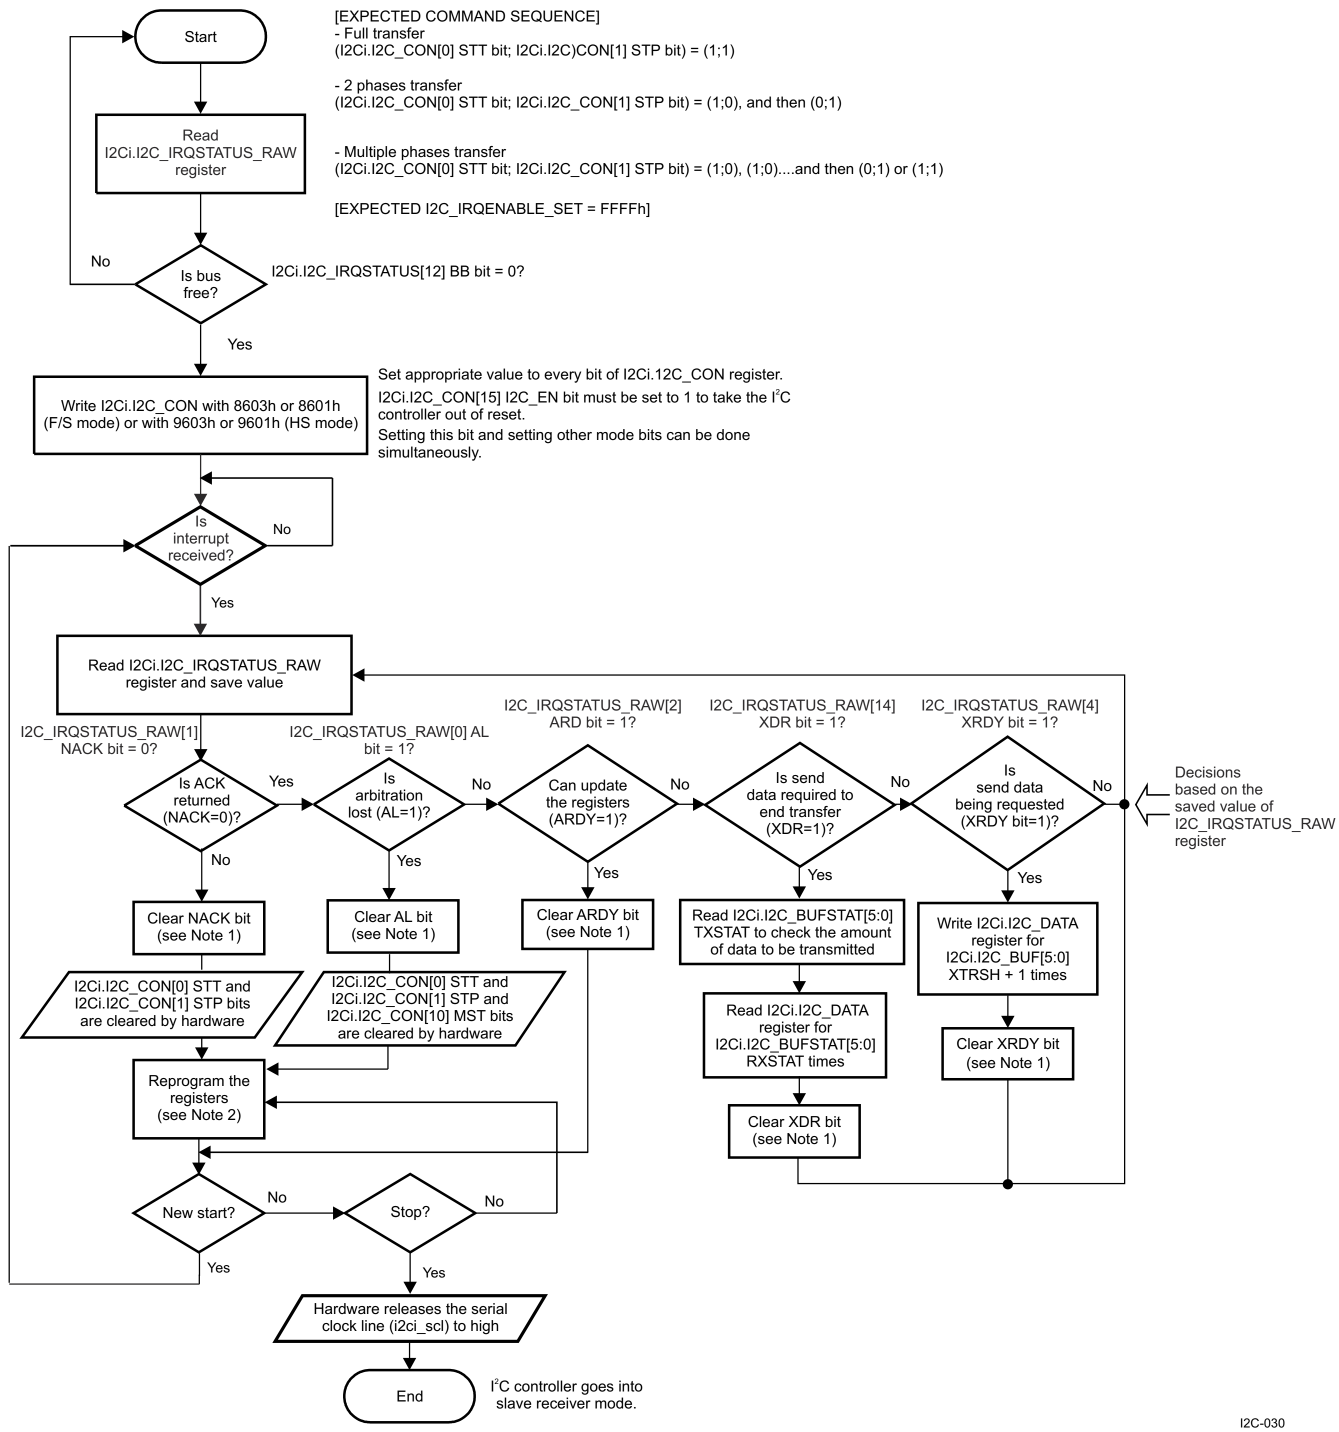
B. Reprogram registers means: I2C*i*.I2C_CON[11] STB and/or I2C*i*.I2C_CON[10] MST bit and/or I2C*i*.I2C_SA[9:0] SA register and/or I2C*i*.I2C_CNT[15:0] DCOUNT register and/or I2C*i*.I2C_CON[0] STT bit and/or I2C*i*.I2C_CON[1] STP bit.

Figure 24-21. HS I^{2}C Master Receiver Mode, Polling Method, in F/S and HS Modes

Table 24-16. HS I^{2}C Register Call Summary for Sequence – Master Receiver Mode, Polling Method, in F/S and HS Modes

Register Name	Register Name	Register Name
I2C*i*.I2C_IRQSTATUS_RAW (1)	I2C*i*.I2C_BUFSTAT (1)	I2C*i*.I2C_BUF (1)
I2C*i*i.I2C_CON (1)	I2C*i*.I2C_DATA (1)	

(1) *i* = 1 to 5



A. The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C*i*.I2C_IRQSTATUS register.

B. Reprogram registers means: I2C*i*.I2C_CON[11] STB and/or I2C*i*.I2C_CON[10] MST bit and/or I2C*i*.I2C_SA[9:0] SA register and/or I2C*i*.I2C_CNT[15:0] DCOUNT register and/or I2C*i*.I2C_CON[0] STT bit and/or I2C*i*.I2C_CON[1] STP bit.

Figure 24-22. HS I²C Master Transmitter Mode, Interrupt Method, in F/S and HS Modes

Note

The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

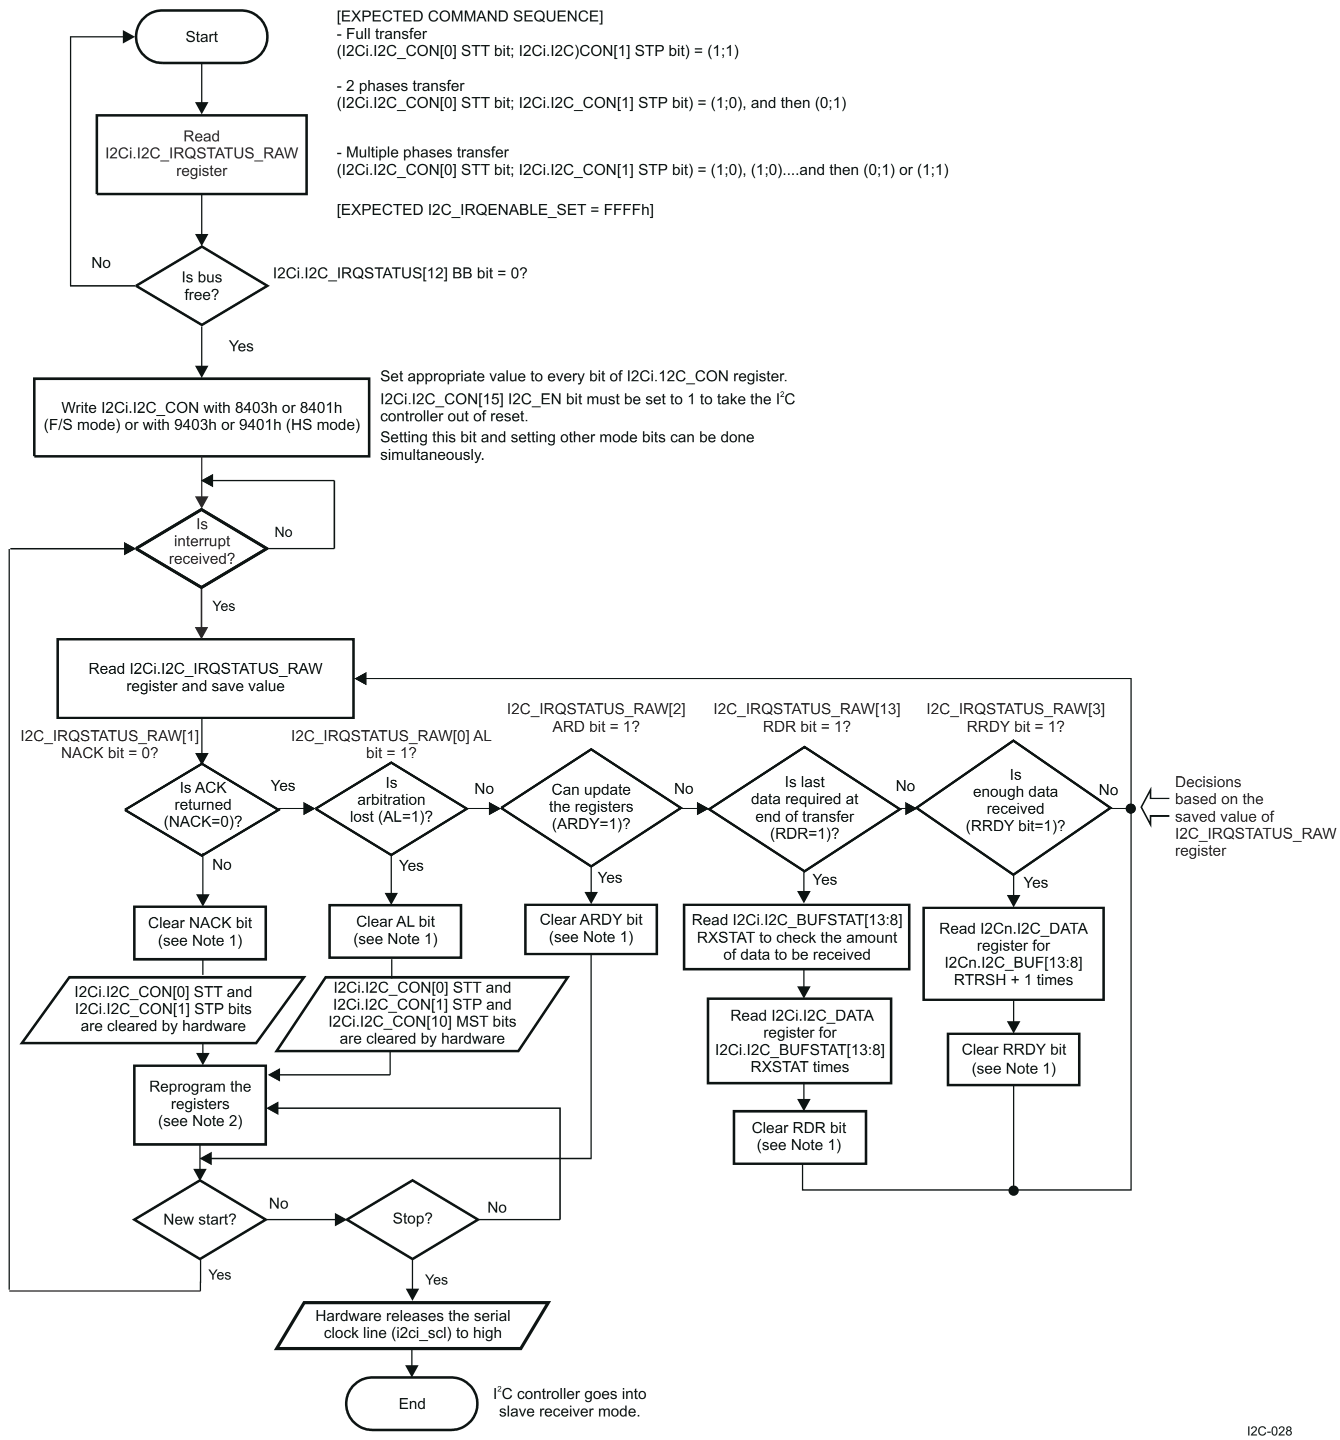
Note

In HS mode, the Sr condition and clock frequency switching are automatically generated by the multimaster HS I^{2}C controller.

Table 24-17. HS I^{2}C Register Call Summary for Sequence – Master Transmitter Mode, Interrupt Method, in F/S and HS Modes

Register Name	Register Name	Register Name
I2C*i*.I2C_IRQSTATUS_RAW (1)	I2C*i*.I2C_BUFSTAT (1)	I2C*i*.I2C_BUF (1)
I2C*i*.I2C_CON (1)	I2C*i*.I2C_DATA (1)	

(1) *i* = 1 to 5



A. The NACK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2C*i*I2C_IRQSTATUS register.

B. Reprogram registers means: I2C*i*.I2C_CON[11] STB and/or I2C*i*.I2C_CON[10] MST bit and/or I2C*i*.I2C_SA[9:0] SA register and/or I2C*i*.I2C_CNT[15:0] DCOUNT register and/or I2C*i*.I2C_CON[0] STT bit and/or I2C*i*.I2C_CON[1] STP bit.

Description	Per-event raw interrupt status vector. The raw status is set even if event is not enabled. Write 1 to set the (raw) status. Used mostly for debug		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	XDR	RDR	BB	ROVR	XUDF	AAS	BF	AERR	STC	GC	XRDY	RRDY	ARDY	NACK	AL

Bits	Field Name	Description	Type	Reset
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
14	XDR	Transmit draining IRQ status. 0x0: Transmit draining inactive. 0x1: Transmit draining enabled.	RW	0
13	RDR	Receive draining IRQ status. 0x0: Receive draining inactive. 0x1: Receive draining enabled.	RW	0
12	BB	Bus busy status. Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free.	R	0
11	ROVR	Receive overrun status. Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation.	RW	0
10	XUDF	Transmit underflow status. Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation.	RW	0
9	AAS	Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized.	RW	0
8	BF	Bus Free IRQ status. 0x0: No action. 0x1: Bus Free.	RW	0
7	AERR	Access Error IRQ status. 0x0: No action. 0x1: Access Error.	RW	0
6	STC	Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected.	RW	0

Bits	Field Name	Description	Type	Reset
5	GC	General call IRQ status. Set to 1 by core when General call address detected and interrupt signaled to IRQ_Crossbar. 0x0: No general call detected. 0x1: General call address detected.	RW	0
4	XRDY	Transmit data ready IRQ status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar. 0x0: Transmision ongoing. 0x1: Transmit data ready.	RW	0
3	RRDY	Receive data ready IRQ status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar. 0x0: No data available. 0x1: Receive data available.	RW	0
2	ARDY	Register access ready IRQ status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to IRQ_Crossbar. 0x0: Module busy. 0x1: Access ready.	RW	0
1	NACK	No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to IRQ_Crossbar. 0x0: Normal operation. 0x1: Not Acknowledge detected.	RW	0
0	AL	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to IRQ_Crossbar. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected.	RW	0

Table 24-31. I2C_IRQSTATUS

24.2 HDQ/1-Wire

This section describes the HDQ™/ 1-Wire® interface for the device.

24.2.1 HDQ1W Overview

The HDQ1W module implements the hardware protocol of the master functions of the TI/Benchmarq HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ1W controller) and the slaves (HDQ/1-Wire external compliant devices).

Figure 24-28 shows the HDQ1W.

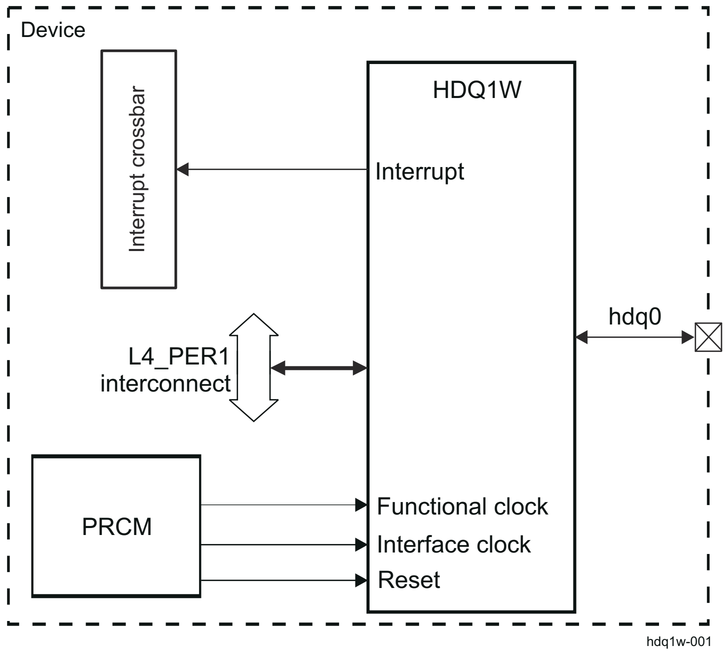

Figure 24-28. HDQ1W Overview

The HDQ1W has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The 1-pin interface is implemented as an open-drain output at the device level.

The main features supported by the HDQ1W are the following:

- Benchmarq HDQ protocol
- Dallas Semiconductor 1-Wire protocol
- Power-down mode

The HDQ1W provides a communication rate of 5 Kbps over an address space of 128 bytes.

A typical application of the HDQ1W is the communication with battery monitor (gas gauge) integrated circuits.

24.2.2 HDQ1W Environment

24.2.2.1 HDQ1W Functional Modes

The HDQ1W has two main modes: HDQ and 1-Wire. Each of these modes includes idle, active, and power-down submodes. Table 24-58 lists the HDQ1W functional modes, and Figure 24-29 shows an overview of a typical application.

Table 24-58. Functional Modes

Functions	Description
HDQ	Benchmarq HDQ protocol
1-Wire	Dallas Semiconductor 1-Wire protocol

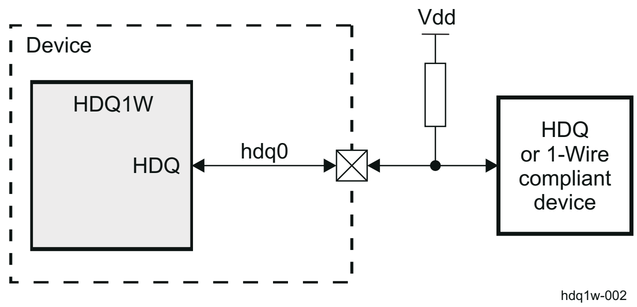

Figure 24-29. HDQ1W Typical Application System Overview

An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command by any of the connected devices, the line is pulled to a logical high level).

The HDQ1W operates according to a command structure that is programmed into transmit command registers (as described in Section 24.2.5.1.2, *HDQ1W Low-level Programming Model*).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

Table 24-59 describes the external signal of the HDQ/1-Wire compliant module.

Table 24-59. I/O Description

Signal	I/O(1)	Description	Value at Reset
hdq_sio	I/O	Serial data input/output. Output is open drain type.	HiZ (pulled to 1 by pullup)

(1) I = Input; O = Output

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers* in *Control Module*.

24.2.2.2 HDQ and 1-Wire (SDQ) Protocols

24.2.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the HDQ_CTRL_STATUS[2] INITIALIZATION bit and then setting the HDQ_CTRL_STATUS[4] GO bit. The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. Sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ_TX_DATA register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5 Kbps. The least-significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time $t_{(B)}$ or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time $t_{(BR)}$. The slave is then ready for a command from the host processor. Figure 24-30 shows this behavior.

An interrupt condition indicates a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

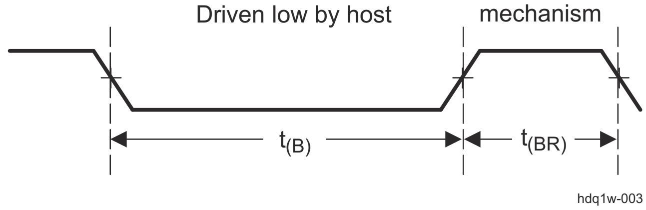

Figure 24-30. HDQ Break-Pulse Timing Diagram

24.2.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-level pulse on the line initiated by the slave. The timing diagram in Figure 24-31 shows the 1-Wire (SDQ) reset sequence.

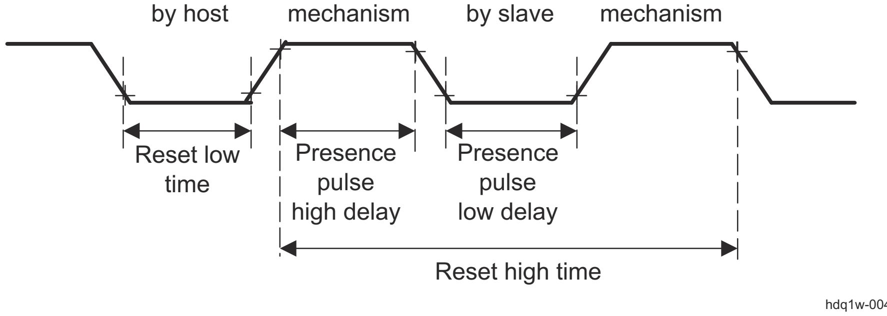

Figure 24-31. 1-Wire (SDQ) Reset Timing Diagram

The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

On the other hand, if the slave sends back its presence pulse within the specified time interval, the communication can be enabled after the reset high time.

24.2.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

The description in this section applies to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in Figure 24-32.

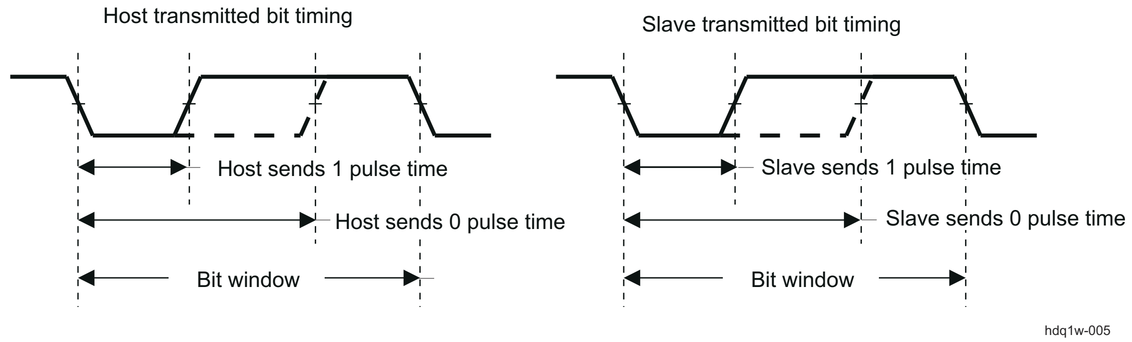

Figure 24-32. HDQ1W Transmitted Bit Timing

The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. Table 24-60 lists the command byte values.

Table 24-60. HDQ/1-Wire Command Byte

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

R/W Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.

AD6-AD0 Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed. The communication sequence example in Figure 24-33 shows a read command at address 0x55; the received data is 0x65.

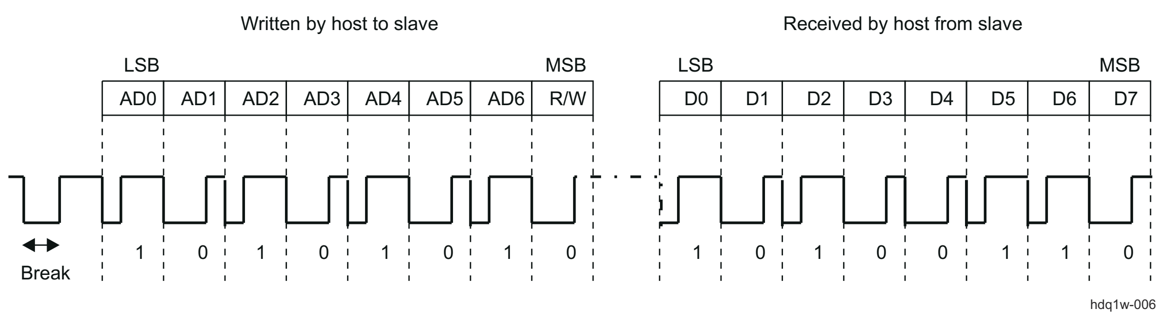

Figure 24-33. HDQ/1-Wire Communication Sequence

24.2.3 HDQ1W Integration

Figure 24-34 shows HDQ1W integration in the device.

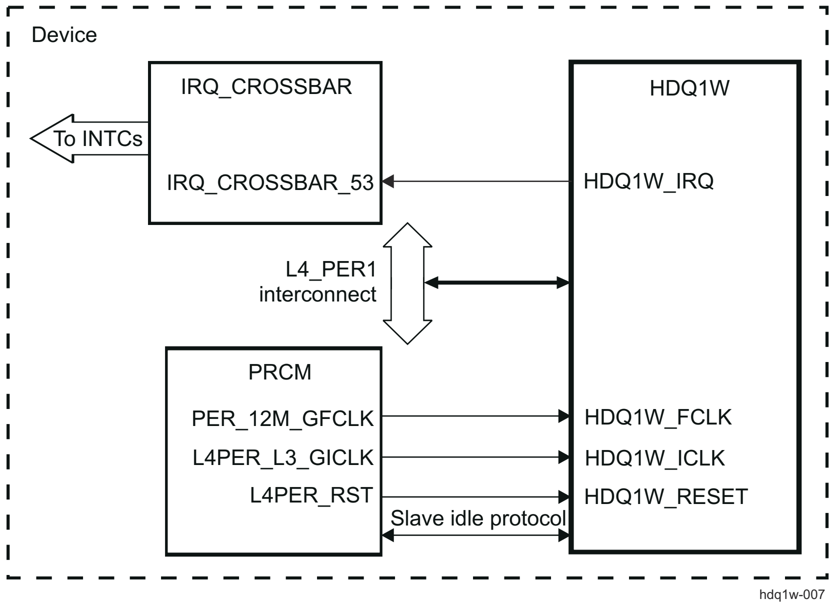

Figure 24-34. HDQ1W Integration

Table 24-61 through Table 24-63 summarize the integration of the module in the device.

Table 24-61. HDQ1W Integration Attributes

Module Instance	Attributes

			DSP1_IRQ_84	
			DSP2_IRQ_84	

Note

The **“Default Mapping”** column in Table 24-63, *HDQ1W Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

24.2.4 HDQ1W Functional Description

The HDQ1W works with HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

24.2.4.1 HDQ1W Block Diagram

Figure 24-35 is the HDQ1W block diagram.

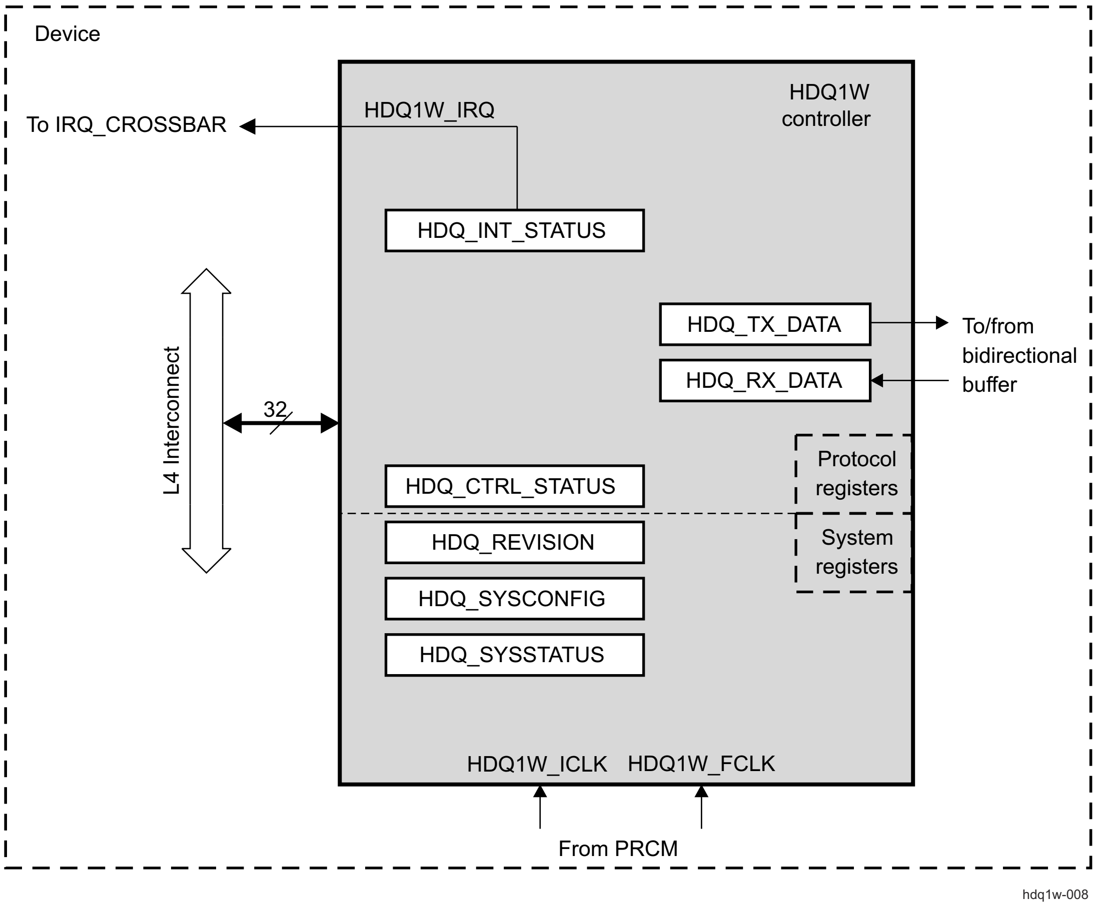

Figure 24-35. HDQ1W Block Diagram

The HDQ_CTRL_STATUS[0] MODE bit allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 24-36 shows the protocol-dedicated register scheme.

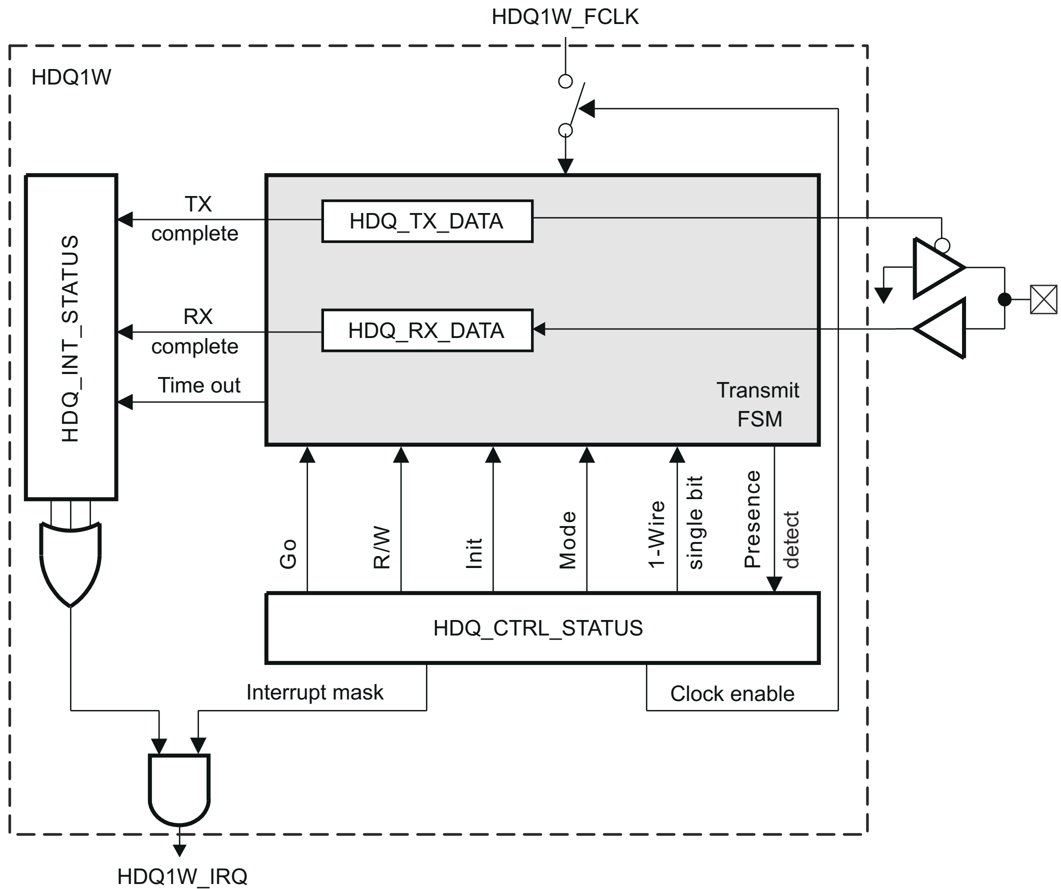

Figure 24-36. Protocol Registers Description

The receive and transmit operations of the HDQ1W module are performed with respect to the timing of the slower HDQ protocol. When the 1-Wire protocol is used, it runs at lower speed than its full capabilities, but is still able to meet the timing requirements and practical considerations.

24.2.4.2 HDQ1W Clocking Configuration

24.2.4.2.1 HDQ1W Clocks

The HDQ1W module operates from two clocks: a functional clock (HDQ1W_FCLK) and an interface clock (HDQ1W_ICLK). When these clocks are set in the PRCM module, the following rule must be observed: HDQ1W_ICLK ≥ HDQ1W_FCLK.

- The HDQ1W_FCLK functional clock is a fixed clock provided by the PRCM module. It is used to clock the internal module logic.

  For more information about the clock and the PRCM register settings, see *CD_L4PER1 Clock Domain*, in chapter *Power, Reset, and Clock Management*.

  When the HDQ1W no longer requires the HDQ1W_FCLK, the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.
- The HDQ1W_ICLK interface clock runs at L4 interconnect clock speed and is used to trigger access to the HDQ1W L4 interface.

  When the HDQ1W no longer requires the HDQ1W_ICLK (no transfer is in progress), the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.

24.2.4.3 HDQ1W Hardware and Software Reset

Global reset of the module is done at the power, reset, and clock management (PRCM) module level (for more information, see *CD_L4PER1 Clock Domain*) or by setting the HDQ_SYSCONFIG[1] SOFTRESET bit to 1. Setting this bit enables an active software reset functionality equivalent to a hardware reset. The HDQ1W_FCLK functional clock must be enabled from the PRCM level and locally through the HDQ_CTRL_STATUS[5] CLOCKENABLE bit (set to 1) for the software reset to complete.

24.2.4.4 HDQ1W Power Management

Table 24-64 describes power-management features available to the HDQ1W.

Table 24-64. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	HDQ_SYSCONFIG [0] AUTOIDLE bit	Auto-idle mode
Slave idle modes	N/A	N/A
Clock enable	HDQ_CTRL_STATUS[5] CLOCKENABLE bit	Power-down mode
Master standby modes	N/A	N/A
Global wake-up enable	N/A	N/A
Wake-up sources enable	N/A	N/A

24.2.4.4.1 Auto-Idle Mode

The HDQ1W provides an auto-idle function in its interconnect clock domain.

The interconnect clock auto-idle power-saving mode is enabled or disabled through the HDQ_SYSCONFIG[0] AUTOIDLE bit. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ1W_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

The auto-idle mode can be enabled in order to reduce power consumption.

24.2.4.4.2 Power-Down Mode

The HDQ1W also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (HDQ_CTRL_STATUS[5] CLOCKENABLE bit) to 0 shuts off the functional clock (HDQ1W_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

Before shutting off the functional clock, the software must wait for transaction-complete interrupt. In write operation the software must check whether the interrupt was generated after address/command byte was sent or after data byte was sent. The functional clock must not be shut off after address/command byte is sent; otherwise, the data is not written to the slave.

The register values are not affected by disabling the functional clock.

24.2.4.4.3

CAUTION

There is no hardware mechanism to prevent cutting off the HDQ1W clocks while the module is performing a transfer. This would result in loss of data being transferred.

24.2.4.5 HDQ Interrupt Requests

The HDQ1W can generate one interrupt:

- HDQ1W_IRQ: Table 24-65 lists the events that can generate this interrupt.

Table 24-65. Events

Event Flag	Event Mask	Sync	Sensitivity	Description
HDQ_INT_STATUS[2] TXCOMPLETE	HDQ_CTRL_STATUS[31] INTERRUPTMASK	Yes	Level	A write operation of one byte was completed.
HDQ_INT_STATUS[1] RXCOMPLETE	HDQ_CTRL_STATUS[31] INTERRUPTMASK	Yes	Level	A byte has been successfully read.
HDQ_INT_STATUS[0] TIMEOUT	HDQ_CTRL_STATUS[31] INTERRUPTMASK	Yes	Level	After a read command initiated by the host, the slave did not pull the line low within the specified time.

24.2.4.6 HDQ Mode (Default)

24.2.4.6.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmarq HDQ protocol
- Power-down mode

24.2.4.6.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the HDQ_CTRL_STATUS[2] INITIALIZATION bit and then setting the HDQ_CTRL_STATUS[4] GO bit creates this pulse by pulling the line down for a defined duration. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the HDQ_INT_STATUS[0] TIMEOUT bit is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register (HDQ_INT_STATUS).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register (HDQ_INT_STATUS). This register is cleared as soon as it is read.

Only one interrupt signal is sent, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

24.2.4.6.3 Single-Bit Mode

In HDQ mode, the single-bit mode (HDQ_CTRL_STATUS[7] ONE_WIRE_SINGLE_BIT bit set to 1) has no effect because the HDQ protocol supports only byte transfers.

24.2.4.6.4 Interrupt Conditions

The HDQ1W provides the following interrupt status:

- Transmission complete:

A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).

- Read complete:

  In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).

- Presence detect/time-out:

  In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).

  In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the host CPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

24.2.4.7 1-Wire Mode

24.2.4.7.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

24.2.4.7.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent when the HDQ_CTRL_STATUS[2] INITIALIZATION bit is set and the HDQ_CTRL_STATUS[4] GO bit is set afterwards.

When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line for a defined duration. The module detects this low-level pulse and sets the HDQ_CTRL_STATUS[3] PRESENCEDETECT bit.

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the HDQ_INT_STATUS[0] TIMEOUT bit is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ_INT_STATUS) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0, or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most-significant bit (MSB) in the receive data register (HDQ_RX_DATA).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the host CPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

24.2.4.7.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (ONE_WIRE_SINGLE_BIT bit HDQ_CTRL_STATUS[7]). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). The ONE_WIRE_SINGLE_BIT bit is cleared by hardware after every single bit is received. Software must set this bit to re-enable reception in single-bit mode. Bit 0 of the RX register (HDQ_RX_DATA) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ_TX_DATA) contains the bit to be sent.

24.2.4.7.4 Interrupt Conditions

The HDQ1W provides the following interrupt status:

- Transmission complete:

  A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).
- Read complete:

  In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).
- Presence detect/time-out:

  In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).

Only one interrupt is generated to the host CPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

24.2.4.7.5 Status Flags

The presence-condition-detected status flag is contained in the HDQ_CTRL_STATUS[3] PRESENCEDETECT bit. This is valid only in 1-Wire mode. The flag is updated when the HDQ_INT_STATUS[0] TIMEOUT bit is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

24.2.4.8 BITFSM Delay

The return-to-one mechanism on the HDQ/1-Wire bus is a simple pull-up resistor. Consequently, an excessive wire load of the HDQ/1-Wire bus can cause a significant delay to the bus rise time. This can prevent the module state machine from working correctly by reading back an improper value caused by the line delay. To correct such condition by software, it is possible to configure the HDQ_CTRL_STATUS[10:8] BITFSM register bitfield with the expected line delay. This way the module state machine waits the proper time interval, before reading back the line value. The delay can be adjusted in 1.33 µs steps. The default value of BITFSM = 0x0 corresponds to 1.33 µs delay.

Bus delay can be calculated as follows: $T_{delay} \approx 2.2 \times R_{pullup} \times C_{line}$

See more information in the *Device Data Manual*.

24.2.5 HDQ1W Low-Level Programming Model

This section describes the low-level hardware programming sequences for configuration and usage of the module. The basic protocol functions, such as slave initialization (reset), read-byte, and write-byte operations, are described. For a description of the high-level functions, see the HDQ/1-Wire protocol documentation and the slave device datasheet.

24.2.5.1 Global Initialization

24.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HDQ1W module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the HDQ1W. Refer to the HDQ1W Module Integration and Environment Sections for further information.

Table 24-66. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. The interface clock must not be slower than the functional clock (HDQ1W_ICLK ≥ HDQ1W_FCLK). For more information about the module configuration, see *Power, Reset, and Clock Management*.
Control Module	Module specific pad muxing and pullup must be set in the control module. If an external pullup is used, the internal pullup/pulldown must be disabled. For more information about the module configuration, see *Control Module*.
IRQ_CROSSBAR/INTC	Interrupt crossbar and interrupt controller configuration must be done to enable the interrupts from HDQ1W module. See *Interrupt Controllers*, and *IRQ_CROSSBAR Module Functional Description*.

Table 24-76. HDQ1W Instance Summary

Module Name	Base Address	Size
HDQ1W	0x480B 2000	4 KiB

24.2.6.2 HDQ1W Registers

CAUTION

The following rules must be observed when accessing the module registers:

- A read from the HDQ_INT_STATUS register or the HDQ_RX_DATA register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the HDQ_CTRL_STATUS register, no access to the HDQ_TX_DATA or HDQ_CTRL_STATUS register is allowed until the processor has been interrupted by the module.
- Polling of the HDQ_INT_STATUS register by software to determine whether an interrupt was generated is not allowed.

CAUTION

The HDQ1W registers are limited to 32-bit data accesses; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.

24.3 UART/IrDA/CIR

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module in the device.

24.3.1 UART/IrDA/CIR Overview

The UART is a simple L4 slave peripheral that utilizes the DMA_SYSTEM or EDMA for data transfer or IRQ polling via CPU. There are 10 UART modules in the device. Only one UART supports IrDA features. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

Figure 24-37 shows the UART module overview.

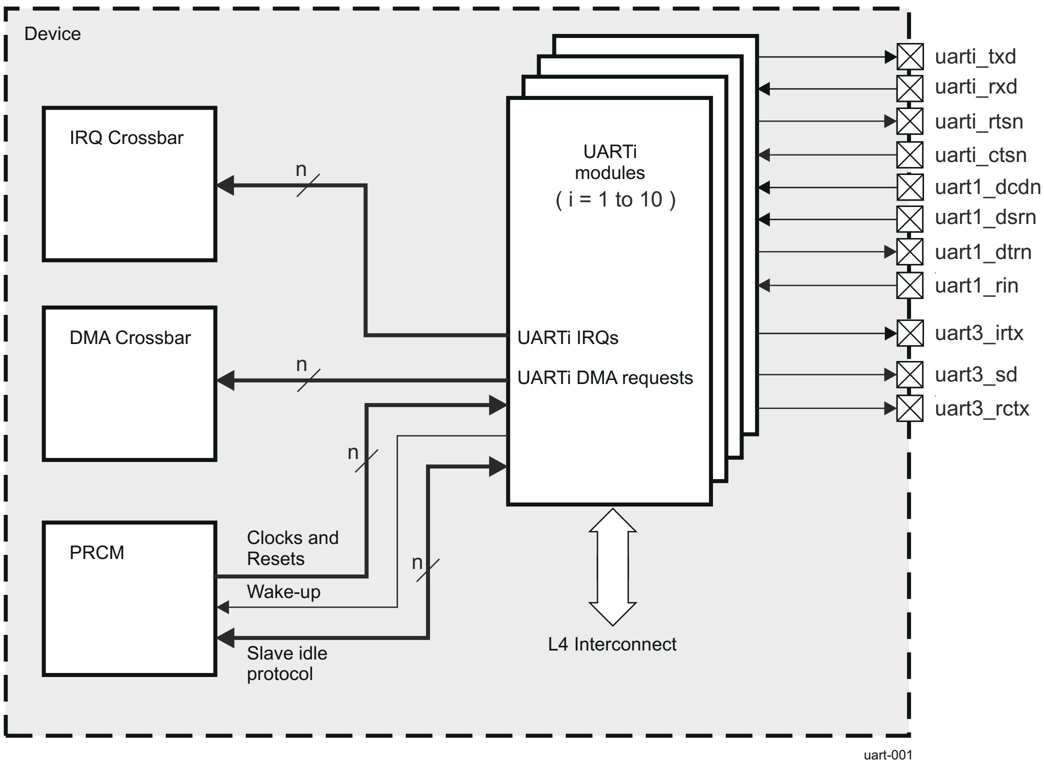

Figure 24-37. UART Overview

24.3.1.1 UART Features

The UARTi (where i = 1 to 10) include the following features:

- 16C750 compatibility
- 64-byte FIFO buffer for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (where N = 1…16,384) operating from a fixed functional clock of 48 MHz or 192 MHz

Oversampling is programmed by software as 16 or 13. Thus, the baud rate computation is one of two options:

- Baud rate = (functional clock / 16) / N
- Baud rate = (functional clock / 13) / N
- This software programming mode enables higher baud rates with the same error amount without changing the clock source
- Break character detection and generation
- Configurable data format:

  – Data bit: 5, 6, 7, or 8 bits
  – Parity bit: Even, odd, none
  – Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- The 48 MHz functional clock option allows baud rates up to 3.6Mbps
- The 192 MHz functional clock option allows baud rates up to 12Mbps
- UART1 module has extended modem control signals (DCD, RI, DTR, DSR)
- UART3 supports IrDA

24.3.1.2 IrDA Features

UART3 supports the following IrDA key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
  – Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  – Uplink/downlink cyclic redundancy check (CRC) generation/detection
  – Asynchronous transparency (automatic insertion of break character)
  – Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  – Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

24.3.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following features to provide CIR support for remote-control applications:

- Transmit mode only (receive mode is not supported)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

24.3.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

- The UART interface is described in Section 24.3.2.1.
- The IrDA interface is described in Section 24.3.2.2, *IrDA Functional Interfaces*.
- The CIR interface is described in Section 24.3.2.3, *CIR Functional Interfaces*.

24.3.2.1 UART Interface

24.3.2.1.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see Figure 24-38).

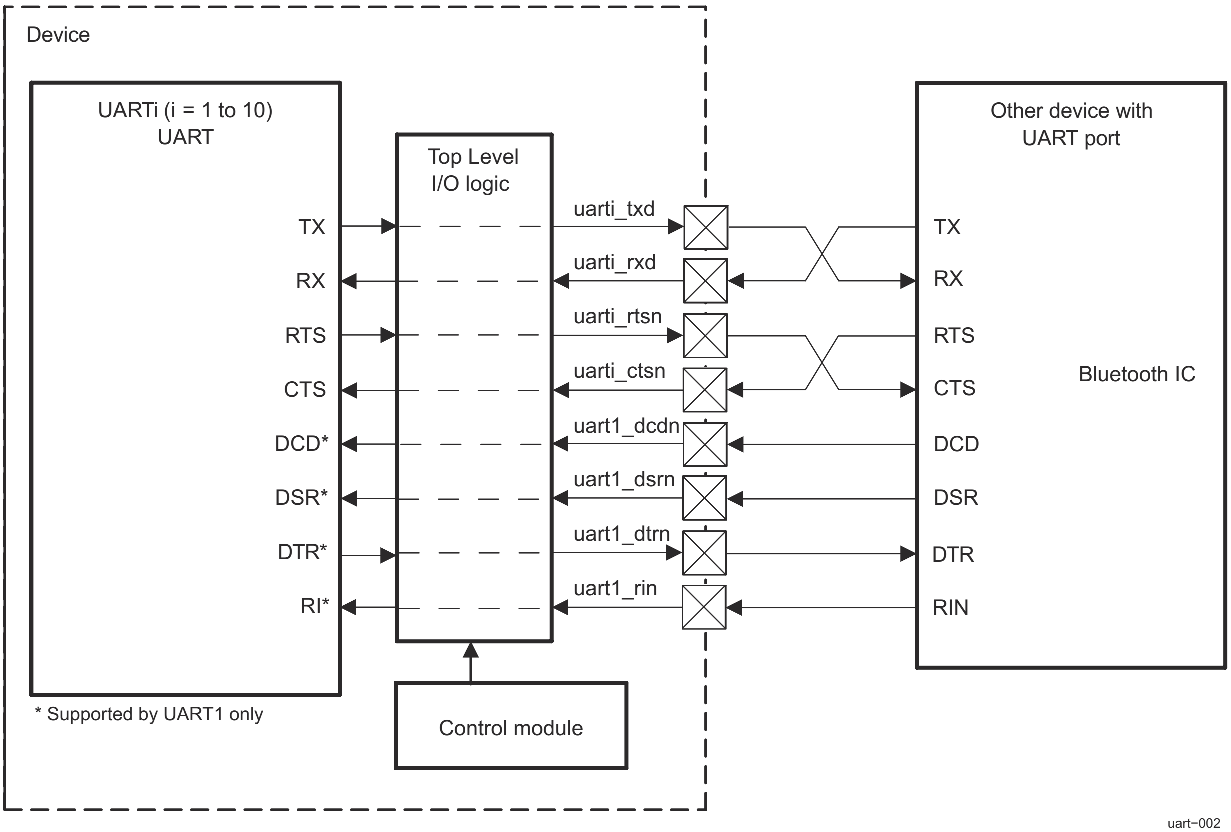

Figure 24-38. UART Mode Bus System Overview

24.3.2.1.2 UART Interface Description

Table 24-85 lists the UART interface input/output (I/O) signals.

Table 24-85. UART Interface Signals

Signal	I/O(1)	Description	Module Level Reset Value
UARTi Interface Signals(2)			
uarti_rxd	I	Serial data input.	HiZ
uarti_txd	O	Serial data output Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UARTi.UART_MDR1[2:0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UARTi.UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).	1
uarti_ctsn	I	Clear to send	HiZ

Table 24-85. UART Interface Signals (continued)

Signal	I/O[(1)]	Description	Module Level Reset Value
		Active-low modem status signal. Reading the UARTi.UART_MSR[4] NCTS_STS bit checks the condition of uarti_ctsn. Reading the UARTi.UART_MSR[0] CTS_STS bit checks a change of state of uarti_ctsn since the last read of the modem status register. The auto-CTS mode uses uarti_ctsn to control the transmitter.	
uarti_rtsn	O	Request to send When active (low), the module is ready to receive data. Setting the UARTi.UART_MCR[1] RTS bit activates uarti_rtsn, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.UART_MCR[1] RTS bit. In auto-RTS mode, uarti_rtsn becomes inactive as a result of the receiver threshold logic.	1
UART1 Modem Signals			
uart1_dcdn	I	Data Carrier Detect Active-low modem status signal. The condition of uart1_dcdn can be checked by reading UART_MSR[7] NCD_STS register bit. Any change in its state can be detected by reading UART_MSR[3] DCD_STS bit.	HiZ
uart1_dsrn	I	Data Set Ready Active-low modem status signal. Reading UART_MSR[5] NDSR_STS register bit checks the condition of uart1_dsrn. Reading UART_MSR[1] DSR_STS bit checks a change of state of uart1_dsrn since the last read of the UART_MSR register.	HiZ
uart1_dtrn	O	Data Terminal Ready When active (low), this signal informs the modem that the module is ready to communicate. It is activated by setting UART_MCR[0] DTR register bit.	1
uart1_rin	I	Ring Indicator Active-low modem status signal. The condition of uart1_rin can be checked by reading UART_MSR[6] NRI_STS register bit. Any change in its state can be detected by reading UART_MSR[2] RI_STS bit.	HiZ

(1) I = Input; O = Output; I/O = Bidirectional
(2) i = 1 to 10

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information on control module settings, see *Pad Configuration Registers*, in *Control Module*.

24.3.2.1.3 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x (<= 230.4 kbps)
- UART 16x with autobauding (>= 1200 bps and >= 115.2 kbps)
- UART 13x (>= 460.8 kbps)

CAUTION

To be used as a UART, the operating mode must be programmed appropriately in the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to select UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 24-39 shows the UART frame data format.

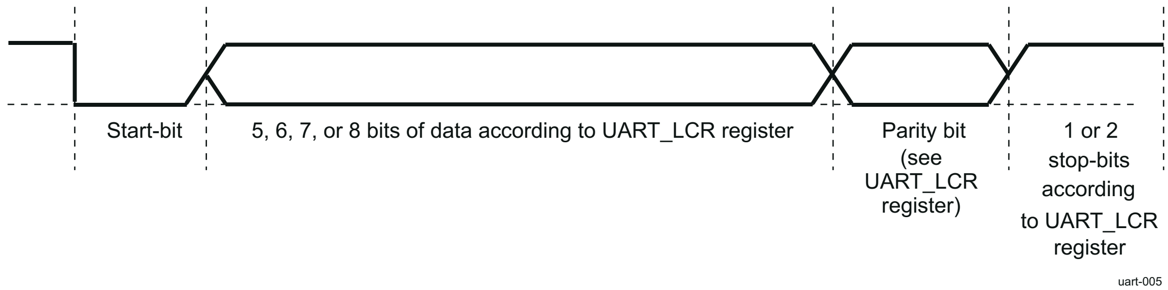

Figure 24-39. UART Frame Data Format

24.3.2.2 IrDA Functional Interfaces

24.3.2.2.1 System Using IrDA Communication Protocol

As Figure 24-40 shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

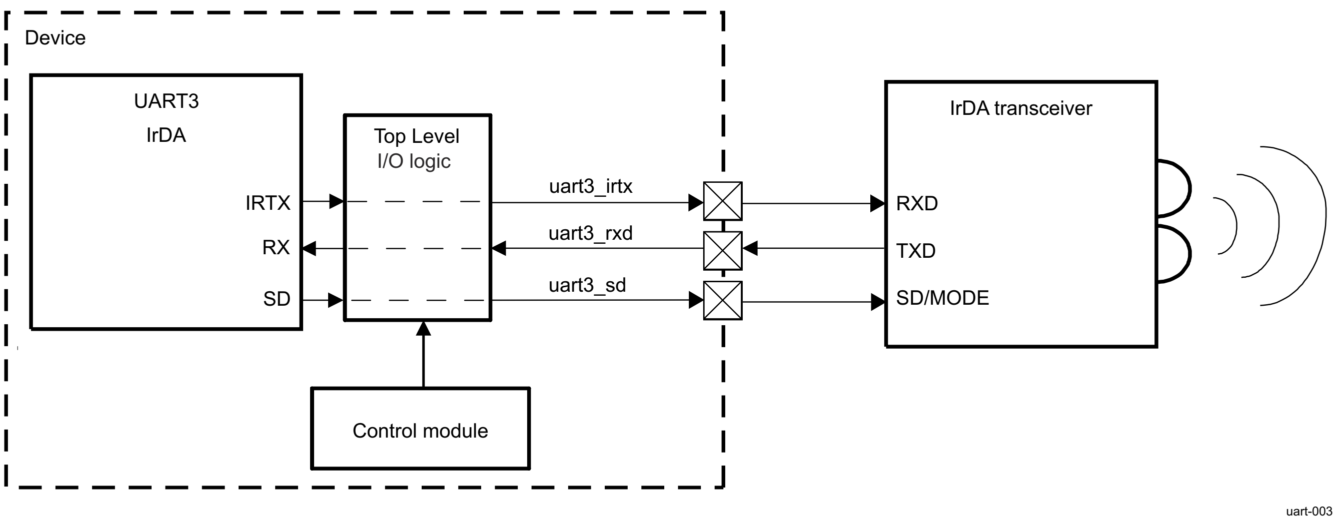

Figure 24-40. IrDA System Overview

24.3.2.2.2 IrDA Interface Description

Table 24-86 lists the IrDA interface I/O signals.

Table 24-86. IrDA I/O Signals

Signal	I/O(1)	Description	Reset
IrDA Signals			
uart3_rxd	I	Serial data input	HiZ
uart3_irtx	O	Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state).	0
uart3_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

(1) I = Input; O = Output

24.3.2.2.3 IrDA Protocol and Data Format

24.3.2.2.3.1 SIR Mode

In SIR mode, data is transferred between the MPUand peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start-bit, 8 data bits, and 1 stop-bit, and is unaffected by the use and settings of the UART3.UART_LCR register.

The UART3.UART_BLR[6] XBOF_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine sends an escape character (0x7D), inverts the fifth bit of the real data to be sent, and then sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, or a frame-length error. At the end of a frame reception, the MPUreads the line status register (UART3.UART_LSR_IRDA) to find possible errors of the received frame.

Note

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the description of the UART3.UART_ACREG[5] DIS_IR_RX bit. This applies to all three modes: SIR, MIR, and FIR.

Infrared output in SIR mode can be 1.6-μs or 3/16 encoding, selected by the UART3.UART_ACREG[7] PULSE_TYPE bit. In 1.6-μs encoding, the infrared pulse width is 1.6 μs; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/baud rate).

For back-to-back frames, the transmitting device must send at least two start flags at the start of each frame.

Note

Reception supports variable-length stop-bits.

24.3.2.2.3.1.1 Frame Format

Figure 24-41 shows the IrDA SIR frame format.

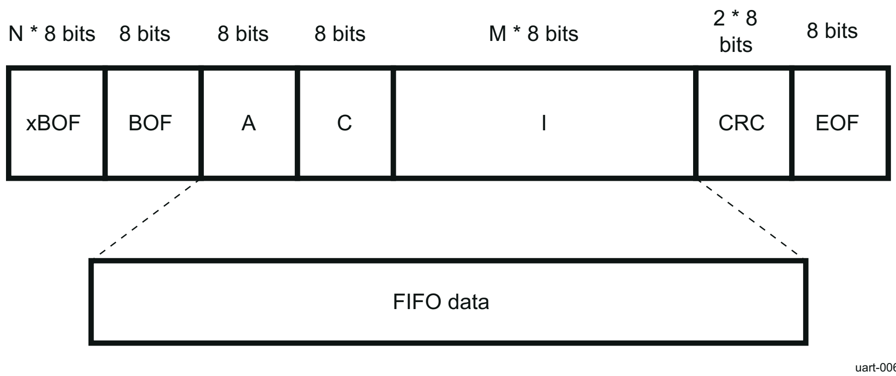

Figure 24-41. IrDA SIR Frame Format

The CRC is applied on the address (A), control (C), and information (I) bytes.

Note

The two words of CRC are written to the FIFO in reception.

24.3.2.2.3.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
  - Inserts a control escape (CE) byte preceding the byte
  - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

  The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).
- In reception:

  For the A, C, I, and CRC fields:
  - Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO.
  - If the byte is equal to the CE byte, discards the CE byte
  - Complements bit 5 of the byte following the CE
  - Sends the complemented byte to the CRC detector and stores it in the RX FIFO

24.3.2.2.3.1.3 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

When a 0x7D character that is followed immediately by a 0xC1 character is received without transparency, the receiver treats the frame as an aborted frame.

24.3.2.2.3.1.4 Pulse Shaping

The SIR mode supports the 3/16 and the 1.6-μs pulse duration methods. The UART3.UART_ACREG[7] PULSE_TYPE bit selects the pulse-width method in transmit mode.

24.3.2.2.3.1.5 Encoder

Serial data from the transmit state-machine are encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the uart3_irtx line is always low, and the counter used to form a pulse on uart3_irtx is cleared continuously.

After the TX FIFO output resets to 0, uart3_irtx rises on the falling edge of the seventh 16XCLK. On the falling edge of the tenth 16XCLK pulse, uart3_irtx falls, creating a 3-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the seventh clock to the tenth clock of each 16-clock bit cycle.

Figure 24-42 shows the IrDA SIR encoding mechanism.

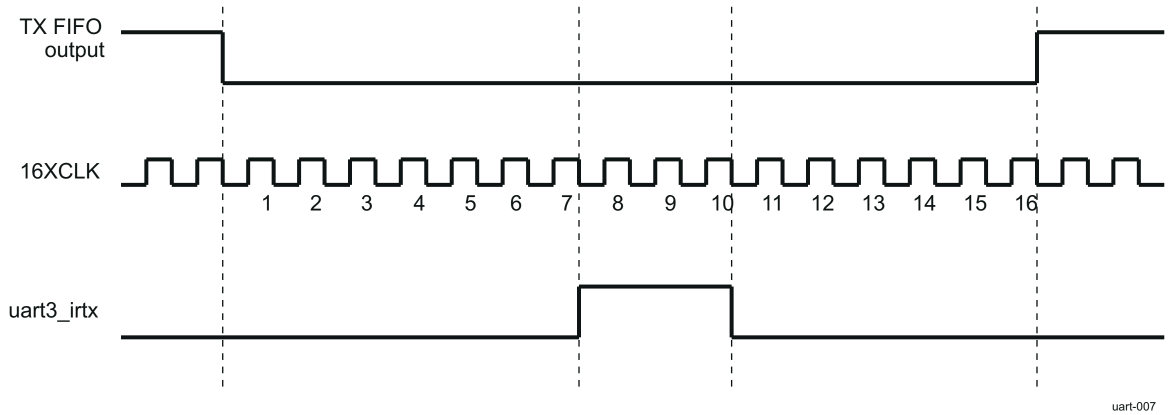

Figure 24-42. IrDA SIR Encoding Mechanism

24.3.2.2.3.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 24-43 shows the IrDA SIR decoding mechanism.

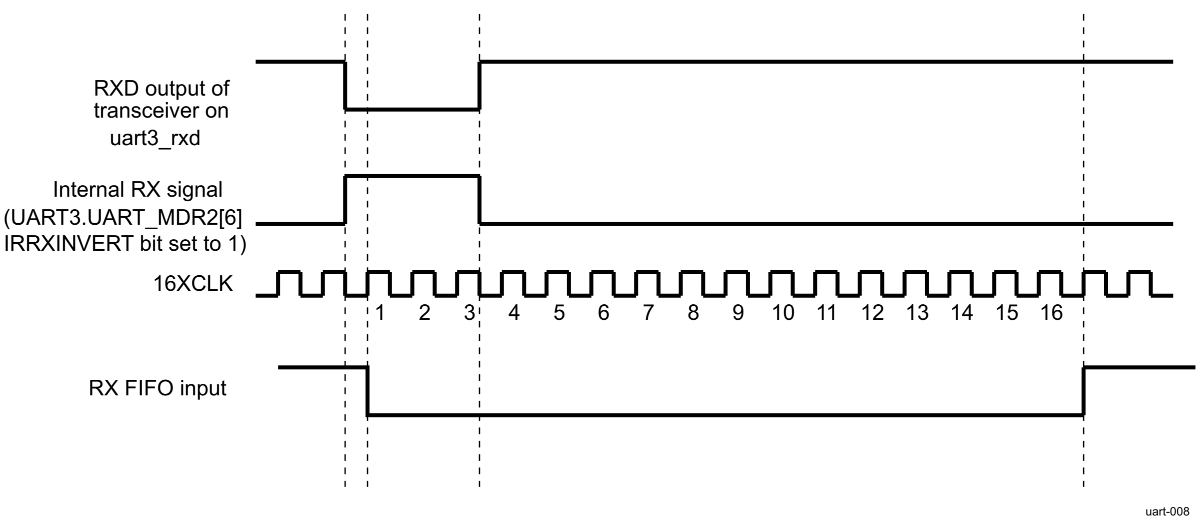

Figure 24-43. IrDA SIR Decoding Mechanism

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the uart3_rxd input can be disabled using the UART3.UART_ACREG[5] DIS_IR_RX bit. The UART3.UART_MDR2[6] IRRXINVERT bit can invert the signal from the transceiver (RXD) pin to the IR RX logic in the UART. This inversion is performed by default.

24.3.2.2.3.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting the UART3.UART_EFR[1:0] bit field (see Table 24-87), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the UART3.UART_XON1_ADDR1[7:0] and UART3.UART_XON2_ADDR2[7:0] bit fields.

Table 24-87. UART_EFR[1:0] IR Address Checking Options

UART_EFR[1]	UART_EFR[0]	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

24.3.2.2.3.2 SIR Free-Format Mode

To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free-format (FF) mode is a subfunction of the existing SIR mode. In FF mode, all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

The FF mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

Figure 24-44 shows SIR FF mode.

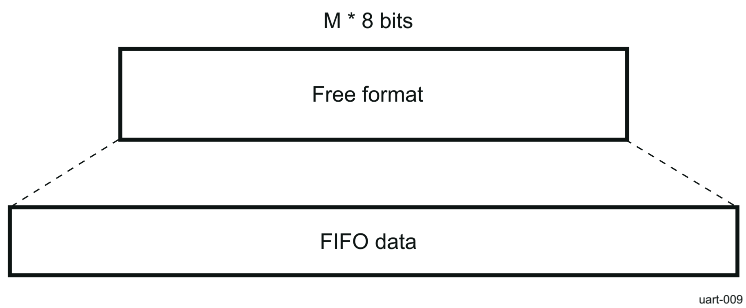

Figure 24-44. SIR FF Mode

In SIR FF mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

24.3.2.2.3.3 MIR Mode

In MIR mode, data is transferred between the MPUand the peripheral devices at 0.576 or 1.152 Mbps. A MIR transmit frame starts with at least two start flags, followed by a frame data and a CRC-16, and ends with a stop flag (see Figure 24-45).

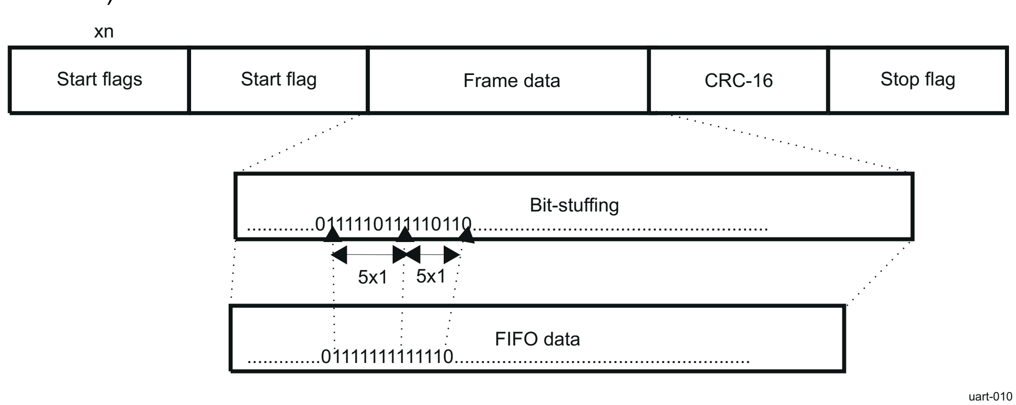

Figure 24-45. MIR Transmit Frame Format

On transmit, the MIR state-machine attaches start flags, a CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

In MIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for start and stop flags (unambiguously, not data, because of bit-stuffing).
- An abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit-stuffing).
- Back-to-back frames are allowed with three or more stop flags between them. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR_IRDA) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

24.3.2.2.3.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by IrDA specifications.

Figure 24-46 shows the MIR baud rate adjustment mechanism.

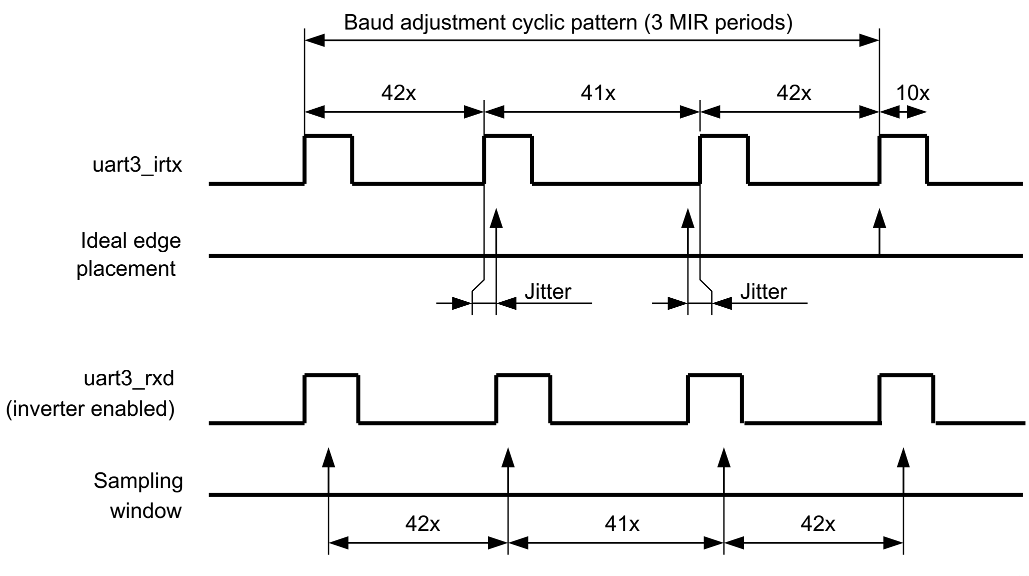

Figure 24-46. MIR Baud Rate Adjustment Mechanism

24.3.2.2.3.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is occupied.

Figure 24-47 shows the SIP.

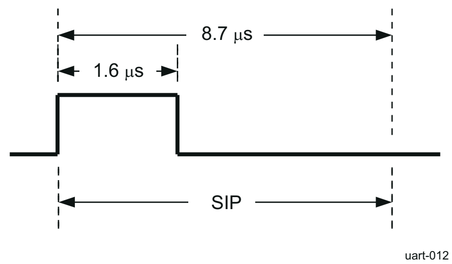

Figure 24-47. SIP

24.3.2.2.3.4 FIR Mode

In FIR mode, data is transferred between the MPU and the peripheral devices at 4 Mbps. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 24-48 shows the FIR transmit frame format.

Figure 24-48. FIR Transmit Frame Format

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see Table 24-88) and generates the SIP (see Section 24.3.2.2.3.3.2, *SIP Generation*).

Table 24-88. 4-PPM Format

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in Table 24-88 are the legal, encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see Table 24-89).

Table 24-89. FIR Preamble, Start Flag, and Stop Flag

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted LSBs of each byte first (see Table 24-90).

Table 24-90. FIR Data Byte Transmission Order Example

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR_IRDA) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

24.3.2.3 CIR Functional Interfaces

24.3.2.3.1 System Using CIR Communication Protocol With Remote Control

UART3 can be connected to an external infrared transceiver in CIR mode (see Figure 24-49).

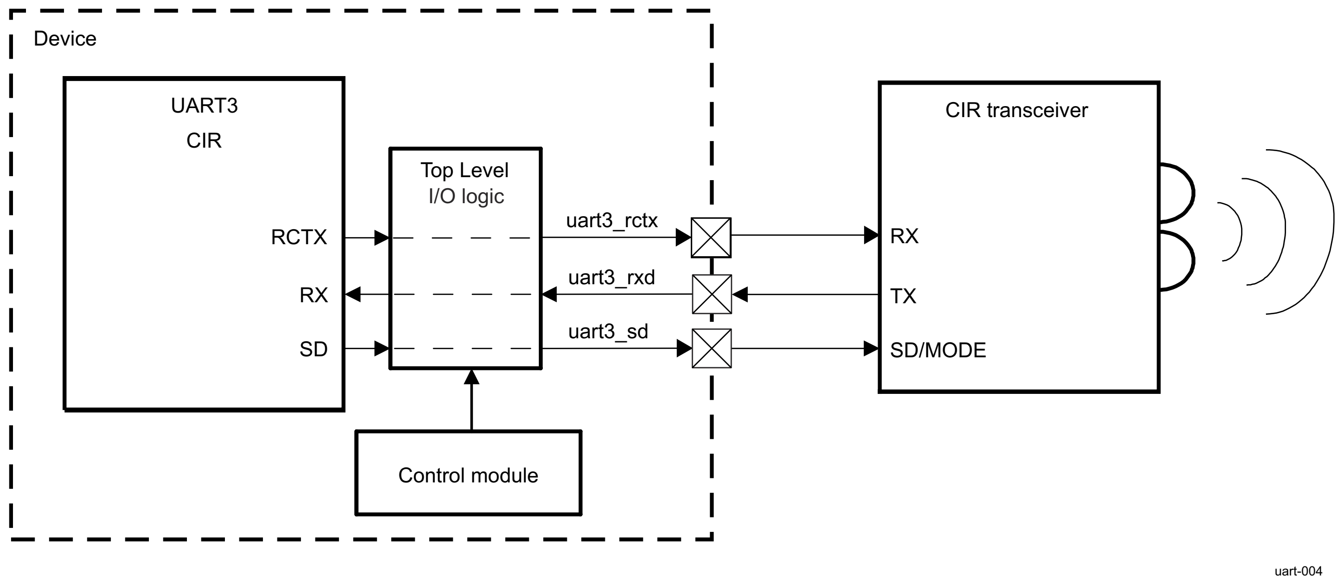

Figure 24-49. CIR System Overview

24.3.2.3.2 CIR Interface Description

Table 24-91 lists the CIR interface I/O signals.

Table 24-91. CIR I/O Signals

Signal	I/O(1)	Description	Reset
CIR Signals			
uart3_rxd	I	Serial data input	HiZ
uart3_rctx	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
uart3_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

(1) I = Input; O = Output

24.3.2.3.3 CIR Protocol and Data Format

In CIR mode, the infrared operation functions as a programmable (universal) remote control.

CIR mode uses a variable PWM technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

24.3.2.3.3.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 24-50).

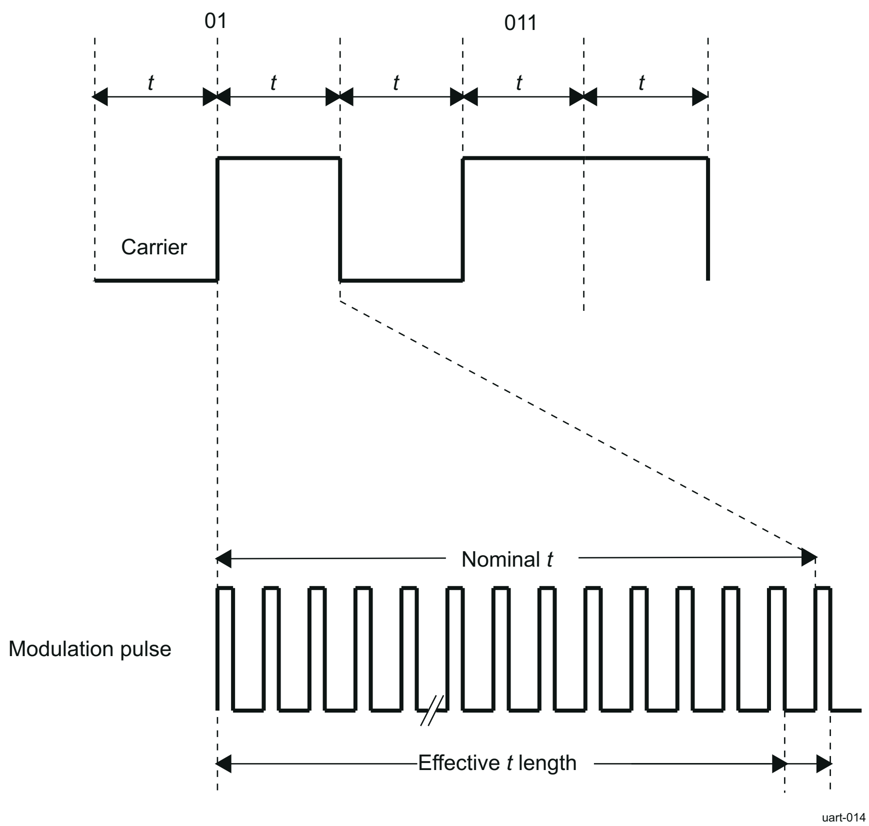

Figure 24-50. CIR Pulse Modulation

24.3.2.3.3.2 Pulse Duty Cycle

The programmer can choose one of four duty cycles for modulation pulses by setting the appropriate value in the UART3.UART_MDR2[5:4] CIR_PULSE_MODE bit field (1/4, 1/3, 5/12, or 1/2).

Figure 24-51 shows the CIR modulation duty cycles.

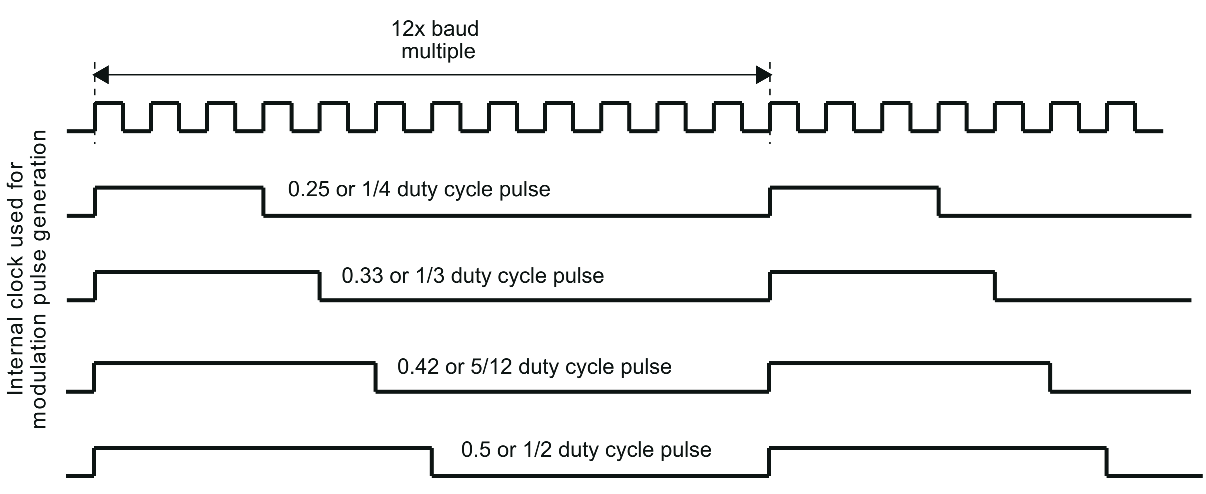

Figure 24-51. CIR Modulation Duty Cycle

The transmission logic ensures that all pulses are transmitted completely (no cutoff during transmission). While transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end requires it.

24.3.2.3.3.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote-control applications:

- Pulse duration encoding (time-extended bit forms): A variable pulse distance, or duration, in which the difference between logic 1 and logic 0 is the length of the pulse width
- Biphase encoding: The encoding of logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively.

Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

CIR mode uses a completely flexible free-format encoding in which 1 is transmitted from the TX FIFO as a modulated pulse with duration *t*.

Similarly, 0 is transmitted as a blank duration T. The MPUconstructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see Figure 24-52).

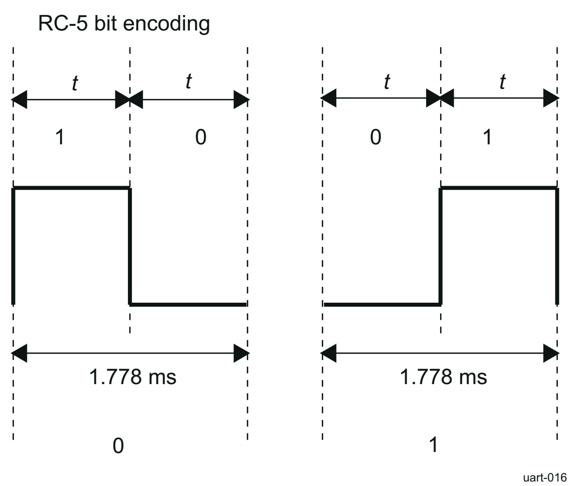

Figure 24-52. RC-5 Bit Encoding

Because CIR mode logic does not impose a fixed format for infrared packets of data, the MPUsoftware can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPUsoftware must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (multiples of *t*) is used to distinguish between 1 and 0. The subsequent SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

Figure 24-53 shows SIRC bit encoding.

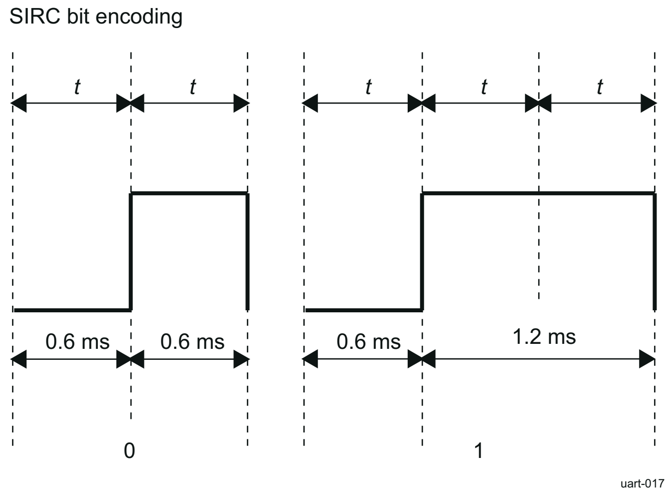

Figure 24-53. SIRC Bit Encoding

To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 24-54 shows a standard RC-5 frame as detected by UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two *t* pulses (digital bits) from the TX FIFO.

S1	S2	T	A4	A3	A2	A1	A0	C5	C4	C3	C2	C1	C0

uart-018

Figure 24-54. RC-5 Standard Packet Format

Where:

S1, S2:	Start-bits (always 1)
T:	Toggle bit
A4..A0:	Address (or system) bits
C5..C0:	Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPUtransmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that lets the command range increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits in the standard frame length varies.

Figure 24-55 shows the packet format and bit encoding. As Figure 24-56 shows, 1 start-bit of 2.4 ms and control codes are followed by data that constitute the entire frame.

S	C0	C1	C2	C3	C4	C5	C6	D0	D1	D2	D3	D4

uart-019

Figure 24-55. SIRC Packet Format

Note

The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for sending and receiving data packets must exercise a scheme of interpacket delay, where successive packets can be sent only after a real-time delay expires.

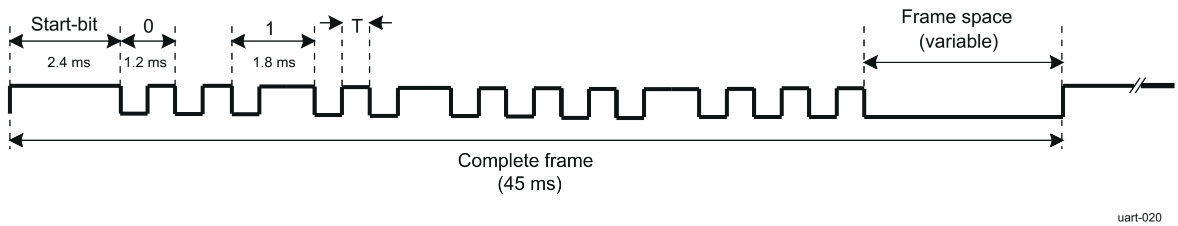

Figure 24-56. SIRC Bit Transmission Example

This document does not describe all encoding methods and techniques; the previous information discusses the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol use.

24.3.3 UART/IrDA/CIR Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-57 shows the device internal connections with related modules for UART functions.

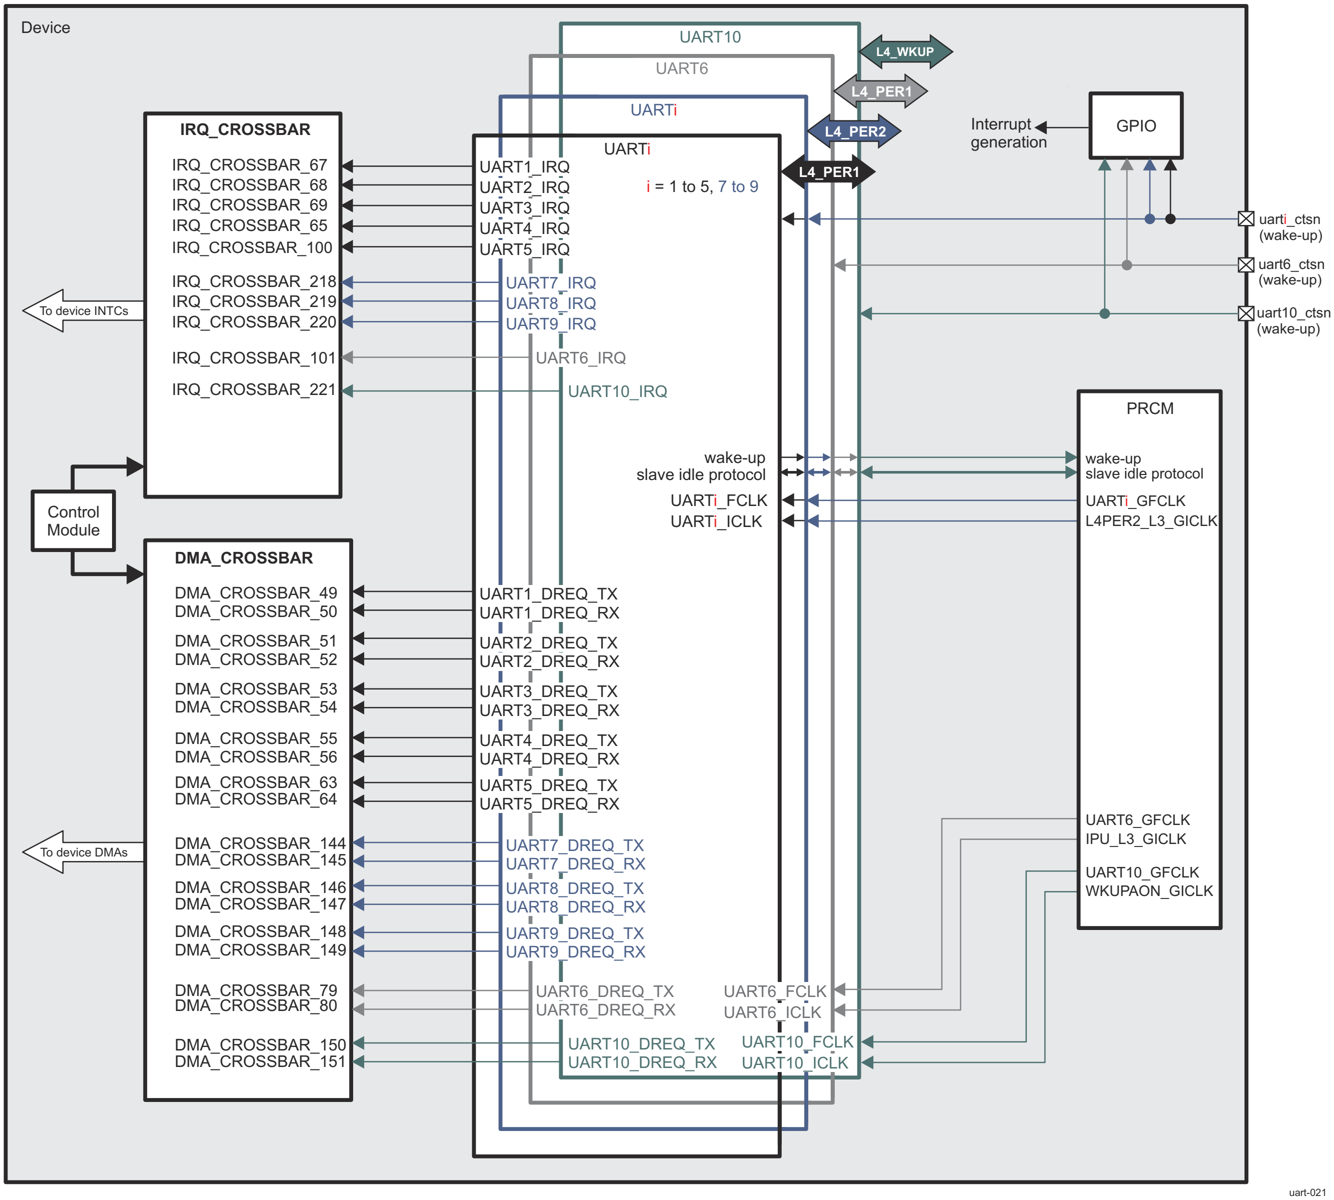

Figure 24-57. UART/IrDA/CIR Integration

Note

For more information about the master standby and slave idle protocols and the wake-up request, see *Clock Domain-Level Clock Management*, in *Power, Reset, and Clock Management*

24.3.3.1

Table 24-92 through Table 24-94 summarize the integration of the module in the device.

Table 24-92. UART Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
UART1	PD_COREAON	Yes	L4_PER1
UART2	PD_COREAON	Yes	L4_PER1
UART3	PD_COREAON	Yes	L4_PER1
UART4	PD_COREAON	Yes	L4_PER1
UART5	PD_COREAON	Yes	L4_PER1
UART6	PD_COREAON	Yes	L4_PER1
UART7	PD_COREAON	Yes	L4_PER2
UART8	PD_COREAON	Yes	L4_PER2
UART9	PD_COREAON	Yes	L4_PER2
UART10	PD_WKUPAON	Yes	L4_WKUP

Table 24-93. UART Clocks and Resets

Clocks				
Module Instance	Destination Signal	Source Signal	Source	Description
UART1	UART1_ICLK	L4PER_L3_GICLK	PRCM	UART1 interface clock
	UART1_FCLK	UART1_GFCLK	PRCM	UART1 functional clock

	UART7_DREQ_RX	DMA_CROSSBAR_145	-	UART 7 – receive request
UART8	UART8_DREQ_TX	DMA_CROSSBAR_146	-	UART 8 – transmit request
	UART8_DREQ_RX	DMA_CROSSBAR_147	-	UART 8 – receive request
UART9	UART9_DREQ_TX	DMA_CROSSBAR_148	-	UART 9 – transmit request
	UART9_DREQ_RX	DMA_CROSSBAR_149	-	UART 9 – receive request
UART10	UART10_DREQ_TX	DMA_CROSSBAR_150	-	UART 10 – transmit request

Table 24-94. UART Hardware Requests (continued)

UART10_DREQ_RX	DMA_CROSSBAR_151	-	UART 10 – receive request

Note

The **Default Mapping** column in Table 24-94, *UART Hardware Requests*, shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

For more information about the device DMA_SYSTEM module, see *System DMA*.

For more information about the device EDMA module, see *Enhanced DMA*.

24.3.4 UART/IrDA/CIR Functional Description

24.3.4.1 Block Diagram

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, IrDA, or CIR) and enables the mechanism corresponding to the chosen function
- Register mode: Enables conditional access to registers

For more information about mode configuration, see Section 24.3.4.7, *Mode Selection*.

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: Different interrupt types are generated depending on the chosen function. In each mode, when an interrupt is generated, the UART_IIR register indicates the interrupt type.
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 24-58 is the UART/IrDA/CIR block diagram.

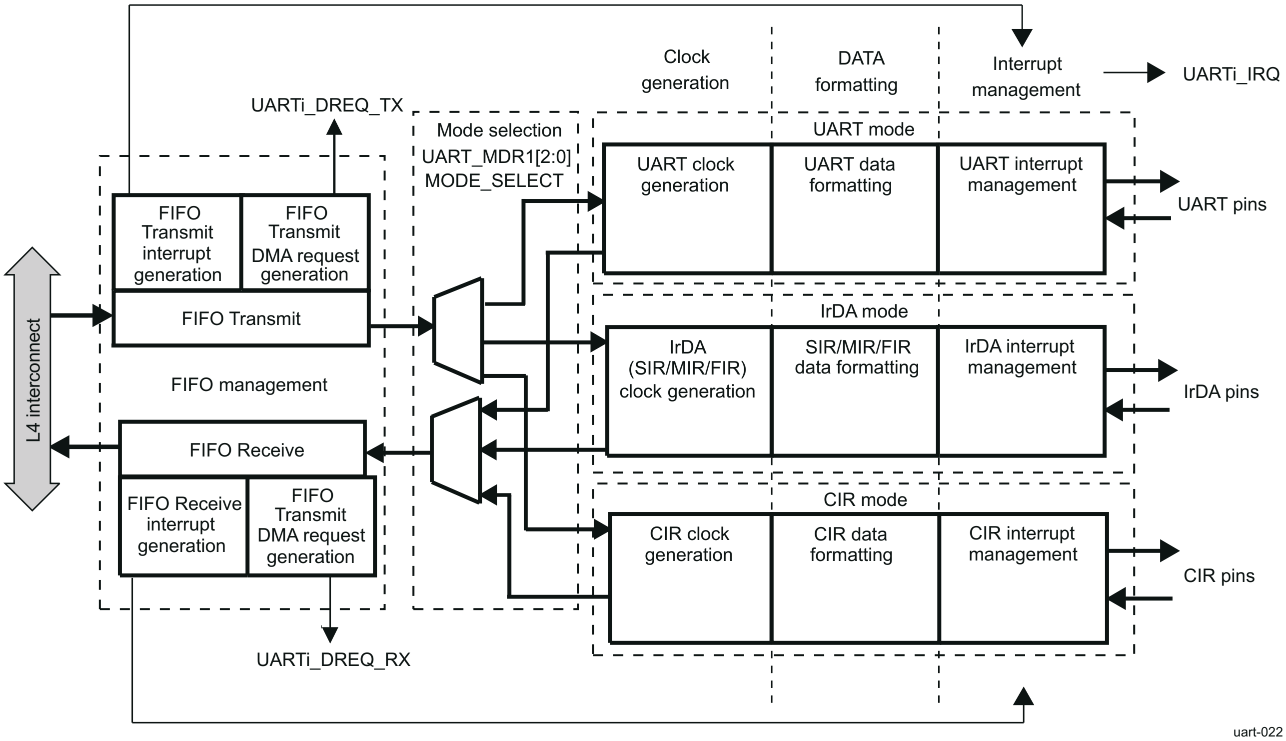

Figure 24-58. UART/IrDA/CIR Functional Block Diagram

24.3.4.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see *Clock Domain-Level Clock Management*, in *Power, Reset, and Clock Management*).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see *Clock Domain Level Clock Management*, in *Power, Reset, and Clock Management*). The UARTi.UART_SYSC[4:3] IDLEMODE bit field controls UART idle mode.

24.3.4.3 Software Reset

The UARTi.UART_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

24.3.4.4 Power Management

24.3.4.4.1 UART Mode Power Management

24.3.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.UART_IER[4] SLEEP_MODE bit to 1 (when the UARTi.UART_EFR[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, uarti_rxd, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rxd line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see Section 24.3.4.5.1.2, *Wake-Up Interrupt*.

Note

There must be no writing to the divisor latches, UARTi.UART_DLL and UARTi.UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UARTi.UART_IER[4] SLEEP_MODE bit before writing to the UARTi.UART_DLL or UARTi.UART_DLH register.

24.3.4.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.UART_SYSC[2] ENAWAKEUP bit and the UARTi.UART_WER register).

For more information, see *Module Level Clock Management*, *Power, Reset, and Clock Management*.

24.3.4.4.2 IrDA Mode Power Management (UART3 Only)

24.3.4.4.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART3.UART_MDR1[3] IR_SLEEP bit to 1.

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RXD, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the RXD line or when data is written to the TX FIFO.

24.3.4.4.2.2 System Power Saving

System power saving for the IrDA mode has the same function as for the UART mode (see Section 24.3.4.4.1.2, *System Power Saving*).

24.3.4.4.3 CIR Mode Power Management (UART3 Only)

24.3.4.4.3.1 Module Power Saving

Module power saving for the CIR mode has the same function as for the IrDA mode (see Section 24.3.4.4.2.1, *Module Power Saving*).

24.3.4.4.3.2 System Power Saving

System power saving for the CIR mode has the same function as for the UART mode (see Section 24.3.4.4.1.2, *System Power Saving*).

24.3.4.4.4 Local Power Management

Table 24-95 describes power-management features available for the UART.

Note

For information about source clock gating and the sleep/wake-up transitions description, see *Module Level Clock Management*, *Power, Reset, and Clock Management*.

Table 24-95. Local Power-Management Features

Feature	Registers	Description
Clock autogating	UART_SYSC[0] AUTOIDLE	This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity.
Slave idle modes	UART_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

24.3.4.5 Interrupt Requests

24.3.4.5.1 UART Mode Interrupt Management

24.3.4.5.1.1 UART Interrupts

UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART_IIR) sets the UARTi.UART_IIR[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART_IIR[5:1] bit field. Table 24-96 summarizes the interrupt control functions.

Table 24-96. UART Mode Interrupts

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	N/A	No Interrupt	N/A	N/A
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears
000010	3	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears
000000	4	Modem status	See the UART_MSR register.	Read the MSR register
010000	5	XOFF interrupt/ special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR register, if special character interrupt
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high)	Read the UART_IIR register

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.UART_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART_IIR register.

24.3.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART_SCR[4] RX_CTS_WU_EN bit is set to 1. The UARTi.UART_IIR register is not modified when this occurs; the UART3.UART_SSR[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

24.3.4.5.2 IrDA Mode Interrupt Management

24.3.4.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.UART_IER_IRDA). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.UART_IIR_IRDA).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.UART_IER_IRDA and UART3.UART_IIR_IRDA mappings, depending on the selected mode.

IrDA modes have eight possible interrupts (see Table 24-97). The interrupt line is activated when any interrupt is generated (there is no priority).

Table 24-97. IrDA Mode Interrupts

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error OR Transmission of the last bit of the IrDA frame completed successfully.	Read the UART_RESUME register OR Read the UART_IIR_IRDA register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR_IRDA register.

24.3.4.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see Section 24.3.4.5.1.2, *Wake-Up Interrupt*).

CAUTION

Wake-up interface implementation in this mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

This does not ensure wake-up event generation as expected when configured in smart-idle mode, and the system wakes up for a short period.

24.3.4.5.3 CIR Mode Interrupt Management

24.3.4.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.UART_IER_CIR). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.UART_IIR_CIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.UART_IER_CIR and UART3.UART_IIR_CIR mappings, depending on the selected mode.

Table 24-98 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.UART_IIR_CIR[5] bit is to indicate that the last bit of infrared data was passed to the uart3_rctx pin.

Table 24-98. CIR Mode Interrupts

IIR_CIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the THR register until the interrupt condition disappears
2	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
3	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

24.3.4.5.3.2 Wake-Up Interrupts

The wake-up interrupt for CIR mode has the same function as that for UART mode (see Section 24.3.4.5.1.2, *Wake-Up Interrupt*).

24.3.4.6 FIFO Management

The FIFO is accessed by reading and writing the UARTi.UART_RHR and UARTi.UART_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART_FCR) and supplementary control register (UARTi.UART_SCR). Reading the UARTi.UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 24-59 shows the FIFO management registers.

Note

Data in the UARTi.UART_RHR register is not overwritten when an overflow occurs.

Note

The UARTi.UART_SFLSR, UARTi.UART_SFREGL, and UARTi.UART_SFREGH status registers are used in IrDA mode only. For information about their use, see Section 24.3.4.8.2.3, *IrDA Data Formatting*.

Note

Bits UARTI.UART_FCR[2] TX_FIFO_CLEAR and UARTI.UART_FCR[1] RX_FIFO_CLEAR are automatically cleared by hardware after 4* UARTi_ICLK + 5* UARTi_FCLK clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

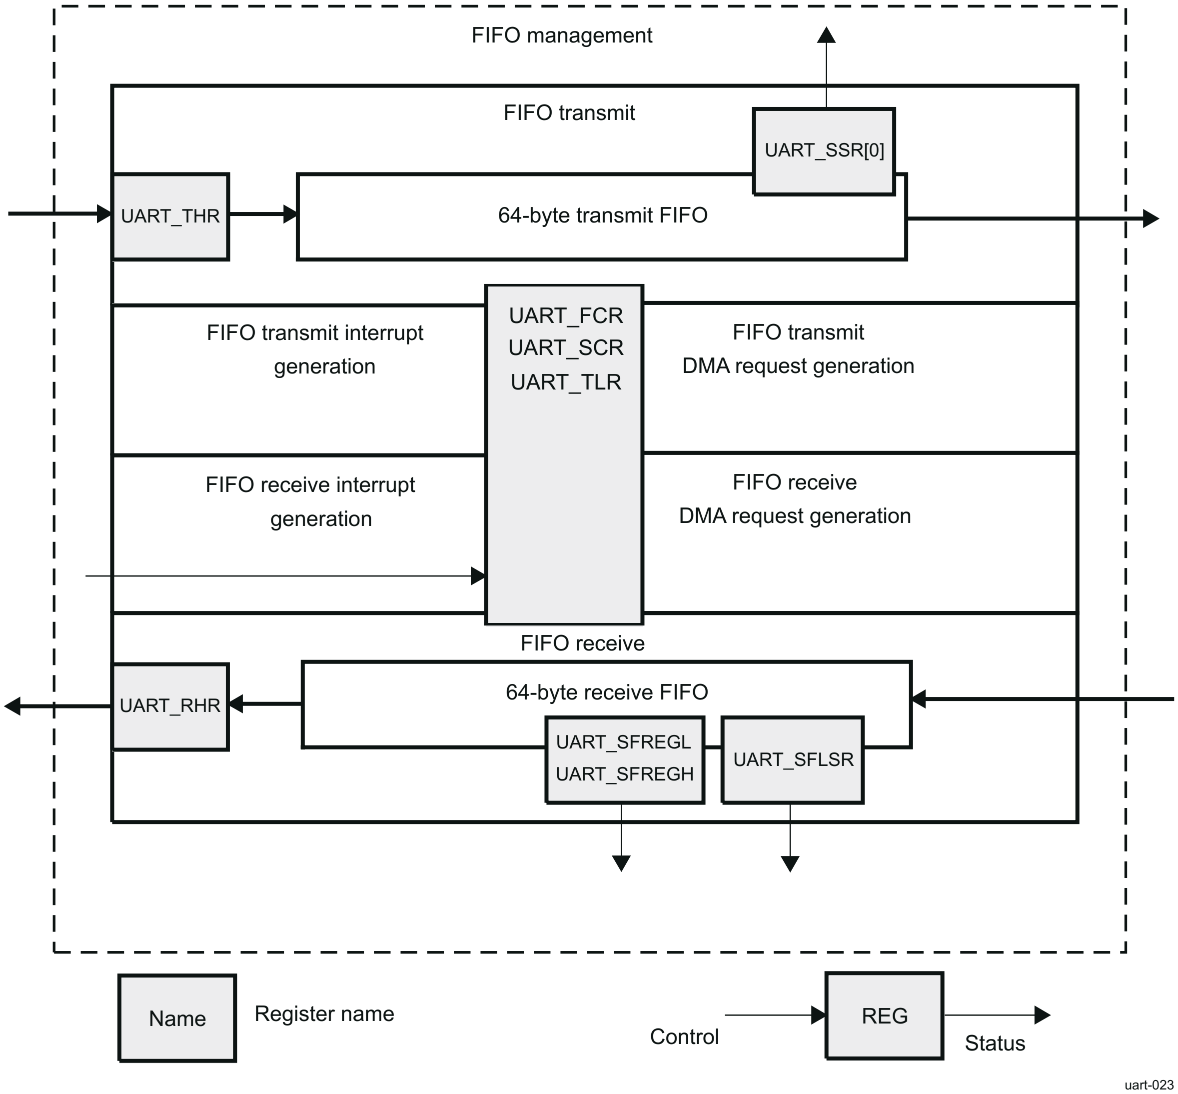

Figure 24-59. FIFO Management Registers

24.3.4.6.1 FIFO Trigger

24.3.4.6.1.1 Transmit FIFO Trigger

Table 24-99 lists the TX FIFO trigger level settings.

Table 24-99. TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) **Note:** The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 space required). All zeros result in unpredictable behavior.

24.3.4.6.1.2 Receive FIFO Trigger

Table 24-100 lists the RX FIFO trigger-level settings.

Table 24-100. RX FIFO Trigger-Level Setting Summary

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) **Note:** The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START and UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.

  Delay = [4 + 16 × (1 + CHAR_LENGTH + Parity + Stop – 0.5)] × Baud_rate + 4 × FCLK

  Note

  The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

24.3.4.6.2 FIFO Interrupt Mode

In FIFO interrupt mode (the FIFO control register UARTi.UART_FCR[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.UART_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA and UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit fields or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG and UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 24-60 shows the generation of the RX FIFO interrupt request.

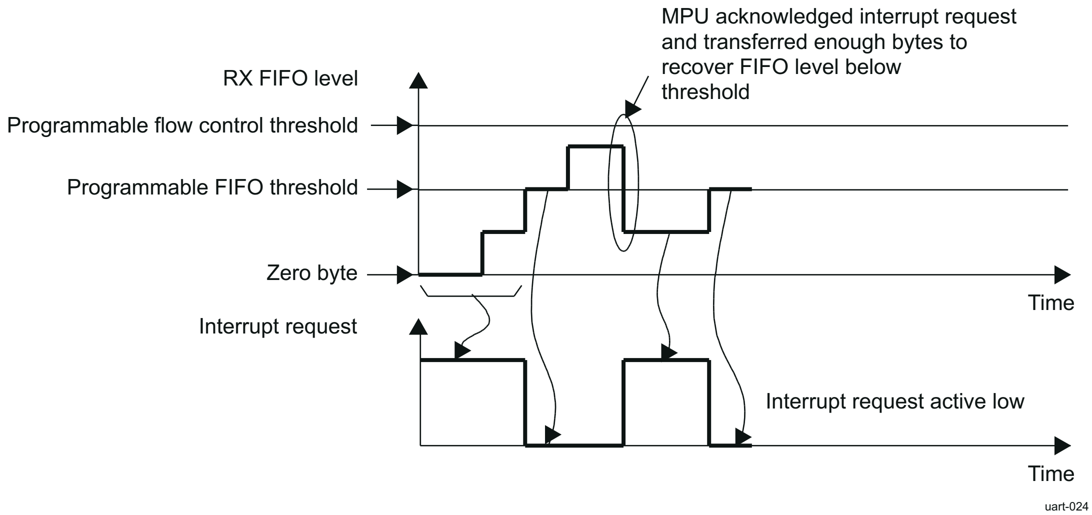

Figure 24-60. RX FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 24-61 shows the generation of the TX FIFO interrupt request.

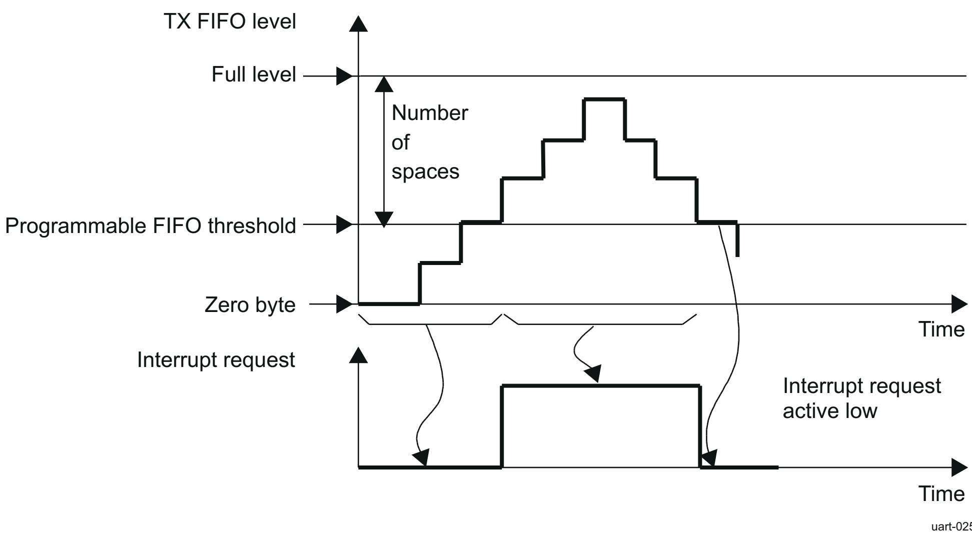

Figure 24-61. TX FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

24.3.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.UART_IER register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.UART_LSR).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

24.3.4.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in Table 24-94, *UART Hardware Requests*, assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the UARTi_DREQ_TX signals (where i = 1 to 10).

The UARTi_DREQ_RX signals are not used by the module in mode 2 and mode 3:

The DMA mode and signals usage can be selected as follows:

- When the UARTi.UART_SCR[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.UART_FCR[3] DMA_MODE bit to 0 enables DMA mode 0. Setting the UARTi.UART_FCR[3] DMA_MODE bit to 1 enables DMA mode 1.
- When the UARTi.UART_SCR[0] DMA_MODE_CTL bit is set to 1, the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field determines DMA mode 0 to mode 3 based on the supplementary control register (SCR) description.

For example:

- If no DMA operation is desired, set theUARTi.UART_SCR[0] DMA_MODE_CTL bit to 1 and the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set the UARTi.UART_SCR[0] DMA_MODE_CTL bit to 0 and the UARTi.UART_FCR[3] DMA_MODE bit to 1, or set the UARTi.UART_SCR[0] DMA_MODE_CTL bit to 1 and the SCR[2:1] DMA_MODE_2 bit field to 01. (The UARTi.UART_FCR[3] DMA_MODE bit is discarded.)

If the FIFOs are disabled (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UARTi.UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

  The threshold value will be the value of the TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET_TX_DMA_THRESHOLD = 0:

  The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

24.3.4.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers UARTi.UART_SCR[0] = 0 and UARTi.UART_FCR[3] = 1:
   a. Set the UARTi.UART_SCR[2:1] DMA_MODE_2 bit fields to 01 (DMA mode 1)
   b. Set the UARTi.UART_SCR[0] DMA_MODE_CTL bit to1 (this setting of UARTi.UART_SCR[0] DMA_MODE-CTL will ignores UARTi.UART_FCR[3] DMA_MODE_CTL bit)

   Note

   It is strongly suggested to do steps 'a' and 'b' in two separate write in order to avoid malfunction of the device.

   c. Set the UARTi.UART_FCR[3] DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART_SCR[0] DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UARTi.UART_ACREG[5] DIS_IR_RX bit

Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

d. Set the UARTi.UART_FCR[2:1] DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
e. Set the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
f. Set the UARTi.UART_FCR[2:1] DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
g. Set the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

2. DMA mode 1 is set (both TX/RX DMA) by registers UARTi.UART_FCR[3] = 0 and UARTi.UART_SCR[0] = 1, UARTi.UART_SCR[2:1] = 01. It is almost the same as above, but steps ‘a’, and ‘b’ can be skipped:
   a. Set the UARTi.UART_FCR[3] DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART_SCR[0] DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UARTi.UART_ACREG[5] DIS_IR_RX bit

   Note

   There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

   b. Set the UARTi.UART_FCR[2:1] DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
   c. Set the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
   d. Set the UARTi.UART_FCR[2:1] DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
   e. Set the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
3. DMA mode 3 is set (TX DMA only) by registers UARTi.UART_FCR[3] = 0 and UARTi.UART_SCR[0] = 1, UARTi.UART_SCR[2:1] = 11. It is the same as above:
   a. Set the UARTi.UART_FCR[3] DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART_SCR[0] DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UARTi.UART_ACREG[5] DIS_IR_RX bit

   Note

   There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

   b. Set the UARTi.UART_FCR[2:1] DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
   c. Set the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
   d. Set the UARTi.UART_FCR[2:1] DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
   e. Set the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

24.3.4.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 24-62 through Figure 24-65 show the supported DMA operations.

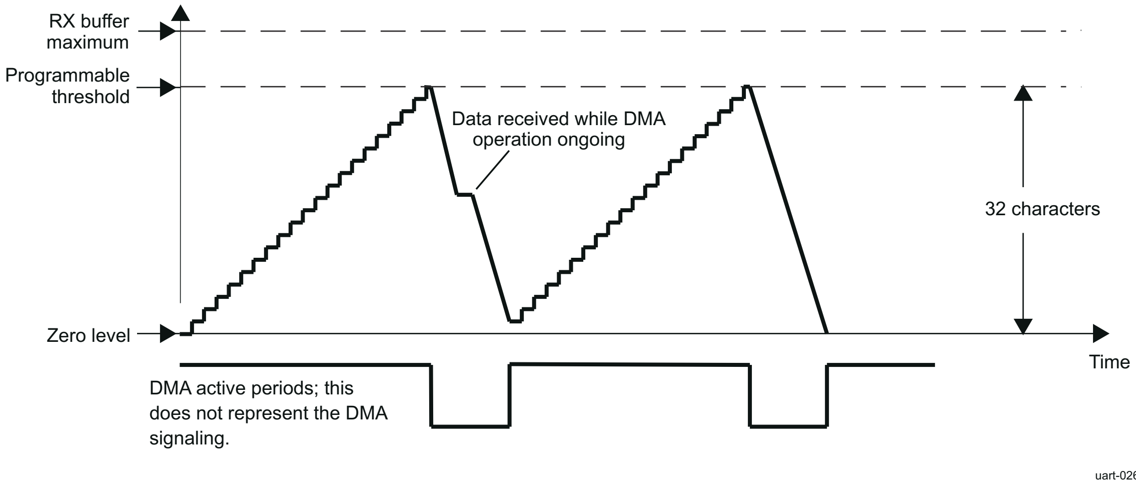

Figure 24-62. Receive FIFO DMA Request Generation (32 Characters)

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

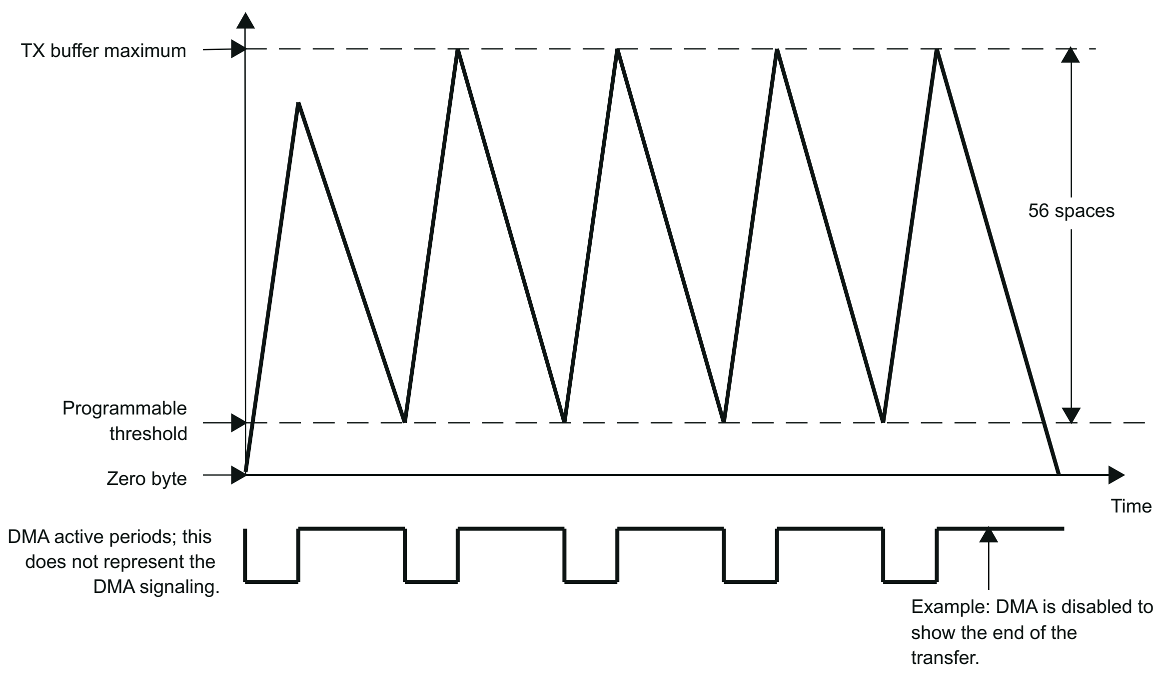

Figure 24-63. Transmit FIFO DMA Request Generation (56 Spaces)

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART_TLR register.

The threshold can be programmed in a number of ways. Figure 24-63 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field or the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART/IrDA/CIR module).

Figure 24-64 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART/IrDA/CIR module.

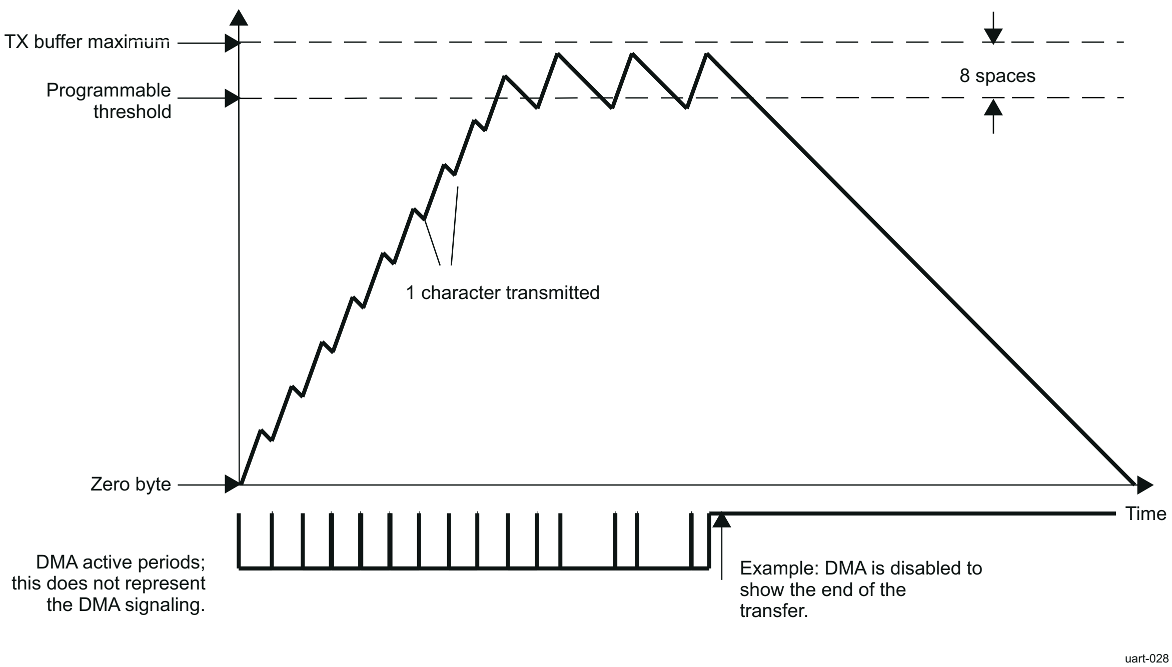

Figure 24-64. Transmit FIFO DMA Request Generation (8 Spaces)

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 24-65). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART_DLL and UARTi.UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

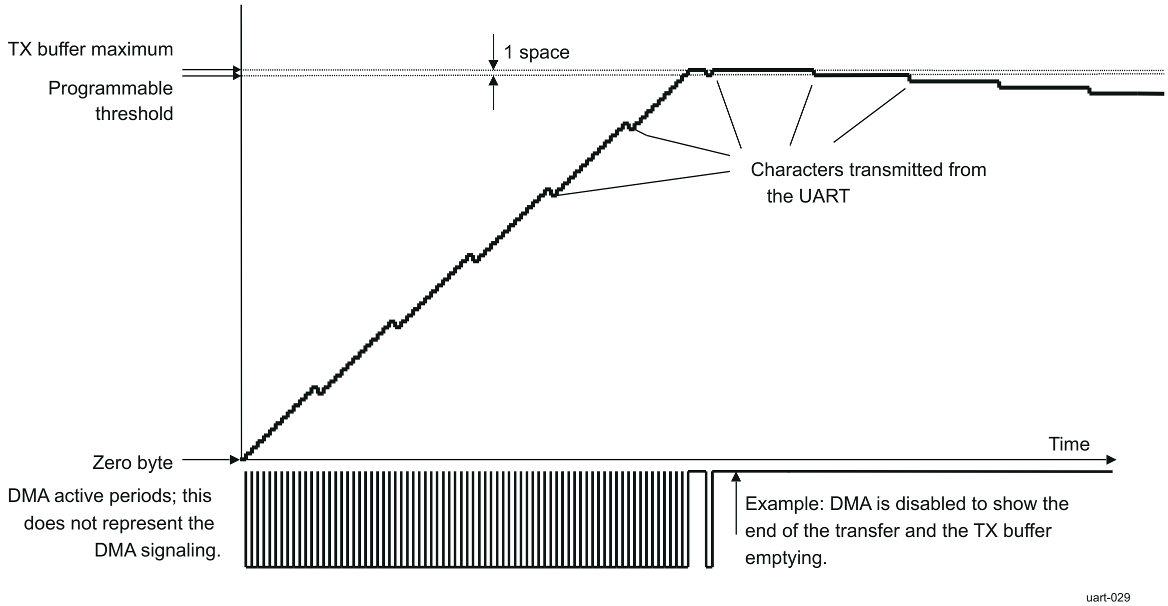

Figure 24-65. Transmit FIFO DMA Request Generation (1 Space)

The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting UART_MDR3[1] NONDEFAULT_FREQ bit and UART_TX_DMA_THRESHOLD register (see Figure 24-66). In the example, UART_TX_DMA_THRESHOLD[5:0] TX_DMA_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the UART_DLL and UART_DLH registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the UART_MDR3[1] NONDEFAULT_FREQ value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

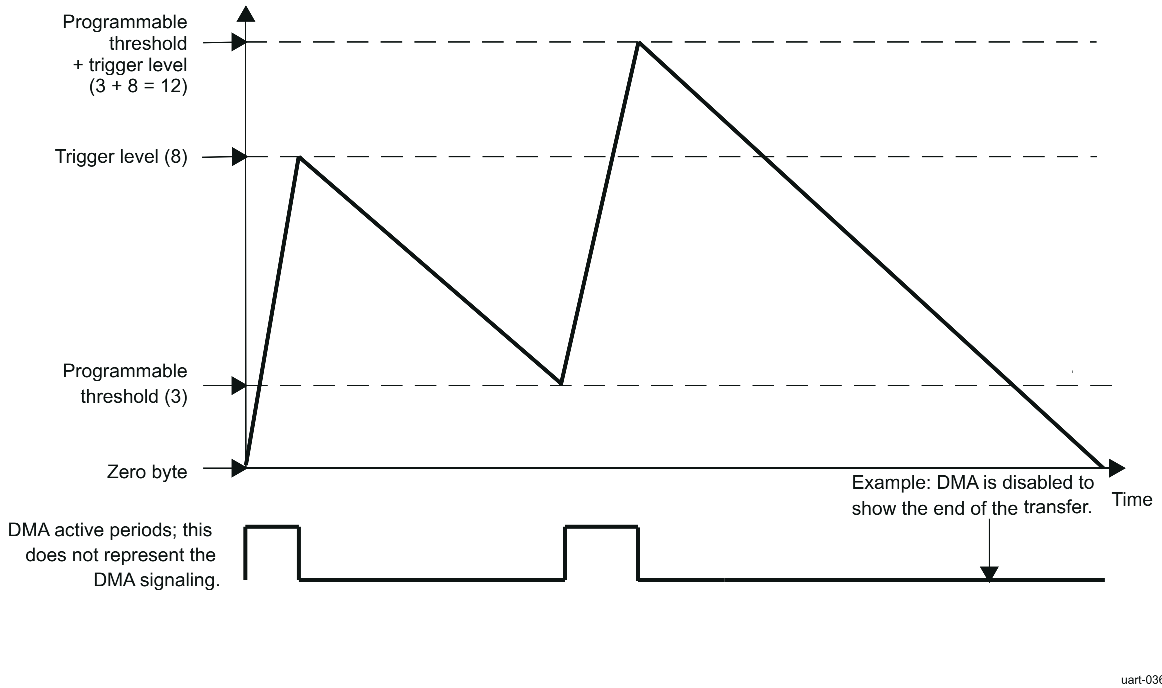

Figure 24-66. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)

24.3.4.6.4.3 DMA Transmission

Figure 24-67 shows DMA transmission.

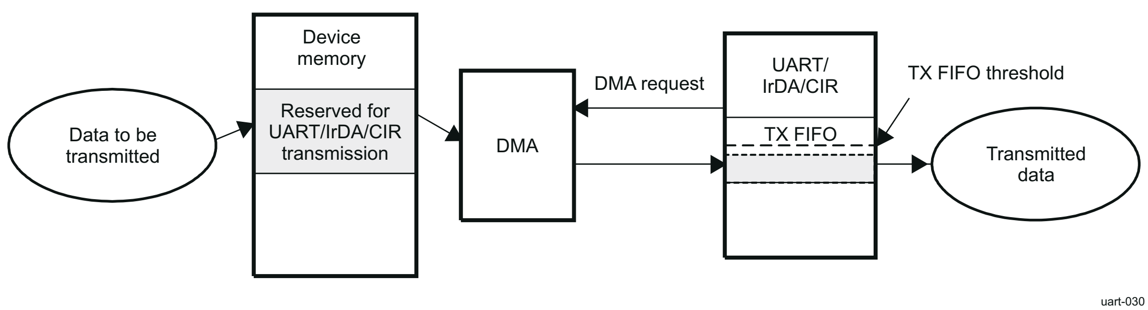

Figure 24-67. DMA Transmission

1. Data to be transmitted are put in the device memory reserved for UART/IrDA/CIR transmission by the DMA:
    a. Until the TX FIFO trigger level is not reached, a DMA request is generated
    b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART_THR empty (TX FIFO empty).

Note

In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UARTi.UART_THR register empties.

24.3.4.6.4.4 DMA Reception

Figure 24-68 shows DMA reception.

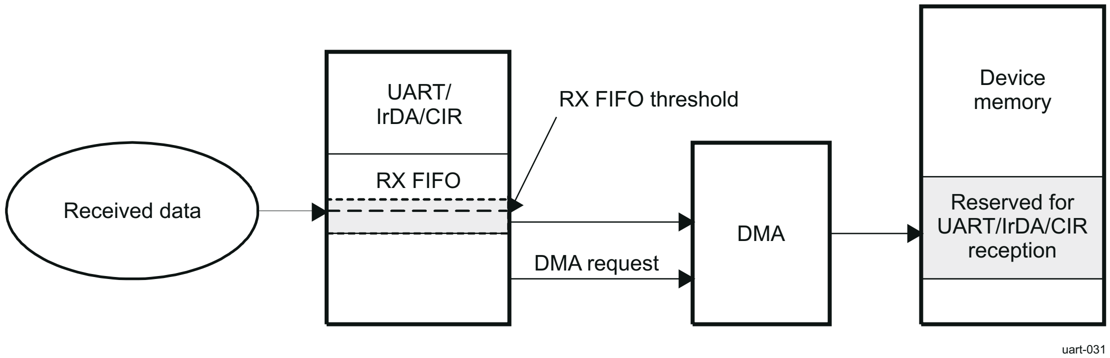

Figure 24-68. DMA Reception

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
   a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
   b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

24.3.4.7 Mode Selection

24.3.4.7.1 Register Access Modes

24.3.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART_LCR register determines the register access mode (see Table 24-101).

Table 24-101. UART/IrDA/CIR Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

24.3.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in Section 24.3.6, *UART/IrDA/CIR Register Manual*.

Table 24-102 through Table 24-104 summarize the register access submodes.

Table 24-102. Subconfiguration Mode A Summary

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

Table 24-103. Subconfiguration Mode B Summary

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 24-104. Suboperational Mode Summary

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

24.3.4.7.1.3 Registers Available for the Register Access Modes

Table 24-105 lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

Table 24-105. UART/IrDA/CIR Register Access Mode Overview

24.3.4.7.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field (see Table 24-106).

Table 24-106. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode (UART3 only)
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode (UART3 only)
0x5:	FIR mode (UART3 only)
0x6:	CIR mode (UART3 only)

MODE_SELECT is effective when the module is in operational mode (see Section 24.3.4.7.1, *Register Access Modes*).

24.3.4.7.2.1 Registers Available for the UART Function

Only the registers listed in Table 24-107 are used for the UART function.

Table 24-107. UART Mode Register Overview

24.3.4.8 Protocol Formatting

24.3.4.8.1 UART Mode

24.3.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 24-69 shows the baud rate generator and associated controls.

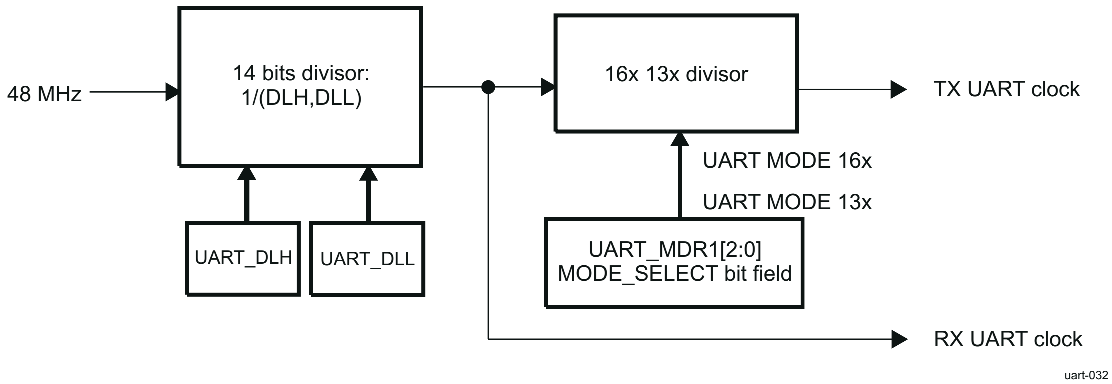

Figure 24-69. Baud Rate Generation

CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT = DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

24.3.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency / (16x baud rate)
- UART 13x mode: Divisor value = Operating frequency / (13x baud rate)

Table 24-110 and Table 24-111 describe the UART baud rate settings.

Table 24-110. UART Baud Rate Settings (48-MHz Clock)

24.3.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

24.3.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART_LCR register.

Character length is specified using the UARTi.UART_LCR[1:0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UARTi.UART_LCR[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 bit fields (see Table 24-112).

Table 24-112. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

24.3.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART_EFR[7:6] AUTO_CTS_EN and AUTO_RTS_EN bit fields, respectively.

With auto-CTS, uarti_ctsn must be active before the module can transmit data.

Auto-RTS activates the uarti_rtsn output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rtsn output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART_TCR register determine the levels at which uarti_rtsn is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

  Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART_TCR register. uarti_rtsn is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, uarti_rtsn is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

  uarti_rtsn is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

  In this case, uarti_rtsn is an active-low signal.
- Auto-CTS:

  The transmitter circuitry checks uarti_ctsn before sending the next data byte. When uarti_ctsn is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_ctsn must be deasserted before the middle of the last stop-bit currently sent.

  The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_ctsn state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

  In this case, uarti_ctsn is an active-low signal.

24.3.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART_EFR) and the modem control register (UARTi.UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART_EFR[3:0] bit field (see Table 24-113).

Two other enhanced features relate to software flow control:

- XON-any function (UARTi.UART_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

  Note

  The XON-any character is written into the RX FIFO even if it is a software flow character.
- Special character (UARTi.UART_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 24-113. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2

Table 24-113. UART_EFR[3:0] Software Flow Control Options (continued)

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2[(1)]
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2[(1)]

(1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 bit field. XON2 is defined in the UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit field.
XOFF1 is defined in the UARTi.UART_XOFF1[7:0] XOFF_WORD1 bit field. XOFF2 is defined in the UARTi.UART_XOFF2[7:0] XOFF_WORD2 bit field.

24.3.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART_IIR[4] bit (if enabled by UARTi.UART_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART_IIR[4] bit is cleared and the XOFF interrupt disappears.

Note

When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

24.3.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

Note

If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

24.3.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud
  - 9.6K baud
  - 4.8K baud
  - 2.4K baud
  - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

Note

The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UARTi.UART_MDR1[2:0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART_DLL, UARTi.UART_DLH, and UARTi.UART_LCR[5:0] bit field settings are not used; instead, UASR is updated with the configuration detected by the autobauding logic.

UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART_LCR, UARTi.UART_DLL, and UARTi.UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART_MDR1[2:0] MODE_ SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

24.3.4.8.1.3.5 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART_LSR register and then reading the UARTi.UART_RHR register identifies errors in a character.

Reading the UARTi.UART_RHR register updates the BI, FE, and PE bits (see Table 24-96 for the UART mode interrupts).

The UARTi.UART_LSR[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

Note

Reading the UARTi.UART_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART_RHR register.

Reading the UARTi.UART_LSR register clears the OE bit if it is set (see Table 24-96 for the UART mode interrupts).

24.3.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPUwith the UARTi.UART_IIR[5:1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the MPU must:

- Reset the RX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

24.3.4.8.1.3.7 Time-Out and Break Conditions

24.3.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rxd) is high for a time that equals 4x the programmed word length + 12 bits. uarti_rxd is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rxd.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rxd or when the UARTi.UART_RHR register is read.

24.3.4.8.1.3.7.2 Break Condition

When a break condition occurs, uarti_txd is pulled low. A break condition is activated by setting the UARTi.UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART_LSR[6] TX_SR_E bit is set to 1).
3. Take a guard time according to stop-bit definition.

4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

24.3.4.8.2 IrDA Mode (UART3 Only)

24.3.4.8.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 24-70 shows the baud rate generator and associated controls.

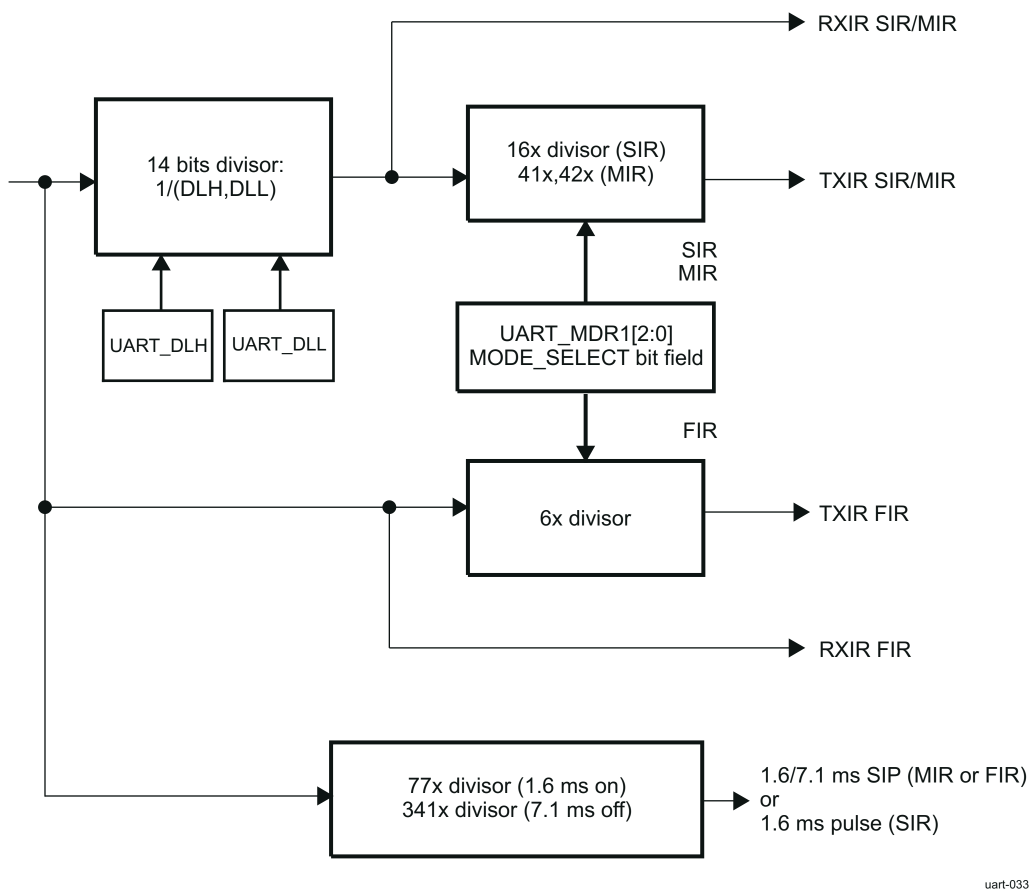

Figure 24-70. Baud Rate Generator

CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT=DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

24.3.4.8.2.2 Choosing the Appropriate Divisor Value

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 24-114 lists the IrDA baud rate settings.

Table 24-114. IrDA Baud Rate Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 µs
9.6 kbps	SIR	16x	3/16	312	9.6153 kbps	+0.16	0	19.5 µs
19.2 kbps	SIR	16x	3/16	156	19.231 kbps	+0.16	0	9.75 µs
38.4 kbps	SIR	16x	3/16	78	38.462 kbps	+0.16	0	4.87 µs
57.6 kbps	SIR	16x	3/16	52	57.692 kbps	+0.16	0	3.25 µs
115.2 kbps	SIR	16x	3/16	26	115.38 kbps	+0.16	0	1.62 µs
0.576 Mbps	MIR	41x/42x	1/4	2	0.5756 Mbps[1]	0	+1.63/-0.80	416 ns
1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps[1]	0	+1.63/-0.80	208 ns
4 Mbps	FIR	6x	4 PPM	–	4 Mbps	0	0	125 ns

(1) Average value

Note

Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

24.3.4.8.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

24.3.4.8.2.3.1 IR RX Polarity Control

The UART3.UART_MDR2[6] IRRXINVERT bit provides the flexibility to invert the uart3_rxd pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the uart3_rxd pin is inverted because most transceivers invert the IR receive pin.

24.3.4.8.2.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3_rxd input can be disabled by the UART3.UART_ACREG[5] DIS_IR_RX bit.

24.3.4.8.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART3.UART_XON1_ADDR1[7:0] XON_WORD1 and UART3.UART_XON2_ADDR2[7:0] XON_WORD2 bit fields.

Setting the UART_EFR[0] bit to 1 selects address1 checking. Setting the UART_EFR[1] bit to 1 selects address2 checking. Setting the UART_EFR[1:0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

24.3.4.8.2.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART3.UART_MDR1[7] FRAME_END_MODE bit to 0. The MPU writes the value of the frame length to the UART3.UART_TXFLH and UART3.UART_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.

- Set-EOT bit method: Set the FRAME_END_MODE bit to 1. The MPU writes 1 to the UART3.UART_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

24.3.4.8.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.UART_ACREG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.UART_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

24.3.4.8.2.3.6 Error Detection

When the UART3.UART_LSR register is read, the UART3.UART_LSR[4:2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see Table 24-97). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

24.3.4.8.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the MPU must:

- Reset the TX FIFO.
- Read the UART3.UART_RESUME register, which clears the internal flag.

This function can be disabled by the UART3.UART_ACREG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

24.3.4.8.2.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see Section 24.3.4.8.1.3.6, *Overrun During Receive*).

24.3.4.8.2.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART3.UART_SFREGH[3:0] MSB and UART3.UART_SFREGL[3:0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART3.UART_SFLSR register. Reading the UART3.UART_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPUmust be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

24.3.4.8.2.4 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

24.3.4.8.2.4.1 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.UART_ACREG[1] ABORT_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

> **CAUTION**
>
> When the TX FIFO is not empty and the UART3.UART_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

24.3.4.8.2.4.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6-μs pulse duration methods. The UART3.UART_ACREG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

24.3.4.8.2.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART3.UART_MDR1[2:0] MODE_SELECT = 0x0) and the UART3.UART_MDR2[3] PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART3.UART_LCR[1:0] CHAR_LENGTH bit field = 0x3 (8 data bits)
- UART3.UART_LCR[2] NB_STOP bit = 0x0 (1 stop-bit)
- UART3.UART_LCR[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

24.3.4.8.2.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors in the received frame.

When the UART3.UART_MDR1[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART3.UART_ACREG[3] SEND_SIP bit.

The MPU can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

24.3.4.8.3 CIR Mode (UART3 Only)

24.3.4.8.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a *t* period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in Figure 24-71.

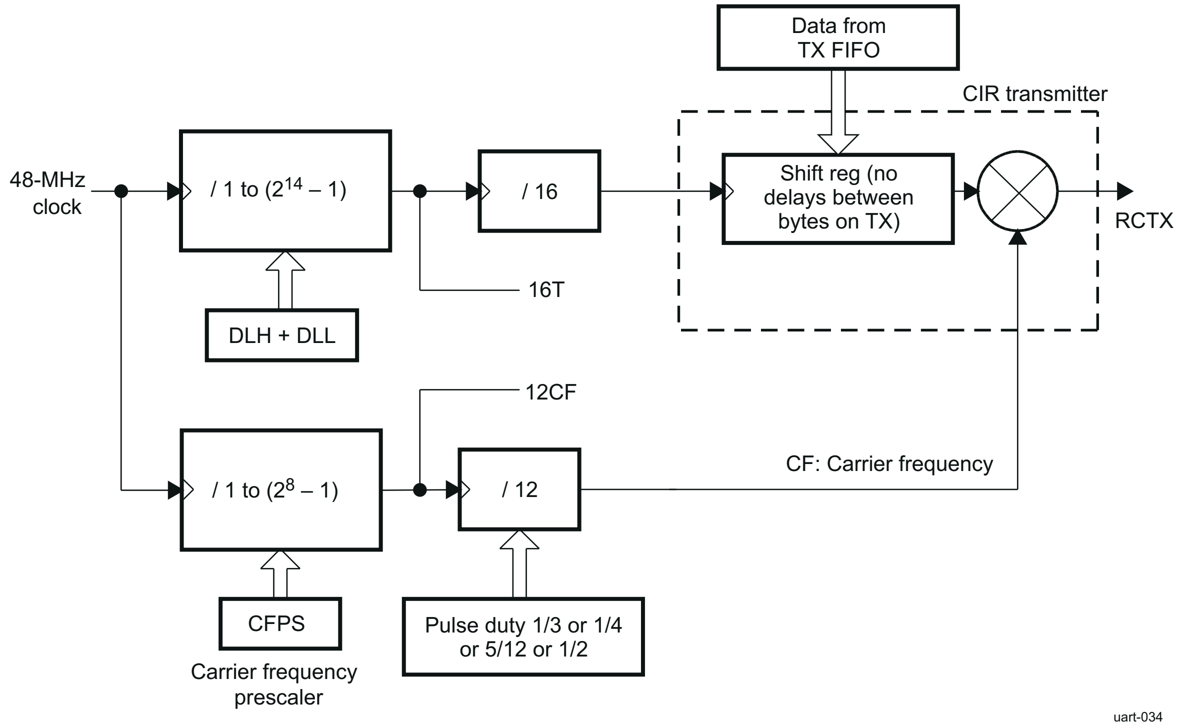

Figure 24-71. CIR Mode Block Components

Based on the requested modulation frequency, the UART3.UART_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

Dividing value = (FCLK / 12) / MODfreq

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

Note

The UART3.UART_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART3.UART_MDR2 register. Table 24-115 shows the duty cycle.

Table 24-115. Duty Cycle

UART_MDR2[5:4]	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

24.3.4.8.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

24.3.4.8.3.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see Section 24.3.4.8.2.3.1, *IR RX Polarity Control*).

24.3.4.8.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a *t* period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART3.UART_MDR1[5] SCT bit and the UART3.UART_ACREG[2] SCTX_EN bit, depending on the timer status
  - Using the UART3.UART_IIR[5] TX_STATUS_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

24.3.5 UART/IrDA/CIR Basic Programming Model

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

Note

Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 24.3.4.7.1, *Register Access Modes*.

24.3.5.1 Global Initialization

24.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the UART/IrDA/CIR module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the UART/IrDA/CIR.

For more information, see Section 24.3.3, *UART/IrDA/CIR Integration*.

Table 24-116. Global Initialization of Surrounding Modules for UART/IrDA/CIR

Surrounding Modules	Comments
PRCM	UART functional and interface clocks must be enabled. For more information, see *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing must be set in the control module. For more information, see *Control Module*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*
Interrupt controllers	Device INTCs must be configured to enable the interrupt request generation. For information about enabling interrupts, see *Interrupt Controllers*.
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
DMA controllers	DMA controllers configuration must be done to enable the module DMA channel request. See Chapter 16, *DMA Controllers*
Interconnects	For information about the L4 interconnect configuration, see *Interconnect*.

24.3.5.1.2 UART/IrDA/CIR Module Global Initialization

The procedure in Table 24-117 can be used to initialize UART when performing software reset.

Table 24-117. UART/IrDA/CIR Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	UART_SYSC[1] SOFTRESET	1
Wait until reset is finished.	UART_SYSS[0] RESETDONE	=1

24.3.5.2 Mode selection

Table 24-118 describes how to set different register access mode.

Table 24-118. Configure Register Access Mode

Step	Register/Bit Field/Programming Model	Value
Set the register access mode A	UART_LCR[7] DIV_EN	1
	UART_LCR[7:0]	≠0xBF
Set the register access mode B	UART_LCR[7:0]	0xBF
Set the operational mode	UART_LCR[7] DIV_EN	0

24.3.5.3 Submode selection

This section describes how to set different register access submode.

Table 24-119. Configure Register Access Submode TCR_TLR

Step	Register/Bit Field/Programming Model	Value
Configure the submode TCR_TLR:		
Configure mode B	see Table 24-118	
Enable writing to register bits UART_MCR[6:5]	UART_EFR[4] ENHANCED_EN	1
Configure mode A	see Table 24-118	0x1
Set the submode TCR_TLR	UART_MCR[6] TCR_TLR	1

Table 24-120. Configure Register Access Submode MSR_SPR

Step	Register/Bit Field/Programming Model	Value
First option to configure the submode MSR_SPR:		
Configure mode B	see Table 24-118	
Set the submode MSR_SPR	UART_EFR[4] ENHANCED_EN	0
Second option to configure the submode MSR_SPR:		
Configure mode B	see Table 24-118	
Enable writing to register bits UART_MCR[6:5]	UART_EFR[4] ENHANCED_EN	1
Set the submode MSR_SPR	UART_MCR[6] TCR_TLR	0

Table 24-121. Configure Register Access Submode XOFF

Step	Register/Bit Field/Programming Model	Value
Configure of the XOFF:		
Configure B	see Table 24-118	
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0

24.3.5.4 Load FIFO trigger and DMA mode settings

24.3.5.4.1 DMA mode Settings

To enable and configure DMA mode, perform the following steps:

Table 24-122. DMA Mode Settings

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration	UART_SCR[0] DMA_MODE_CTL	-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	=0
Select the DMA mode, for more information see Section 24.3.4.6.4	UART_FCR[3] DMA_MODE	-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	=1
Select the DMA mode, for more information see Section 24.3.4.6.4	UART_SCR[2:1] DMA_MODE_2	-

24.3.5.4.2 FIFO Trigger Settings

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

Table 24-123. Load FIFO Triggers Defined by the FCR

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 24-119	0x-
Set the desire RX FIFO trigger level	UART_FCR[5:4] TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7:6] RX_FIFO_TRIG	0x-

Table 24-124. Load FIFO Triggers Defined by the TLR

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 24-119	0x-
Set the desire RX FIFO trigger level	UART_TLR[7:4] RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3:0] TX_FIFO_TRIG_DMA	0x-

Table 24-125. Load FIFO Triggers Defined by the Concatenated Value

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 24-119	0x-
Set the register bit	UART_SCR[7] RX_TRIG_GRANU1	1
Set the desire RX FIFO trigger level	UART_TLR[7:4] RX_FIFO_TRIG_DMA UART_FCR[7:6] RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6] TX_TRIG_GRANU1	1
Set the desire TX FIFO trigger level	UART_TLR[3:0] TX_FIFO_TRIG_DMA UART_FCR[5:4] TX_FIFO_TRIG	0x-

24.3.5.5 Protocol, Baud rate and interrupt settings

24.3.5.5.1 Baud rate settings

Table 24-126. Baud Rate Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Switch to register configuration mode B	see Table 24-118	
Enable access to UART_IER[7:4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see Table 24-118	
Disable sleep mode	UART_IER[4] SLEEP_MODE	0
Switch to register configuration mode A or B	see Table 24-118	
Set the appropriate divisor value	UART_DLL[7:0] CLOCK_LSB UART_DLH[5:0] CLOCK_MSB	0x-

24.3.5.5.2 Interrupt settings

Table 24-127. Interrupt Settings

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see Table 24-118	0x7
Enable access to UART_IER[7:4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see Table 24-118	

Table 24-127. Interrupt Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER[7] CTS_IT	0x-
	UART_IER[6] RTS_IT	
	UART_IER[5] XOFF_IT	
	UART_IER[4] SLEEP_MODE	
	UART_IER[3] MODEM_STS_IT	
	UART_IER[2] LINE_STS_IT	
	UART_IER[1] THR_IT	
	UART_IER[0] RHR_IT	

24.3.5.5.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

Table 24-128. Protocol Settings

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see Section 24.3.4.8.1.3.1 , *Frame Formatting*	UART_LCR[5] PARITY_TYPE_2	0x-
	UART_LCR[4] PARITY_TYPE_1	
	UART_LCR[3] PARITY_EN	
	UART_LCR[2] NB_STOP	
	UART_LCR[1:0] PARITY_LENGTH	
Switch to register operational mode	UART_LCR[7] DIV_EN	0
	UART_LCR[6] BREAK_EN	

24.3.5.5.4 UART/IrDA(SIR/MIR/FIR)/CIR

Table 24-129. UART/IrDA/CIR Mode Selection

Step	Register/Bit Field/Programming Model	Value
Load the desired UART mode, see Section 24.3.4.7.2, *UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection*	UART_MDR1[2:0] MODE_SELECT	0x-

24.3.5.6 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

24.3.5.6.1 Hardware Flow Control Configuration

Table 24-130. Hardware Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 24-119	0x7
Load the start and halt trigger value.	UART_TCR[7:4] AUTO_RTS_START	0x-
	UART_TCR[3:0] AUTO_RTS_HALT	
Enable or disable receive and transmit hardware flow control mode.	UART_EFR[7] AUTO_CTS_EN	0x-
	UART_EFR[6] AUTO_RTS_EN	

24.3.5.6.2 Software Flow Control Configuration

Table 24-131. Software Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see Table 24-121	

Table 24-131. Software Flow Control Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Load the software control characters	UART_XON1_ADDR1[7:0] XON_WORD1	0x-
	UART_XON2_ADDR2[7:0] XON_WORD2	
	UART_XOFF1[7:0] XOFF_WORD1	
	UART_XOFF2[7:0] XOFF_WORD2	
Set the register access submode TCR_TLR	see Table 24-119	
Enable or disable XON any function (0: Disable; 1: Enable).	UART_MCR[5] XON_EN	--
Load start and halt trigger value for software flow control	UART_TCR[7:4] AUTO_RTS_START	0x-
	UART_TCR[3:0] AUTO_RTS_HALT	
Enable or disable special character function (0: Disable; 1: Enable)	UART_EFR[5] SPEC_CHAR	0x-
Set the software flow control mode	UART_EFR[3:0] SW_FLOW_CONTROL	0x-

24.3.5.7 IrDA Programming Model (UART3 Only)

24.3.5.7.1 SIR mode

24.3.5.7.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 115.2 kbps, FIFOs disabled, 2 stop-bits, and 8-bit word length:

Table 24-132. SIR Mode Receive Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x80
Load the baud rate(115.2 Kbps)	UART_DLL[7:0] CLOCK_LSB	0x1A
	UART_DLH[5:0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2:0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x00
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

24.3.5.7.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 115.2 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

Table 24-133. SIR Mode Transmit Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x80
Load the baud rate (115.2 Kbps)	UART_DLL[7:0] CLOCK_LSB	0x1A
	UART_DLH[5:0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2:0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x00
Force DTR output to active	UART_MCR[0] DTR	1
Enable the THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 6 bytes	UART_TXFLL[7:0] TXFLL	0x06
Set the seven starts of frame transmission	UART_EBLR[7:0] EBLR	0x08
Set SIR pulse width to be 1.6 µs	UART_ACREG[7] PULSE_TYPE	1

24.3.5.7.2 MIR mode

24.3.5.7.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled.

Table 24-134. MIR Mode Receive Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x80
Load the baud rate (1.152bps)	UART_DLL[7:0] CLOCK_LSB	0x01
	UART_DLH[5:0] CLOCK_MSB	0x00
Set MIR mode	UART_MDR1[2:0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x00
Force outputs DTR and RTS to active	UART_MCR[1:0]	0x3
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

24.3.5.7.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled.

Table 24-135. MIR Mode Transmit Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x80
Load the baud rate (115.2 kbps)	UART_DLL[7:0] CLOCK_LSB	0x01
	UART_DLH[5:0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2:0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x00
Force DTR output to active	UART_MCR[0] DTR	1
Enable the THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 60 bytes	UART_TXFLL[7:0] TXFLL	0x3C
Set the eight additional starts of frame transmission	UART_EBLR[7:0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

24.3.5.7.3 FIR mode

24.3.5.7.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

Table 24-136. FIR Mode Receive Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7:0] CLOCK_LSB	0x0
	UART_DLH[7:0] CLOCK_MSB	
FIFO clear and enable	UART_FCR[2:0]	0x7
Set the FIFO trigger level	see Section 24.3.5.4, *Load FIFO trigger and DMA mode settings*	

Table 24-136. FIR Mode Receive Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Set FIR mode	UART_MDR1[2:0] MODE_SELECT	0x5
Set frame length	UART_RXFLL[7:0] RXFLL	0xA
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x00
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

24.3.5.7.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

Table 24-137. FIR Mode Transmit Settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7:0] CLOCK_LSB	0x0
	UART_DLH[5:0] CLOCK_MSB	
FIFO clear and enable	UART_FCR[2:0]	0x7
Set the FIFO trigger level	see Section 24.3.5.4, *Load FIFO trigger and DMA mode settings*	
Set FIR mode	UART_MDR1[2:0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7:0]	0x00
Set FIR mode and enable auto-SIP mode	UART_MDR1[7:0]	0x45
Set frame length	UART_TXFLL[7:0] TXFLL	0x4
	UART_TXFLH[7:0] TXFLH	0x0
Force DTR output to active	UART_MCR[0] DTR	1
Enable the THR interrupt	UART_IER_IRDA[1] THR_IT	1
Set the eight additional starts of frame transmission	UART_EBLR[7:0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

24.3.6 UART/IrDA/CIR Register Manual

24.3.6.1 UART/IrDA/CIR Instance Summary

Table 24-138. UART/IrDA/CIR Instance Summary

Module Name	Module Base Address	Size
UART1	0x4806 A000	136 Bytes
UART2	0x4806 C000	136 Bytes
UART3	0x4802 0000	136 Bytes
UART4	0x4806 E000	136 Bytes
UART5	0x4806 6000	136 Bytes
UART6	0x4806 8000	136 Bytes
UART7	0x4842 0000	136 Bytes
UART8	0x4842 2000	136 Bytes
UART9	0x4842 4000	136 Bytes
UART10	0x4AE2 B000	136 Bytes

24.3.6.2.2 UART/IrDA/CIR Register Description

Table 24-143. UART_THR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000 0x4806 E000 0x4806 6000 0x4806 8000 0x4842 0000 0x4842 2000 0x4842 4000 0x4AE2 B000	**Instance**	UART1 UART2 UART3 UART4 UART5 UART6 UART7 UART8 UART9 UART10
Description	The transmitter section consists of the transmit holding register (THR) and the transmit shift register. The THR is a 64-byte FIFO. The local host (LH) writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location 0 of the FIFO stores the data.		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								THR							

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write has no effect.	W	0x000000
7:0	THR	Transmit holding register	W	0x-

Table 24-144. UART_RHR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000 0x4806 E000 0x4806 6000 0x4806 8000 0x4842 0000 0x4842 2000 0x4842 4000 0x4AE2 B000	**Instance**	UART1 UART2 UART3 UART4 UART5 UART6 UART7 UART8 UART9 UART10
Description	The receiver section consists of the receiver holding register (RHR) and the receiver shift register. The RHR is a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location 0 of the FIFO stores the single data character. **Note:** If an overflow occurs, the data in the RHR is not overwritten.		
Type	R		

31–8	7–0
RESERVED	RHR

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0	R	0x000000
7:0	RHR	Receive holding register	R	0x-

Table 24-145. UART_DLL

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000 0x4806 E000 0x4806 6000 0x4806 8000 0x4842 0000 0x4842 2000 0x4842 4000 0x4AE2 B000	**Instance**	UART1 UART2 UART3 UART4 UART5 UART6 UART7 UART8 UART9 UART10
Description	This register, with UART_DLH, stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH stores the most-significant part of the divisor. DLL stores the least-significant part of the divisor.		
Type	RW		

31–8	7–0
RESERVED	CLOCK_LSB

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7:0	CLOCK_LSB	Stores the 8-bit LSB divisor value	RW	0x00

Description
There are 8 types of interrupt in these modes, received EOF, LSR interrupt, TX status, status FIFO interrupt, RX overrun, last byte in RX FIFO, THR interrupt and RHR interrupt and they can be enabled/disabled individually.
Note: The TX_STATUS_IT interrupt reflects two possible conditions. The UART_MDR2[0] should be read to determine the status in the event of this interrupt.

Physical Address	0x4806 A004 0x4806 C004 0x4802 0004 0x4806 E004 0x4806 6004 0x4806 8004 0x4842 0004 0x4842 2004 0x4842 4004 0x4AE2 B004	**Instance**	UART1 UART2 UART3 UART4 UART5 UART6 UART7 UART8 UART9 UART10
Description	There are 6 types of interrupt in these modes, TX status, status FIFO interrupt, RX overrun, last byte in RX FIFO, THR interrupt and RHR interrupt and they can be enabled/disabled individually. Notes: The RX_STOP_IT interrupt is generated based on the value set in the BOF Length register (UART_EBLR). In IR-CIR mode, contrary to the IR-IRDA mode, the TX_STATUS_IT has only one meaning corresponding to the case UART_MDR2[0] = 0.

RESERVED	THR_EMPTY	STS_FIFO_FULL	RX_LAST_BYTE	FRAME_TOO_LONG	ABORT	CRC	STS_FIFO_E	RX_FIFO_E

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0.	R	0x000000
7	THR_EMPTY	Read 0x0: Transmit holding register (TX FIFO) is not empty. Read 0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete.	R	1
6	STS_FIFO_FULL	Read 0x0: Status FIFO not full Read 0x1: Status FIFO full	R	0
5	RX_LAST_BYTE	Read 0x0: The RX FIFO (RHR) does not contain the last byte of the frame to be read.	R	0

Bits	Field Name	Description	Type	Reset
		Read 0x1: The RX FIFO (RHR) contains the last byte of the frame to be read. This bit is set only when the last byte of a frame is available to be read. It determines the frame boundary. It is cleared on a single read of the LSR register. See the note below.		
4	FRAME_TOO_LONG	Read 0x0: No frame-too-long error in frame Read 0x1: Frame-too-long error in the frame at the top of the STATUS FIFO, (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH and RXFLL registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected.	R	0
3	ABORT	Read 0x0: No abort pattern error in frame Read 0x1: Abort pattern is received. SIR and MIR: Abort pattern FIR: Illegal symbol	R	0
2	CRC	Read 0x0: No CRC error in frame Read 0x1: CRC error in the frame at the top of the STATUS FIFO (next character to be read)	R	0
1	STS_FIFO_E	Read 0x0: Status FIFO not empty Read 0x1: Status FIFO empty	R	1
0	RX_FIFO_E	Read 0x0: No data in the RX FIFO Read 0x1: At least one data character in the RX FIFO	R	1

Description	Transmission control register This register stores the RX FIFO threshold levels to start/stop transmission during hardware/software flow control. Notes: Trigger levels from 0 to 60 bytes are available with a granularity of 4. (Trigger level = 4 x [4-bit register value]) The programmer must ensure that UART_TCR[3:0] > UART_TCR[7:4] when auto-RTS or software flow control is enabled to avoid a mis-operation of the device. In FIFO interrupt mode with flow control, the programmer must ensure that the trigger level to halt transmission is greater than or equal to the RX FIFO trigger level (UART_TLR[7:4] or UART_FCR[7:6]); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because a DMA request is sent each time a byte is received.

Table 24-169. UART_MDR2 (continued)

Description	Mode definition register 2 IR-IrDA and IR-CIR modes only. UART_MDR2[0] describes the status of the interrupt in UART_IIR[5]. The IRTX_UNDERRUN bit should be read after an UART_IIR[5] TX_STATUS_IT interrupt. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in UART_MDR1[2:0]. **Note:** The UART_MDR2[6] gives the flexibility to invert the RX pin in the UART to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.
Type	RW

Physical Address	0x4806 A02C 0x4806 C02C 0x4802 002C 0x4806 E02C 0x4806 602C 0x4806 802C 0x4842 002C 0x4842 202C 0x4842 402C 0x4AE2 B02C	**Instance**	UART1 UART2 UART3 UART4 UART5 UART6 UART7 UART8 UART9 UART10
Description	Transmit frame length register high IrDA modes only. The UART_TXFLL and UART_TXFLH registers hold the 13-bit transmit frame length (expressed in bytes). UART_TXFLL holds the LSBs and UART_TXFLH holds the MSBs. The frame length value is used if the frame length method of frame closing is used.

Description	UART autobauding status register UART autobauding mode only. This status register returns the speed, the number of bits by characters, and the type of the parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. **Note:** When the UART is in autobauding mode, this register, instead of the UART_LCR, UART_DLL, and UART_DLH registers, is used to set up transmission according to the characteristics of the previous reception. To reset the autobauding hardware (to start a new AT detection), set UART_MDR1[2:0] to 111 (reset value), then set UART_MDR1[2:1] to 010 (UART in autobaud mode). To set the UART to standard mode (no autobaud), set UART_MDR1[2:1] to 000.

Description	Auxiliary control register. IR-IrDA and IR-CIR modes only.		
Type	RW		

31–8	7	6	5	4	3	2	1	0
RESERVED	PULSE_TYPE	SD_MOD	DIS_IR_RX	DIS_TX_UNDERRUN	SEND_SIP	SCTX_EN	ABORT_EN	EOT_EN

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	PULSE_TYPE	SIR pulse width select 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 μs	RW	0
6	SD_MOD	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low.	RW	0
5	DIS_IR_RX	0x0: Normal operation (RX input automatically disabled during transmit but enabled outside of transmit operation) 0x1: Disables RX input (permanent state - independent of transmit)	RW	0
4	DIS_TX_UNDERRUN	It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting UART_ACREG[4] = 1, garbage data is sent over TX line. 0x0: Long stop-bits cannot be transmitted; TX underrun is enabled. 0x1: Long stop-bits can be transmitted; TX underrun is disabled.	RW	0

Bits	Field Name	Description	Type	Reset
3	SEND_SIP	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is cleared automatically at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse.	RW	0
2	SCTX_EN	Store and controlled TX start. When UART_MDR1[5] = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.	RW	0
1	ABORT_EN	Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame. If TX FIFO is not empty and UART_MDR1[5] = 1, UART IrDA starts a new transfer with data of the previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.	RW	0
0	EOT_EN	EOT (end of transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in set-EOT bit frame closing method. This bit is cleared automatically when the LH writes to the THR (TX FIFO).	RW	0

	0x4842 4048		UART9
	0x4AE2 B048		UART10
Description	BOF length register IR-IrDA and IR-CIR modes only. In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must account for the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. The value 0 sends 1 BOF plus 255 XBOF. In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags). In IR-CIR mode, this register specifies the number of consecutive 0s to be received before generating the RX_STOP interrupt (UART_IIR[2]). All received 0s are stored in the RX FIFO. When the register is set to 0, this feature is deactivated and always in reception state, which can be disabled by setting the UART_ACREG[5] to 1. **Note:** If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with 0s and passed into the RX FIFO.

Description	Wake-up enable register The UART wake-up enable register is used to mask and unmask a UART event that would subsequently notify the system. An event is any activity in the logic that could cause an interrupt and/or an activity that would require the system to wake up. Even if the wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART registers the interrupt.

Description	Carrier frequency prescaler Because the consumer IR works at modulation rates of 30 to 56.8 kHz, the 48-MHz clock must be prescaled before the clock can drive the IR logic. This register sets the divisor rate to give a range to accommodate the remote-control requirements in baud multiples of 12x. The value of the CFPS at reset is 0105 decimal, which equals 38.1 kHz output from starting conditions. The 48-MHz carrier is prescaled by the CFPS, which is then divided by the 12x baud multiple.

24.4 Multichannel Serial Peripheral Interface

This section describes the four Multichannel Serial Peripheral Interface (McSPI) modules for the device.

24.4.1 McSPI Overview

The SPI is a master/slave synchronous serial bus. There are four separate McSPI modules (McSPI1, McSPI2, McSPI3, and McSPI4) in the device (see Figure 24-72). All these four modules support up to four external devices (four chip selects) and are able to work as both master and slave.

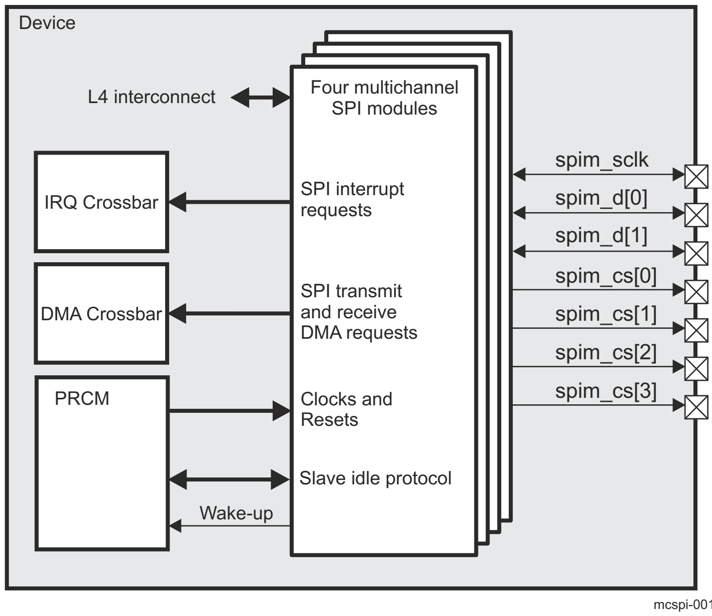

Figure 24-72. Multichannel SPI Modules

The McSPI modules include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Master multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes
  - Flexible input/output (I/O) port controls per channel
  - Programmable clock granularity
  - SPI configuration per channel. This means, clock definition, polarity enabling and word width
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel

24.4.2 McSPI Environment

24.4.2.1 Basic McSPI Pins for Master Mode

Figure 24-73 shows all of the McSPI interface signals in master mode.

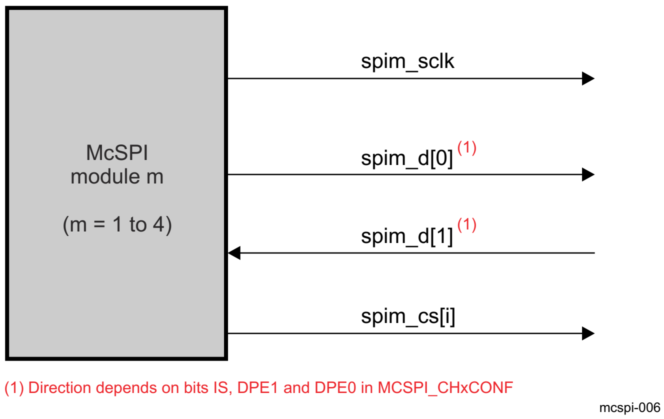

Figure 24-73. McSPI Interface Signals in Master Mode

Table 24-196 describes the McSPI I/O in master mode.

Table 24-196. McSPI I/O Description (Master Mode)

Device-Level Signal Name	Module Signal Name	I/O[1]	Description
spim_sclk	SPICLK	O	SPIm module serial clock output
spim_d[0]	SPIDAT[0]	O[2]	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[16] DPE0.
spim_d[1]	SPIDAT[1]	I[2]	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[17] DPE1.
spim_cs[i]	SPIEN[x]	O	SPIm module chip-select i output

(1) I = Input; O = Output
(2) Example configuration only.

Note

For the spim_sclk signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

24.4.2.2 Basic McSPI Pins for Slave Mode

Figure 24-74 shows all of the McSPI interface signals in slave mode.

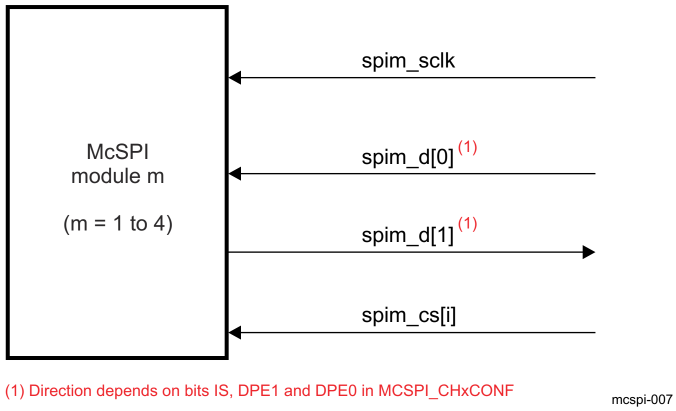

Figure 24-74. McSPI Interface Signals in Slave Mode

Table 24-197 describes the McSPI I/O in slave mode.

Table 24-197. McSPI I/O Description (Slave Mode)

Device-Level Signal Name	Module Signal Name	I/O[1]	Description
spim_sclk	SPICLK	I	McSPIm module serial clock input
spim_d[0]	SPIDAT[0]	I[2]	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[16] DPE0.
spim_d[1]	SPIDAT[1]	O[2]	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_CHxCONF[18] IS and MCSPI_CHxCONF[17] DPE1.
spim_cs[i]	SPIEN[x]	I	McSPIm module chip-select i input. Can be selected through MCSPI_CH0CONF[22:21] SPIENSLV bit field

(1) I = Input; O = Output
(2) Example configuration only.

24.4.2.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (SPIEN[x]) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length

  McSPI supports any SPI word ranging from 4 bits to 32 bits long (the MCSPI_CHxCONF[11:7] WL bit field).

  SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- SPI enable (SPIEN[x], for channel x of instance m)

  The polarity of the SPI enable signals is programmable (the MCSPI_CHxCONF[6] EPOL bit). SPIEN[x] signals can be active high or low.

  Assertion of the SPIEN[x] signals is programmable and can be done manually or automatically. The manual assertion mode is available in single master mode only. SPIEN[x] can be kept active between words with the MCSPI_CHxCONF[20] FORCE bit.

  Two consecutive words for two different slave devices can go along with active SPIEN[x] signals with different polarity.
- Programmable start-bit

In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting the MCSPI_CHxCONF[23] SBE bit to 1. The MCSPI_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.

- Programmable SPI clock
  - Bit rate

    In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock managment [PRCM] module). Table 24-198 lists the SPICLK bit rates obtained for data transfer when programming the clock divider (the MCSPI_CHxCONF[5:2] CLKD bit field).

Table 24-198. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz[(1)]
2	24 MHz[(1)]
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz

(1) These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

  - Polarity and phase

    The polarity (the MCSPI_CHxCONF[1] POL bit) and the phase (the MCSPI_CHxCONF[0] PHA bit) of the SPI serial clock (SPICLK) are configurable to offer four combinations. Software selects the right combination, depending on the device. See Table 24-199 and Figure 24-75.

Table 24-199. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Description
0	0	Mode 0	SPICLK is inactive low and sampling occurs at the rising edge.
0	1	Mode 1	SPICLK is inactive low and sampling occurs at the falling edge.
1	0	Mode 2	SPICLK is inactive high and sampling occurs at the falling edge.
1	1	Mode 3	SPICLK is inactive high and sampling occurs at the rising edge.

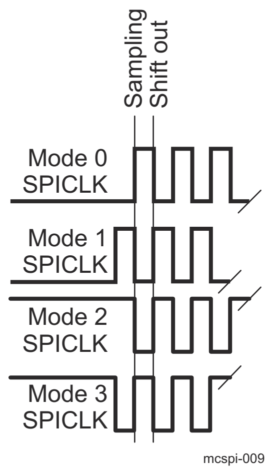

Figure 24-75. Phase and Polarity Combinations

24.4.2.3.1 Transfer Format

In master and slave modes, the McSPI drives the data lines when SPIEN[x] is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

  When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one-half cycle of SPICLK after the assertion of SPIEN.

  Therefore, the first edge of the SPICLK line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

  On the next SPICLK edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

  This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See Figure 24-76.

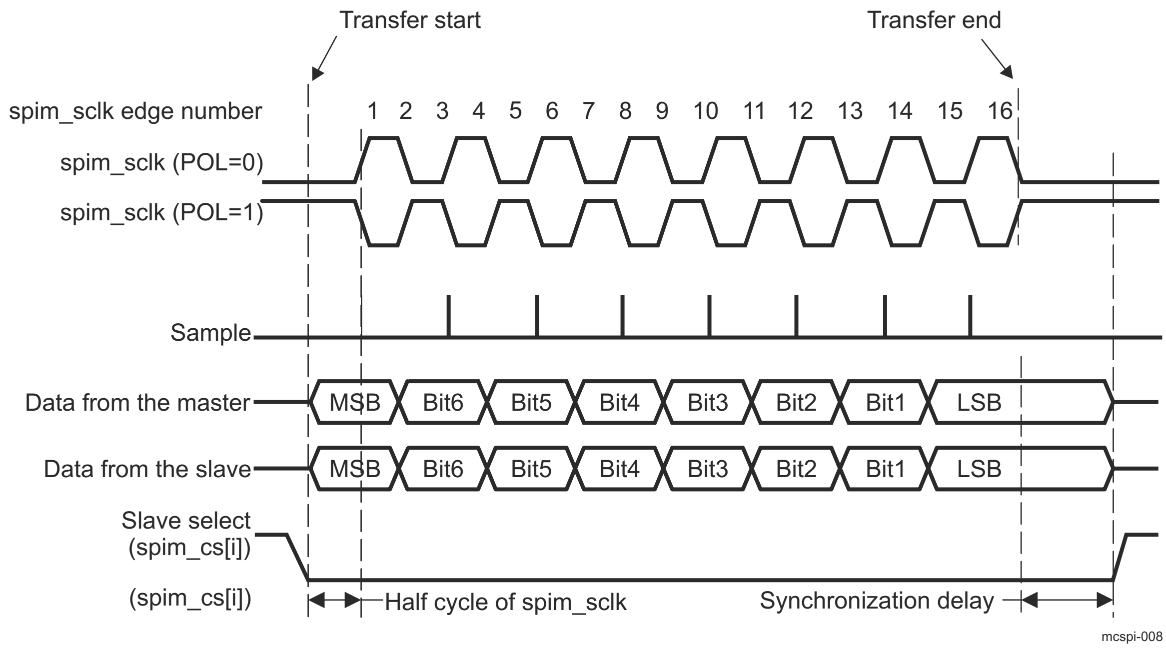

Figure 24-76. Full-Duplex Transfer Format With PHA = 0

- Transmission in mode 1 and mode 3 (PHA = 1)

  When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following SPICLK edge (one-half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the activation of SPIEN[x] and the first SPICLK edge.

  The received data bit is shifted into the shift register on the third SPICLK edge.

  This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

Note

The minimum synchronization delay is one cycle of SPICLK, if the frequency of SPICLK equals the frequency of SPIm_FCLK (McSPIm functional clock) in master mode. The minimum synchronization delay is one-half cycle of SPICLK, if the frequency of SPICLK is lower than the frequency of SPIm_FCLK in the master and slave modes.

- Transmission with a start-bit (SBE = 1)

  When the MCSPI_CHxCONF[23] SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

  Figure 24-77 shows an example of a data transfer with an extra start-bit.

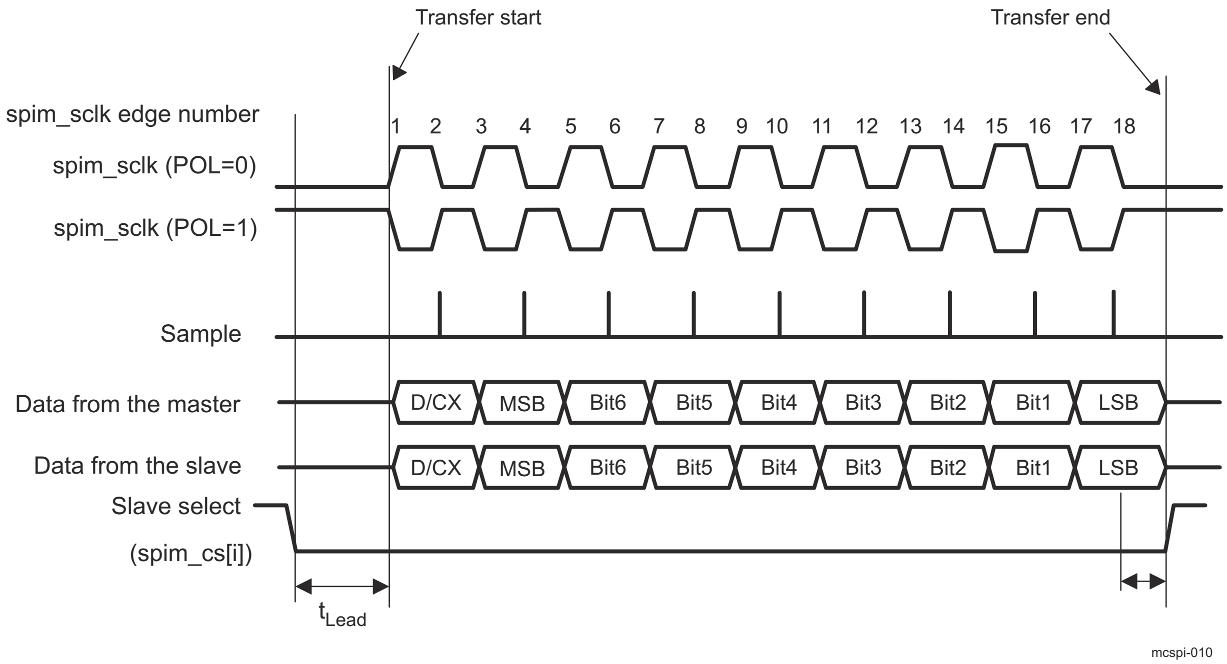

Figure 24-77. Extended SPI Transfer With a Start-Bit (SBE = 1)

24.4.2.4 SPI in Master Mode

Figure 24-78 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

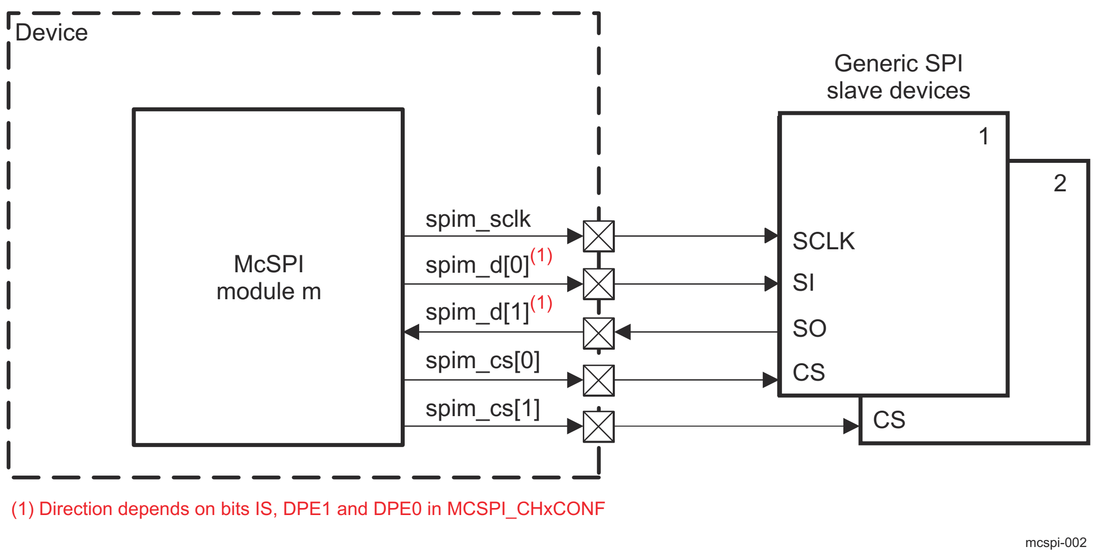

Figure 24-78. McSPI Master Mode (Full Duplex)

Figure 24-79 shows the master single mode, which can also be configured in receive-only mode.

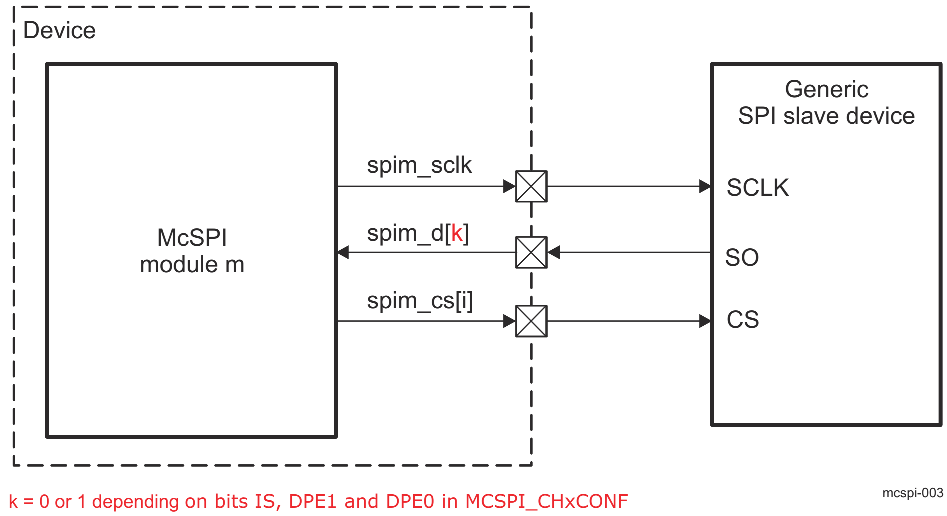

Figure 24-79. McSPI Master Single Mode (Receive Only)

24.4.2.5 SPI in Slave Mode

Figure 24-80 shows a case in slave mode (full-duplex).

Note

Only channel 0 can be configured as slave, but the chip-enable signal can be connected to any SPIEN[x] pin and then rerouted internally to channel 0 (the MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0]). For more information, see Section 24.4.4.4, *Slave Mode*.

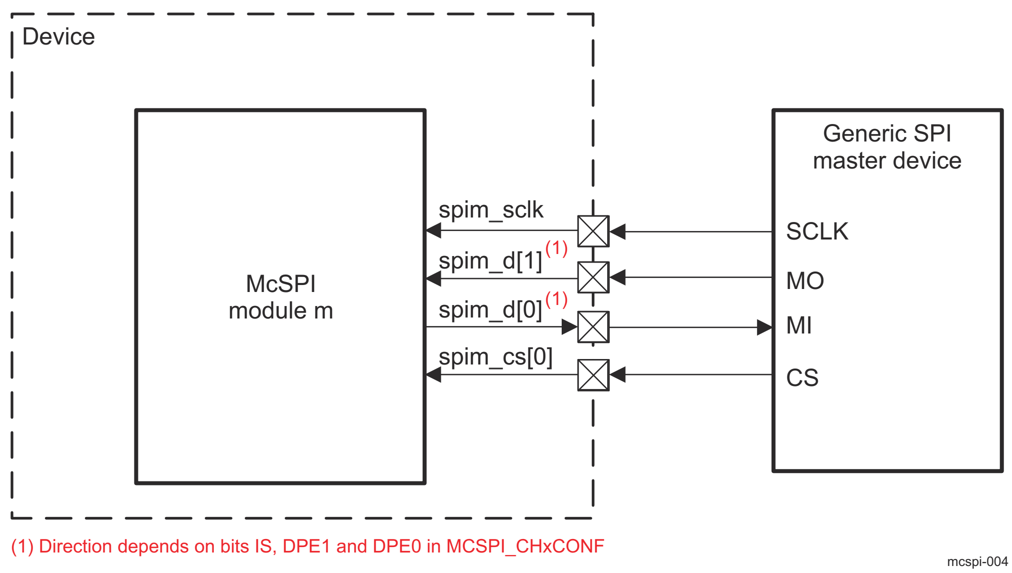

Figure 24-80. McSPI Slave Mode (Full Duplex)

Figure 24-81 shows the slave single mode, which can also be configured in transmit-only mode.

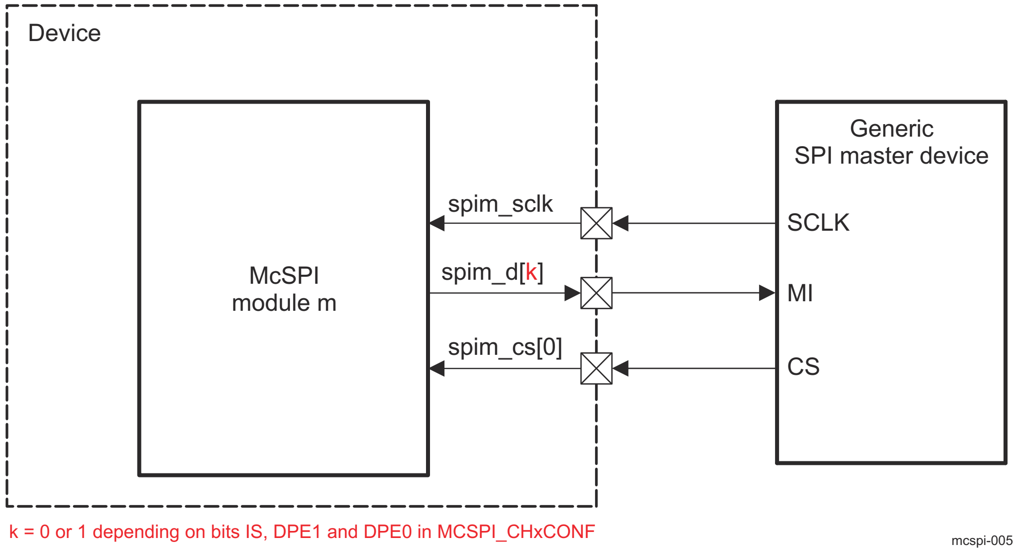

Figure 24-81. McSPI Slave Single Mode (Transmit Only)

24.4.3 McSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-82 shows McSPI integration.

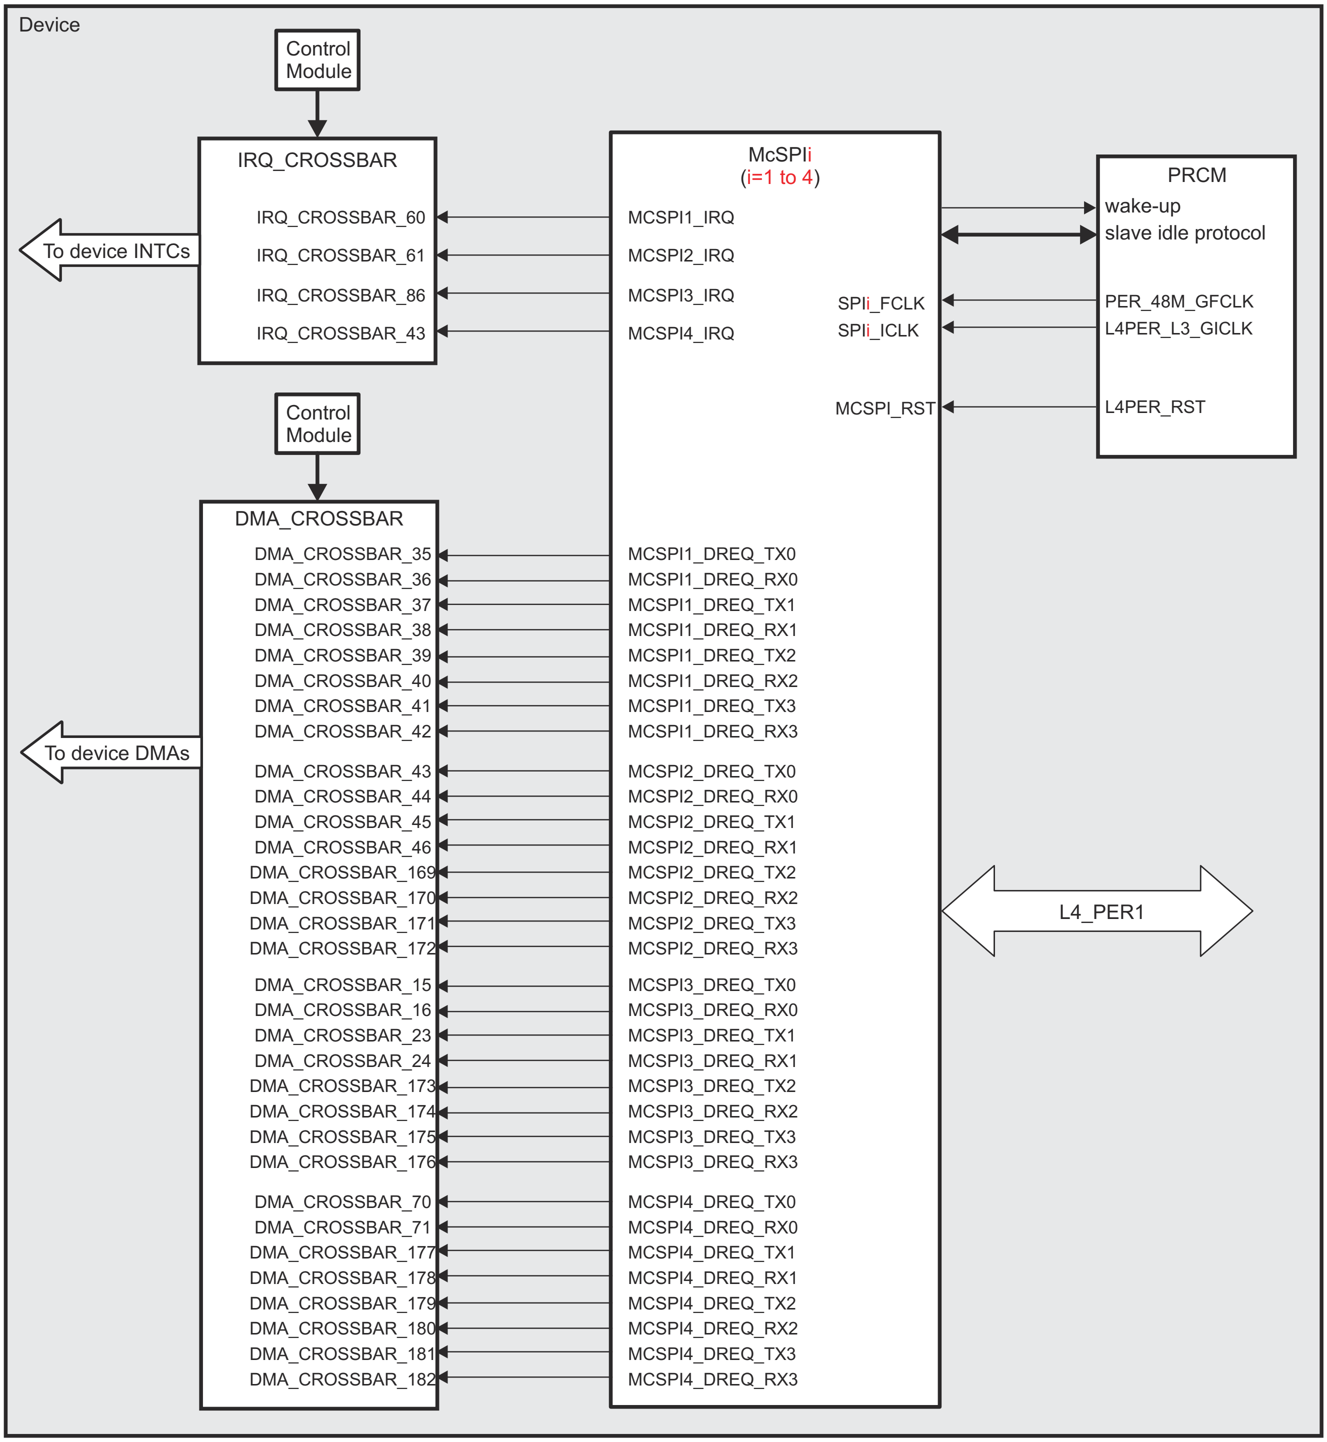

Figure 24-82. McSPI Integration

Table 24-200 through Table 24-202 summarize the integration of the module in the device.

Note

The Default Mapping column in Table 24-202 *McSPI Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.

Note

For more information about the device interrupt controllers, see *Interrupt Controllers*.
For more information about the device DMA_SYSTEM module, see *System DMA*.
For more information about the device EDMA module, see *Enhanced DMA*.

24.4.4 McSPI Functional Description

24.4.4.1 McSPI Block Diagram

Figure 24-83 shows the McSPI module.

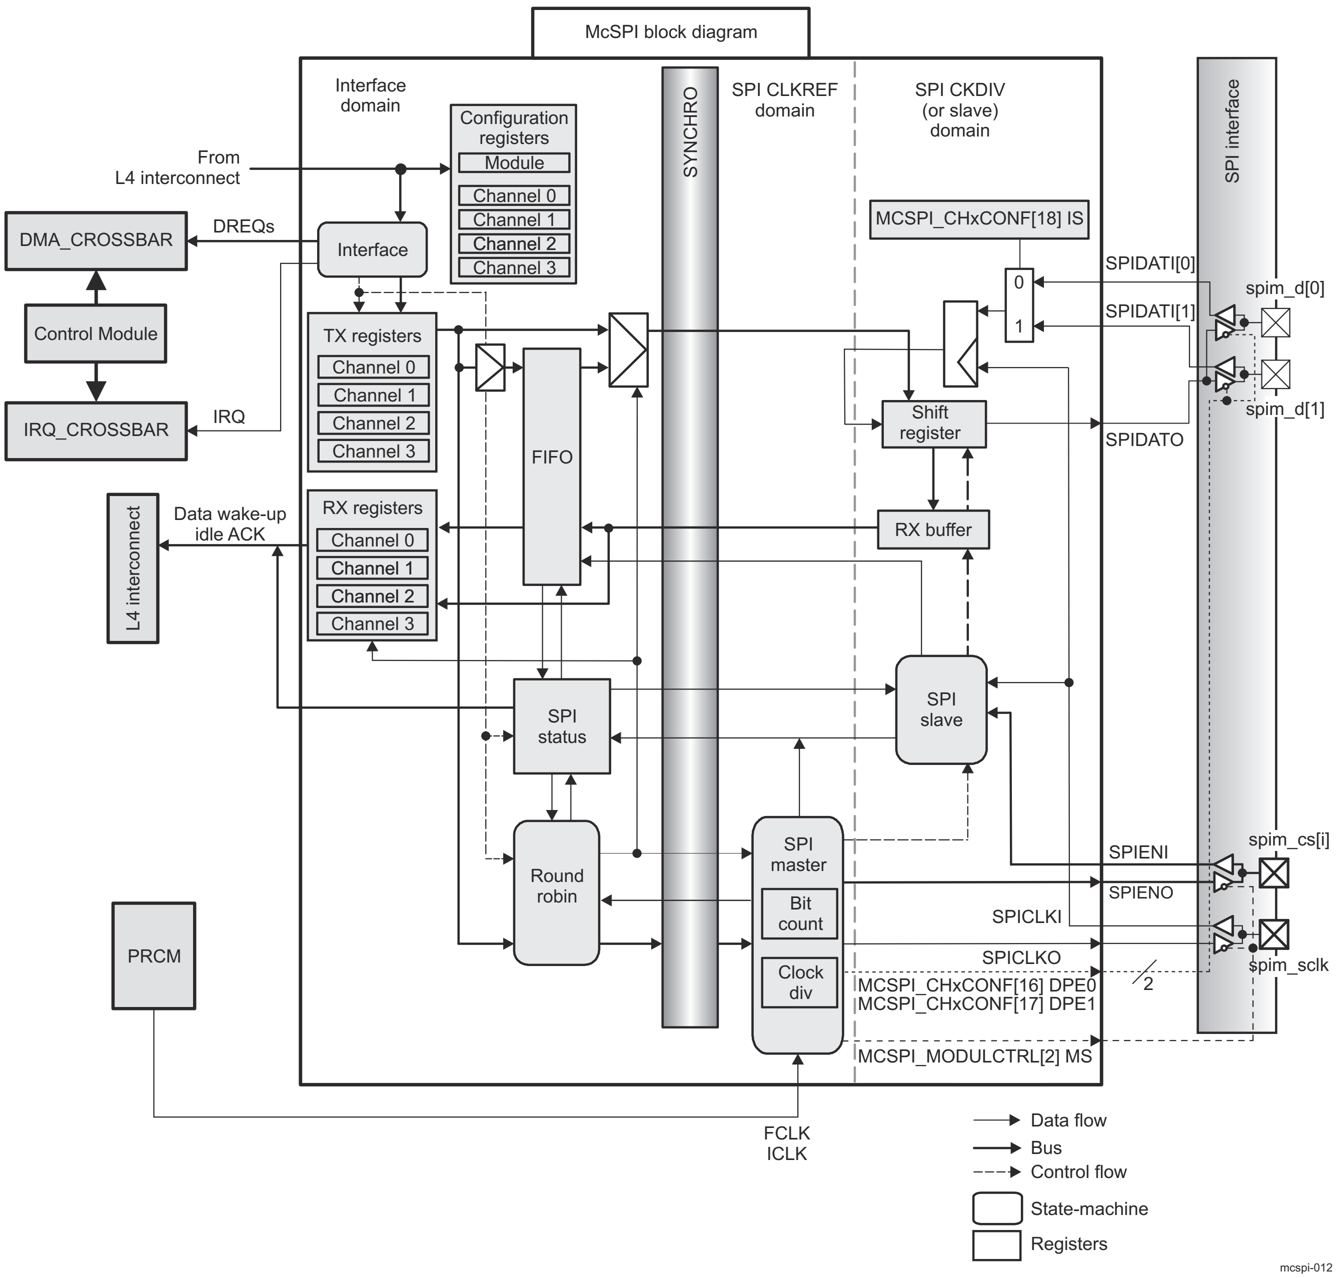

Figure 24-83. McSPI Block Diagram

24.4.4.2 Reset

The McSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPI_RST). McSPI can be reset by software through the MCSPI_SYSCONFIG[1] SOFTRESET bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the MCSPI_SYSCONFIG register is not affected by that software reset.

24.4.4.3 Master Mode

24.4.4.3.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN) signals.

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Note

There is a fixed chip select line allocation in multichannel master mode. Channel x SPIEN[x] is mapped to spim_cs[i] pin.

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information about interrupts, see Section 24.4.4.7.1, *Interrupt Events in Master Mode*).

24.4.4.3.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the MCSPI_CHxCONF[13:12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPI_TXx transmitter register state, the MCSPI_RXx receiver register state, and round-robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- **Rule 1:** Only enabled channels (the MCSPI_CHxCTRL[0] EN bit) can be scheduled for transmission and/or reception.
- **Rule 2:** If its MCSPI_TXx transmitter register is not empty (the MCSPI_CHxSTAT[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI_TXx register is empty when the shift register is assigned, the TXx_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- **Rule 3:** An enabled channel can be scheduled if its receive register is not full (the MCSPI_CHxSTAT[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPI_RXx register cannot be overwritten. The SPI1.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set to this mode.

When SPI word transfer completes (the MCSPI_CHxSTAT[2] EOT bit is set), the updated MCSPI_TXx register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

Figure 24-84 shows an example of a full-duplex system with a master device (McSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

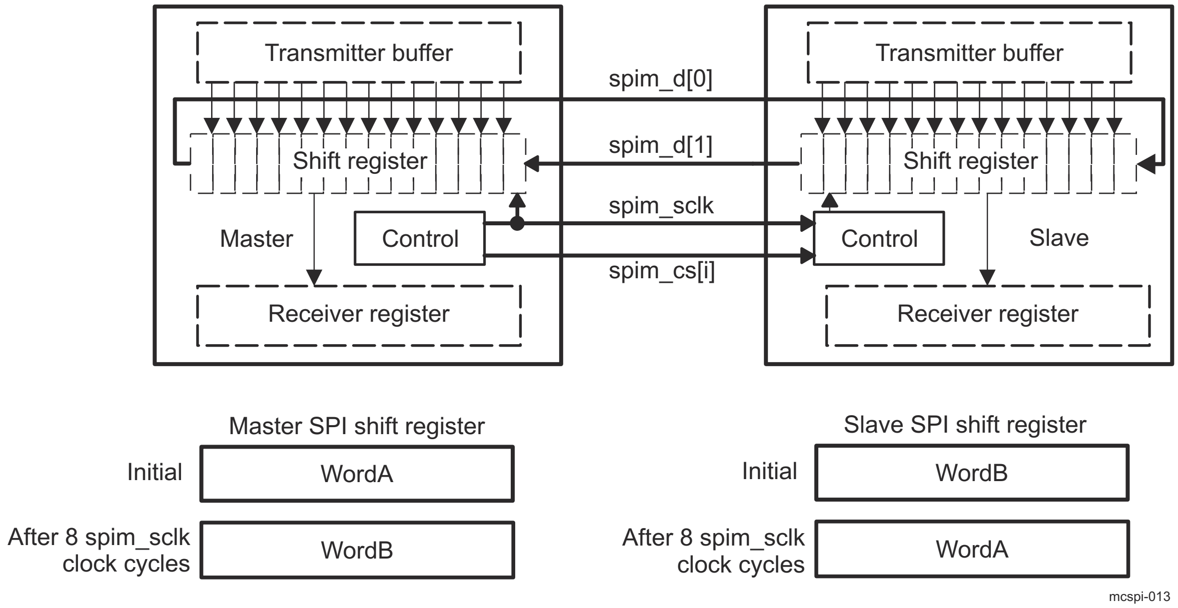

Figure 24-84. SPI Full-Duplex Transmission (Example)

24.4.4.3.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the microprocessor unit (MPU) from reading the MCSPI_RXx register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the MCSPI_CHxCONF[13:12] TRM bit field). Transmission starts only after data is loaded into the MCSPI_TXx register.

Rule 1 and Rule 2, defined in Section 24.4.4.3.2, apply in this mode.

Rule 3, defined in Section 24.4.4.3.2, does not apply.

In master transmit-only mode, the MCSPI_RXx register state FULL does not prevent transmission and the MCSPI_RXx register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the RX0_OVERFLOW bit in the MCSPI_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX_FULL interrupt and the DMA read requests.

The transfer status is given by the MCSPI_CHxSTAT[2] EOT bit.

24.4.4.3.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the MCSPI_TXx register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the MCSPI_CHxCONF[13:12] TRM bit field).

The master receive-only mode enables channel scheduling only on the empty state of the MCSPI_RXx register.

Rule 1 and Rule 3, defined in Section 24.4.4.3.2, apply in this mode.

Rule 2, defined in Section 24.4.4.3.2, does not apply.

In the master receive-only mode, software must write dummy data to the MCSPI_TXx register. Only one dummy write is enough to receive any number of words from the slave. Software must ensure that the MCSPI_TXx register is always full (the TXx_EMPTY bits of MCSPI_IRQSTATUS) when receiving. The content of the MCSPI_TXx register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the MCSPI_TXx register, the TXx_EMPTY and TXx_UNDERFLOW bits in the MCSPI_IRQSTATUS register are never set in receive-only mode.

The MCSPI_CHxSTAT[2] EOT bit gives the status of serialization. The RXx_FULL bits of the MCSPI_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI_RXx register. The MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

24.4.4.3.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel (MCSPI_MODULCTRL[2] MS = 0 and MCSPI_MODULCTRL[0] SINGLE = 1), the assertion of the SPIEN[x] signal is optional depending on device connected to the controller. In 3-pin mode (MCSPI_MODULCTRL[1] PIN34 = 1) the controller starts transmitting data when a write to the MCSPI_TXx register or the FIFO is performed. In 4-pin mode (MCSPI_MODULCTRL[1] PIN34 = 0) the assertion and de-assertion of SPIEN[x] is controlled by software using the MCSPI_CHxCONF[20] FORCE bit.

24.4.4.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the SPI word transfer to complete (wait until the MCSPI_CHxSTAT[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

24.4.4.3.5.2 Force SPIEN[x] Mode

Continuous transfers are allowed manually by keeping the SPIEN[x] signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIEN[x] line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIEN[x] active mode is supported when:

- A single channel is used (with the MCSPI_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (MCSPI_CHxCONF).

  The state of the SPIEN[x] signal is programmable:
  - Writing 1 to the MCSPI_CHxCONF[20] FORCE bit drives the SPIEN[x] line high when the MCSPI_CHxCONF[6] EPOL bit is set to 0. SPIEN[x] is driven low when the MCSPI_CHxCONF[6] EPOL bit is set to 1.
  - Writing 0 to the MCSPI_CHxCONF[20] FORCE bit drives the SPIEN[x] line low when the MCSPI_CHxCONF[6] EPOL bit is set to 0. SPIEN[x] is driven high when the MCSPI_CHxCONF[6] EPOL bit is set to 1.
- A single channel is enabled (the MCSPI_CHxCTRL[0] EN bit is set to 1). The first enabled channel activates the SPIEN[x] line.

When the channel is enabled, the SPIEN[x] signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the MCSPI_TXx register (the MCSPI_CHxSTAT[1] TXS bit), the status of the MCSPI_RXx register (the MCSPI_CHxSTAT[1] RXS bit), and the defined mode (the MCSPI_CHxCONF[13:12] TRM bit field) of the channel enabled.

The MCSPI_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RXx_FULL bit in the MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RXx register.

A change in the configuration parameters is propagated directly on the SPI interface. If the SPIEN[x] signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

Note

To avoid data corruption, SPIEN polarity and SPICLK phase and SPICLK polarity must not be modified when the SPIEN[x] signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the MCSPI_CHxCTRL[0] EN bit set to 0) and SPIEN[x] can be forced to its INACTIVE state using the MCSPI_CHxCONF[20] FORCE bit.

Figure 24-85 and Figure 24-86 show successive transfers with SPIEN[x] maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

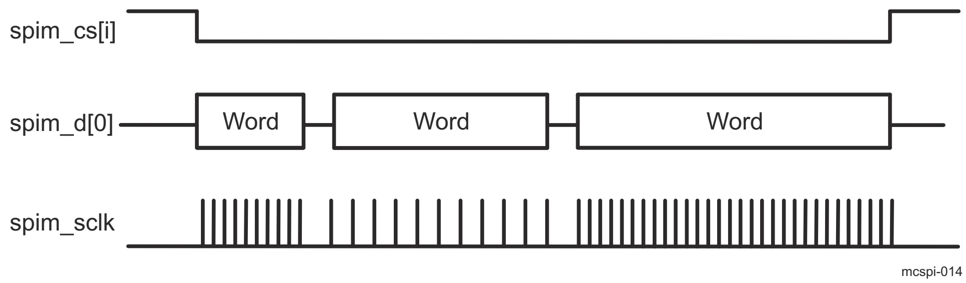

Figure 24-85. Continuous Transfers With SPIEN[x] Maintained Active (Single-Data-Pin Interface Mode)

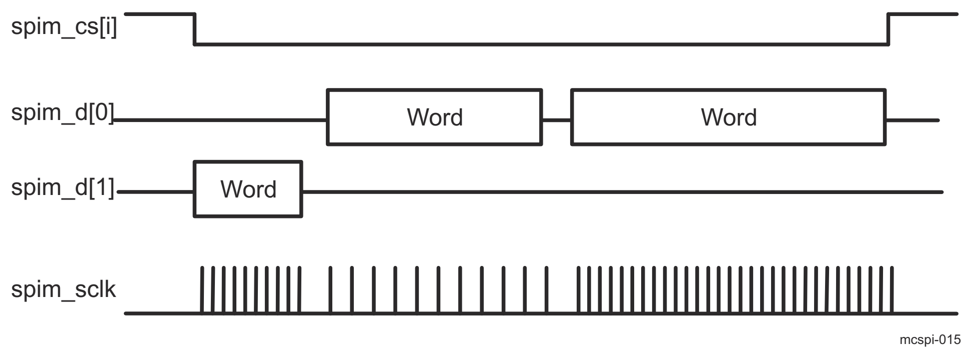

Figure 24-86. Continuous Transfers With SPIEN[x] Maintained Active (Dual-Data-Pin Interface Mode)

Note

The SPIEN[x] signal can be maintained active via software using the MCSPI_CHxCONF[20] FORCE bit only when the MCSPI_MODULCTRL[0] SINGLE bit is set to 0x1.

24.4.4.3.5.3 Turbo Mode

Turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI_RXx register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the SPI1.MCSPI_CHxCONF[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 24.4.4.3.2, *Master Transmit-and-Receive Mode (Full Duplex)*). An enabled channel can be scheduled if its receive register is full (the MCSPI_CHxSTAT[0] RXS bit) when the shift-register is assigned until the shift register is full.

The MCSPI_RXx register cannot be overwritten in turbo mode. Consequently, the MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

24.4.4.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the SPI word to indicate whether the next SPI word must be handled as a command or as data. This feature is available only in master mode. Start-bit mode cannot be used at the same time as turbo mode and/or force SPIEN[x] mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the MCSPI_CHxCONF[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the MCSPI_CHxCONF[24] SBPOL bit is set to 0, the SPI word must be handled as a command. When the MCSPI_CHxCONF[24] SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the MCSPI_CHxCONF[24] SBPOL bit before writing the SPI word to be transmitted to the TX register.

24.4.4.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in master mode with automatic CS generation (the MCSPI_MODULCTRL[0] SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when MCSPI_MODULCTRL[1] PIN34 set to 0.

This mode is programmable per channel through the MCSPI_CHxCONF[26:25] TCS0 bit field.

Figure 24-87 shows the CS SPIEN timing controls.

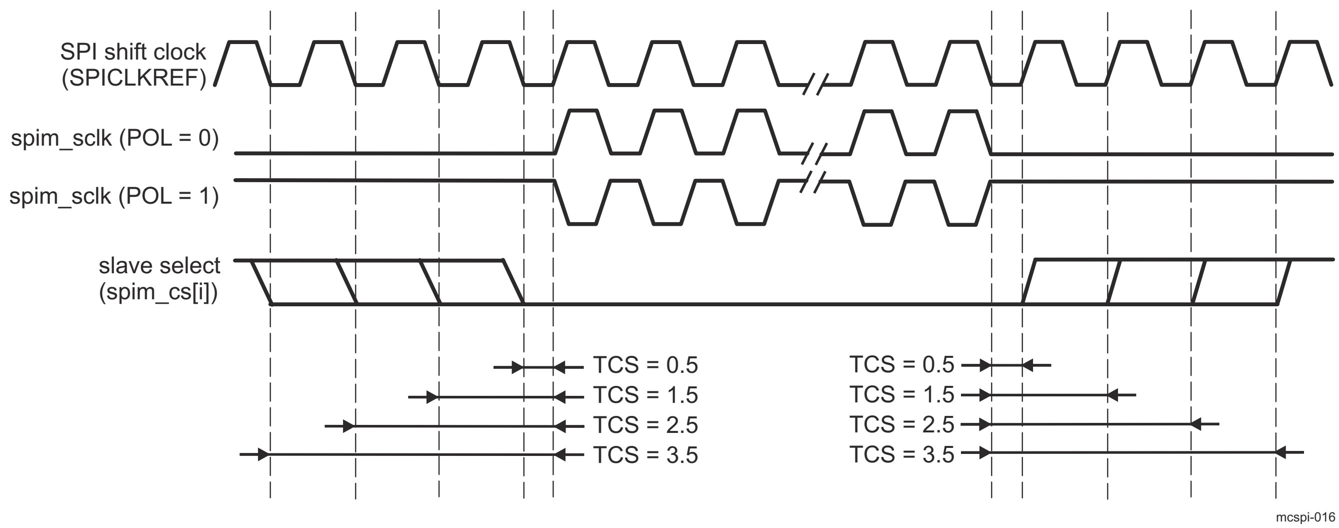

Figure 24-87. CS (SPIEN) Timing Controls

Note

Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

24.4.4.3.8 Programmable SPI Clock

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the MCSPI_CHxCONF[5:2] CLKD bit field) to generate the bit rate of the serial output clock SPICLK. Table 24-203 summarizes the supported divisor values.

Table 24-203. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz[(1)]
2	24 MHz[(1)]

Table 24-203. SPI Master Clock Rates (continued)

Divider	Clock Rate
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192 and higher: Division not supported	–

(1) These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

24.4.4.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the MCSPI_CHxCONF[5:2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the MCSPI_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the MCSPI_CHxCTRL[15:8] EXTCLK bit field is concatenated with the MCSPI_CHxCONF[5:2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the MCSPI_CHxCONF[1] POL and MCSPI_CHxCONF[0] PHA bits (see Table 24-204).

Table 24-204. CLKSPIO High/Low Time Computation

Clock Ratio F_{RATIO}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{HIGH_REF}	T_{LOW_REF}
Even ≥ 2	T_ref × (F_{RATIO}/2)	T_ref × (F_{RATIO}/2)
Odd ≥ (POL = PHA)	T_ref × (F_{RATIO}– 1)/2	T_ref × (F_{RATIO} + 1)/2
Odd ≥ (POL ≠ PHA)	T_ref × (F_{RATIO}+ 1)/2	T_ref × (F_{RATIO} – 1)/2

Note

F_{RATIO} = SPICLK frequency (F_{OUT}) division ratio
T_{HIGH} = SPICLK high time period
T_{LOW} = SPICLK low time period
T_ref = FCLK period
T_{HIGH_REF} = FCLK high time period
T_{LOW_REF} = FCLK low time period

If the CLKG bit is set to 1; F_{RATIO} = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

Duty_cycle = (1 – 1/F_{RATIO})/2

Table 24-205 shows examples of clock granularity with a clock source frequency of 48 MHz.

Table 24-205. Clock Granularity Examples

EXTCLK	CLKD	CLKG	F_{RATIO}	PHA	POL	T_{HIGH} (ns)	T_{LOW} (ns)	T_{PERIOD} (ns)	Duty Cycle	F_{OUT} (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50–50	48
X	1	0	2	X	X	20.8	20.8	41.6	50–50	24
X	2	0	4	X	X	41.6	41.6	83.2	50–50	12
X	3	0	8	X	X	83.2	83.2	166.4	50–50	6
0	0	1	1	X	X	10.4	10.4	20.8	50–50	48
0	1	1	2	X	X	20.8	20.8	41.6	50–50	24
0	2	1	3	1	0	41.6	20.8	62.4	66–33	16
0	2	1	3	1	1	20.8	41.6	62.4	33–66	16
0	3	1	4	X	X	41.6	41.6	83.2	50–50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6–49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50–50	0.545

24.4.4.4 Slave Mode

To select the McSPI slave mode, set the MCSPI_MODULCTRL[2] MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN[x]) and receives an SPI clock (SPICLK) from the external SPI master device. Only channel 0 can be configured as a slave but through the MCSPI_CH0CONF[22:21] SPIENSLV bit field any of the SPIEN[x] signals can be used to select the McSPI module. In slave mode and when the MCSPI_MODULCTRL[1] PIN34 is set to 0x0 (default behavior), the McSPI uses the edge of SPIEN[x] to detect word length. For this reason, SPIEN[x] must become inactive between each word.

When the MCSPI_MODULCTRL[1] PIN34 is set to 0x0, the McSPI does not support SPIEN[x] active between SPI words. In this case, the McSPI uses the edge to detect word length.

When the MCSPI_MODULCTRL[1] PIN34 is set to 0x1, a multiword transfer can be performed without needing the external SPI master to deactivate SPIEN[x] between each word as in this case the McSPI module works in 3-pin slave mode and SPIEN[x] is not needed.

24.4.4.4.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section, register names such as SPI1.MCSPI_CHxCTRL stand for SPI1.MCSPI_CH0CTRL, where x = 0 (channel 0 control register).

Figure 24-88 shows an example of four slaves wired on a single master device.

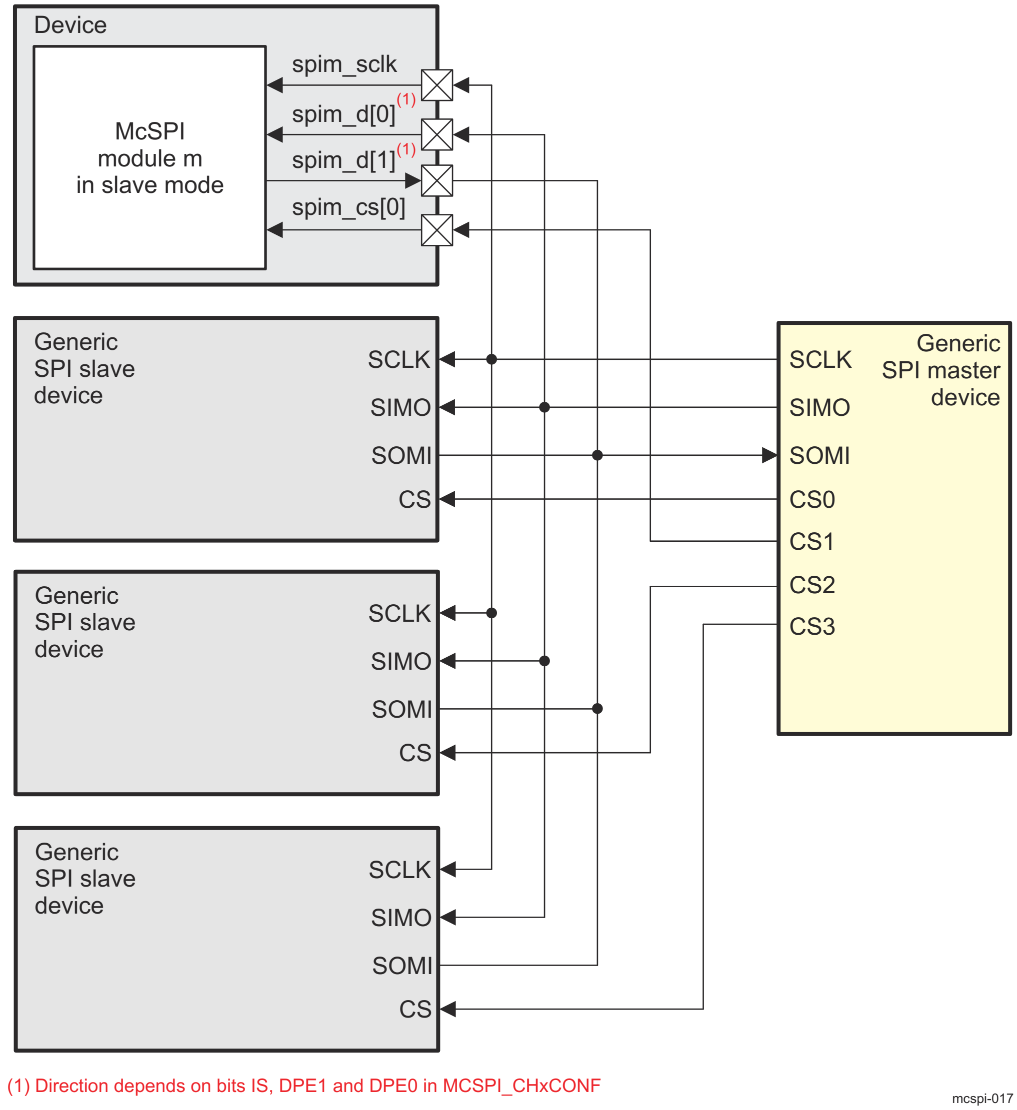

Figure 24-88. Example of McSPI Slave With One Master and Multiple Slave Devices on Channel 0

Channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the MCSPI_CHxCTRL[0] EN bit (where x = 0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any of the SPIEN[x] ports. This is programmable with the MCSPI_CHxCONF[22:21] SPIENSLV bit field (where x = 0).
- Its own transmitter register, MCSPI_TXx (where x = 0), on top of the common transmit shift register. If the MCSPI_TXx register is empty, the MCSPI_CHxSTAT[1] TXS bit (where x = 0) is set. If McSPI is selected by an external master (the active signal on the SPIEN[x] port assigned to channel 0), the MCSPI_TXx register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI_TXx register must be loaded before McSPI is selected by a master.
- Its own receiver register, MCSPI_RXx (where x = 0), on top of the common receive shift register. If the MCSPI_RXx register is full, the MCSPI_CHxSTAT[0] RXS bit (where x = 0) is set.

Note

The MCSPI_TXx and MCSPI_RXx registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the MCSPI_CHxCONF register (where x = 0):
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
  - SPI word length, programmable with the WL bits
  - SPIEN[x] polarity, programmable with the EPOL bit
  - SPICLK polarity, programmable with the POL bit
  - SPICLK phase, programmable with the PHA bit

  The SPICLK frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The MCSPI_CHxCONF[5:2] CLKD bit field (where x = 0) is not used in slave mode.

  Note

  The configuration of the channel can be loaded in the MCSPI_CHxCONF register (where x = 0) only when the channel is disabled.
- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the MCSPI_CHxCONF[15] DMAR bit (where x = 0) for reading and the MCSPI_CHxCONF[14] DMAW bit (where x = 0) for writing.
- Four interrupt events (see Section 24.4.4.7.2, *Interrupt Events in Slave Mode*)

24.4.4.4.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x0).

In slave transmit-and-receive mode, the MCSPI_TXx register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TXx register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When the SPI word transfer completes (the MCSPI_CHxSTAT0[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RXx register (see Section 24.4.4.7.2, *Interrupt Events in Slave Mode*).

24.4.4.4.3 Slave Transmit-Only Mode

The slave transmit-only mode is programmable (set the MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x2) and avoids the requirement for the MPU to read the MCSPI_RXx register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RXx register.

When the SPI word transfer completes, the MCSPI_CHxSTAT[2] EOT bit is set (where x = 0).

Figure 24-89 shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave, 1 bit transfers in the master. After eight cycles of the serial clock SPICLK, WordB transfers from the slave to the master.

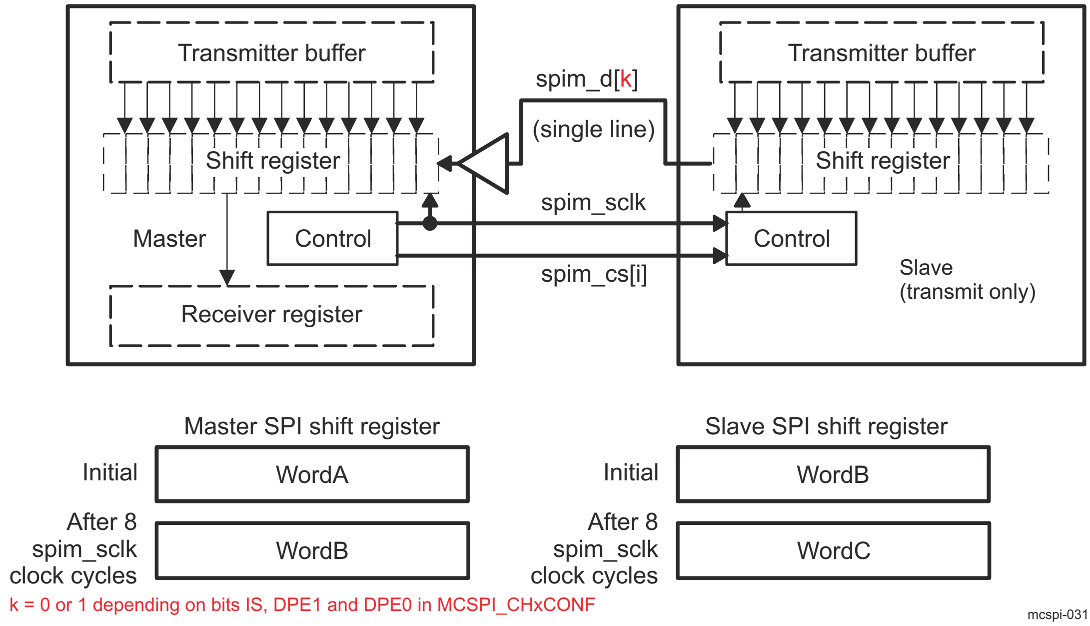

Figure 24-89. SPI Half-Duplex Transmission (Transmit-Only Slave)

24.4.4.4.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x1).

In receive-only mode, the MCSPI_TXx register must be loaded before the McSPI is selected by an external SPI master device. The MCSPI_TXx register content is always loaded into the shift register whether it is updated or not. The TXx_UNDERFLOW event is activated accordingly and does not prevent transmission.

When the SPI word transfer completes (the MCSPI_CHxSTAT0[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use the McSPI as a slave receive-only device, the TXx_EMPTY and TXx_UNDERFLOW interrupts and the DMA write requests must be disabled due to the state of the MCSPI_TXx register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 24-90 shows a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave.

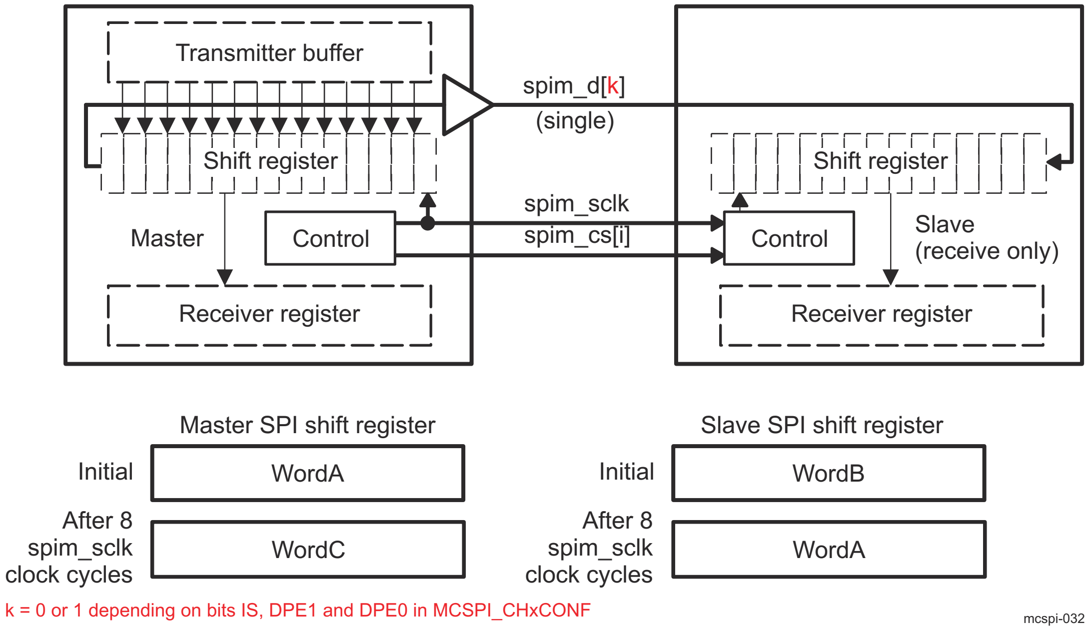

Figure 24-90. SPI Half-Duplex Transmission (Receive-Only Slave)

24.4.4.5 3-Pin or 4-Pin Mode

Depending on targeted application the SPI interface can be configured to use 3 or 4 pins through the MCSPI_MODULCTRL[1] PIN34 bit. If this bit is set to 0, McSPI is in 4-pin mode using the SPICLK, SPIDAT[0], SPIDAT[1] and SPIEN[x] signals. If PIN34 is set to 1 the controller is in 3-pin mode and SPIEN[x] is not used. In this mode all options related to chip select management are useless (EPOL, FORCE and TCS0 bits of MCSPI_CHxCONF). 3-pin and 4-pin operation applies to both master and slave modes.

24.4.4.6 FIFO Buffer Management

The McSPI controller has a built-in 128-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the MCSPI_CHxCONF[28] FFER or MCSPI_CHxCONF[27] FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Master or slave mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (MCSPI_CHxCONF[11:7] WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see Figure 24-91) or receive (see Figure 24-92) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see Figure 24-93).

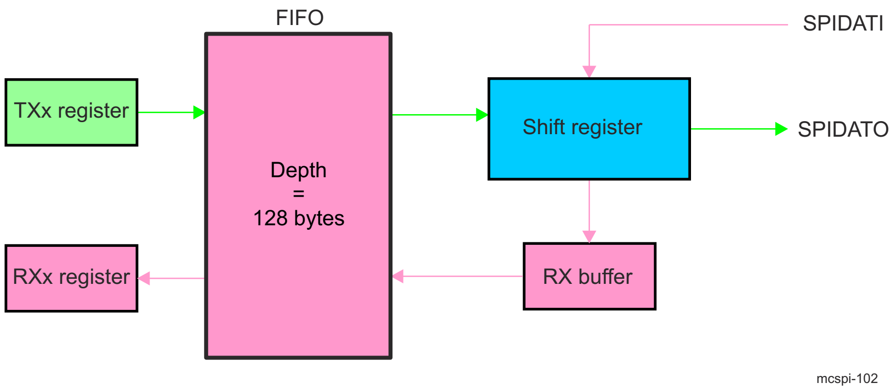

Figure 24-91. Buffer Used in Transmit Direction Only

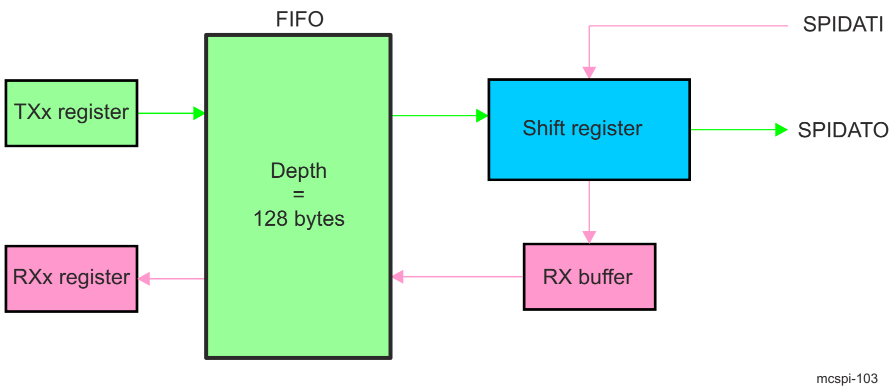

Figure 24-92. Buffer Used in Receive Direction Only

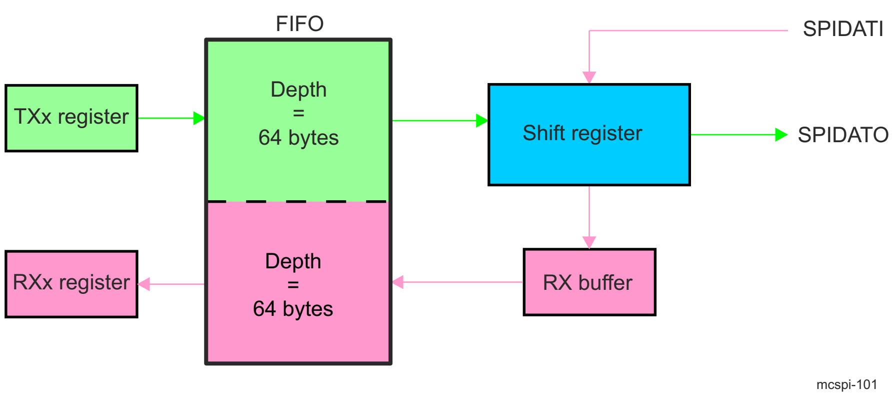

Figure 24-93. Buffer Used for Transmit and Receive Directions

Two levels (MCSPI_XFERLEVEL[5:0] AEL and MCSPI_XFERLEVEL[13:8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the SPI word length. The driver must set these values as a multiple of the SPI word length defined in MCSPI_CHxCONF[11:7] WL. Table 24-206 lists the number of bytes written in the FIFO, depending on the word length.

Table 24-206. FIFO Writes, Word Length Relationship

	SPI Word Length (WL)		
	3 ≤ WL≤ 7	8 ≤ WL ≤ 15	16 ≤ WL ≤ 31
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

24.4.4.6.1 Buffer Almost Full

The MCSPI_XFERLEVEL[15:8] AFL bit field is needed when the buffer is used to receive an SPI word from a slave (the MCSPI_CHxCONF[28] FFER bit must be set to 1). It defines the almost-full buffer status. See Figure 24-94.

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the MPU to enable the system to read AFL + 1 bytes from the receive register.

Note

AFL + 1 must correspond to a multiple value of the MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is deasserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

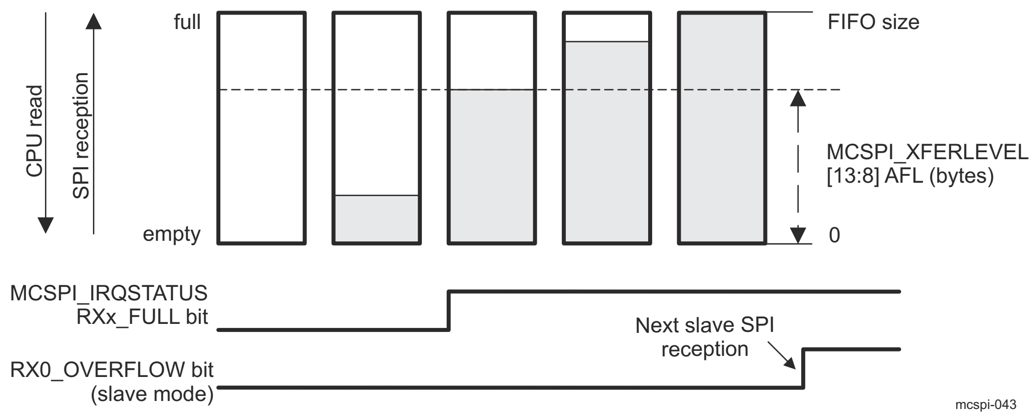

Figure 24-94. Buffer Almost Full Level (AFL)

Note

The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_RXx request is asserted on the same conditions as the MCSPI_IRQSTATUS RXx_FULL flag.

24.4.4.6.2 Buffer Almost Empty

The MCSPI_XFERLEVEL[7:0] AEL bit field is needed when the buffer is used to transmit an SPI word to a slave (the MCSPI_CHxCONF[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See Figure 24-95.

When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the MPU to enable the system to write AEL + 1 bytes to the transmit register.

Note

AEL + 1 must correspond to a multiple value of the MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is deasserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

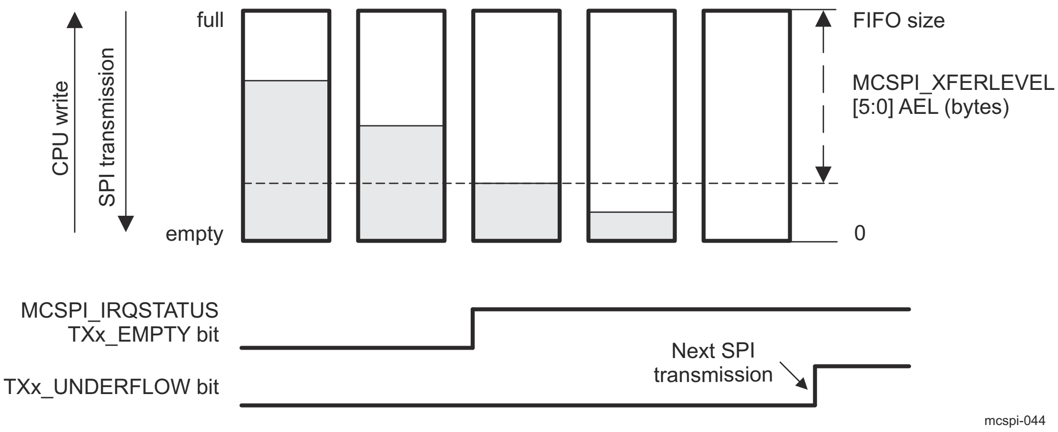

Figure 24-95. Buffer Almost Empty Level (AEL)

Note

The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_TXx request is asserted on the same conditions as the MCSPI_IRQSTATUS TXx_EMPTY flag.

24.4.4.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the MCSPI_XFERLEVEL[31:16] WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of SPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many SPI transfers have been done. For received words, software must poll the CHxSTAT[5] RXFFE bit and read the MCSPI_RXx receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the MCSPI_IRQSTATUS[17] EOW bit is set), the user can disable the channel and poll the MCSPI_CHxSTAT[5] RXFFE bit to know the last SPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

24.4.4.7 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the MCSPI_IRQSTATUS register (RXx_FULL, TXx_UNDERFLOW, TXx_EMPTY, etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the MCSPI_IRQENABLE register (RXx_FULL_ENABLE, TXx_UNDERFLOW_ENABLE, TXx_EMPTY_ENABLE, etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

24.4.4.7.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the state of the MCSPI_TXx register are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the state of the MCSPI_RXx register is RXx_FULL.

24.4.4.7.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see Section 24.4.4.3.4, *Master Receive-Only Mode*). When the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as the MPU has not performed the number of writes into the MCSPI_TXx register defined by the MCSPI_XFERLEVEL[5:0] AEL bit field. The MPU must perform the correct number of writes.

24.4.4.7.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPI_TXx register or the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TXx register, because the channel is enabled. To avoid having a TXx_UNDERFLOW event, the MCSPI_TXx register must seldom be loaded.

The MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.4.4.7.1.3 RXx_ FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_ FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI_XFERLEVEL[13:8] AFL threshold.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as the MPU has not performed AFL + 1 reads into MCSPI_RXx. The MPU must perform the correct number of reads.

24.4.4.7.1.4 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.4.4.7.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the state of the MCSPI_TXx register are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the state of the MCSPI_RXx are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI_IRQSTATUS register.

24.4.4.7.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as the MPU has not performed the number of writes into the MCSPI_TXx register defined by MCSPI_XFERLEVEL[5:0] AEL bit field. The MPU must perform the correct number of writes.

24.4.4.7.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the MCSPI_TXx register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TXx register because the channel is enabled.

The MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.4.4.7.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register is being filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the MCSPI_XFERLEVEL[13:8] AFL bit field.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as the MPU has not performed AFL + 1 reads into MCSPI_RXx. The MPU must perform the correct number of reads.

24.4.4.7.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the MCSPI_RXx register or FIFO is full when a new SPI word is received. The MCSPI_RXx register is always overwritten with the new SPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW event indicates an error (data loss) in slave mode.

The MCSPI_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.4.4.7.2.5 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.4.4.7.3 Interrupt-Driven Operation

An interrupt enable bit in the MCSPI_IRQENABLE register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must :

1. Read the MCSPI_IRQSTATUS register to identify which event occurred.
2. Read the MCSPI_RXx register that corresponds to the event to remove the source of an RXx_FULL event or write into the MCSPI_TXx register that corresponds to the event to remove the source of a TXx_EMPTY event. No action is required to remove the source of the WKS (wake-up), TXx_ UNDERFLOW, and RX0_OVERFLOW events.
3. Set the corresponding bit of the MCSPI_IRQSTATUS register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

24.4.4.7.4 Polling

When the interrupt capability of an event is disabled in the MCSPI_IRQENABLE register, the interrupt line is not asserted, but the status bits in the MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx_FULL: To remove the source of the event, the MPU must read the corresponding MCSPI_RXx register .
- TXx_EMPTY: To remove the source of the event, the MPU must write into the corresponding MCSPI_TXx register.
- WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the MCSPI_IRQSTATUS register to 1. This does not affect the interrupt line state.

24.4.4.8 DMA Requests

Each McSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the SPI1.MCSPI_CHxCONF[15] DMAR bit. The DMA read request line is deasserted when reading of the MCSPI_RXx register of the McSPI channel completes.

The DMA write request line is asserted when the McSPI channel is enabled and the MCSPI_TXx register of the McSPI channel is empty. A DMA write request can be individually masked with the SPI1.MCSPI_CHxCONF[14] DMAW bit. The DMA write request line is deasserted when loading of the MCSPI_TXx register of the channel completes.

24.4.4.9 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

24.4.4.9.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogated) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The MCSPI_SYSCONFIG[0] AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

24.4.4.9.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the PER_48M_GFCLK or L4PER_L3_GICLK output clock, the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM IDLE request is configurable through the MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgment modes are:

- Force-idle mode (the MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0): The McSPI module acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The McSPI never acknowledges an IDLE request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The McSPI acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the McSPI also offers an additional granularity on the PER_48M_GFCLK and L4PER_L3_GICLK gating. The MCSPI_SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the PER_48M_GFCLK, L4PER_L3_GICLK, neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the McSPI to determine on which part of the module the conditions to acknowledge the PRCM IDLE request are tested. For example, if PER_48M_GFCLK is not shut down on a PRCM IDLE request, the McSPI considers only L4PER_L3_GICLK and the associated pending activities before acknowledging the request.

Some McSPI features are associated with L4PER_L3_GICLK and others with PER_48M_GFCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the McSPI acknowledges an IDLE request.

The settings of the CLOCKACTIVITY bit field and the associated features are:

- CLOCKACTIVITY set to 00: ICLK off and FCLK off, ICLK and FCLK are considered for generating the acknowledge. This setting also means that FCLK and ICLK are likely to be shut down on a PRCM IDLE request.
- CLOCKACTIVITY set to 01: ICLK on and FCLK off, ICLK is not shut down on a PRCM IDLE request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK off and FCLK on, FCLK is not shut down on a PRCM IDLE request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK on and FCLK on, none of the clocks are shut down. This means the McSPI can potentially acknowledge the IDLE request without checking the internal functions linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, software must ensure consistent programming between CLOCKACTIVITY and the PER_48M_GFCLK and L4PER_L3_GICLK control bits in the PRCM module. If the McSPI is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

24.4.4.9.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when the MCSPI_SYSCONFIG[2] ENAWAKEUP and MCSPI_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch back the interface clock and the functional clock. A wakeup is requested when channel 0 is enabled and an asynchronous selection occurs on the mcspim.csx port associated with channel 0 (see the definition for the MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0] in the register table description).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- Before the beginning of the second SPI word serialization when the McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- Before the end of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the MCSPI_RXx register (where x = 0) before the completion of the second SPI word serialization.

Table 24-207 lists the supported cases in smart-idle mode.

Table 24-207. Smart-Idle Mode and Wake-Up Capabilities

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode	No wake-up event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the SPIEN[x] port associated with channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

24.4.4.9.2.2 Transitions From Smart-Idle Mode to Normal Mode

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the MCSPI_IRQSTATUS[16] WKS bit) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the MCSPI_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MCSPI_IRQENABLE and MCSPI_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register MCSPI_IRQSTATUS is updated with the event causing the wakeup; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

24.4.4.9.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.
  - In force-idle mode, the McSPI responds unconditionally to the IDLE request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if the MCSPI_SYSCONFIG[2] ENAWAKEUP and MCSPI_WAKEUPENABLE[0] WKEN bits are set.
  - The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI_IRQSTATUS register.
  - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.
  - An IDLE request during an SPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.
- The module exits force-idle mode through the idle and wake-up hardware handshake protocol.

  The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

24.4.5 McSPI Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the McSPI module.

24.4.5.1 Global Initialization

24.4.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McSPI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McSPI. For further information, see Section 24.4.3, *McSPI Integration* and Section 24.4.2, *McSPI Environment*.

Table 24-208 lists the information on the global initialization of the surrounding modules.

Table 24-208. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	MCSPI_FCLK functional clock must be enabled. See *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.
L4 Interconnect	For information about L4_PER1 interconnect configuration, see *L4 Interconnects*, in *Interconnect*.
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
Device DMAs	Device DMAs configuration must be done to enable the module DMA channel requests.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see *Interrupt Controllers*

24.4.5.1.2 McSPI Global Initialization

24.4.5.1.2.1 Main Sequence – McSPI Global Initialization

The procedure in Table 24-209 can be used to initialize McSPI when performing software reset.

Table 24-209. McSPI Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	MCSPI_SYSCONFIG[1] SOFTRESET	1
Wait until reset is finished?	MCSPI_SYSSTATUS[0] RESETDONE	=1
Configure static settings (such as SPI master or slave) as required.	MCSPI_MODULCTRL[8:0]	0x-
Write MCSPI_SYSCONFIG	MCSPI_SYSCONFIG	0x-

24.4.5.2 Operational Mode Configuration

24.4.5.2.1 McSPI Operational Modes

The selection of the working mode is done with the MCSPI_CHxCONF register.

Table 24-210. McSPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set receive mode for the channel.	MCSPI_CHxCONF[13:12] TRM	0x1
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHxCONF	0x-

Table 24-210. McSPI Receive Mode Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 24-211. McSPI Transmit Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit mode for the channel.	MCSPI_CHxCONF[13:12] TRM	0x2
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHxCONF	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 24-212. McSPI Transmit-and-Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode for the channel.	MCSPI_CHxCONF[13:12] TRM	0x0
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPI_CHxCONF	0x-
Reset the status bits.	MCSPI_IRQSTATUS	0x0

24.4.5.2.1.1 Common Transfer Sequence

McSPI module allows the transfer of one or several words, according to different modes:

- MASTER Normal, MASTER Turbo, SLAVE
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN[x] lines assertion/deassertion: automatic, manual

For all these sequences, the host process contains the main process and the interrupt routines.

The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

Table 24-213 represents the main sequence which is common to all transfers.

In multi-channel master mode, the sequences of different channels can be run simultaneously.

Table 24-213. Common Transfer Sequence (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	0x-
Write MCSPI_CHxCONF to configure the channel	MCSPI_CHxCONF	0x-
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait for the first write request (TX empty or DMA write)		
Write the transmitter register with data	MCSPI_TXx	0x-
Wait for the host event for end of transfer		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

24.4.5.2.1.2 End of Transfer Sequences

The end of transfer depends on the transfer mode. Table 24-214 summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 24-214. End of Transfer Sequences

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
MASTER Normal	End of transfer sequence	See Section 24.4.5.2.1.3		See Section 24.4.5.2.1.4.1	See Section 24.4.5.2.1.4.2	See Section 24.4.5.2.1.5.1	See Section 24.4.5.2.1.5.2
	Minimum number of word	1	1	1	1	1	2
	DMA transfer size		N		N		N-1
MASTER Turbo	End of transfer sequence	See Section 24.4.5.2.1.3		See Section 24.4.5.2.1.4.1	See Section 24.4.5.2.1.4.2	See Section 24.4.5.2.1.6.1	See Section 24.4.5.2.1.6.2
	Minimum number of word	1	1	1	1	2	3
	DMA transfer size		N		N		N-2
SLAVE	End of transfer sequence	See Section 24.4.5.2.1.3		See Section 24.4.5.2.1.4.1	See Section 24.4.5.2.1.4.2	See Section 24.4.5.2.1.7	
	Minimum number of word	1	1	1	1	1	1
	DMA transfer size		N		N	N	N

The transfer to execute has a size of N words.

The different sequences can be merged in one process to manage transfers of several types. The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write_count = 0
- read_count = 0
- channel_enable = FALSE
- last_transfer = FALSE
- last_request = FALSE

They are initialized before starting the channel.

24.4.5.2.1.3 Transmit-and-Receive (Master and Slave)

If the requests are configured in DMA, write_count and read_count are assigned with 'N' when the DMA handlers have completed their 'N' OCP accesses.

Table 24-215. Transmit-and-Receive (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait for write_count = N **AND** read_count = N		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

Table 24-216. Transmit-and-Receive (Master and Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: TXx_EMPTY		
Write the transmitter register with data	MCSPI_TXx	0x-
Increment write_count +1		
IF: RXx_FULL		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		

Table 24-216. Transmit-and-Receive (Master and Slave) (Interrupt Routine) (continued)

Step	Register/Bit Field/Programming Model	Value
ENDIF		

24.4.5.2.1.4 Transmit-Only (Master and Slave)

24.4.5.2.1.4.1 Based on Interrupt Requests

Table 24-217. Transmit-Only With Interrupts (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait until last transfer = TRUE		
Wait for end of transfer	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel	MCSPI_CHxCTRL[0] EN	0

Table 24-218. Transmit-Only With Interrupts (Master and Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: TXx_EMPTY **AND** write_count < N		
Write the transmitter register with data	MCSPI_TXx	0x-
Increment write_count +1		
ELSEIF: write_count ≥ N		
last_transfer = TRUE		
ENDIF		

24.4.5.2.1.4.2 Based on DMA Write Requests

When the DMA handler has completed its ‘N’ OCP accesses, write_count is assigned with ‘N’.

Table 24-219. Transmit-Only With DMA (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait until write_count = N		
Disable DMA write request	MCSPI_CHxCONF[14] DMAW	0
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel	MCSPI_CHxCTRL[0] EN	0

Table 24-220. Transmit-Only With DMA (Master and Slave) (Interrupt Routine)

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: TXx_EMPTY **AND** write_count = N		
last_transfer = TRUE		
ENDIF		

24.4.5.2.1.5 Master Normal Receive-Only

Step	Register/Bit Field/Programming Model	Value
Read MCSPI_IRQSTATUS	MCSPI_IRQSTATUS	0x-
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS[channel x bits]	0b1111
IF: RXx_FULL		
Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		

24.4.5.2.1.8 Transfer Procedures With FIFO

These flows describe the transfer with FIFO.

The McSPI module allows the transfer of one or several words, according to different modes:
- MASTER Normal, MASTER Turbo, SLAVE
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see Section 24.4.4.6, *FIFO Buffer Management*.

Table 24-231. FIFO Mode Common Sequence (Master) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS	1
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	1
Write MCSPI_CHxCONF to configure the channel	MCSPI_CHxCONF	0x-
Write MCSPI_XFERLEVEL	MCSPI_XFERLEVEL	0x-
Start the channel	MCSPI_CHxCTRL[0] EN	1
IF: Receive only		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	MCSPI_TXx	0x-
ENDIF		
Wait for the host event for end of transfer		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

24.4.5.2.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in Section 24.4.5.2.1.8, *Transfer Procedures With FIFO*.

In multi-channel, only one channel can use the FIFO.

Before enabling the FIFO for a channel (MCSPI_CHxCONF[28] FFER and MCSPI_CHxCONF[27] FFEW bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Slave mode, the channel 0 only can be activated. The correct SPIEN line is chosen in MCSPI_CHxCONF[22:21] SPIENSLV bits (where x = 0).

The McSPI module can start the transfer only when the first write request has been released by writing the MCSPI_TXx register, even in receive-only mode (only one write request occurs in this case).

24.4.5.2.1.8.2 End of Transfer Sequences in FIFO Mode

Table 24-232 summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 24-232. End of Transfer Sequences in FIFO Mode

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See Figure 24-96	See Figure 24-98	See Figure 24-99
No	See Figure 24-97	See Figure 24-98	See Figure 24-100

The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:
- write_count = N
- read_count = N
- last_request = FALSE

They are initialized before starting the channel.

24.4.5.2.1.8.3 Transmit-and-Receive With Word Count

Figure 24-96 shows the flow of a transfer in transmit-and-receive mode, with word count.

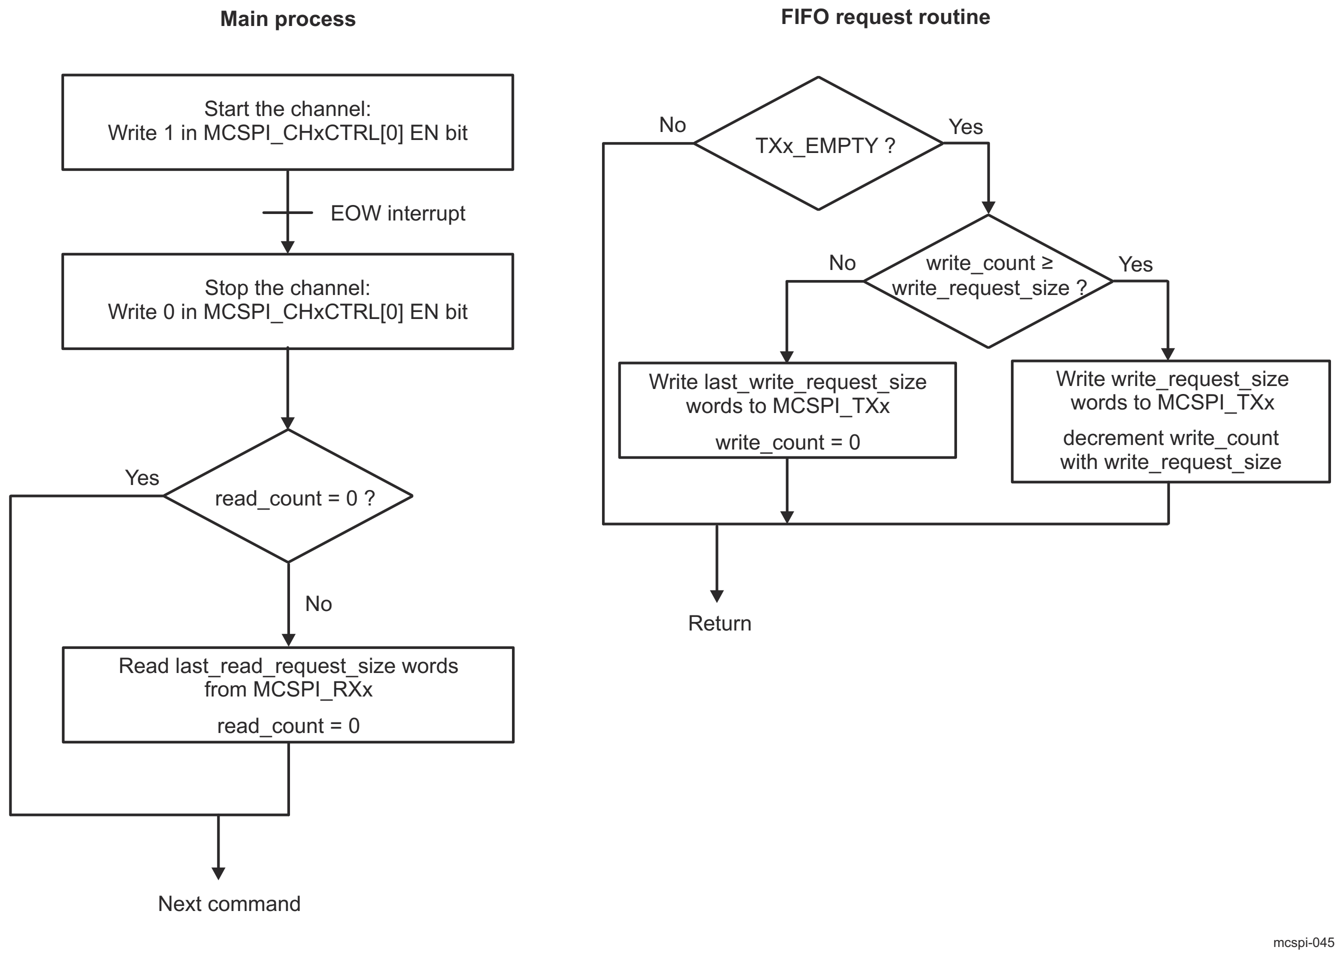

Figure 24-96. FIFO Mode Transmit-and-Receive With Word Count (Master)

24.4.5.2.1.8.4 Transmit-and-Receive Without Word Count

Figure 24-97 shows the flow of a transfer in transmit-and-receive mode, without word count.

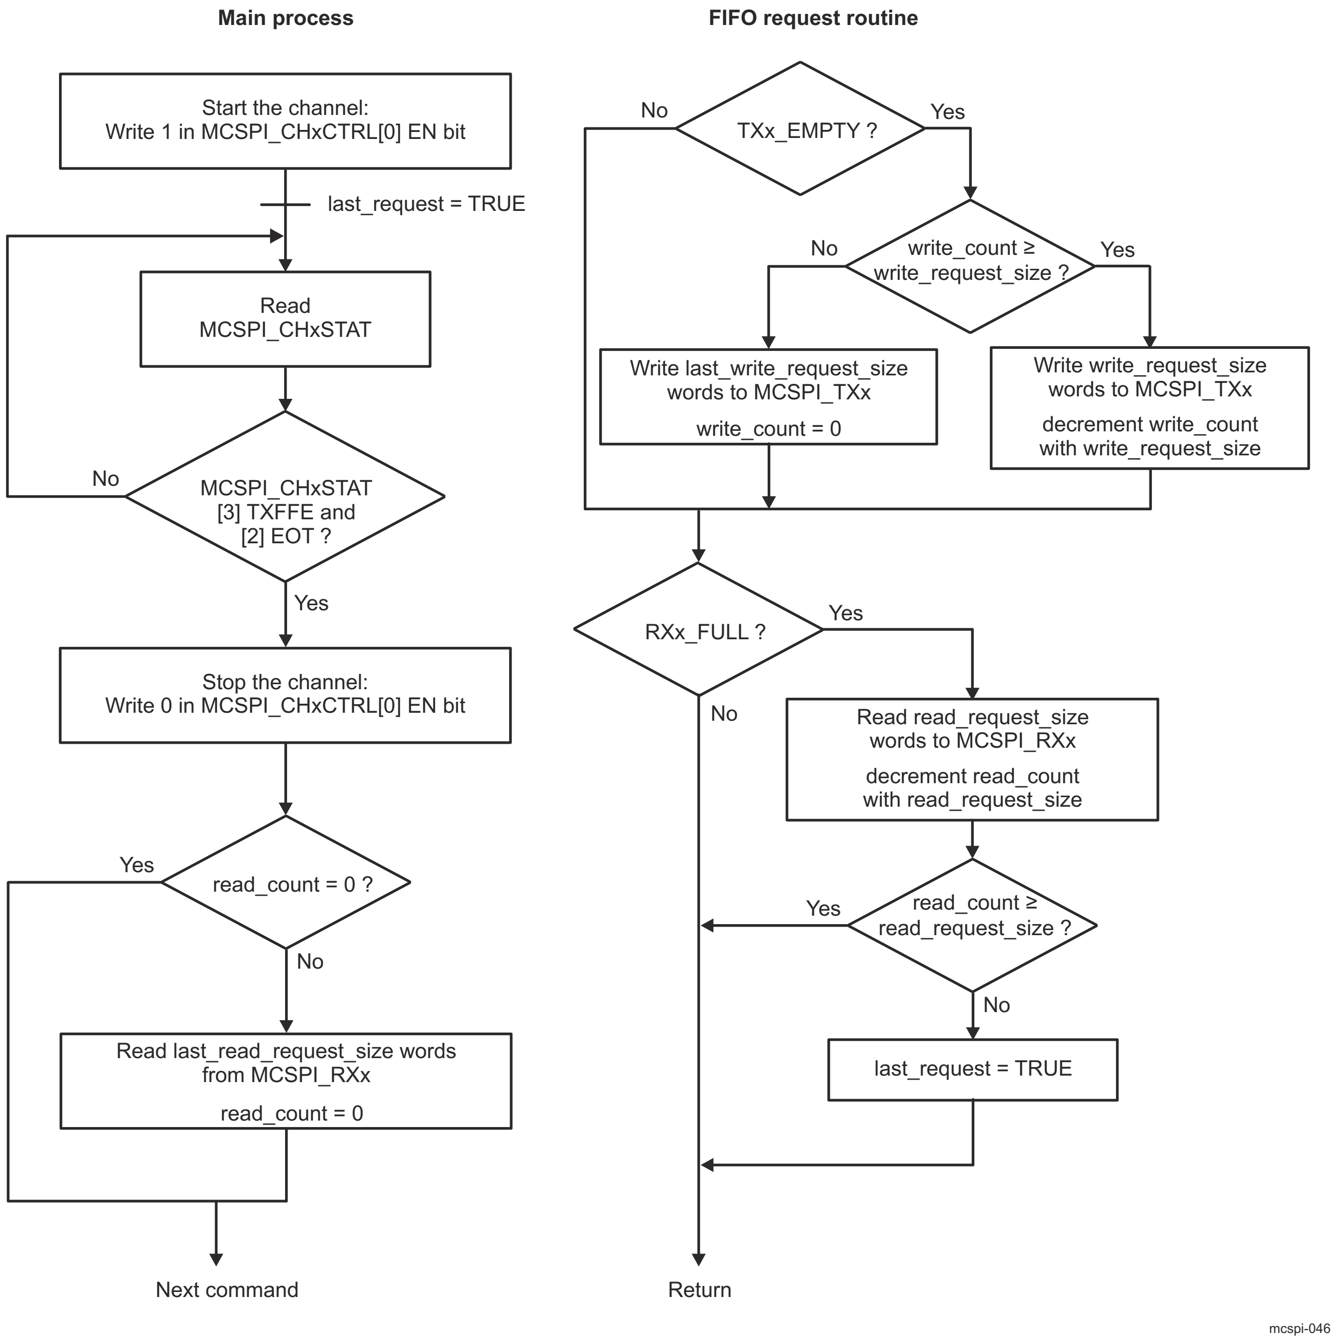

Figure 24-97. FIFO Mode Transmit-and-Receive Without Word Count (Master)

24.4.5.2.1.8.5 Transmit-Only

Figure 24-98 shows the flow of a transfer in transmit-only mode, with or without word count. The difference between word count enabled or not is just on the condition after starting the channel:

- word count enable: wait for EOW interrupt
- word count disable: wait for write_count = 0

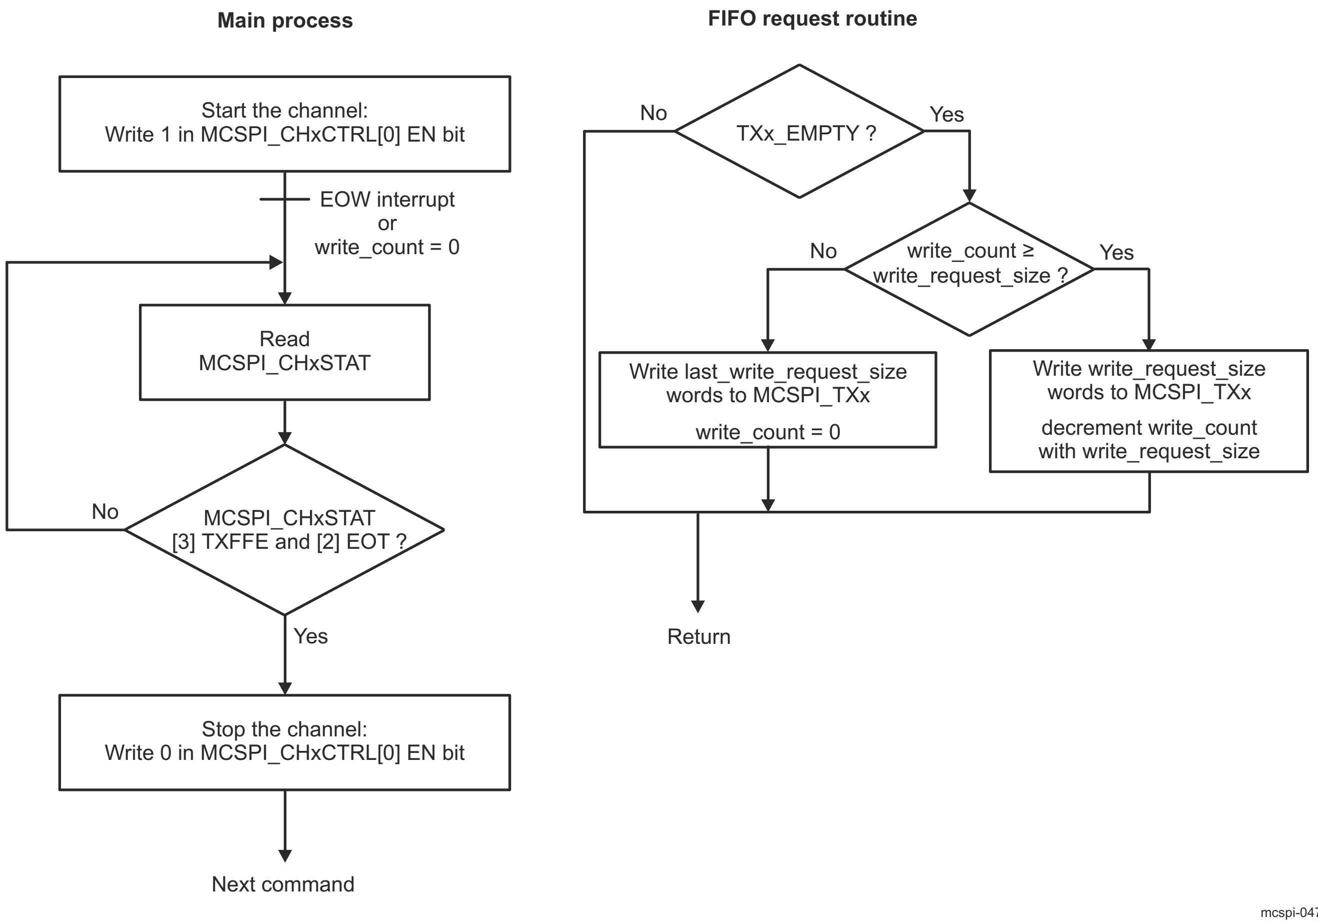

Figure 24-98. FIFO Mode Transmit-Only (Master)

24.4.5.2.1.8.6 Receive-Only With Word Count

Figure 24-99 shows the flow of a transfer in receive-only mode, with word count.

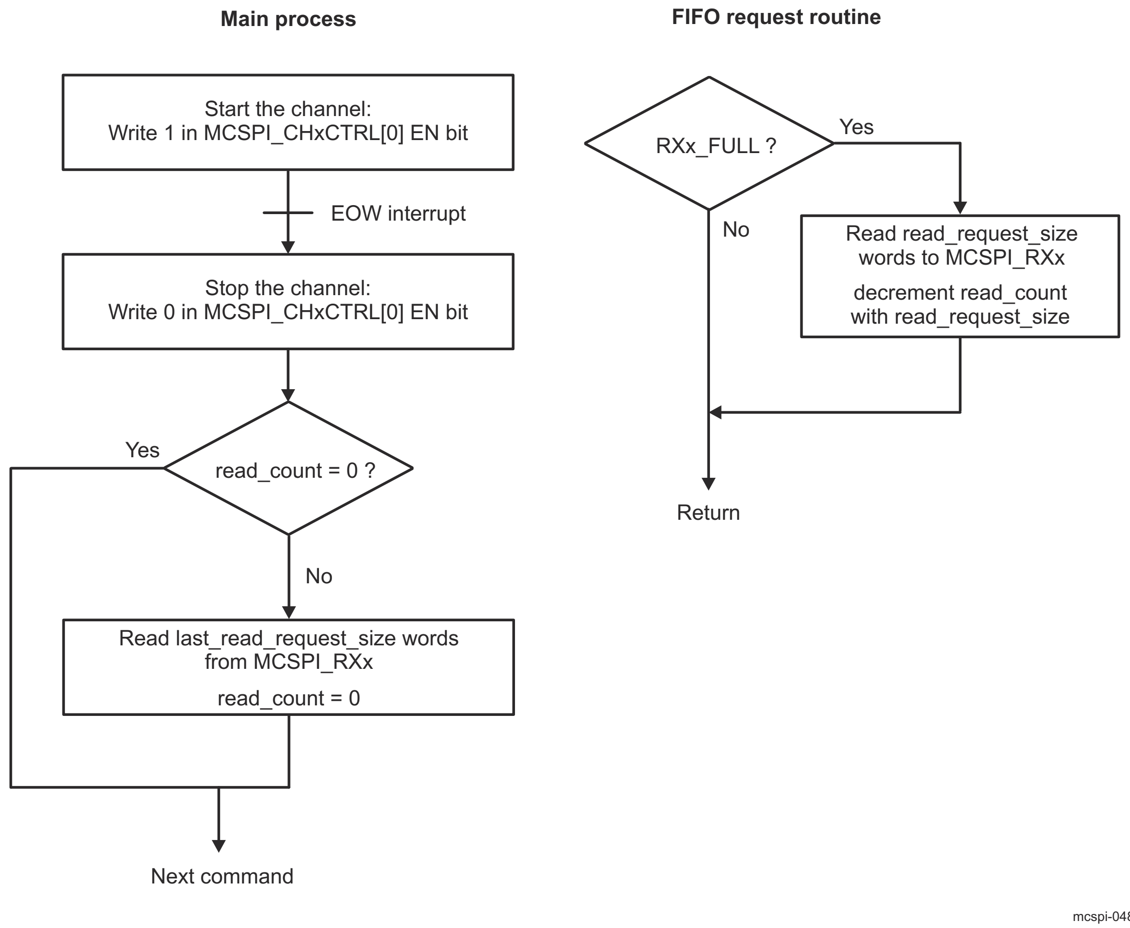

Figure 24-99. FIFO Mode Receive-Only With Word Count (Master)

24.4.5.2.1.8.7 Receive-Only Without Word Count

Figure 24-100 shows the flow of a transfer in receive-only mode, without word count.

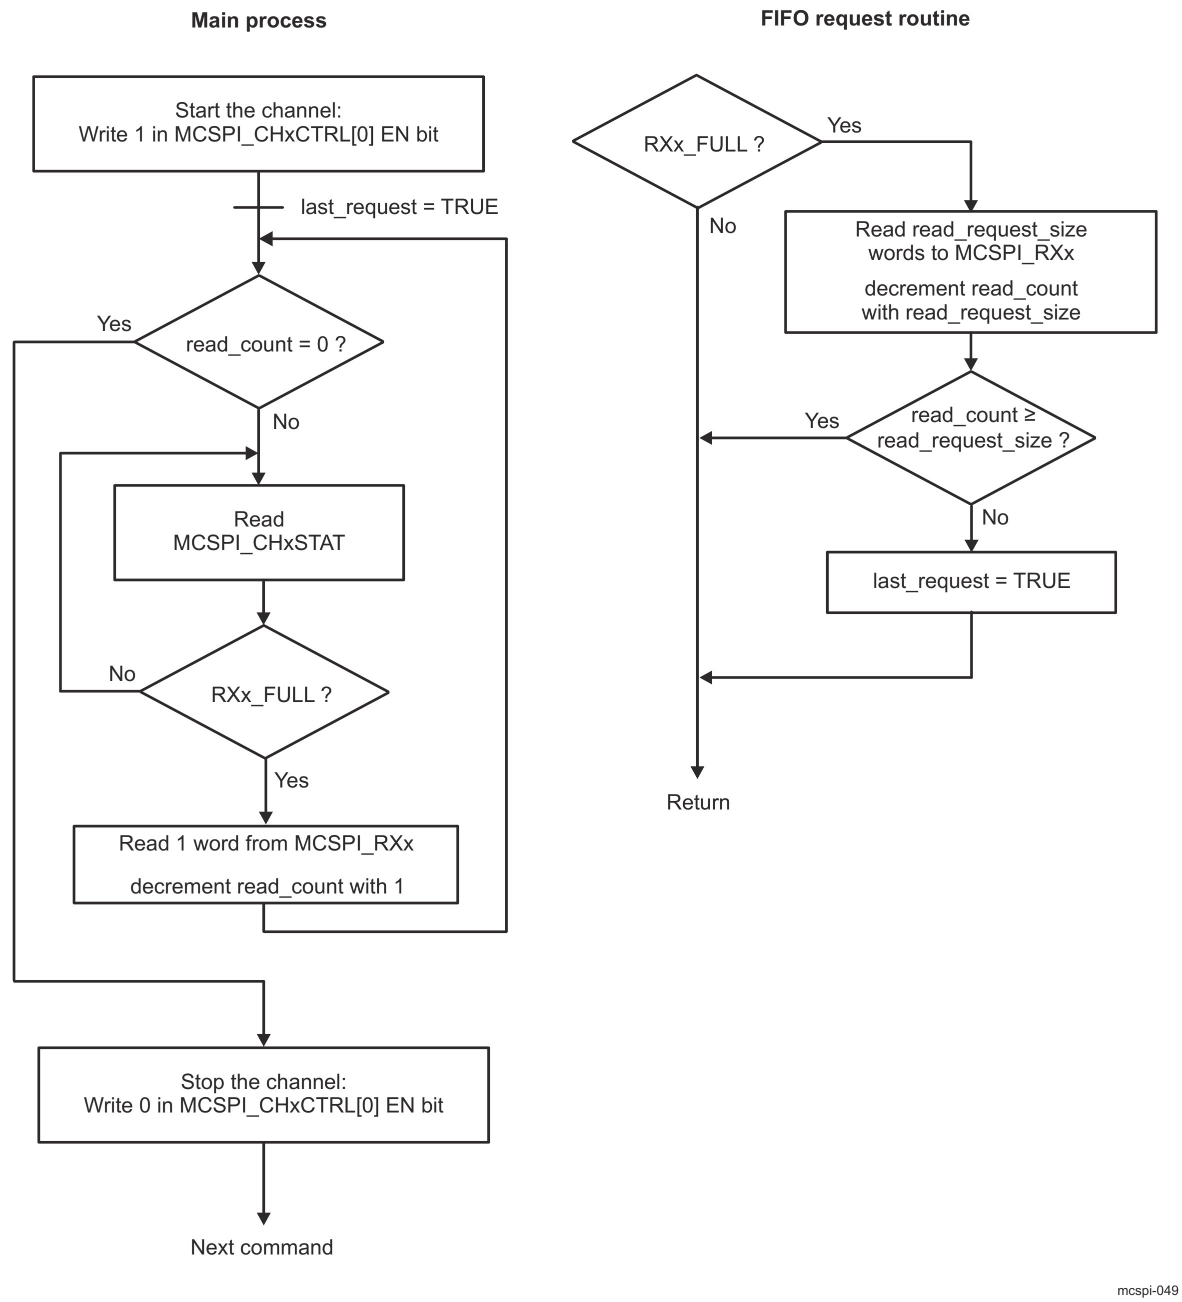

Figure 24-100. FIFO Mode Receive-Only Without Word Count (Master)

24.4.5.3 Common Transfer Procedures Without FIFO – Polling Method

24.4.5.3.1 Receive-Only Procedure – Polling Method

Table 24-233 lists the receive-only procedure using the polling method.

Table 24-233. Receive-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 24-210.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Wait for end-of-transfer.	MCSPI_CHxSTAT[2] EOT	=1
Read the receiver register.	MCSPI_RXx	0x-

Table 24-233. Receive-Only Procedure – Polling Method (continued)

Step	Register/Bit Field/Programming Model	Value
Stop the channel if no more data is expected.	MCSPI_CHxCTRL[0] EN	0

24.4.5.3.2 Receive-Only Procedure – Interrupt Method

Table 24-234 lists the receive-only procedure using the interrupt method.

Table 24-234. Receive-Only Procedure – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-210.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Enable the interrupt for the receiver register.	MCSPI_IRQENABLE[2] RX_FULL_ENABLE	1
Wait for interrupt.		
Read the status register.	MCSPI_IRQSTATUS[2] RX_FULL	1
Disable the interrupt if no more data is expected.	MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0
Stop the channel if no more data is expected.	MCSPI_CHxCTRL[0] EN	0
Read the receiver register.	MCSPI_RXx	0x-

24.4.5.3.3 Transmit-Only Procedure – Polling Method

Table 24-235 lists the transmit-only procedure using the polling method.

Table 24-235. Transmit-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-211	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Write the transmitter register with data.	MCSPI_TXx	0x-
Wait until end of transfer?	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0

24.4.5.3.4 Transmit-and-Receive Procedure – Polling Method

Table 24-235 lists the transmit-and-receive procedure using the polling method.

Table 24-236. Transmit-and-Receive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-212.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Write the transmitter register with data.	MCSPI_TXx	0x-
Wait until transmit/receive word?	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0
Read the receiver register.	MCSPI_TXx	0x-

Table 24-243. MCSPI_HL_SYSCONFIG

Address Offset	0x10		
Physical Address	0x4809 8010 0x4809 A010 0x480B 8010 0x480B A010	**Instance**	McSPI1 McSPI2 McSPI3 McSPI4
Description	Clock management configuration		
Type	RW		

31:4	3:2	1	0
RESERVED	IDLEMODE	FREEEMU	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x0000000
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's IDLE state follows (acknowledges) the system's IDLE requests unconditionally, that is, regardless of the module's internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements. Module shall not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the module's internal requirements. Module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module "swake-up" output(s) is (are) implemented.	RW	0x2
1	FREEEMU	Sensitivity to emulation (debug) suspend input signal. 0x0: Module is sensitive to emulation suspend. 0x1: Module is not sensitive to emulation suspend.	RW	0

Bits	Field Name	Description	Type	Reset
0	SOFTRESET	Software reset. (Optional) Write 0x0: No action Read 0x0: Reset done, no pending action Read 0x1: Reset (software or other) ongoing Write 0x1: Initiate software reset	RW	0

Table 24-247. MCSPI_SYSCONFIG

Address Offset	0x110		
Physical Address	0x4809 8110 0x4809 A110 0x480B 8110 0x480B A110	**Instance**	McSPI1 McSPI2 McSPI3 McSPI4
Description	This register allows controlling various parameters of the configuration interface and is not affected by software reset.		
Type	RW		

31:10	9:8	7:5	4:3	2	1	0
RESERVED	CLOCKACTIVITY	RESERVED	SIDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reads return 0	RW	0x000000

Bits	Field Name	Description	Type	Reset
9:8	CLOCKACTIVITY	Clocks activity during wake-up mode period 0x0: Interface and functional clocks may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched off. 0x2: Functional clock is maintained. Interface clock may be switched off. 0x3: Interface and functional clocks are maintained.	RW	0x0
7:5	RESERVED	Reads returns 0	RW	0x0
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the McSPI acknowledges it unconditionally and goes in inactive mode. Interrupt, DMA requests and wake-up lines are unconditionally deasserted and the module wake-up capability is deactivated even if the [2] ENAWAKEUP bit is set. 0x1: If an IDLE request is detected, the request is ignored and the module does not switch to wake-up mode, and keeps on behaving normally. 0x2: If an IDLE request is detected, the module will switch to wake-up mode based on its internal activity, and the wake-up capability can be used if the bit [2] ENAWAKEUP is set. 0x3: Reserved - do not use.	RW	0x2
2	ENAWAKEUP	Wake-up feature control 0x0: Wake-up capability is disabled. 0x1: Wake-up capability is enabled.	RW	1
1	SOFTRESET	Software reset. During reads it always returns 0. 0x0: (write) Normal mode 0x1: (write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.	RW	0
0	AUTOIDLE	Internal interface clock-gating strategy 0x0: Interface clock is free-running. 0x1: Automatic interface clock gating strategy is applied, based on the interface activity.	RW	1

Description	This register is used to check the correctness of the system interconnect either internally to peripheral bus, or externally to device I/O pads, when the module is configured in system test (SYSTEST) mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED	SSB	SPIENDIR	SPIDATDIR1	SPIDATDIR0	WAKD	SPICLK	SPIDAT_1	SPIDAT_0	SPIEN_3	SPIEN_2	SPIEN_1	SPIEN_0

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reads returns 0.	RW	0x00000
11	SSB	Set status bit 0x0: No action. Writing 0 does not clear already set status bits. This bit must be cleared before trying to clear a status bit of the MCSPI_IRQSTATUS register. 0x1: Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits in the MCSPI_IRQSTATUS register.	RW	0
10	SPIENDIR	Set the direction of the SPIEN[3:0] lines and SPICLK line. 0x0: Output (as in master mode) 0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1]. 0x0: Output 0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0]. 0x0: Output 0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	SPICLK line (signal data value) If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If [10] SPIENDIR = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this bit.	RW	0
5	SPIDAT_1	SPIDAT[1] line (signal data value) If [9] SPIDATDIR1 = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this bit. If [9] SPIDATDIR1 = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.	RW	0
4	SPIDAT_0	SPIDAT[0] line (signal data value) If [8] SPIDATDIR0 = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this bit. If [8] SPIDATDIR0 = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.	RW	0

Bits	Field Name	Description	Type	Reset
3	SPIEN_3	SPIEN[3] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[3] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.	RW	0
2	SPIEN_2	SPIEN[2] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[2] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.	RW	0
1	SPIEN_1	SPIEN[1] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[1] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.	RW	0
0	SPIEN_0	SPIEN[0] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[0] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.	RW	0

Table 24-258. Register Call Summary for Register MCSPI_SYST

Multichannel Serial Peripheral Interface

- McSPI Register Summary: [0]

Table 24-259. MCSPI_MODULCTRL

Address Offset	0x128		
Physical Address	0x4809 8128 0x4809 A128 0x480B 8128 0x480B A128	**Instance**	McSPI1 McSPI2 McSPI3 McSPI4
Description	This register is dedicated to the configuration of the serial peripheral interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							FDAA	MOA	INITDLY			SYSTEM_TEST	MS	PIN34	SINGLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reads returns 0.	RW	0x000000

Bits	Field Name	Description	Type	Reset
8	FDAA	FIFO DMA address 256-bit aligned This bit is used when a FIFO is managed by the module and DMA connected to the controller provides only 256-bit aligned address. If this bit is set the enabled channel which uses the FIFO has its data managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TXx and MCSPI_RXx registers. 0x0: FIFO data managed by MCSPI_TXx and MCSPI_RXx registers. 0x1: FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.	RW	0
7	MOA	Multiple word interface access: this bit can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit interface word access. This is possible for WL < 16. 0x0: Multiple word access disabled 0x1: Multiple word access enabled with FIFO	RW	0
6:4	INITDLY	Initial SPI delay for first transfer: this field is an option only available in SINGLE master mode. The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock. No clock output provided to the boundary and chip select is not active in 4-pin mode within this period. 0x0: No delay for first spi transfer. 0x1: The controller wait 4 SPI bus clock 0x2: The controller wait 8 SPI bus clock 0x3: The controller wait 16 SPI bus clock 0x4: The controller wait 32 SPI bus clock	RW	0x0
3	SYSTEM_TEST	Enables the system test mode 0x0: Functional mode 0x1: System test mode (SYSTEST)	RW	0
2	MS	Master/slave 0x0: Master - The module generates the SPICLK and SPIEN[3:0]. 0x1: Slave - The module receives the SPICLK and SPIEN[3:0].	RW	1
1	PIN34	Pin mode selection: This bit is used in master or slave mode to configure the SPI pin mode (3-pin or 4-pin). If asserted the controller only uses SIMO, SOMI, and SPICLK clock pin for SPI transfers. 0x0: SPIEN is used as a chip-select. 0x1: SPIEN is not used. In this mode all related options to chip-select have no meaning.	RW	0
0	SINGLE	Single channel/Multi Channel (master mode only) 0x0: More than one channel will be used in master mode. 0x1: Only one channel will be used in master mode. This bit must be set in Force SPIEN[x] mode.	RW	0

Description	This register is dedicated to the configuration of the channel x		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED		CLKG	FFER	FFEW	TCS0		SBPOL	SBE	SPIENSLV		FORCE	TURBO	IS	DPE1	DPE0	DMAR	DMAW	TRM		WL					EPOL	CLKD				POL	PHA

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Read returns 0.	R	0x0
29	CLKG	Clock divider granularity this bit defines the granularity of channel clock divider: power of 2 or one clock cycle granularity. When this bit is set the register MCSPI_CHxCTRL[15:8] EXTCLK must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of [5:2] CLKD and MCSPI_CHxCTRL[15:8] EXTCLK values 0x0: Clock granularity of power of 2 0x1: One clock cycle granularity	RW	0
28	FFER	FIFO enabled for receive: Only one channel can have this bit field set. 0x0: The buffer is not used to receive data. 0x1: The buffer is used to receive data.	RW	0
27	FFEW	FIFO enabled for transmit: Only one channel can have this bit field set. 0x0: The buffer is not used to transmit data. 0x1: The buffer is used to transmit data.	RW	0
26:25	TCS0	Chip-select time control This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0

Bits	Field Name	Description	Type	Reset
24	SBPOL	Start-bit polarity 0x0: Start-bit polarity is held to 0 during SPI transfer. 0x1: Start-bit polarity is held to 1 during SPI transfer.	RW	0
23	SBE	Start-bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by bit [24] SBPOL	RW	0
22:21	SPIENSLV	Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits for other cases. 0x0: Detection enabled only on SPIEN[0] 0x1: Detection enabled only on SPIEN[1] 0x2: Detection enabled only on SPIEN[2] 0x3: Detection enabled only on SPIEN[3]	RW	0x0
20	FORCE	Manual SPIEN assertion to keep SPIEN active between SPI words (single channel master mode only). 0x0: Writing 0 into this bit drives low the SPIEN line when [6] EPOL=0, and drives it high when [6] EPOL=1. 0x1: Writing 1 into this bit drives high the SPIEN line when [6] EPOL=0, and drives it low when [6] EPOL=1.	RW	0
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer). 0x1: Turbo is activated to maximize the throughput for multiple SPI words transfer.	RW	0
18	IS	Input Select 0x0: Data line 0 (SPIDAT[0]) selected for reception 0x1: Data line 1 (SPIDAT[1]) selected for reception	RW	1
17	DPE1	Transmission enable for data line 1 0x0: Data line 1 (SPIDAT[1]) selected for transmission 0x1: No transmission on Data Line1 (SPIDAT[1])	RW	1
16	DPE0	Transmission Enable for data line 0 0x0: Data Line0 (SPIDAT[0]) selected for transmission 0x1: No transmission on data line 0 (SPIDAT[0])	RW	0
15	DMAR	DMA read request The DMA read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled	RW	0
14	DMAW	DMA write request. The DMA write request line is asserted when The channel is enabled and the transmitter register of the channel is empty. The DMA write request line is deasserted on load completion of the transmitter register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0

Bits	Field Name	Description	Type	Reset
13:12	TRM	Transmit/receive modes 0x0: Transmit-and-receive mode 0x1: Receive-only mode 0x2: Transmit-only mode 0x3: Reserved	RW	0x0
11:7	WL	SPI word length 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: The SPI word is 4 bits long 0x4: The SPI word is 5 bits long 0x5: The SPI word is 6 bits long 0x6: The SPI word is 7 bits long 0x7: The SPI word is 8 bits long 0x8: The SPI word is 9 bits long 0x9: The SPI word is 10 bits long 0xA: The SPI word is 11 bits long 0xB: The SPI word is 12 bits long 0xC: The SPI word is 13 bits long 0xD: The SPI word is 14 bits long 0xE: The SPI word is 15 bits long 0xF: The SPI word is 16 bits long 0x10: The SPI word is 17 bits long 0x11: The SPI word is 18 bits long 0x12: The SPI word is 19 bits long 0x13: The SPI word is 20 bits long 0x14: The SPI word is 21 bits long 0x15: The SPI word is 22 bits long 0x16: The SPI word is 23 bits long 0x17: The SPI word is 24 bits long 0x18: The SPI word is 25 bits long 0x19: The SPI word is 26 bits long 0x1A: The SPI word is 27 bits long 0x1B: The SPI word is 28 bits long 0x1C: The SPI word is 29 bits long 0x1D: The SPI word is 30 bits long 0x1E: The SPI word is 31 bits long 0x1F: The SPI word is 32 bits long	RW	0x00
6	EPOL	SPIEN polarity 0x0: SPIEN is held high during the ACTIVE state. 0x1: SPIEN is held low during the ACTIVE state.	RW	0

Bits	Field Name	Description	Type	Reset
5:2	CLKD	Frequency divider for SPICLK (only when the module is a Master SPI device). A programmable clock divider divides the SPI reference clock (FCLK) with a 4-bit value, and results in a new clock SPICLK available to shift-in and shift-out data. By default, the clock divider ratio has a power of 2 granularity when [29] CLKG is cleared. Otherwise, this field is the 4-LSB bit of a 12-bit register concatenated with clock divider extension MCSPI_CHxCTRL[15:8] EXTCLK register. The value description below defines the clock ratio when [29] CLKG is set to 0. 0x0: 1 0x1: 2 0x2: 4 0x3: 8 0x4: 16 0x5: 32 0x6: 64 0x7: 128 0x8: 256 0x9: 512 0xA: 1024 0xB: 2048 0xC: 4096 0xD: 8192 0xE: 16384 0xF: 32768	RW	0x0
1	POL	SPICLK polarity (see Section 24.4.2.3.1, *Transfer Format*) 0x0: SPICLK is held low during the INACTIVE state 0x1: SPICLK is held high during the INACTIVE state	RW	0
0	PHA	SPICLK phase (see Section 24.4.2.3.1, *Transfer Format*) 0x0: Data are latched on odd-numbered edges of SPICLK. 0x1: Data are latched on even-numbered edges of SPICLK.	RW	0

Description	This register provides transfer levels needed while using FIFO buffer during transfer.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WCNT																AFL								AEL							

Bits	Field Name	Description	Type	Reset
31:16	WCNT	SPI word counter. This field holds the programmable value of number of SPI word to be transferred on channel which is using the FIFO buffer. When transfer had started, a read back in this field returns the current SPI word transfer index. 0x0: Counter not used 0x1: One word ... 0xFFFE: 65534 SPI words 0xFFFF: 65535 SPI words	RW	0x0000

Bits	Field Name	Description	Type	Reset
15:8	AFL	Buffer almost full This field holds the programmable almost-full level value used to determine almost full buffer condition. If the user wants an interrupt or a DMA read request to be issued during a receive operation when the data buffer holds at least n bytes, then the buffer AFL must be set with n-1. 0x0: 1 byte 0x1: 2 bytes ... 0xFE: 255 bytes 0xFF: 256 bytes	RW	0x00
7:0	AEL	Buffer almost empty. this field holds the programmable almost-empty level value used to determine almost empty buffer condition. If the user wants an interrupt or a DMA write request to be issued during a transmit operation when the data buffer is able to receive n bytes, then the buffer AEL must be set with n-1. 0x0: 1 byte 0x1: 2 bytes ... 0xFE: 255 bytes 0xFF: 256 bytes	RW	0x00

24.5 Quad Serial Peripheral Interface

24.5.1 Quad Serial Peripheral Interface Overview

The quad serial peripheral interface (QSPI) module is a kind of SPI module that allows single, dual, or quad read access to external SPI devices. This module has a memory mapped register interface, which provides a direct interface for accessing data from external SPI devices and thus simplifying software requirements. The QSPI works as a master only.

The one QSPI in the device is primarily intended for fast booting from quad-SPI flash memories. Figure 24-101 shows the QSPI module overview.

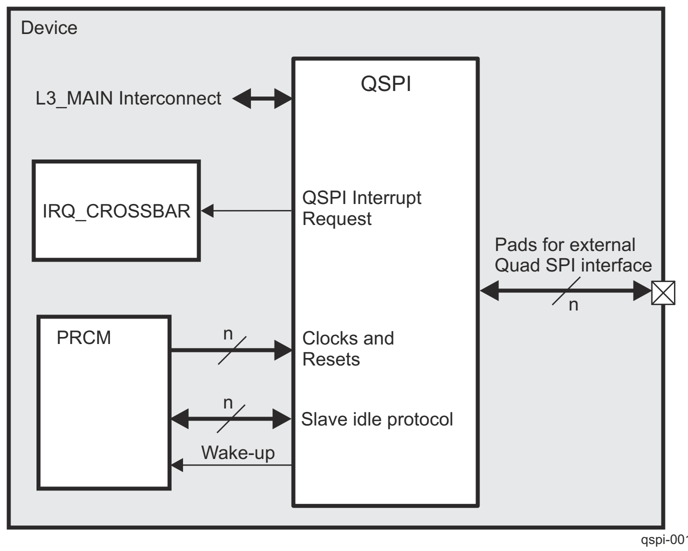

Figure 24-101. QSPI Overview

The QSPI supports the following features:

- General SPI features:
  - Programmable clock divider
  - Six pin interface
  - Programmable length (from 1 to 128 bits) of the words transferred
  - Programmable number (from 1 to 4096) of the words transferred
  - 4 external chip-select signals
  - Support for 3-, 4-, or 6-pin SPI interface
  - Optional interrupt generation on word or frame (number of words) completion
  - Programmable delay between chip select activation and output data from 0 to 3 QSPI clock cycles
  - Programmable signal polarities
  - Programmable active clock edge
  - Software-controllable interface allowing for any type of SPI transfer
  - Control through L3_MAIN configuration port
- Serial flash interface (SFI) features:
  - Serial flash read/write interface
  - Additional registers for defining read and write commands to the external serial flash device
  - 1 to 4 address bytes
  - Fast read support, where fast read requires dummy bytes after address bytes; 0 to 3 dummy bytes can be configured.
  - Dual read support
  - Quad read support
  - Little-endian support (only for memory mapped registers used to configure QSPI controller and not SPI content accesses)

– Linear increment addressing mode only

The QSPI supports only dual and quad reads. Dual or quad writes are not supported. In addition, there is no "pass through" mode supported where the data present on the QSPI input is sent to its output.

Note

The QSPI module does not support cache line wrap mode.

24.5.2 QSPI Environment

Figure 24-102 shows a typical connection of the QSPI module to the external quad-SPI flash memory.

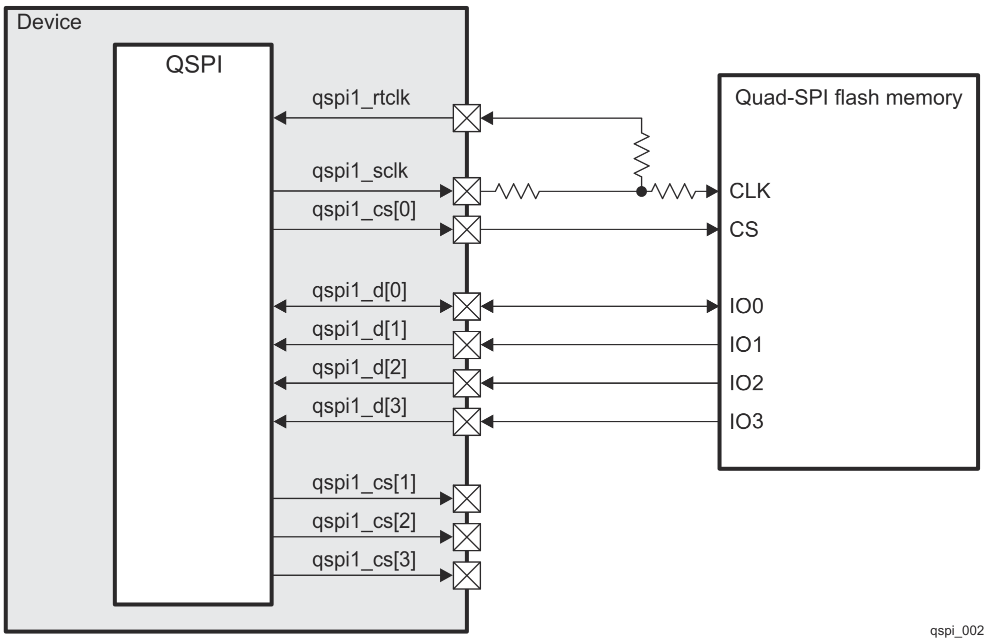

Figure 24-102. QSPI Connected to an External Quad-SPI Flash Memory

Table 24-277 lists and describes the QSPI I/O signals.

Table 24-277. QSPI I/O Signals

QSPI Signal/Pad name	I/O[1]	Description					
		3-pin[2] SPI Read (Single Read)	3-pin[2] SPI Write (Single Write)	4-pin[2] SPI Read (Single Read)	4-pin[2] SPI Write (Single Write)	4-pin[2] SPI Read (Dual Read)	6-pin[2] SPI Read (Quad Read)

QSPI Signal/Pad name	I/O(1)	Description					
		3-pin(2) SPI Read (Single Read)	3-pin(2) SPI Write (Single Write)	4-pin(2) SPI Read (Single Read)	4-pin(2) SPI Write (Single Write)	4-pin(2) SPI Read (Dual Read)	6-pin(2) SPI Read (Quad Read)
qspi1_rtclk	I	The qspi1_sclk output must be connected to the qspi1_rtclk input, and is used for controlling the timing of the read return data when the QSPI module operates in Mode 0. In case Mode 3 is used, there is no need to connect the qspi1_sclk to the qspi1_rtclk.					

(1) I = Input; O = Output
(2) This is the pin count at the SPI flash memory side. The pin count at the device side is increased by one because of the qspi1_rtclk signal. References to the pin count throughout this chapter consider the pin count at the SPI flash memory side.

Note

In order to ensure proper timing, precise layout and routing requirements must be followed. For layout and routing requirements for all QSPI signals, see section “PCB Guidelines” of the device Data Manual.

24.5.3 QSPI Integration

Figure 24-103 shows the integration of the QSPI module in the device.

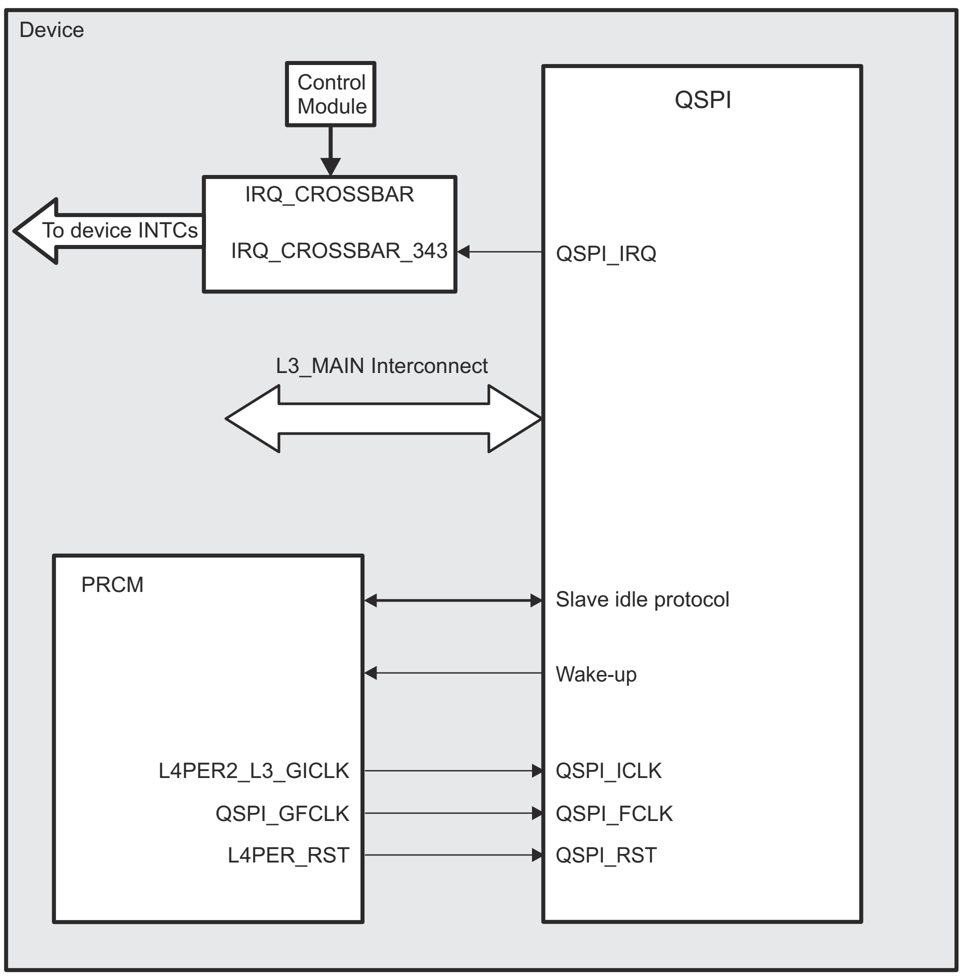

Figure 24-103. QSPI Integration

Table 24-278 through Table 24-280 summarize the integration of the QSPI in the device.

Note

The Default Mapping column in Table 24-280 shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device interrupt controller (INTC) through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device INTCs, see *Interrupt Controllers*.

Note

For the description of the interrupt source, see Section 24.5.4.3, *QSPI Interrupt Requests*.

24.5.4 QSPI Functional Description

24.5.4.1 QSPI Block Diagram

Iinitial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the qspi1_d[0] signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. Figure 24-104 shows the QSPI block diagram.

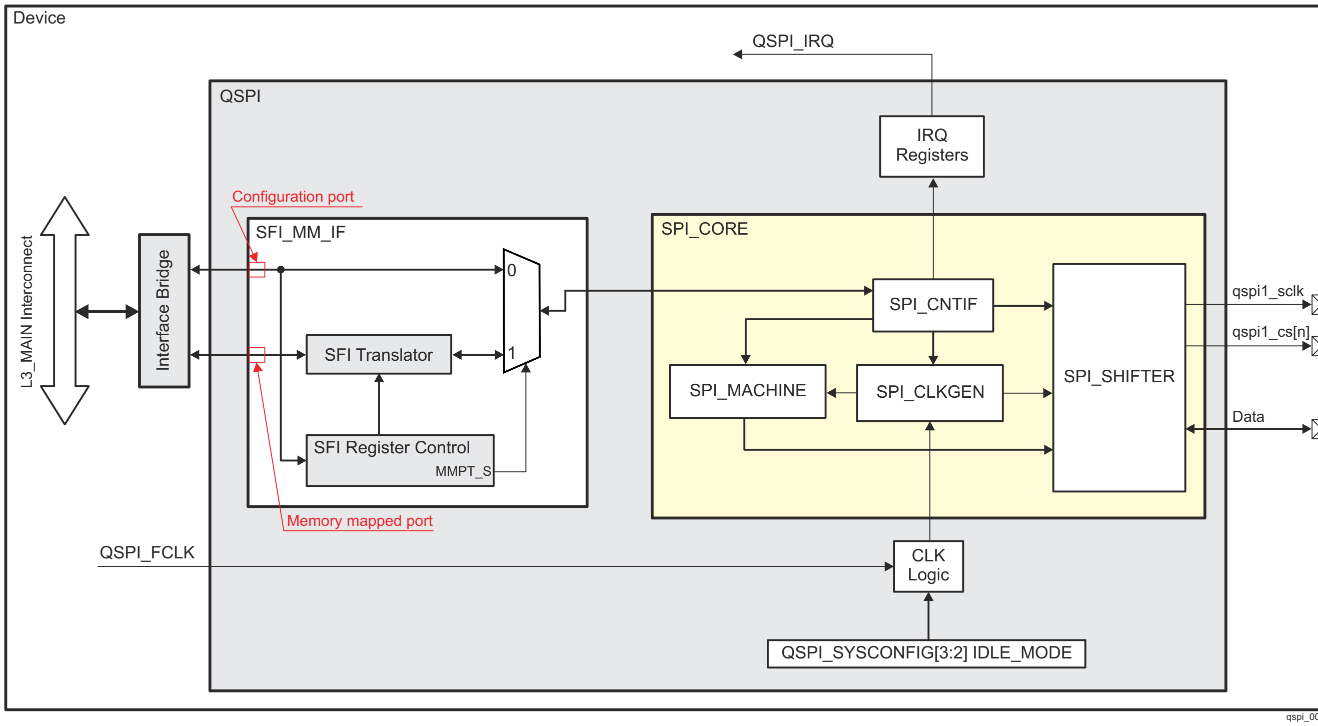

Figure 24-104. QSPI Block Diagram

The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI_MM_IF) and the second one is the SPI core (SPI_CORE). The SFI_MM_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI_MM_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI_CORE comprises the following four subblocks:

- SPI control interface (SPI_CNTIF)
- SPI clock generator (SPI_CLKGEN)
- SPI control state machine (SPI_MACHINE)
- SPI data shifter (SPI_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI_MM_IF block to the L3_MAIN interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI_MM_IF block because it is intended to ease the communication with serial flash devices. If the SPI_CORE is used to communicate with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

Note

The SFI_MM_IF block only allows reading and writing to an externaly connected SPI flash device. The SFI_MM_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI_CORE block.

24.5.4.1.1 SFI Register Control

The SFI register control block consists of the following five configuration registers:

- QSPI_SPI_SETUP0_REG
- QSPI_SPI_SETUP1_REG
- QSPI_SPI_SETUP2_REG
- QSPI_SPI_SETUP3_REG
- QSPI_SPI_SWITCH_REG

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI_SPI_SETUPi_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI_SPI_SETUPi_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the QSPI_SPI_SETUPi_REG[9:8] NUM_A_BYTES bit field
- Number of “dummy bytes” that may be needed to support the fast read mode function of some serial flash devices. The QSPI_SPI_SETUPi_REG[11:10] NUM_D_BYTES bit field specifies the number of "dummy bits." In addition, the QSPI_SPI_SETUPi_REG[28:24] NUM_D_BITS bit field can also specify the number of "dummy bits."
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI_SPI_SETUPi_REG[13:12] READ_TYPE bit field. (i is equal to 0, 1, 2 and 3 and means that the QSPI_SPI_SETUPi_REG registers are associated with each of the four supported chip-selects [that is, four supported output SPI flash devices])

The QSPI_SPI_SWITCH_REG register acts as a static switch which allows the configuration port (shown in Figure 24-104) to connect directly to the SPI_CORE block, or allows the memory-mapped port (also shown in Figure 24-104) to connect to the SPI_CORE block. This is done using the QSPI_SPI_SWITCH_REG[0] MMPT_S bit.

In addition, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

24.5.4.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.

6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

24.5.4.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:
- The QSPI_PID register, which is read only and contains QSPI revision associated information
- The QSPI_SPI_CLOCK_CNTRL_REG register, which is used to control external SPI clock (qspi1_sclk)
- The QSPI_SPI_DC_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI_SPI_CMD_REG register used to control the operation of the SPI command. This register is also used to configure and transfer data.
- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
  – QSPI_SPI_DATA_REG
  – QSPI_SPI_DATA_REG_1
  – QSPI_SPI_DATA_REG_2
  – QSPI_SPI_DATA_REG_3

  These four registers compose a 128-bit shift register.
- The QSPI_SPI_STATUS_REG register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the QSPI_SPI_STATUS_REG[0] BUSY bit is 0x0. The QSPI becomes busy when a write to the QSPI_SPI_CMD_REG[18:16] CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1_sclk clock and clearing of the BUSY bit is synchronized to the QSPI_FCLK clock.

The register group QSPI_SPI_DATA_REG_3, QSPI_SPI_DATA_REG_2, QSPI_SPI_DATA_REG_1 and QSPI_SPI_DATA_REG is treated as a single 128-bit word for shifting data in and out. The QSPI_SPI_DATA_REG_3 register is used for the most significant bits and the QSPI_SPI_DATA_REG is used for the least significant bits.This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at QSPI_SPI_DATA_REG_3[31] position and the least significant bit, that is bit 0 of the data read, will be located at the QSPI_SPI_DATA_REG[0] position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The QSPI_SPI_CMD_REG[25:19] WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set to 0x7 and the data byte should be written to the lower byte of the QSPI_SPI_DATA_REG register. By setting the word length to 0x7 the QSPI_SPI_DATA_REG register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the QSPI_SPI_DATA_REG and the rest 8 most significant bits of data should be written to the lower byte of the QSPI_SPI_DATA_REG_1 register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the QSPI_SPI_DATA_REG_2 register is also used and the previously described logic applies. The QSPI_SPI_DATA_REG_3 register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the QSPI_SPI_CMD_REG[11:0] FLEN bit field.

Note

The QSPI module does not support a "pass through" mode where the data present on qspi1_d[1] is sent to qspi1_d[0], when 4-pin non-dual read mode is used. This means that setting the QSPI_SPI_CMD_REG[18:16] CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1_d[0] pad to be used as an output.

24.5.4.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI_FCLK clock as an input, and generates the qspi1_sclk, which is a divided version of the QSPI_FCLK clock. The divide ratio is a 16-bit value configured through the QSPI_SPI_CLOCK_CNTRL_REG[15:0] DCLK_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI_FCLK clock is divided by the DCLK_DIV value + 1 to provide the qspi1_sclk clock. When DCLK_DIV = 0x0 the QSPI_FCLK clock equals the DCLK clock. The value in the DCLK_DIV bit field applies only when the QSPI_SPI_CLOCK_CNTRL_REG[31] CLKEN bit is set to 0x1. Figure 24-105 shows the SPI_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the QSPI_SPI_CMD_REG[18:16] CMD bit field is not executed and the QSPI_SPI_STATUS_REG[0] BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

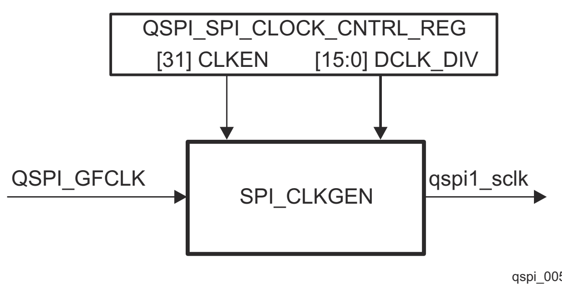

Figure 24-105. SPI_CLKGEN Block

24.5.4.1.5 SPI Control State-Machine

The SPI control state-machine (SPI_MACHINE) manages the operation of the SPI_CORE block. SPI_MACHINE takes control and configuration information from the registers in the SPI_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI_MACHINE also generates status information, which is sent back to the SPI_CNTIF block.

Writing a valid value to the QSPI_SPI_CMD_REG[18:16] CMD bit field sets immediately the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1, activates the corresponding qspi1_cs[n] (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when QSPI_SPI_CMD_REG[25:19] WLEN number of bits are shifted in or out. If the value of the QSPI_SPI_STATUS_REG[27:16] WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this increments the value of the WDCNT bit field from 0x0 and starts shifting data in or out again. This is repeated until the WDCNT bit field reaches the frame length (QSPI_SPI_CMD_REG[11:0] FLEN), that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI_MACHINE is waiting for write to the CMD bit field the corresponding qspi1_cs[n] (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the QSPI_SPI_CMD_REG[25:19] WLEN bit field.

The SPI_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding qspi1_cs[n] (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

24.5.4.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI_MACHINE and SPI_CNTIF blocks, data is shifted in or out on falling or rising edge of qspi1_sclk clock depending on the SPI clock mode selected. Table 24-281 lists the four defined clock modes of operation for the QSPI.

Table 24-281. SPI Clock Modes Definition

Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock
1	0	1	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
2	1	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

Note

Mode 1 and Mode 2 are not supported and should not be used.

The CKPi and CKPHi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register control the clock modes. Each of these 4 bits corresponds to an output chip select.

Figure 24-106 shows all four clock modes. In addition, through the DDi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register the data can be delayed from one to three qspi1_sclk clock cycles after the corresponding qspi1_cs[n] (n = 0 to 3) goes active. The active state of each chip-select can also be controlled through the CSPi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register.

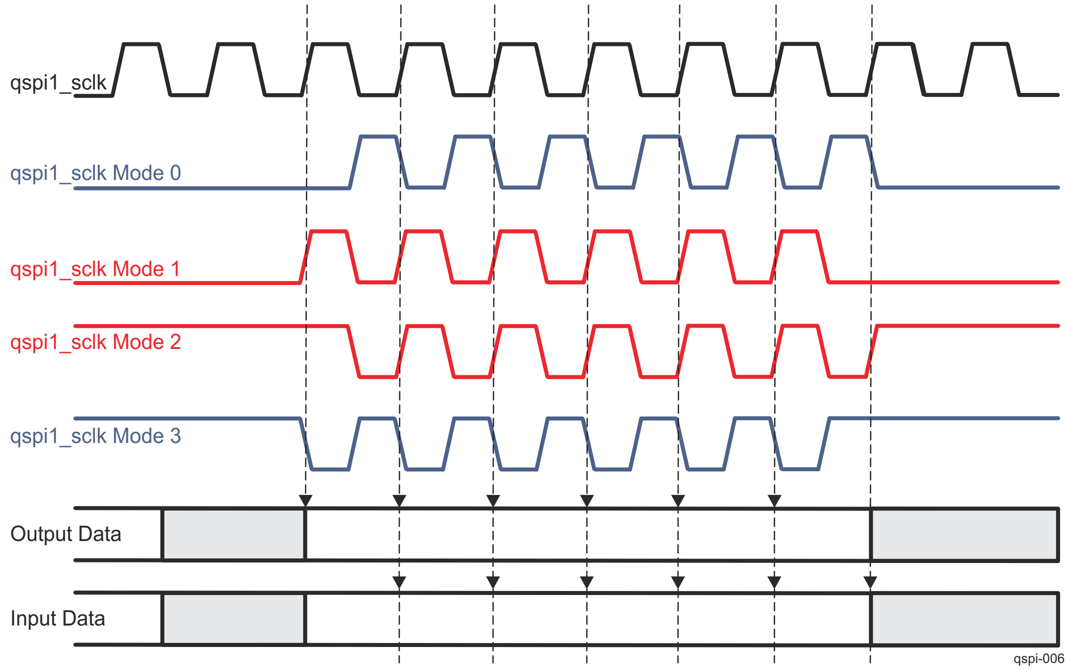

Figure 24-106. SPI Clock Modes

24.5.4.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI_FCLK clock is gated based on the values loaded in the QSPI_SYSCONFIG[3:2] IDLE_MODE bit field. Three modes are supported:

- Force-idle: The QSPI_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI_FCLK clock is gated by the QSPI, depending on its internal requirements.

24.5.4.3 QSPI Interrupt Requests

The QSPI generates one interrupt request which is connected to the IRQ_CROSSBAR module. This interrupt request, QSPI_IRQ, is connected to the IRQ_CROSSBAR_343 input. The QSPI_IRQ interrupt line can be activated by one of the interrupt events listed in Table 24-282.

Figure 24-107 shows a logical representation of the QSPI interrupt generation scheme.

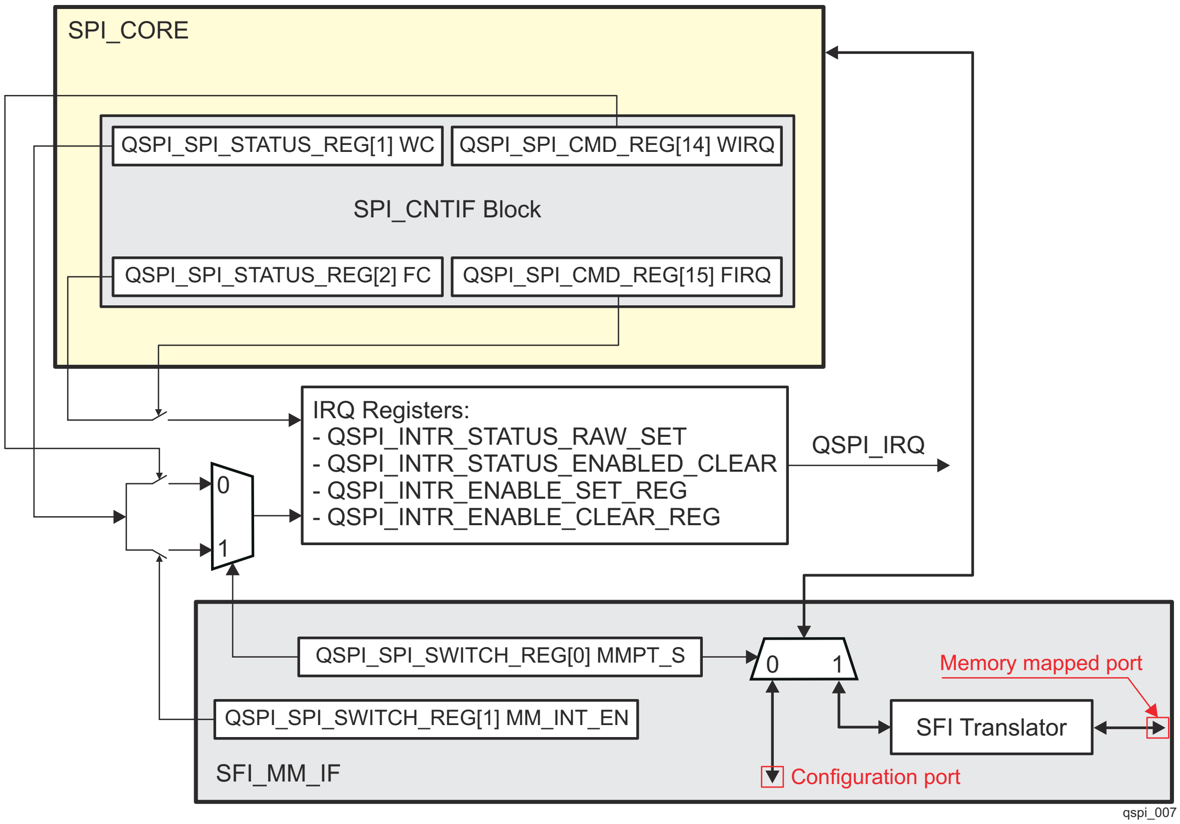

Figure 24-107. Logical Representation of the QSPI Interrupt Generation Scheme

QSPI_SPI_STATUS_REG[1] WC and QSPI_SPI_STATUS_REG[2] FC are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (WIRQ or FIRQ) in the QSPI_SPI_CMD_REG register allows these events (WC and FC) to generate an interrupt. The WC and FC bits are reset every time the user writes to the QSPI_SPI_CMD_REG register or reads the QSPI_SPI_STATUS_REG register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the QSPI_INTR_ENABLE_SET_REG register. These interrupts can be disabled by setting the corresponding bits in the QSPI_INTR_ENABLE_CLEAR_REG register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register to 0x1, which also clears the corresponding bit in the QSPI_INTR_STATUS_RAW_SET register. The status flags in the QSPI_INTR_STATUS_RAW_SET register are set even if the corresponding interrupt is disabled unlike those in the QSPI_INTR_STATUS_ENABLED_CLEAR register, which are set only if the corresponding interrupt is enabled.
- The QSPI also generates an interrupt if a certain bit in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the QSPI_INTR_ENABLE_SET_REG register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 when an IRQ condition occurs.

- Even if interrupts are not enabled, a certain status bit in the QSPI_INTR_STATUS_RAW_SET register can also be cleared by setting to 0x1 the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register.

It must be considered that the previously described scenario applies if the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1.

Note

The QSPI_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
  - during operations using the memory-mapped port by setting to 0x1 both the QSPI_SPI_SWITCH_REG[1] MM_INT_EN and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
  - during operations using the configuration port by setting to 0x1 both the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the QSPI_SPI_CMD_REG[15] FIRQ and QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET bits.

The QSPI_IRQ interrupt line is also activated when both the conditions are met.

Table 24-282 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 24-282. QSPI Events

Event Flag	Event Mask	Description
QSPI_INTR_STATUS_RAW_SET[1] WIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[1] WIRQ_ENA QSPI_SPI_STATUS_REG[1] WC	QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[1] WIRQ_ENA_CLR QSPI_SPI_CMD_REG[14] WIRQ	Word complete interrupt event. Asserted each time after a word is transferred or received.
QSPI_INTR_STATUS_RAW_SET[0] FIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[0] FIRQ_ENA QSPI_SPI_STATUS_REG[2] FC	QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[0] FIRQ_ENA_CLR QSPI_SPI_CMD_REG[15] FIRQ	Frame complete interrupt event. Asserted each time after a frame is transferred or received.

24.5.4.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the four supported external SPI devices. The L3_MAIN start address at which the configuration port is available is 0x4B30 0000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with one of the four supported external SPI devices. This memory region starts at 0x5C00 0000 and ends at 0x5FFF FFFF L3_MAIN address.

The CTRL_CORE_CONTROL_IO_2[10:8] QSPI_MEMMAPPED_CS bit field provides a functionality for remapping the previously described address space which starts at 0x5C00 0000 L3_MAIN address to one of the four supported chip selects or to the configuration registers. The CTRL_CORE_CONTROL_IO_2 register resides in the CTRL_MODULE_CORE.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in Table 24-284. These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory) the SPI_CORE module should be used and the data exchanged is available thorough these four data registers, which can be accessed only through the configuration port. When a communication with an external SPI flash memory is desired, the memory-mapped port should be used.

In other words, to read from an external SPI flash memory, first configure the QSPI through the configuration port and then perform a read through the memory-mapped port.

24.6 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

24.6.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP module can operate in both transmit and receive modes. The McASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

Although intercomponent digital audio interface reception (DIR) mode (i.e. S/PDIF stream receiving) is not natively supported by the McASP module, a specific TDM mode implementation for the McASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

The device have integrated eight McASP modules with:

- McASP1 and McASP2 supporting up to 16 channels with independent TX/RX clock/sync domain
- McASP3 through McASP8 modules supporting up to 4 channels with independent TX/RX clock/sync domain

Figure 24-108 shows the McASP modules in the device.

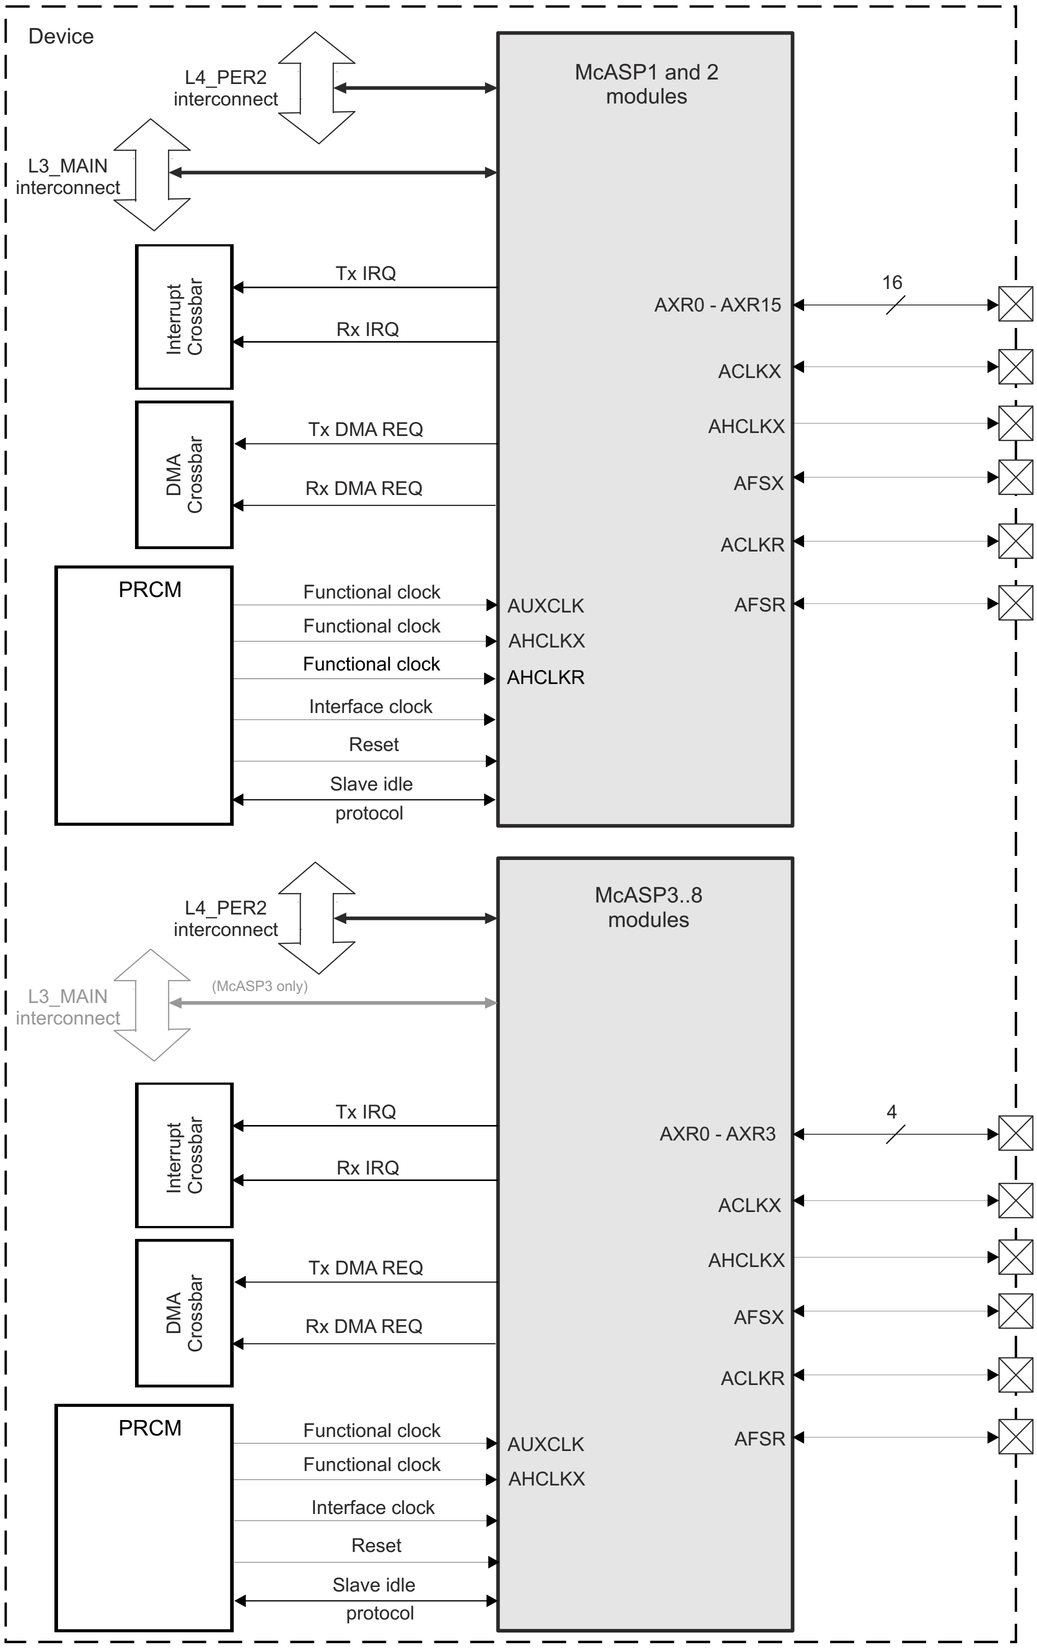

Figure 24-108. McASP Modules Overview

McASP module includes the following main features:

- Two modules (McASP1 and McASP2) supporting up to 16 channels each and independent TX/RX clock/sync domains.
- Six modules (McASP3, McASP4, McASP5, McASP6, McASP7, and McASP8) supporting up to 4 channels each and unified clock/sync domain.
- Independent serializer for each AXRx channel of each McASPx module.
- Idle request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- 2 x interconnect slave interface ports:
  - A configuration (CFG) port supplied with an internal L4-interconnect interface clock
  - A slave DMA data port synchronized with functional clock
- Two independent clock generator modules for transmit and receive.
  - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- McASP module functional clock can be generated:
  - internally (master mode)
  - supplied over McASP serial interface (slave mode)
  - has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator.
  - TDM streams from 2 to 32, and 384 time slots.
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
  - Data formatter for bit manipulation.
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT):
  - S/PDIF, IEC60958-1, AES-3 formats.
  - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Support for 2x DMA requests (one per direction):
  - 1 level-sensitive transmit direct memory access (DMA) request common for all of the McASP serializers
  - 1 level-sensitive receive direct memory access (DMA) request common for all of the McASP serializers
  - All transmit DMA requests are mapped to the device DMA crossbar
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupt Crossbar

Note

Because a serializer receive and transmit channels data is shared on the same McASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

24.6.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case. Figure 24-109 shows the McASP modules in their environment in the device.

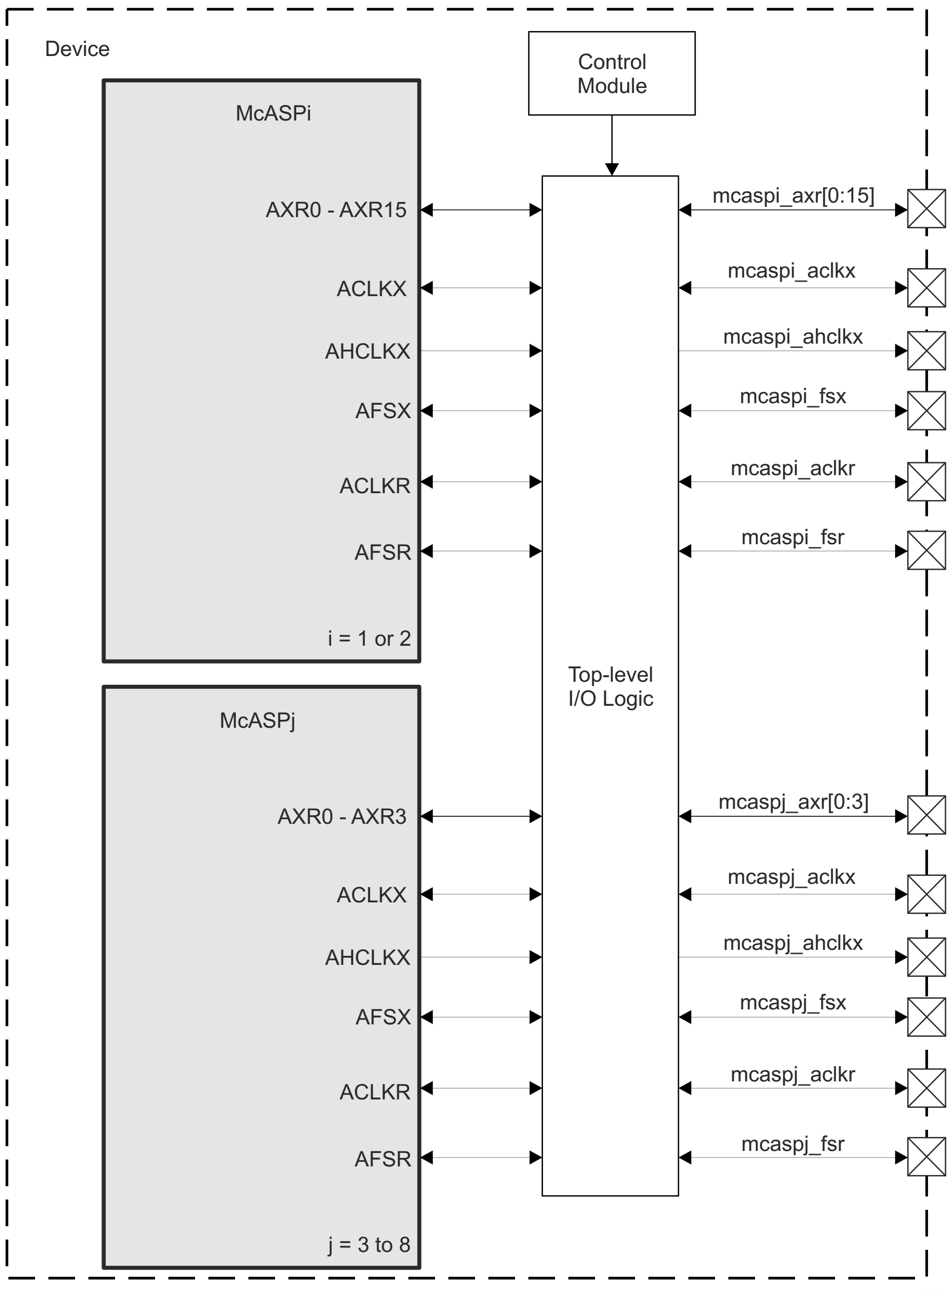

Figure 24-109. McASP Environment

24.6.2.1 McASP Signals

Table 24-325 describes the McASP pins, their corresponding signal names at device level and specifies their links to functions.

Table 24-325. McASP I/O Signals

ACLKR	mcasp8_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcasp8_fsr	I/O	Receive frame synchronization	HiZ

(1) I = Input; O = Output; I/O = Bidirectional

Note

For the mcaspx_aclkx, mcaspx_ahclkx and mcaspx_aclkr signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

Note

The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the *Pad Configuration Registers*, and *Control Module Register Manual*, in *Control Module*.

Note

A serializer AXR data pin is shared between the transmit and receive logic of that serializer. The direction of data is determined in the MCASP_PDIR and the function (Tx or Rx) is selected in the corresponding serializer control register MCASP_XRSRCTLn.

24.6.2.2 Protocols and Data Formats

24.6.2.2.1 Protocols Supported

The McASP supports a wide variety of protocols:

- Transmit section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.

  - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections of the module may be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
  - Automatically aligns data internally in either Q31 or integer formats.
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

Note

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode for McASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.
- Stereo Support Only (Mono means send data 2x via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

Note

The McASP does NOT natively support DIR-mode reception (i.e. receiving in the S/PDIF format). To allow this, the McASP can use a DIR-input to I2S-output converter implemented by an external device (i.e. external DIR component). To facilitate reception in this case, the TDM mode of McASP receivers logic is extended to support a non-standard 384-slot TDM stream.

Note

An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

24.6.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a McASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 24-110 shows two of the three basic components: the clock signal (ACLKX/ACLKR) and the data signals AXRn. Figure 24-110 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the McASP are configured to operate synchronously.

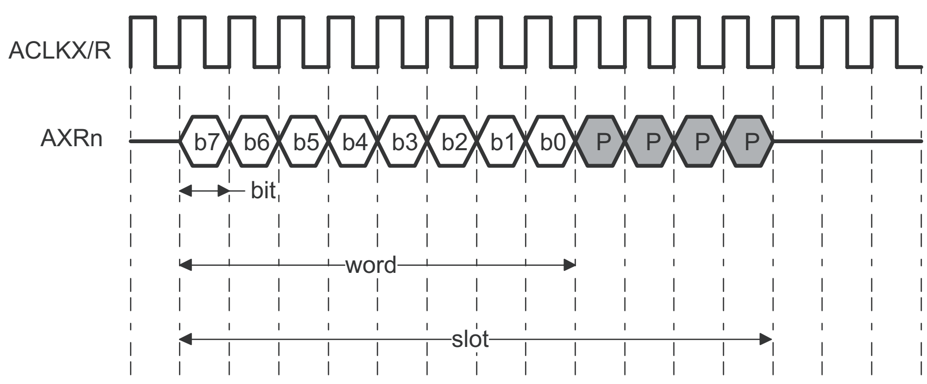
- Bit:

  A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.
- Word:

  A word is a group of bits that make up the data being transferred between the McASP and the external device. Figure 24-110 shows an 8-bit word.
- Slot:

  A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In Figure 24-110, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on an AXRn pin with either MSB or LSB first.

  When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, i.e. left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. Figure 24-111 shows these options.



(1) b7:b0 - bits. Bits b7 to b0 form a word.

(2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.

(3) In this example, the data is transmitted MSB first, left-aligned.

mcasp-003

Figure 24-110. Definition of Bit, Word, and Slot

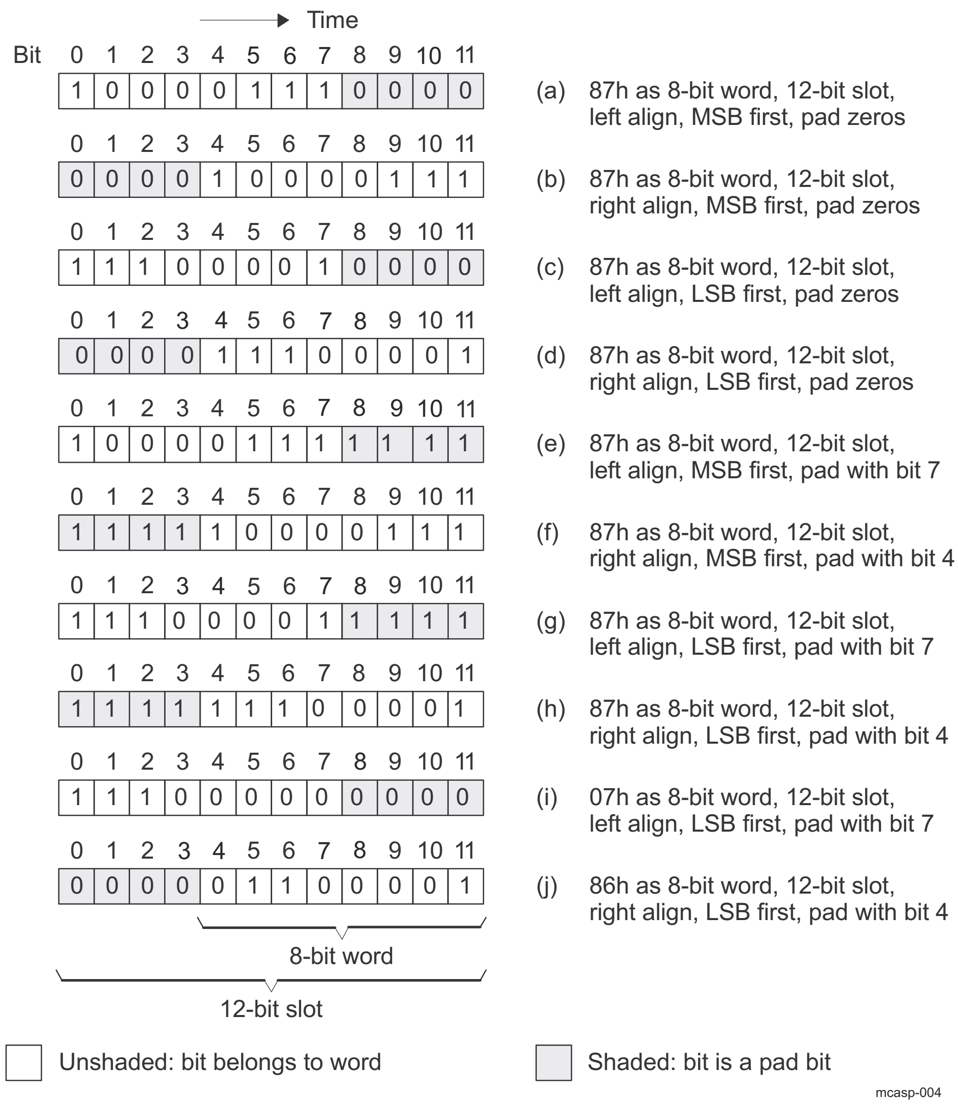


Figure 24-111. Bit Order and Word Alignment Within a Slot Examples

- Frame

  The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. Figure 24-112 shows an example frame of data and the frame definitions. In operation, the transmitter uses AFSX, and the receiver - AFSR signal. Figure 24-112 does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter/receiver uses AFSX/AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously. This example shows two slots in a frame (I2S format) and a frame-sync (FS) duration of a slot length.

  This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see Section 24.6.2.2.3, *TDM Format* and Section 24.6.2.2.5, *S/PDIF-Coding Format*.

Note

All of the McASP serializers share the same, device pad accessible, clock and frame signals, as follows:

– AHCLKX, ACLKX, and AFSX for the transmitting section
– ACLKR and AFSR for the receiving section

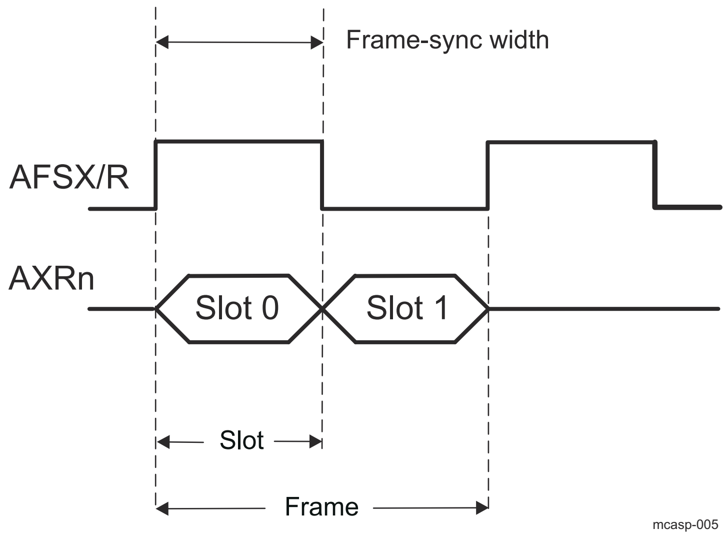

Figure 24-112. Definition of Frame and Frame-Sync Width

The following terms are used throughout this chapter:

- TDM: Time-division multiplexed. See Section 24.6.2.2.3 for details on the TDM protocol
- I2S: Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on each AXRn data pin.
- DIR: Digital audio interface receive. The McASP does NOT natively support receiving in S/PDIF format on AXRn data pins and requires an external DIR-to-TDM or DIR-to-I2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT/DIR format, a McASP time slot corresponds to a DIT/DIR subframe.

24.6.2.2.3 TDM Format

The TDM format is used to transfer data between the host CPU and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one McASP data pin - AXRn is illustrated on Figure 24-113.

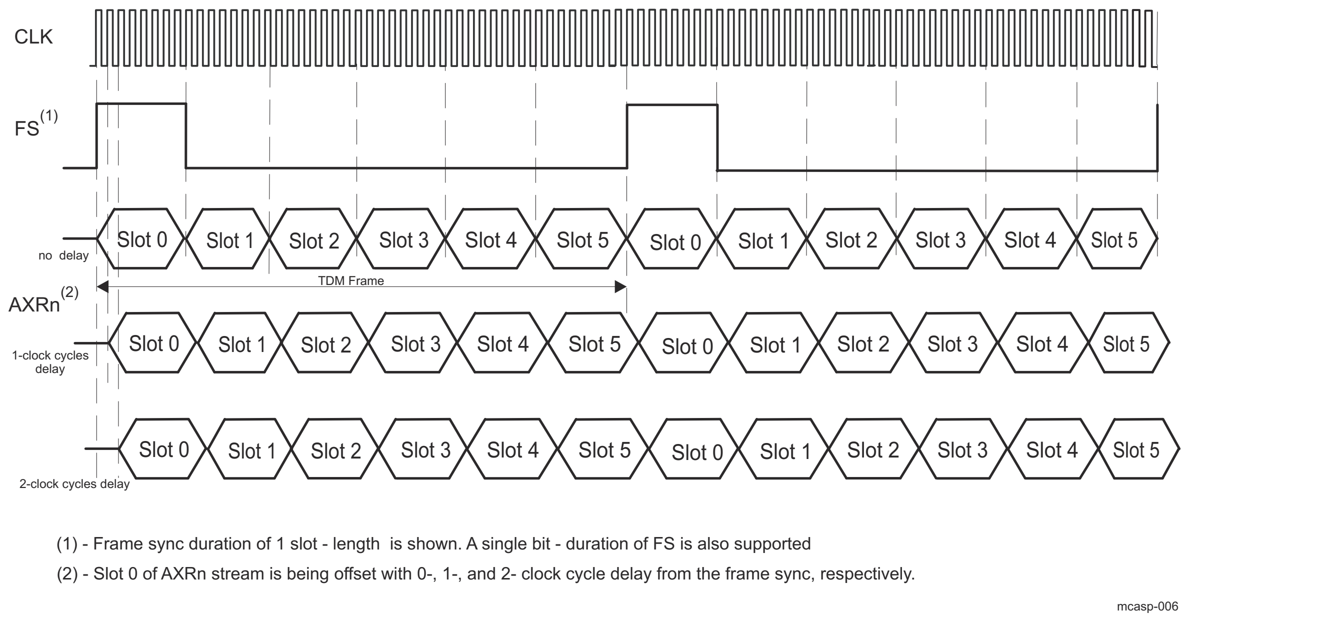

Figure 24-113. TDM Format - 6 channel example

The TDM format uses three signals In a basic synchronous serial interface: data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also Section 24.6.2.2.2), the latter being also refered to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For McASP, there is an option to offset the first bit of the first slot with a 0-,1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does not determine the boundaries of a slot, there is a requirement for a connected transmitter and receiver to agree on the number of transferred bits per slot.

In a typical audio system involving McASP module, a single TDM data frame is transferred during each sample period Ts of a data converter. The user has following choices to implement multiple channels:

- Use more data slots (on a price of higher speed serial clock) per frame transmitted/received on just one of the available McASP data pins AXRn.
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the McASP pins AXRn.

24.6.2.2.4 I2S Format

The TDM transfer mode of the McASP supports the I2S format when frame is configured to have 2 slots. I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format equals size of a slot. The frame signal is also referred to as "word select" in the I2S format.

The I2S protocol is illustrated on Figure 24-114.

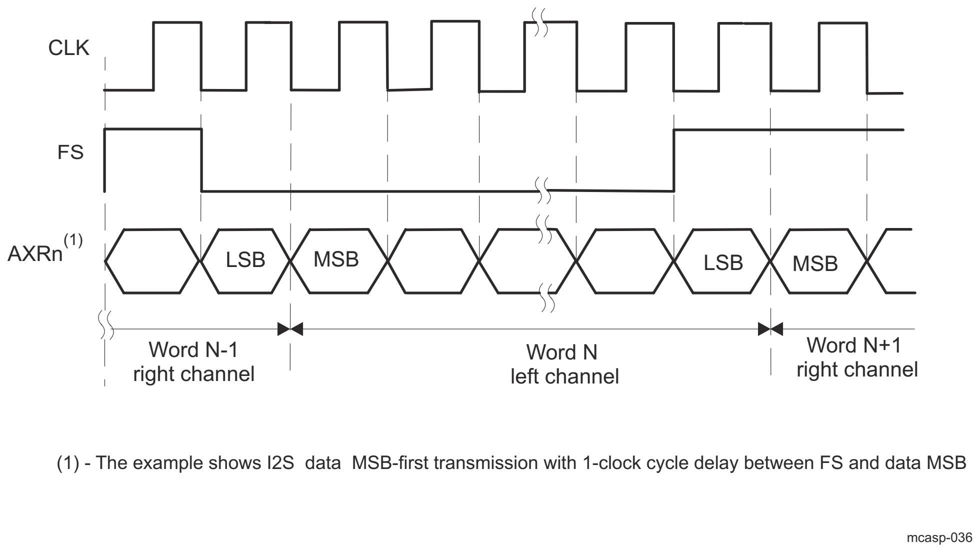

Figure 24-114. I2S Format Overview

24.6.2.2.5 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphase-mark encoded output. The S/PDIF format is supported by the DIT- transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

Note

The DIR- reception of S/PDIF format frames is NOT natively supported from the device McASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the McASP TDM-only compatible receiver input.

24.6.2.2.5.1 Biphase-Mark Code

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). For each serializer transmitter n, the clock, frame, and data are embedded in only one signal - the data signal AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 24-115 and Table 24-326 show how data is encoded to the BMC format.

As shown in Figure 24-115, the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to 128 × f_S, where f_S is the sample rate (see Section 24.6.2.2.5.3, *Frame Format*, for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

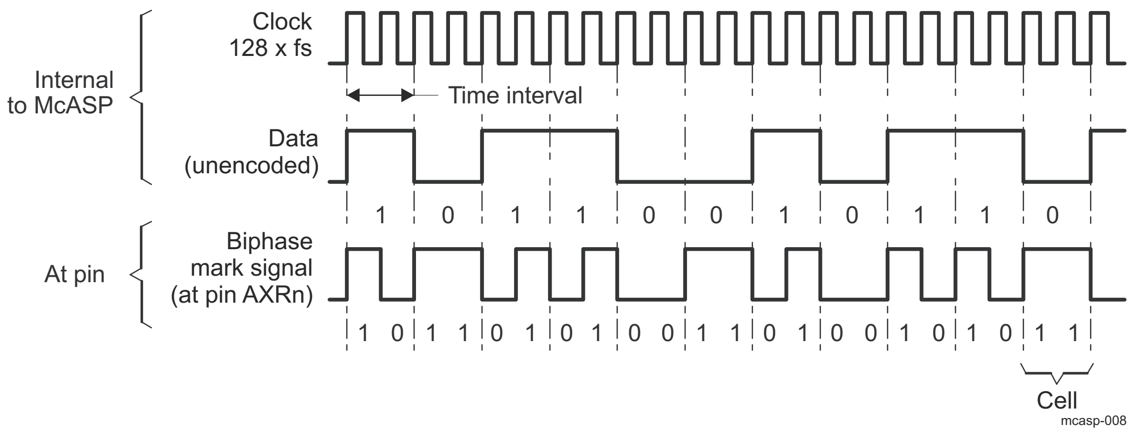

Figure 24-115. Biphase-Mark Code

Table 24-326. Biphase-Mark Encoder

Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at Pin AXRn
0	0	11
0	1	00
1	0	10
1	1	01

24.6.2.2.5.2 S/PDIF Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. Figure 24-116 shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 24-327.
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in Table 24-327, the preambles (time intervals 0–3) are also defined with even parity.

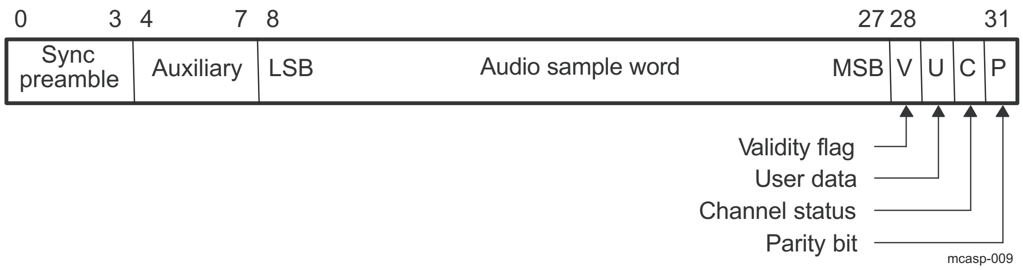

Figure 24-116. S/PDIF Subframe Format

As listed in Table 24-327, the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

Table 24-327. Preamble Codes

Preamble Code[(1)]	Previous Logical State	Logical States on pin AXRn[(2)]	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

(1) Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.
(2) The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

24.6.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see Figure 24-117). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s. The S/PDIF format clock rate is therefore 128 × f_s (128 = 32 cells per subframe × 2 clocks per cell × 2 subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is 128 × 192 kHz = 24.58 MHZ.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

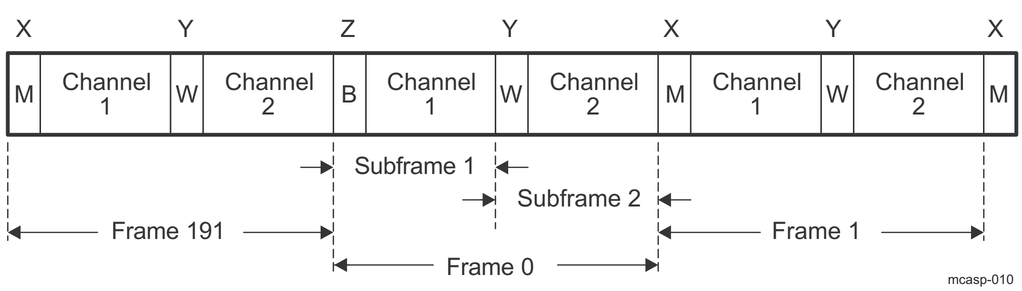

Figure 24-117. S/PDIF Frame Format

24.6.3 McASP Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

McASP module includes the following features:

- Slave idle protocol
- One DMA request for transmit event
- One DMA request for receive event
- One interrupt request (IRQ) for transmit
- One interrupt request (IRQ) for receive

Figure 24-118 shows McASP integration.

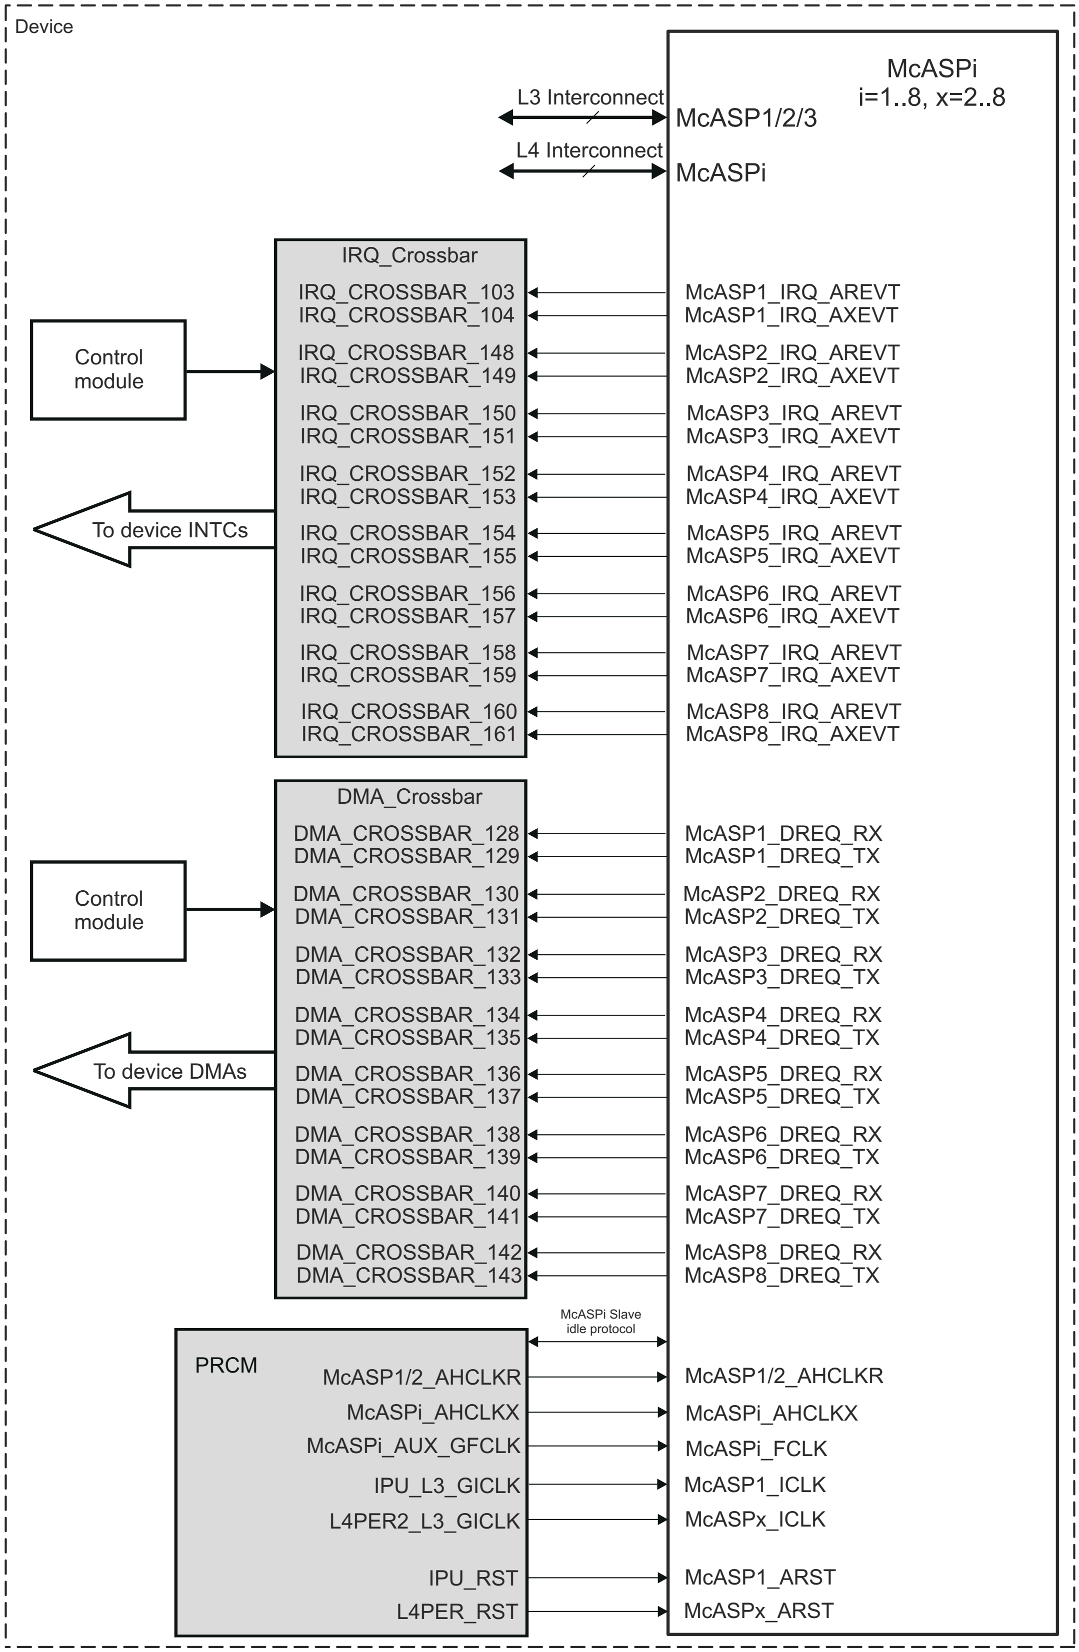

Figure 24-118. McASP Integration

Note

For more information about the slave idle protocol, see *Module Level Clock Management* of *Power, Reset, and Clock Management*.

Table 24-328 through Table 24-330 summarize McASP integration in the device.

Table 24-328. McASP Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
McASP1	PD_COREAON	No	L3_MAIN L4_PER2
McASP2	PD_COREAON	No	L3_MAIN L4_PER2

Note

The **Default Mapping** column in Table 24-330 *McASP Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

For more information about the device DSP1_EDMA and DSP2_EDMA modules, see *DSP Integrated EDMA Subsystem*.

Note

- For the description of the interrupt source, see Section 24.6.4.12, *McASP Events and Interrupt Requests*.
- For the description of the DMA source, see Section 24.6.4.13, *DMA Requests*.

24.6.4 McASP Functional Description

In the text throughout this section a single instance of McASP is described assuming that all modules are functionally identical. For module availability and integration differences, see Section 24.6.2, *McASP Environment*, and Section 24.6.3, *McASP Integration*

24.6.4.1 McASP Block Diagram

Figure 24-119 shows the major blocks of the McASP module. McASP1 and McASP2 have 16 serializers each, and McASPn (n = 3 to 8) have 4 serializers each. The serializers share a clock and frame-sync generator, format unit, and error-checking logic independently for the receive and transmit part.

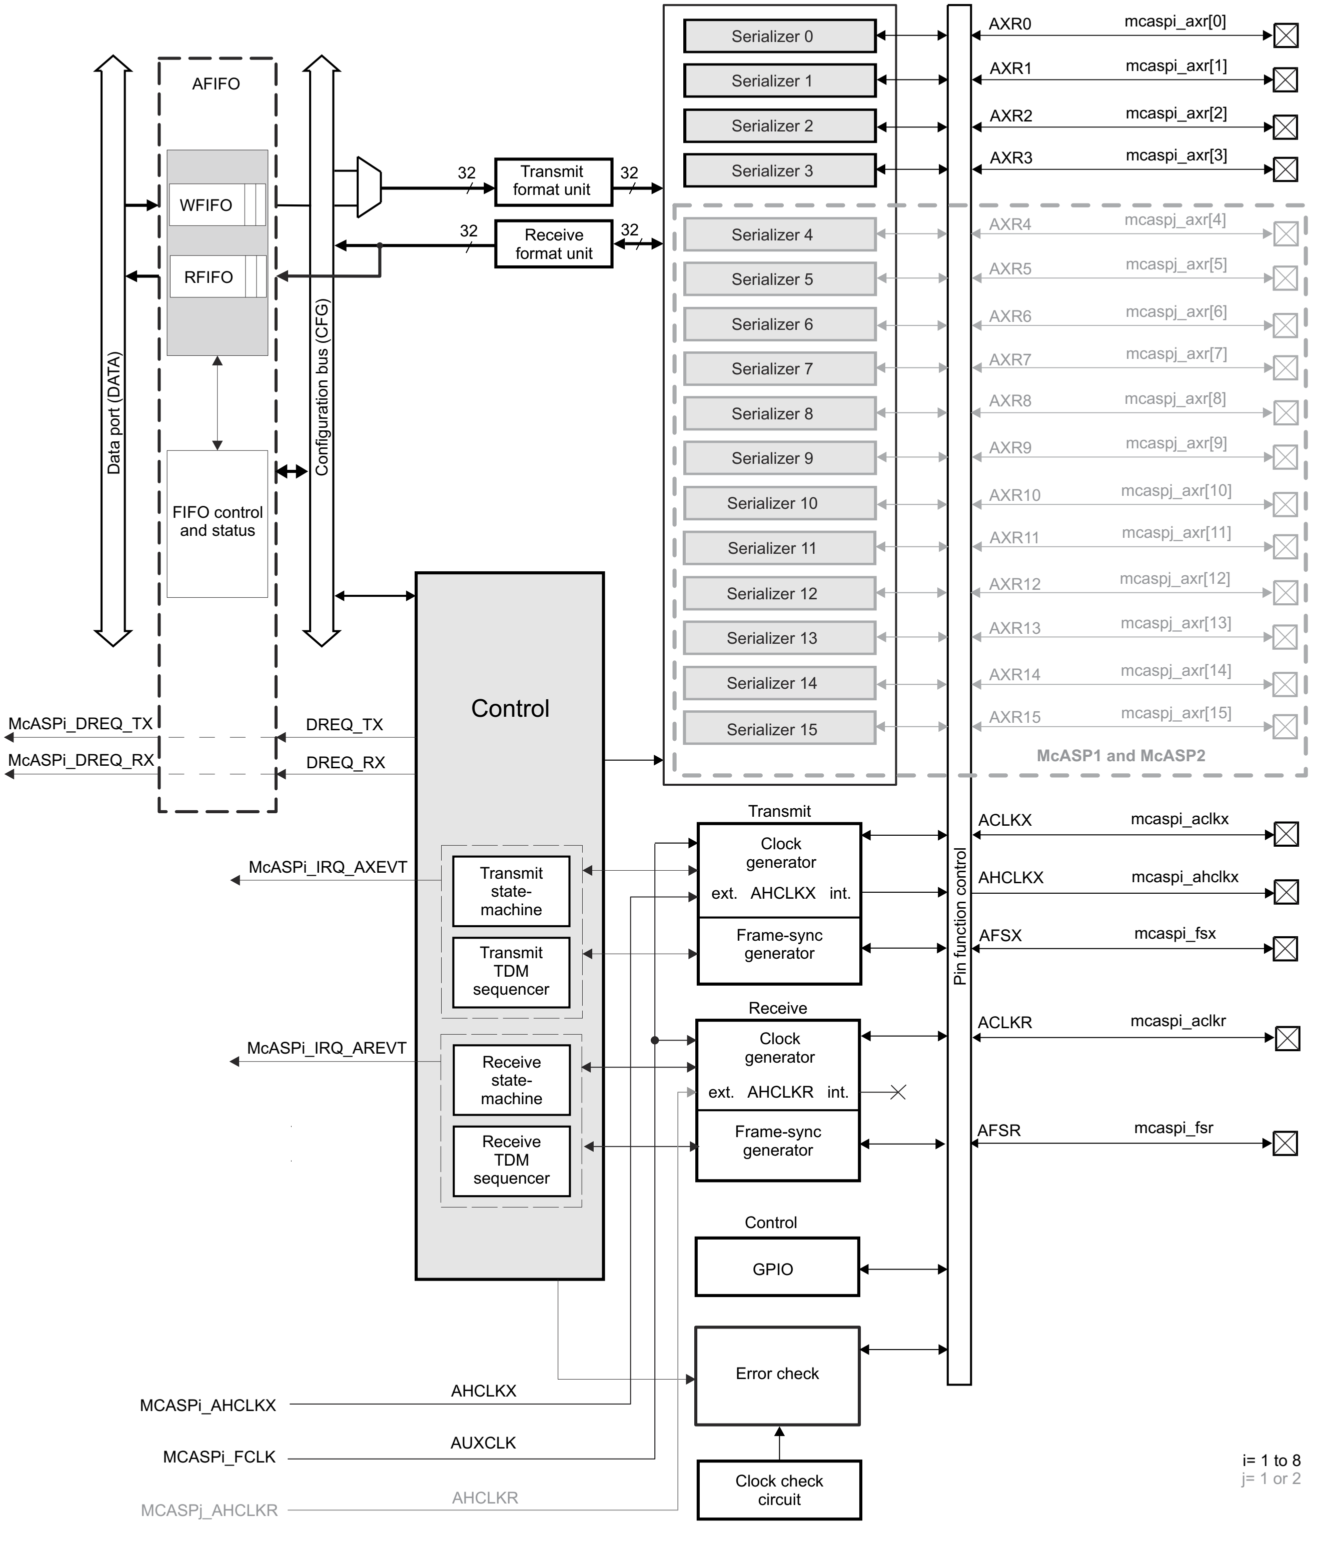

Figure 24-119. McASP Module Block Diagram

Note

The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

24.6.4.2 McASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the McASP serializers. The first three scenarios are identical between the Tx and Rx part of the McASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for McASP receivers - RCLK is derived from the bit rate clock of the McASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the McASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

24.6.4.2.1 McASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- MCASP_ACLKXCTL
- MCASP_AHCLKXCTL

In case, the transmit bit clock, ACLKX, is generated internally, the MCASP_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKXCTL[4:0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in Section 24.6.4.2, the MCASP_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKXCTL[11:0] HCLKXDIV bit field) from the McASP internal clock source AUXCLK.

Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see Figure 24-120). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If MCASP_ACLKXCTL[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If MCASP_ACLKXCTL[7] CLKXP = 1, the CLKX mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

It can be seen in Figure 24-120 that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between McASP transmitters and receivers. This is used for example in the McASP loopback mode.

Note

The polarity of ACLKX can be controlled in MCASP_ACLKXCTL[7] CLKXP, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the MCASP_AHCLKXCTL[14] HCLKXP bit.

Note

In a similar way, the polarity of AHCLKX clock can be controlled in MCASP_AHCLKXCTL[14] HCLKXP, regardless of the AHCLKX signal being internally or externally sourced.

Figure 24-120 is the block diagram of the transmit clock generator.

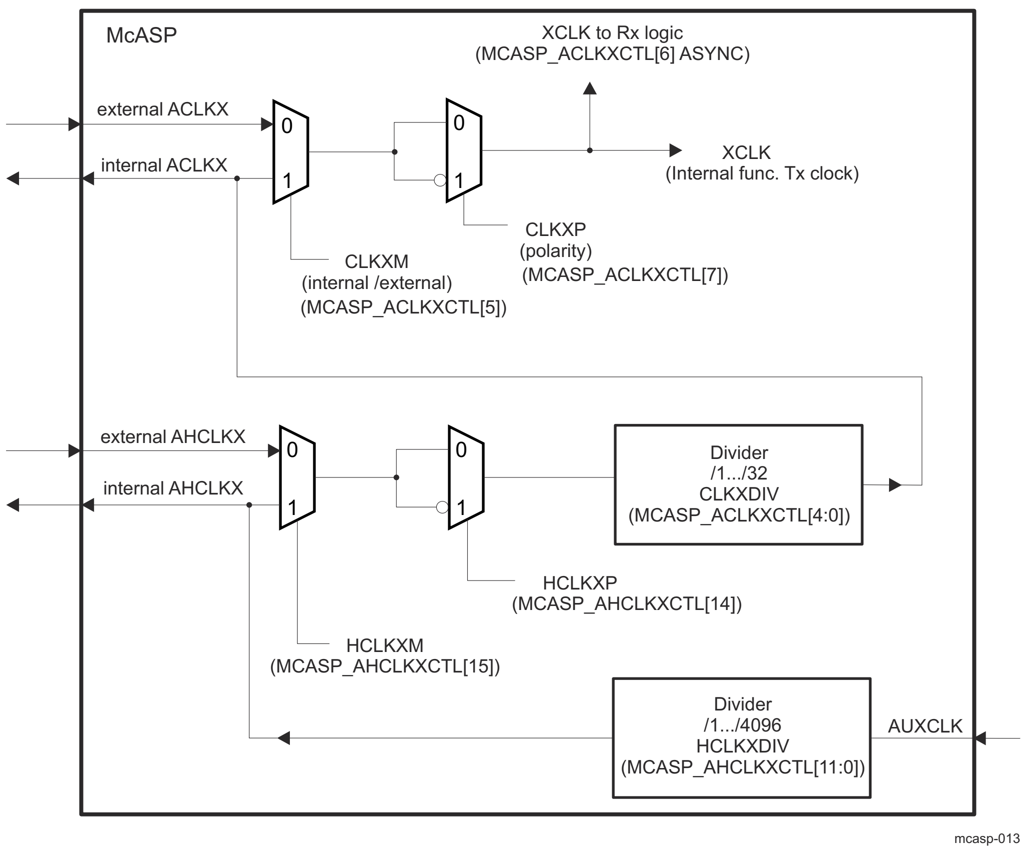

Figure 24-120. Transmit Clock Generator Block Diagram

Note

In this device:

- ACLKX is mapped on the device ball mcaspi_aclkx, where i = 1 to 8
- internal AHCLKX is mapped on the device ball mcaspi_ahclkx
- external AHCLKX is mapped on MCASPi_AHCLKX clock from the PRCM

For more on McASP integration, see Section 24.6.2, *McASP Environment*, and Section 24.6.3, *McASP Integration*.

24.6.4.2.2 McASP Receive Clock

The McASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- MCASP_ACLKRCTL
- MCASP_AHCLKRCTL

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the MCASP_ACLKRCTL[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKRCTL[4:0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in Section 24.6.4.2) and the MCASP_AHCLKRCTL[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKRCTL[11:0] HCLKRDIV bit field) from the McASP internal clock source AUXCLK.

Note

The polarity of ACLKR can be controlled in MCASP_ACLKRCTL[7] CLKRP, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in MCASP_AHCLKRCTL[14] HCLKRP, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the McASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see Figure 24-120 and Figure 24-121) becomes source of the receive clock (RCLK output), when the MCASP_ACLKXCTL[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to Section 24.6.4.2.4.

Figure 24-121 is the block diagram of the receive clock generator.

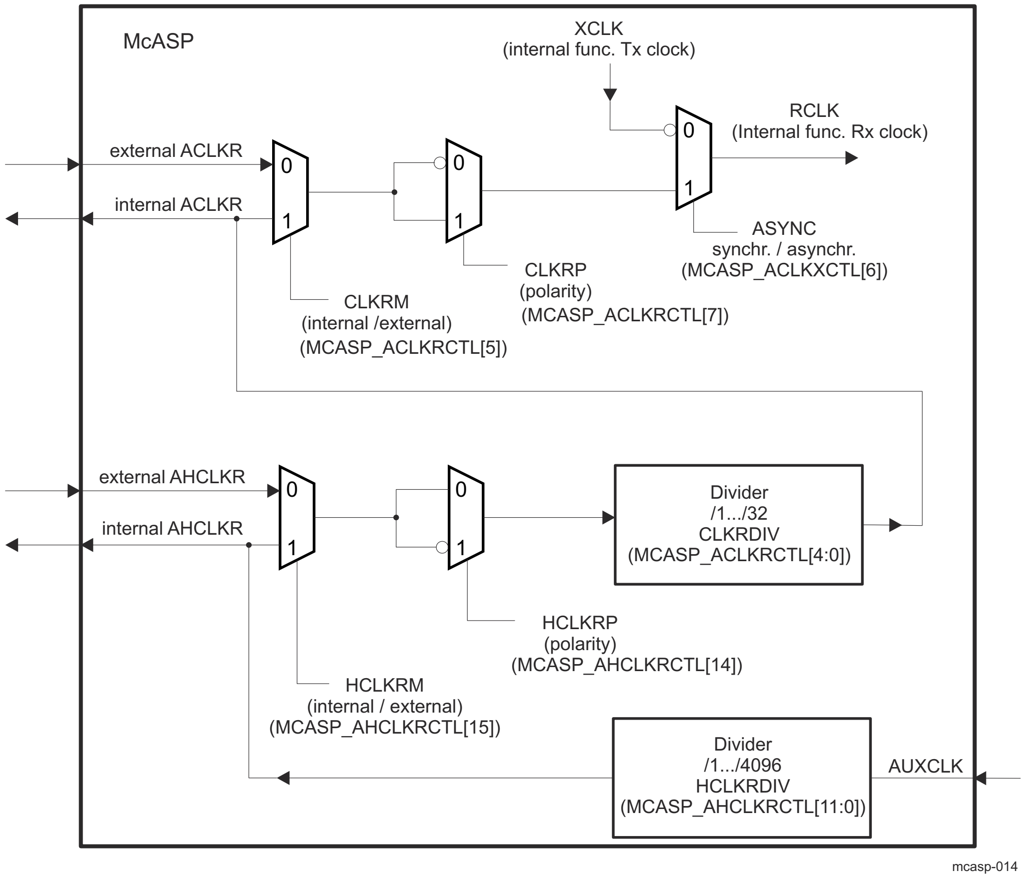

Figure 24-121. Receive Clock Generator Block Diagram

Note

In this device:

- ACLKR is mapped on the device ball mcaspi_aclkr, where i = 1 to 8
- internal AHCLKR is tied-off
- external AHCLKR is mapped on PRCM MCASPi_AHCLKR from PRCM for McASP1 and McASP2
- external AHCLKR is tied-off for McASP3 through McASP8

For more on McASP integration, see Section 24.6.2, *McASP Environment*, and Section 24.6.3, *McASP Integration*.

24.6.4.2.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The McASP frame sync generator logic is illustrated in Figure 24-122. I/O buffers are not part of the McASP module, and are not shown in the figure.

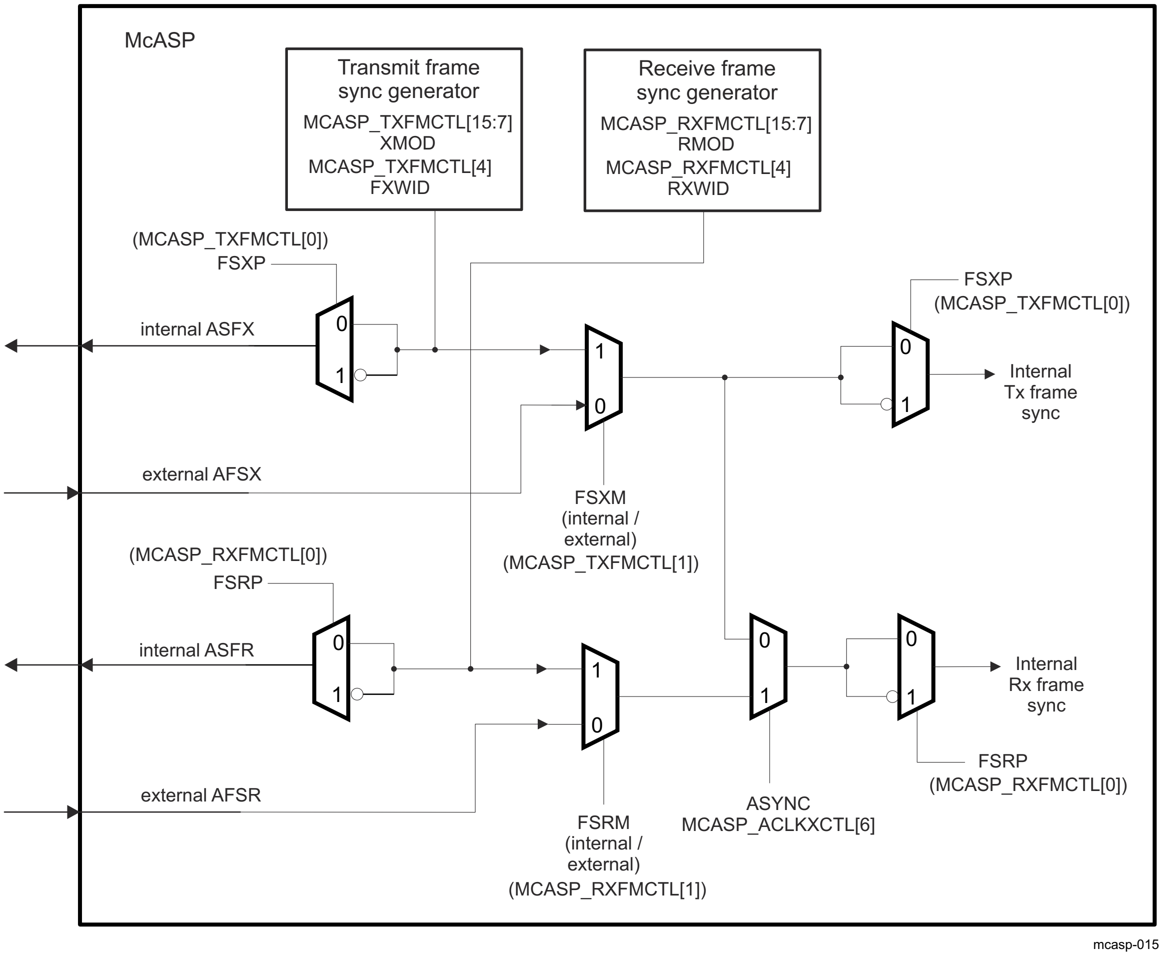

Figure 24-122. Frame Sync Generator Block Diagram

Note

For more on McASP integration, see Section 24.6.2, *McASP Environment*, and Section 24.6.3, *McASP Integration*.

For the transmit logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_TXFMCTL[1] FSXM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_TXFMCTL[0] FSXP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_TXFMCTL[4] FXWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_TXFMCTL[15:7] XMOD, as follows:
  - For DIT mode (384 slots) - MCASP_TXFMCTL[15:7] XMOD = 0x180
  - For I2S mode (2 TDM slots) - MCASP_TXFMCTL[15:7] XMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP_TXFMCTL[15:7] XMOD set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_TXFMT[17:16] XDATDLY

For the receive logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_RXFMCTL[1] FSRM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_RXFMCTL[0] FSRP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_RXFMCTL[4] FRWID

- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_RXFMCTL[15:7] RMOD, as follows:
  – For I2S mode (2 TDM slots) - MCASP_RXFMCTL[15:7] RMOD = 0x2
  – For TDM mode (from 3 to 32 TDM slots) - MCASP_RXFMCTL[15:7] RMOD set in range 0x3 - 0x20
  – For the special 384-slot TDM mode - MCASP_RXFMCTL[15:7] RMOD=0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_RXFMT[17:16] RDATDLY
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to Section 24.6.4.2.4.

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

Note

Certain restrictions apply to the receive and transmit logic settings, when MCASP_ACLKXCTL[6] ASYNC is set to 0b0. They are described in Section 24.6.4.2.4.

24.6.4.2.4 Synchronous and Asynchronous Transmit and Receive Operations

Synchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the Figure 24-121, with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When MCASP_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP_TXDITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ * RMOD product value must equal XSSZ * XMOD product value)
- The settings in MCASP_ACLKRCTL are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

Asynchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

Note

Synchronous transmit and receive operations are allowed only in the McASP TDM (I2S) mode (i.e. when MCASP_TXDITCTL[0] DITEN=0b0).

24.6.4.3 Serializers

The McASP serializers shift serial data in (Rx) and out (Tx) of the McASP. A given serializer n consists of a shift register (XRSRn) with a single-entry data buffer XRBUFn used either for transmitting (write accessible in register MCASP_TXBUFn) or for receiving (read accessible in register MCASP_RXBUFn) data. In addition, each serializer has a dedicated control register (MCASP_XRSRCTLn) and a serial bidirectional data pin - AXRn. The register MCASP_XRSRCTLn allows n-th serializer to be configured as a transmitter, receiver, or as inactive.

There are transmit and receive data formatting units to support data alignment options of the McASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSRn shifter configured as a receiver in MCASP_XRSRCTLn, shifts in data through McASP corresponding device level bidirectional data pad AXRn. A given serializer XRSRn shifter configured as a transmitter in MCASP_XRSRCTLn, shifts out data on McASP corresponding device level bidirectional data pad AXRn.

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for McASP there are at most a couple of zones, one for transmit and one for receive.

Figure 24-123 is the serializer block diagram.

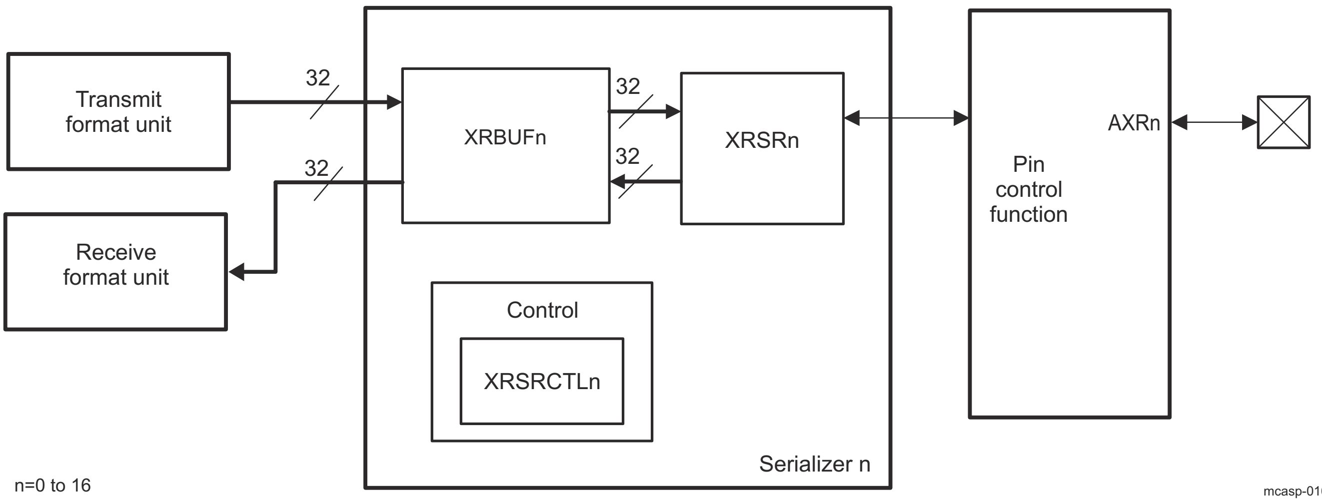

Figure 24-123. Individual Serializer and Connections Within McASP

Transmission on the n-th serializer is performed as follows:

The McASP is serviced by writing data into the register MCASP_TXBUFn, which is an alias of the serializer data buffer - XRBUFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFn register in the serializer. The data is then copied from the XRBUFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

Reception from the n-th serializer is performed as follows:

The data is shifted into the McASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFn,and can be accessed in the MCASP_RXBUFn register, which is an alias of the serializer data buffer - XRBUFn for receive function. When software reads the data from this register, the McASP passes the data through the receive format unit, hence it returns the formatted data.

Serializer controls:

A serializer n is configured as inactive via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x0.

For a transmitting serializer, the MCASP_XRSRCTLn[3:2] DISMOD bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x1.

Receive function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x2.

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see Section 24.6.2.2.5

24.6.4.4 Format Units

The McASP has one transmit data formatting unit and one receive data formatting unit, shared between the device McASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers.

Note

The McASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP_RXFMT/MCASP_TXFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the MCASP_RXFMT/MCASP_TXFMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in MCASP_RXFMT/ MCASP_TXFMT means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

24.6.4.4.1 Transmit Format Unit

The McASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

Figure 24-124 shows the transmit formatting unit.

The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register - MCASP_TXFMT:

- XRVRS: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

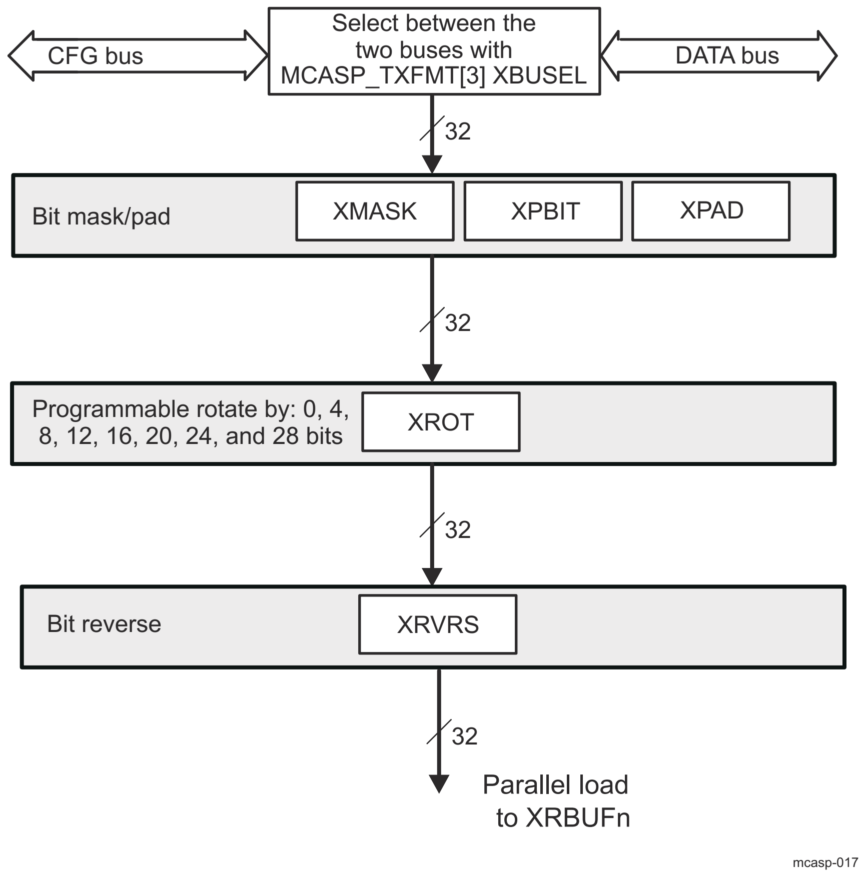

Figure 24-124. Transmit Format Unit

As shown in Figure 24-124, the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_TXFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the Section 24.6.4.10.1.3, *Transfers Through the DATA Port*, and Section 24.6.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP_TXMASK[31:0] XMASK contents. The masked data is then right-rotated to MCASP_TXFMT[2:0] XROT positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

24.6.4.4.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots.

XSSZ should always be programmed to match the slot size of the serial stream.

Note

Note that, TDM word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

The Table 24-331 show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The Table 24-331 assumes that all slot size (SLOT in Table 24-331) and word size (WORD in Table 24-331) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter by the MPU or DSP (typically Q31 or integer).

Table 24-331. McASP TFU TDM Mode Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_TXFMT bits	
			XROT(1)	XRVRS
MSB first(2)	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first(2)	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

24.6.4.4.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP_TXFMT[17:16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP_TXFMT[2:0] XROT =
  - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
  - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
  - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0xFFFFFF00 – 0xFFFF0000
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP_TXFMT[2:0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in Table 24-332 should be applied to McASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the McASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

Table 24-332. McASP TFU DIT-Mode Example Settings

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFFF000	0x3
LEFT	24	8	0xFFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated by MPU on the McASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the Table 24-332, the user must set XMASK=0xFFFFF000, and to select a right-rotation to 12 positions (XROT=0x3).

- After applying 0-s (XPAD=0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF.Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVRS = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the McASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table McASP TFU Example Settings, user is supposed to set XMASK=0x0000FFFF, and to select right-rotation to 0 positions (XROT=0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

24.6.4.4.2 Receive Format Unit

The McASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

Figure 24-125 shows the receive format unit (RFU).

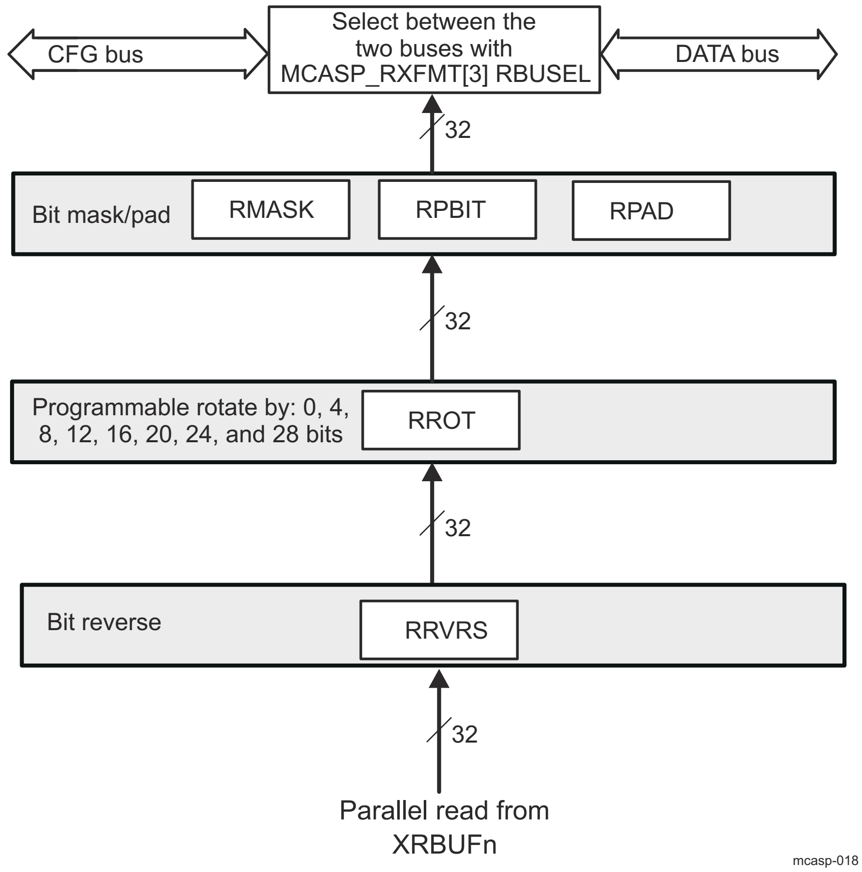

Figure 24-125. Receive Format Unit

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - MCASP_RXFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on Figure 24-125, the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_RXFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the Section 24.6.4.10.1.3, *Transfers Through the DATA Port*, and Section 24.6.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

24.6.4.4.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

Note

Note that the word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 24-333 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

Table 24-333. McASP RFU Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RXFMT bits	
			RROT[1]	RRVRS
MSB first[2]	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first[2]	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 24-333 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 24-125), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer).

24.6.4.5 State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the McASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP_TXFMT) and it reports the McASP status and error conditions in the transmitter status register (MCASP_TXSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP_RXFMT) and it reports the McASP status and error conditions in the receiver status register (MCASP_RXSTAT).

24.6.4.6 TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of MCASP_RXTDM/ MCASP_TXTDM and determines if the McASP should receive/transmit in that time slot.

There are two possibilities for a slot: The McASP either performs Rx/Tx operations during the time slot (transmit/ receive bit is active), or the McASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control register MCASP_XRSRCTLn[3:2] DISMOD. Refer also to Section 24.6.4.9.2.1, *TDM Time Slots Generation and Processing*, for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

In case of a DIT-transmission (S/PDIF transfers): the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP_TXBUFn register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the MCASP_TXTDM register and reports the current transmit slot to the MCASP_TXTDMSLOT[9:0] XSLOTCNT bit field.

24.6.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit and receive control register (MCASP_GBLCTL). A valid serial clock must be supplied to the McASP to assert the software reset bits in the MCASP_GBLCTL register.

24.6.4.8 McASP Power Management

Table 24-334 describes power-management features available to the McASP.

Table 24-334. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	PWRIDLESYSCONFIG[1:0] IDLE_MODE	Force-idle, no-idle, and smart-idle modes are available.

> **CAUTION**
>
> No wakeup schema is supported for the McASP. To ensure a correct behavior after enabling McASP at device PRCM level, the user software is strongly recommended to choose *No Idle* mode, setting PWRIDLESYSCONFIG[1:0] IDLE_MODE to 0x1. Before disabling McASP at device PRCM level, user software is strongly recommended to choose a *Smart-Idle* mode, setting PWRIDLESYSCONFIG[1:0] IDLE_MODE to 0x2.

24.6.4.9 Transfer Modes

24.6.4.9.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

When operating in burst frame sync mode (see Figure 24-126), as specified for transmit (MCASP_TXFMCTL[15:7] = 0) and receive (MCASP_RXFMCTL[15:7] RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (MCASP_RXFMCTL[4] FRWID = 0, MCASP_TXFMCTL[4] FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUFn (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUFn (for every serializer set to operate as a receiver) has been read.

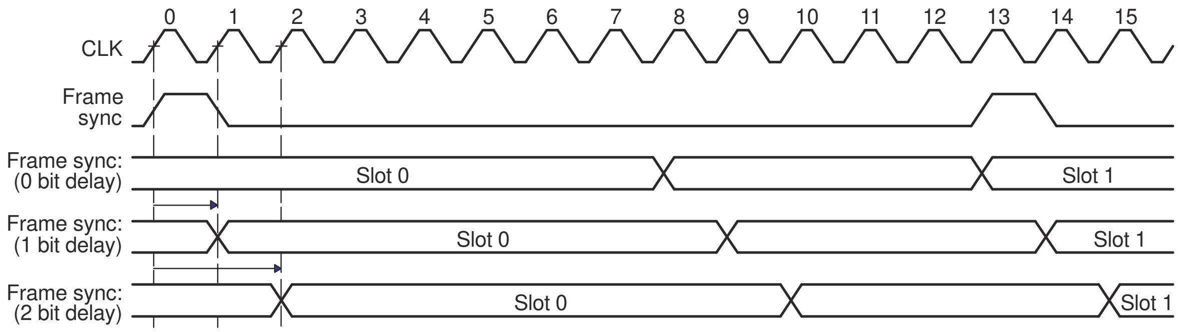

Figure 24-126. Burst Frame Sync Mode

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- MCASP_PFUNC: The clock, frame, data pins must be configured for McASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDSET, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_GBLCTL: Follow the initialization sequence in Section 24.6.5.1.2, *McASP Global Initialization*, to configure this register.
- MCASP_AMUTE: Not applicable. Leave at default.
- MCASP_LBCTL: If loopback mode is desired, configure this register according to Section 24.6.4.14 Loopback Modes, otherwise leave this register at default.
- MCASP_TXDITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- MCASP_RXMASK/MCASP_TXMASK: Mask desired bits according to Section 24.6.4.4, *Format Units*.
- MCASP_RXFMT/MCASP_TXFMT: Program all fields according to data format desired. See Section 24.6.4.4, *Format Units*.
- MCASP_RXFMT/MCASP_TXFMT: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/ FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. See Section 24.6.4.2, *McASP Clock and Frame-Sync Configurations*.
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 24.6.4.2, *McASP Clock and Frame-Sync Configurations*.
- MCASP_RXTDM/MCASP_TXTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- MCASP_EVTCTLR/MCASP_EVTCTLX: Program all fields according to interrupts desired.
- MCASP_RXCLKCHK/MCASP_TXCLKCHK: Not applicable. Leave at default.
- MCASP_XRSRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- MCASP_DITCSRAi, MCASP_DITCSRBi, MCASP_DITUDRAi, MCASP_DITUDRBi: Not applicable. Leave at default.

24.6.4.9.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in Section 24.6.2.2.3.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to transmit

For more details on McASP transmitting serializers clock and frame sync options, refer to the Section 24.6.4.2.1, *Transmit Clock*, and Section 24.6.4.2.3, *Frame-Sync Generator* .

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:
- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on McASP receiving serializers clock and frame sync options, refer to Section 24.6.4.2.2, *Receive Clock*, and Section 24.6.4.2.3, *Frame-Sync Generator* .

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:
- MCASP_PFUNC: The clock, frame, data pins must be configured for McASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDSET, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_GBLCTL: Follow the initialization sequence is described in the Section 24.6.5.2, *Operational Modes Configuration*.
- MCASP_AMUTE: Leave this register at default state.
- MCASP_LBCTL: If loopback mode is desired, configure this register according to Section 24.6.4.14, otherwise leave this register at default.
- MCASP_TXDITCTL: DITEN must be left at default 0 to select TDM mode (transmitters only).
- MCASP_RXMASK/MCASP_TXMASK: Mask desired bits according to Section 24.6.4.4, *Format Units*.
- MCASP_RXFMT/MCASP_TXFMT: Program all fields according to data format desired. See the Section 24.6.4.4, *Format Units*.
- MCASP_RXFMCTL/MCASP_TXFMCTL: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by McASP. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. For more inforamtion, refer to Section 24.6.4.2.
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. For more details, refer to Section 24.6.4.2.
- MCASP_RXTDM/MCASP_TXTDM: Program all fields according to the time slot characteristics desired.
- MCASP_EVTCTLX: Program all fields according to transmit interrupts desired.
- MCASP_RXCLKCHK/MCASP_TXCLKCHK: Program all fields according to clock checking desired.
- MCASP_XRSRCTLn: Program all fields according to serializer operation desired.

Note

The MCASP_DITCSRAi, MCASP_DITCSRBi, MCASP_DITUDRAi, MCASP_DITUDRBi (i=0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

24.6.4.9.2.1 TDM Time Slots Generation and Processing

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring MCASP_TXTDM and/or MCASP_RXTDM registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either MCASP_TXTDM or MCASP_RXTDM to determine if the McASP transmits/receives in that time slot.

Note

If a MCASP_TXTDM/MCASP_RXTDM bit defines an active slot (number of slot matches the bit position), the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. McASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP_XRSRCTLn[3:2] DISMOD.

Figure 24-127 shows when the transmit DMA event - AXEVT is generated. See Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation* for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUFn to XRSRn generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

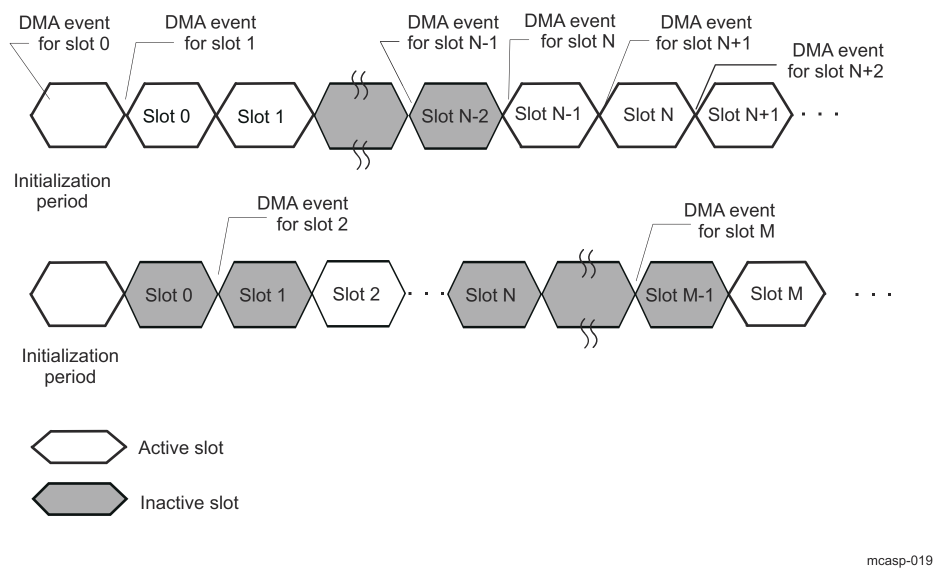

Figure 24-127. Transmit DMA Event (AXEVT) Generation in TDM Time Slots

24.6.4.9.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The receive TDM time slot register (MCASP_RXTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXRn, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in MCASP_RXFMCTL to 384 (0x180) to receive 384 time slots

24.6.4.9.3 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see Section 24.6.2.2.5, *S/PDIF Coding Format*.

24.6.4.9.3.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphase-mark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

Note

The transmit TDM time slot register (MCASP_TXTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see Section 24.6.4.4.1.2.

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

24.6.4.9.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP_TXFMCTL):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP_TXFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- MCASP_PFUNC: The data pin - AXRn must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- MCASP_PDIR: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- MCASP_GBLCTL: Global initialization
- MCASP_AMUTE: Leave this register at default state.
- MCASP_TXDITCTL: The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as desired.
- MCASP_TXMASK: Mask the desired bits, depending upon left-aligned or right-aligned internal data.

- MCASP_TXFMT: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the Section 24.6.4.4.1.2 .
- MCASP_TXFMCTL: Configure the bits according to former discussions.
- MCASP_ACLKXCTL: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- MCASP_AHCLKXCTL: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- MCASP_TXTDM: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP_EVTCTLX: Program all fields according to the interrupts desired.
- MCASP_TXCLKCHK: Program all fields according to the clock checking desired.
- MCASP_XRSRCTLn: Set SRMOD = 1 (transmitter) for the DIT pins.
- MCASP_DITCSRAi and MCASP_DITCSRBi: Program the channel status bits as desired.
- MCASP_DITUDRAi and MCASP_DITUDRBi: Program the user data bits as desired.

Note

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphase Mark Encoded Data - see Section 24.6.2.2.5.1).

24.6.4.9.3.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP_DITCSRAi and MCASP_DITCSRBi) and user data registers (MCASP_DITUDRAi and MCASP_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in Section 24.6.2.2.5.2, *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP_DITCSRA0 to MCASP_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP_DITCSRB0 to MCASP_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP_DITUDRA0 to MCASP_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP_DITUDRB0 to MCASP_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in Figure 24-117. There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in Table 24-335.

Table 24-335. Channel Status and User Data for Each DIT Block

24.6.4.10 Data Transmission and Reception

The McASP is serviced by writing data to the MCASP_TXBUFn registers for transmit operations, and by reading data from the MCASP_RXBUFn registers for receive operations. The McASP sets status flags and notifies the software whenever data is ready to be serviced. The Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation*, discusses data-ready status in details.

The McASP transmit/receive XRBUFn buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA initiated data transfers on the device for McASP transmit (Tx) purposes.
- Configuration bus (CFG): The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

Section 24.6.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 24.6.4.10.1.4, *Transfers Through the Configuration Bus (CFG),* discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in Section 24.6.4.10.1.5, *Using the device CPUs for McASP Servicing*, and Section 24.6.4.10.1.6, *Using the DMA for McASP Servicing*, respectively.

McASP DATA port allows DMAs to access the McASP transmit buffer more efficiently on the L3_MAIN-interconnect or L4_PER2 interconect, using burst transfers. The physical addresses to access these registers are listed in Section 24.6.6.2.5.

24.6.4.10.1 Data Ready Status and Event/Interrupt Generation

24.6.4.10.1.1 Transmit Data Ready

The transmit data ready flag - XDATA in the MCASP_TXSTAT register reflects the data ready status of XRBUFn buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUFn to its corresponding XRSRn shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUFn is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTLn[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP_TXBUFn is written to by the host, the MCASP_XRSRCTLn[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the McASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_TXBUFn register has to be currently written. Once all requested MCASP_TXBUFn are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP_TXSTAT[5] XDATA bit is written to 0b1, or once MCASP_TXBUFn registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the AXEVT event is automatically generated on MCASPi_DREQ_TX line (if enabled in the MCASP_XEVTCTL register) to notify the DMA of the MCASP_TXBUFn empty status. An interrupt - MCASPi_IRQ_AXEVT can be also generated if the XDATA interrupt is enabled in the MCASP_EVTCTLX register (for details, see Section 24.6.4.12.1, *Transmit Data Ready Interrupt*).

For DMA requests, the McASP does not require that MCASP_TXSTAT be read between DMA events. This means that, even if MCASP_TXSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

Figure 24-128 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP interface clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the CPU can begin servicing the McASP by writing word C into the MCASP_TXBUFn (service time). The CPU must write word C into the MCASP_TXBUFn within the setup time required by the McASP (setup time).

The maximum service time (see Figure 24-128) can be calculated as:

Service Time = Time Slot – AXEVT Latency –Setup Time

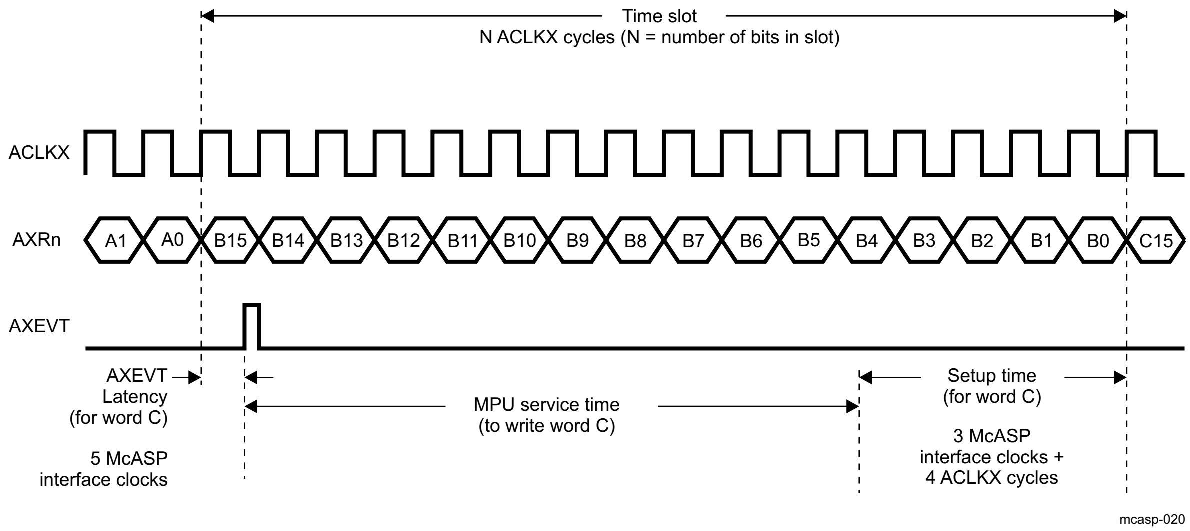

Figure 24-128. MPU Service Time Upon Transmit DMA Event (AXEVT)

24.6.4.10.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the MCASP_RXSTAT register reflects the data ready status of XRBUFn buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSRn to its corresponding XRBUFn data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer - RXBUFn already contains received data (i.e. a buffer is full) and is ready to transfer it to the host (MPU/DSP). The receive data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTLn [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP_RXBUFn is read from the host, the MCASP_XRSRCTLn [5] RRDY is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the McASP host (RDATA=0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_RXBUFn register has to be currently read. Once all requested MCASP_RXBUFn are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

The global RDATA flag can be cleared when the MCASP_RXSTAT[5] RDATA bit is written to 0b1, or once MCASP_RXBUFn registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA is set, the AREVT event is automatically generated on MCASPi_DREQ_RX line (if enabled in the MCASP_REVTCTL register) to notify the DMA of the MCASP_RXBUFn full status. An interrupt - MCASPi_IRQ_AREVT can be also generated if the RDATA interrupt is enabled in the MCASP_EVTCTLR register (for details, see Section 24.6.4.12.1, *Receive Data Ready Interrupt*).

Figure 24-129 shows the timing details of when AREVT event is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to five McASP interface clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the CPU can begin servicing the McASP by reading Word A from the MCASP_RXBUFn (service time). The CPU must read Word A from the MCASP_RXBUFn register no later than the setup time required by the McASP (Setup Time).

The maximum service time (see Figure 24-129) can be calculated as:
Service Time = Time Slot - AREVT Latency - Setup Time

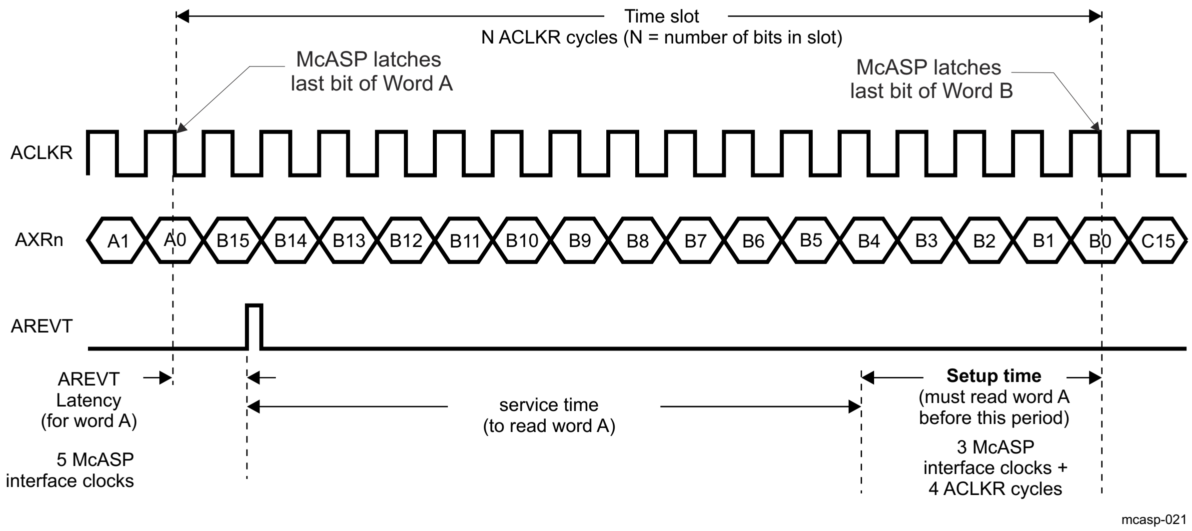

Figure 24-129. CPU Service Time Upon Receive Event (AREVT)

24.6.4.10.1.3 Transfers Through the Data Port (DATA)

> **CAUTION**
>
> To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the MCASP_TXFMT/MCASP_RXFMT register, respectively. Failure to do so may result in software malfunction.

> **Note**
>
> McASP1, McASP2, and McASP3, whose data ports are accessible directly via L3_MAIN, do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In a typical McASP transfer scenario, the DMA Controller write accesses the XRBUFn transmit buffer through the McASP data port (DATA) on L3_MAIN Interconect for McASP1/2/3 and on L4_PER2 Interconect for McASP4/5/6/7/8 . CPU hosts can access both XRBUFn transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the McASP Tx buffer through Interconect DATA port location. Refer to Section 24.6.6.2.5. Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in Section 24.6.4.11.

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in Section 24.6.6.2.5, the same physical DATA port address is used regardless of a read or write access is performed. The McASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

> **Note**
>
> DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the McASP configuration registers addressing their corresponding McASP DATA port.

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port adress) to service all of the active slot transmitting serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See Section 24.6.6.2.5).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, the DMA/CPU should write to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

Note

For write transfers through McASP DATA port it is preferable to use DMA on corresponding Interconect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port adress) to service all of the active slot receiving serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See Section 24.6.6.2.5).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the MPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0,1 and 3 in this exact order, upon each receive data ready event.

Note

To service a serializer for a transmit or receive operation through the McASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to Section 24.6.6.2.5), respectively.

See Section 24.6.6.2.5, *McASP_DATA Register Summary*, for more details about XRBUFn buffer physical address corresponding to the McASP DATA port on:

- Main Interconect (L3_MAIN or L4_PER2)

Note

When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in MCASP_TXTDM) and *transmit* (Tx enabled in MCASP_XRSRCTLn) within each time slot. Failure to do so results in a buffer underrun condition (see Section 24.6.4.15.1, *Buffer Underrun Error - Transmitter*). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in MCASP_RXTDM) and *receive* (Rx enabled in MCASP_XRSRCTLn) within each time slot. Failure to do results in a buffer overrun condition (see Section 24.6.4.15.2, *Buffer Overrun Error - Receiver*).

24.6.4.10.1.4 Transfers Through the Configuration Bus (CFG)

CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the MCASP_TXFMT/MCASP_RXFMT registers, respectively. Failure to do so may result in software malfunction.

Note

McASP1, McASP2, and McASP3, whose data ports are accessible directly via L3_MAIN do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In this method, the DMA/CPU accesses the XRBUFn transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUFn transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of McASP CFG port actual for L4_PER2 accesses. The XRBUFn buffer of the n-th serializer configured as a transmitter is aliased - MCASP_TXBUFn in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the MCASP_TXBUF2 register. Similarly, the XRBUFn buffer of the n-th serializer configured as a receiver is aliased - MCASP_RXBUFn in the CFG port address space. For example, the XRBUF3 receive buffer is mapped as the MCASP_RXBUF3 register.

Accessing the XRBUF through the DATA port (see Section 24.6.4.10.1.3) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index , while accessing through the peripheral configuration port - CFG, the DMA/CPU must provide the exact MCASP_TXBUFn or MCASP_RXBUFn address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP_TXBUFn and MCASP_RXBUFn addresses corresponding to McASP CFG port, see Section 24.6.6.2.1, *MCASP_CFG Register Summary*.

24.6.4.10.1.5 Using a Device CPU for McASP Servicing

The device CPUs can be used to service the McASP transmit channels through interrupts (upon MCASPi_IRQ_AXEVT and MCASPi_IRQ_AREVT interrupts). Because these interrupt events are connected to device IRQ_CROSSBAR module, they could be software mapped to input IRQ lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP_TXSTAT register and RDATA bit in the MCASP_RXSTAT register can be performed by device CPUs, respectively. As discussed in Section 24.6.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 24.6.4.10.1.4, *Transfers Through the Configuration Bus (CFG)* , the device CPUs can access McASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective MCASP_EVTCTLX/MCASP_EVTCTLR registers, to generate interrupts MCASPi_IRQ_AXEVT/ MCASPi_IRQ_AREVT to the device CPUs upon data ready

24.6.4.10.1.6 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP transmit and receive logic through the DATA port, although the DMA can also service the McASP through the configuration bus (CFG). The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see Figure 24-119). The data transfer is managed by the AFIFO according to generated transmit and receive events in the McASP and data is fed to transmit buffers and fetched from receive buffers as described in Section 24.6.4.11. The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from McASP module, these events are collected in AFIFO and on specific AFIFO conditions described in Section 24.6.4.11 the requests (transmit or receive) are forwarded to a DMA controller via MCASPi_DREQ_TX and MCASPi_DREQ_RX outputs. If the AFIFO is disabled (default state) it is transperrant for the McASP module and all request are directly sent to the DMA controller.

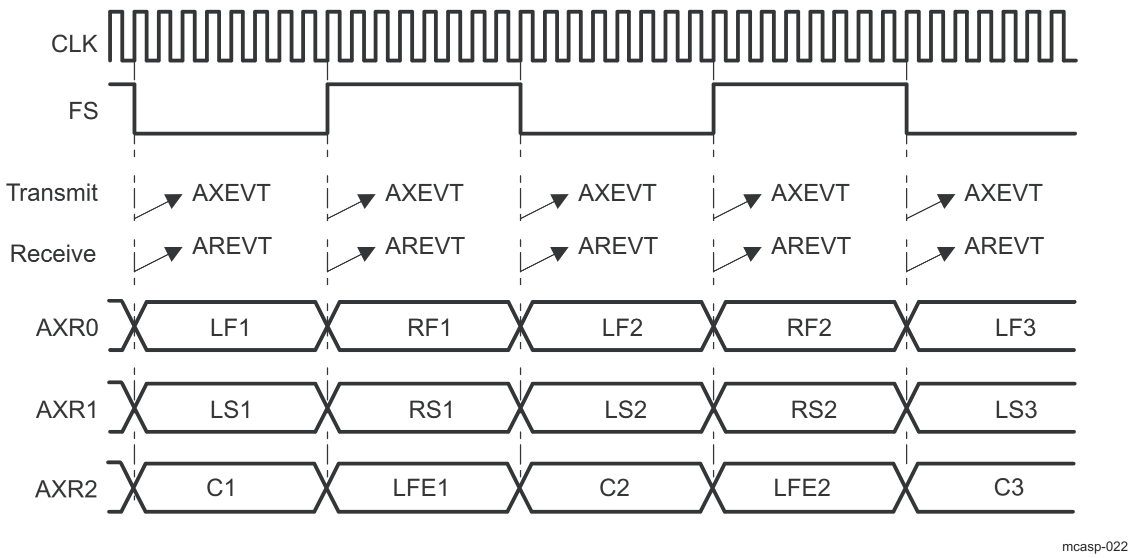

Figure 24-130. DMA Transmit and Receive Event in an Audio Example – One Event

In transmit mode, the DMA event - AXEVT (MCASPi_DREQ_TX output), which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP TXBUFn transmit buffers. In receive mode, the DMA event AREVT (MCASPi_DREQ_RX output) which is triggered upon each RDATA transition from 0 to 1, is used to service the McASP RXBUFn receive buffers.

Figure 24-130 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the McASP signals - AXR0, AXR1 and AXR2. It shows the points at which events AXEVT/AREVT are triggered.

In Figure 24-130, a Tx DMA event AXEVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP_XEVTCTL register. Similarly, Rx DMA event AREVT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP_REVTCTL register.

24.6.4.11 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 24-131 for a high-level block diagram of the AFIFO. The AFIFO may be enabled/disabled and configured via the WFIFOCTL and RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP.

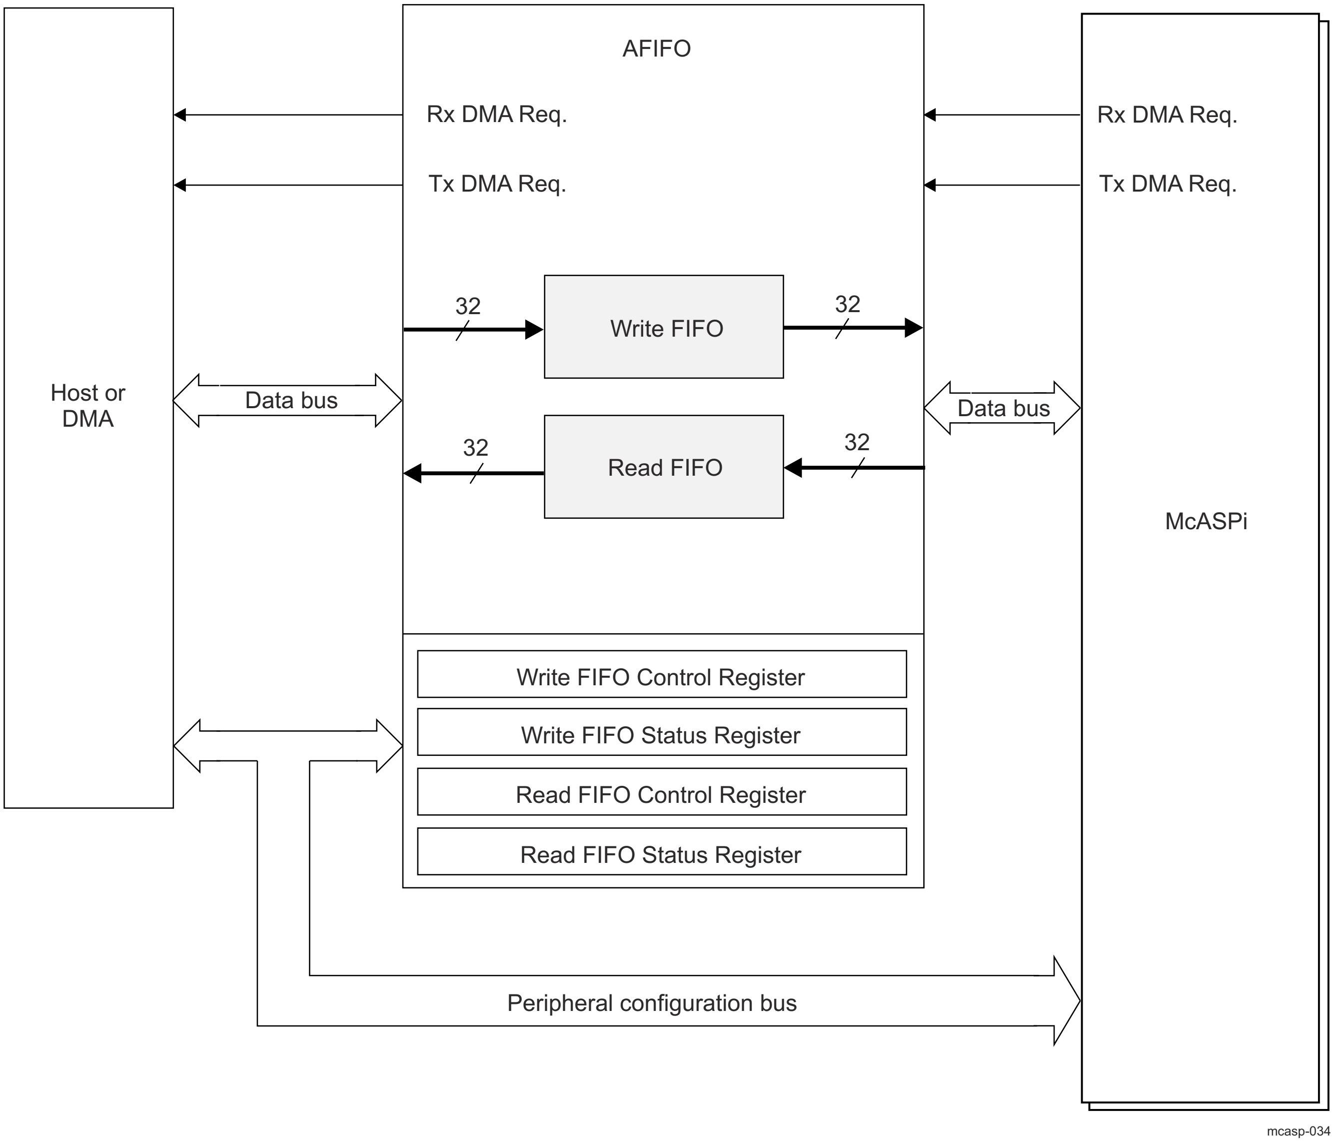

Figure 24-131. McASP Audio FIFO (AFIFO) Block Diagram

24.6.4.11.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is "invisible" to the McASP. When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes WNUMDMA 32-bit words to the McASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the McASP. (See description for WFIFOCTL[7:0] WNUMDMA.) If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

24.6.4.11.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, WFIFOCTL[15:8] WNUMEVT should be set to a non-zero integer multiple of the value in WFIFOCTL[7:0] WNUMDMA. If transmit DMA event pacing is not desired, then the value in WFIFOCTL[15:8] WNUMEVT should be set equal to the value in WFIFOCTL[7:0] WNUMDMA.

24.6.4.11.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the McASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the McASP. (See description for RFIFOCTL[7:0] RNUMDMA.) If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than RNUMEVT words, those words will be read correctly, emptying the FIFO.

24.6.4.11.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least RNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once RNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another RNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, RFIFOCTL[15:8] RNUMEVT should be set to a non-zero integer multiple of the value in RFIFOCTL[7:0] RNUMDMA. If receive DMA event pacing is not desired, then the value in RFIFOCTL[15:8] RNUMEVT should be set equal to the value in RFIFOCTL[7:0] RNUMDMA.

24.6.4.11.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

24.6.4.12 McASP Events and Interrupt Requests

Table 24-336 lists all the transmit event flags. Table 24-337 lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any McASPi serializer configured as transmitter or receiver respectivly.

Table 24-336. TX Events

Event Mask[2]	Event Flag	Map to [1]	Description
MCASP_EVTCTLX[0] XUNDRN	MCASP_TXSTAT[0] XUNDRN	MCASPi_IRQ_AXEVT	Transmit buffer underrun
MCASP_EVTCTLX[1] XSYNCERR	MCASP_TXSTAT[1] XSYNCERR	MCASPi_IRQ_AXEVT	Unexpected transmit frame sync
MCASP_EVTCTLX[2] XCKFAIL	MCASP_TXSTAT[2] XCKFAIL	MCASPi_IRQ_AXEVT	Transmit clock failure
MCASP_EVTCTLX[3] XDMAERR	MCASP_TXSTAT[7] XDMAERR	MCASPi_IRQ_AXEVT	DATA port transmit error
MCASP_EVTCTLX[4] XLAST	MCASP_TXSTAT[4] XLAST	MCASPi_IRQ_AXEVT	Transmit last slot interrupt
MCASP_EVTCTLX[5] XDATA	MCASP_TXSTAT[5] XDATA	MCASPi_IRQ_AXEVT	Transmit data-ready interrupt
MCASP_EVTCTLX[7] XSTAFRM	MCASP_TXSTAT[6] XSTAFRM	MCASPi_IRQ_AXEVT	Transmit start of frame interrupt

Table 24-336. TX Events (continued)

Event Mask[(2)]	Event Flag	Map to [(1)]	Description
n.a.	MCASP_TXSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR | XCKFAIL | XUNDRN | XSYNCERR). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_TXSTAT[3] XTDMSLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every McASPi module generates separate IRQ event.
(2) Global events for all transmitting serializers in a single McASPi module.

Table 24-337. RX Events

Event Mask[(2)]	Event Flag	Map to[(1)]	Description
MCASP_EVTCTLR[0] ROVRN	MCASP_RXSTAT[0] ROVRN	MCASPi_IRQ_AREVT	Receive buffer overrun
MCASP_EVTCTLR[1] RSYNCERR	MCASP_RXSTAT[1] RSYNCERR	MCASPi_IRQ_AREVT	Unexpected receive frame sync
MCASP_EVTCTLR[2] RCKFAIL	MCASP_RXSTAT[2] RCKFAIL	MCASPi_IRQ_AREVT	Receive clock failure
MCASP_EVTCTLR[3] RDMAERR	MCASP_RXSTAT[7] RDMAERR	MCASPi_IRQ_AREVT	DATA port receive error
MCASP_EVTCTLR[4] RLAST	MCASP_RXSTAT[4] RLAST	MCASPi_IRQ_AREVT	Receive last slot
MCASP_EVTCTLR[5] RDATA	MCASP_RXSTAT[5] RDATA	MCASPi_IRQ_AREVT	Receive data-ready
MCASP_EVTCTLR[7] RSTAFRM	MCASP_RXSTAT[6] RSTAFRM	MCASPi_IRQ_AREVT	Receive start of frame
n.a.	MCASP_RXSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR | RCKFAIL | ROVRN | RSYNCERR). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RXSTAT[3] RTDMSLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every McASP module generates separate IRQ event.
(2) Global events for all receiving serializers in a single McASPi module. These events and masks are available in same format for every McASPi module

Software has to read the MCASP_TXSTAT/MCASP_RXSTAT register to determine which event occurs at a global level for McASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the MCASP_XRSRCTLn registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASPi_IRQ_AXEVT) is asserted (active high) when one of the MCASP_TXSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_EVTCTLX bit. Similarly, a Rx interrupt line (MCASPi_IRQ_AREVT) is asserted (active high) when one of MCASP_RXSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_EVTCTLR bit. See also Section 24.6.4.12.4, *Multiple Interrupts* and the Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation*.

24.6.4.12.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the MCASP_TXSTAT register and XDATA is enabled in MCASP_EVTCTLX. The Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when XDATA is set in the MCASP_TXSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

24.6.4.12.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if RDATA is 1 in the MCASP_RXSTAT register and RDATA is enabled in MCASP_EVTCTLR. The Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when RDATA flag is set in the MCASP_RXSTAT register.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

24.6.4.12.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP_TXSTAT):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP_EVTCTLX). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_TXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP_RXSTAT) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (MCASP_EVTCTLR). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_RXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

24.6.4.12.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in MCASP_TXSTAT is set and the interrupt is enabled in MCASP_EVTCTLX.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP_TXSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in MCASP_TXSTAT/ MCASP_RXSTAT and the interrupt enabled in MCASP_EVTCTLX/MCASP_EVTCTLR generates a request on the McASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to MCASP_TXSTAT/MCASP_RXSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

24.6.4.13 DMA Requests

The McASP can generate one DMA request to the DMA_CROSSBAR to transmit (MCASPi_DREQ_TX) or receive (MCASPi_DREQ_RX) data. A DMA request to transmit data is generated if the XDATDMA bit in the

MCASP_XEVTCTL register is cleared. A DMA request to receive data is generated if the RDATDMA bit in the MCASP_REVTCTL register is cleared.

24.6.4.14 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between McASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

Figure 24-132shows the basic logical connection of the serializers in loopback mode.

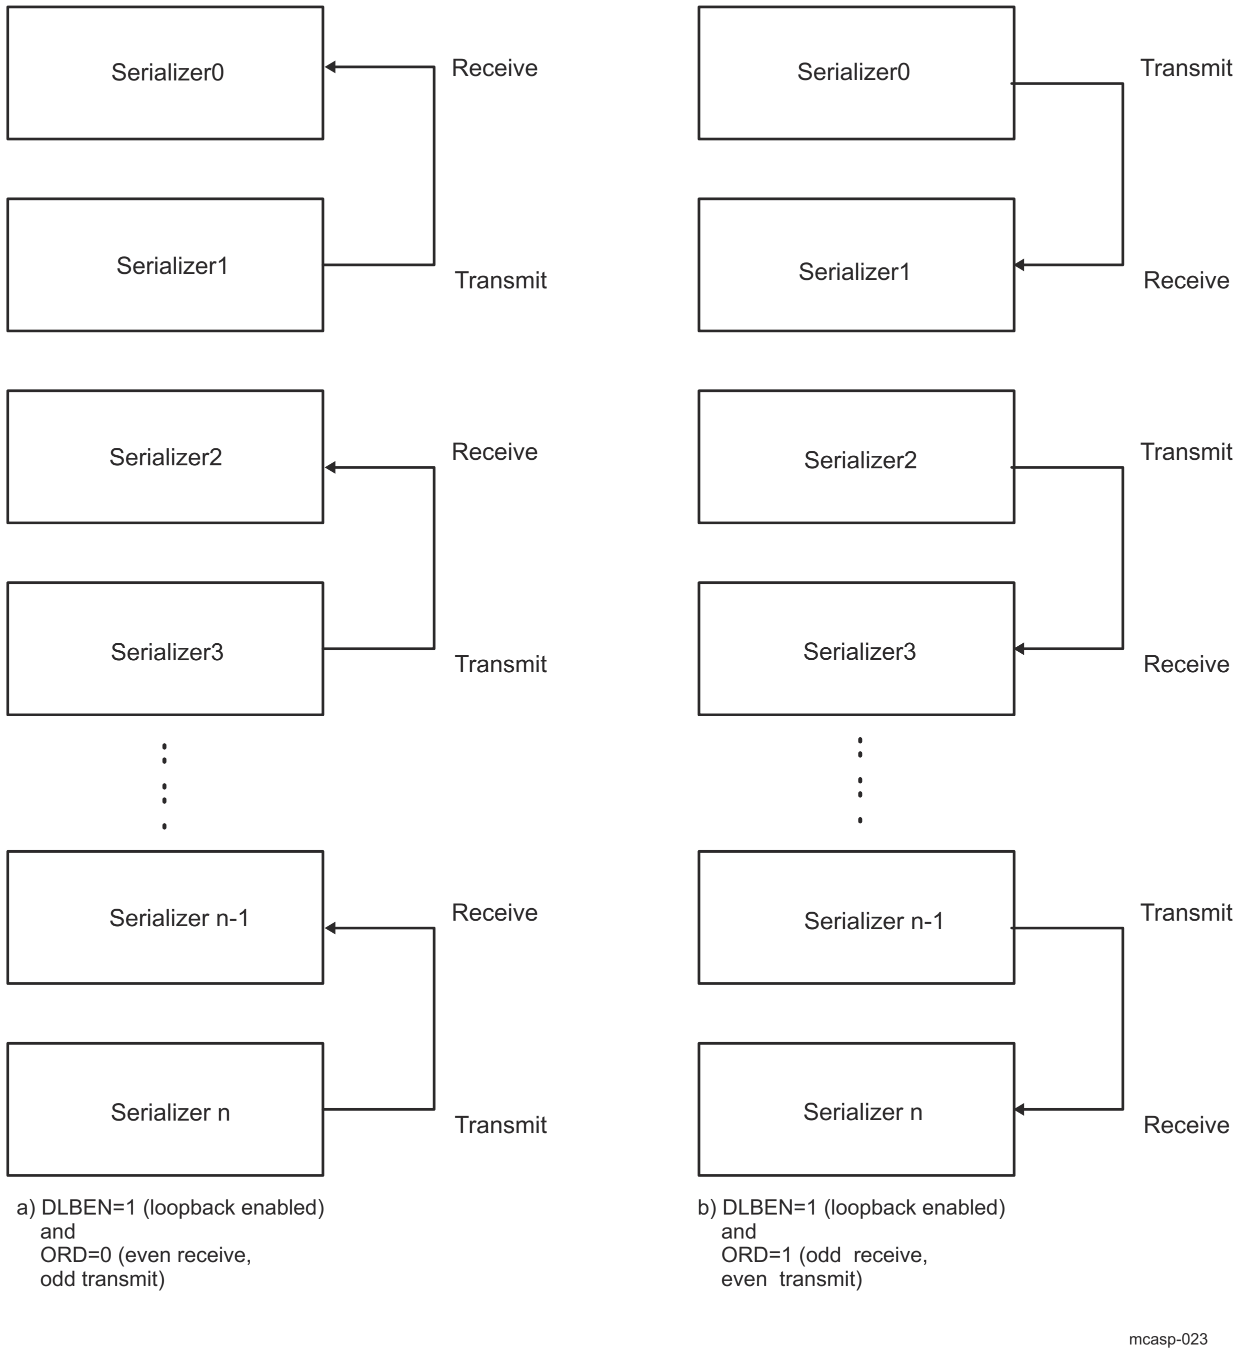

Figure 24-132. McASP Serializers Operation in Loopback Mode

Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - MCASP_LBCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (bit IOLBEN of the MCASP_LBCTL) between a McASP module internal loopback and a device I/O level loopback.

When a **McASP internal loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b0), it is NOT necessary to configure MCASP_PFUNC and MCASP_PDIR registers for McASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a McASP output pin by setting the corresponding MCASP_PFUNC bit to 0 (i.e. to function as McASP, not GPIO) and MCASP_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b1), the MCASP_PFUNC and MCASP_PDIR registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (i.e. reaching device I/O buffers).

Hence, the corresponding padconfiguration registers must be appropriately configured in the device Control Module - CTRL_MODULE_CORE_PAD. For more details, see *Pad Configuration Rregisters*, in *Control Module*.

When In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bitfield of the MCASP_LBCTL register to 0x1 and the ASYNC bit of the MCASP_ACLKXCTL register to 0b0.

24.6.4.14.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The MCASP_LBCTL[0] DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal McASP operation.
- The MCASP_LBCTL[4] IOLBEN bit must be set to select between internal (McASP local) loopback mode or device I/O level loopback mode.
- The MCASP_LBCTL[3:2] MODE bitfield must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP_LBCTL[1] ORD must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The bit - MCASP_ACLKXCTL[6] ASYNC must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The bitfields - MCASP_RXFMCTL[15:7] RMOD and MCASP_TXFMCTL[15:7] XMOD must be set within range (0x2- 0x20) to indicate TDM mode.

Note

Loopback mode does not apply to DIT or burst mode, because McASP receivers do NOT natively support DIR - reception.

24.6.4.15 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

24.6.4.15.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUFn buffer to XRSRn shift register, but the corresponding (MCASP_TXBUFn) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP_TXSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

24.6.4.15.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding MCASP_RXBUFn register has not yet been read since the last time the transfer occured. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The MCASP_RXSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

24.6.4.15.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the XDMAERR flag in the MCASP_TXSTAT register, occurs when the DMA or device CPU writes more words to the DATA port of the McASP than it should.

The MCASP_TXSTAT[7] XDMAERR=0b1 indicates that the DMA or device CPU wrote too many words to the McASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in MCASP_TXSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

24.6.4.15.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the RDMAERR flag in the MCASP_RXSTAT register, occurs when the DMA or device CPU reads more words from the DATA port of the McASP than it should.

The MCASP_RXSTAT[7] RDMAERR indicates that the DMA or device CPU read too many words from the McASP DATA port for a given receive AREVT event. Reading too few words results in a receiver overrun error setting ROVRN in MCASP_RXSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP receiver and the DMA must be reinitialized to resynchronize them.

24.6.4.15.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
   - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
   - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

24.6.4.15.6 Clock Failure Detection

24.6.4.15.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP_TXCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP_TXSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
   a. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP_EVTCTLX)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP_RXCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP_RXSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
   a. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register (MCASP_EVTCTLR)

24.6.4.15.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see Figure 24-133) works off the internal McASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (MCASP_TXCLKCHK) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in MCASP_TXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in MCASP_TXSTAT is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in MCASP_EVTCTLX is set.

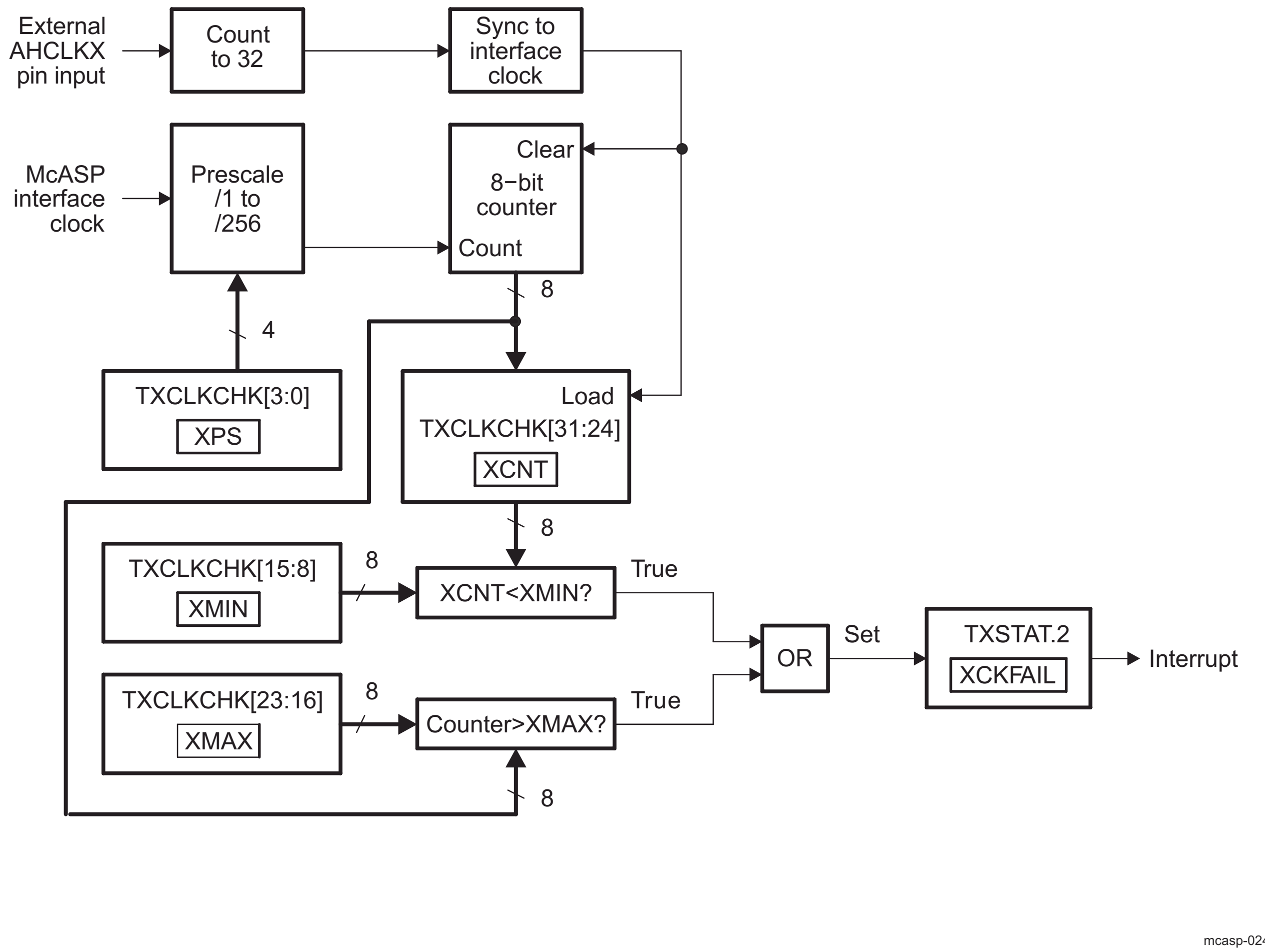

Figure 24-133. Transmit Clock Failure Detection Circuit Block Diagram

24.6.4.15.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (see Figure 24-134) works off both the internal McASP interface clock and the high-frequency serial clock (AHCLKR) coming from the device clock generator. It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP_RXCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (RCKFAIL in MCASP_RXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

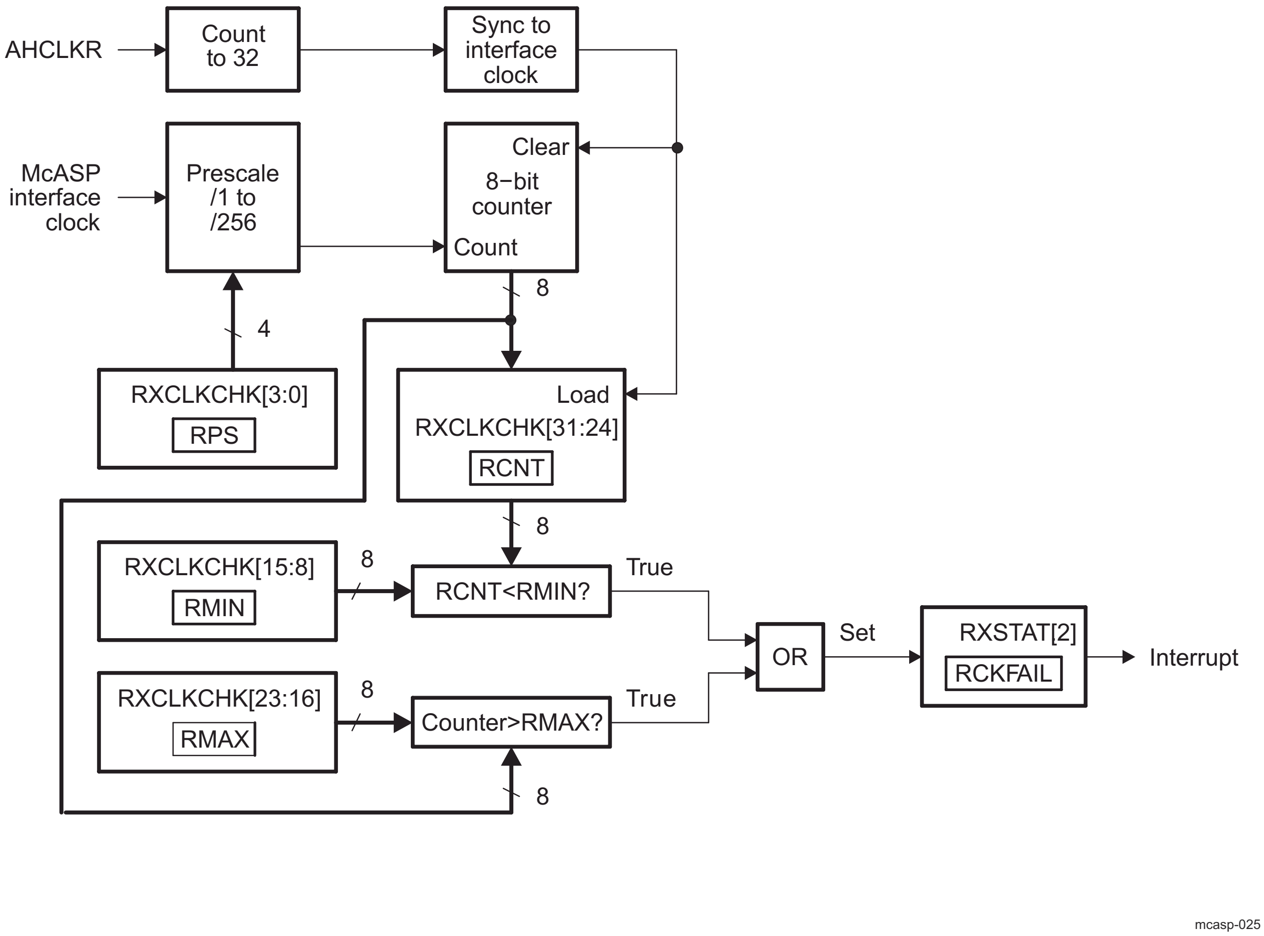

Figure 24-134. Receive Clock Failure Detection Circuit Block Diagram

24.6.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

24.6.5.1 Global Initialization

24.6.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see *McASP Integration*, and *McASP Environment*).

Table 24-338, describes the global initialization of surrounding modules.

Table 24-338. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See *Pad Configuration Registers*, in *Control Module*).
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to enable the interrupts from the McASP. For more details on IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
(Optional) DMA_CROSSBAR	DMA configuration must be done to enable the McASP DMA data channel requests. For more information on DMA_CROSSBAR module configuration, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
(Optional) L4_PER2 and L3_MAIN Interconnects	For more information about the interconnect configuration, see *L3_MAIN Interconnect Overview* in *L3 Interconnect*.

Note

The IRQ_CROSSBAR and the DMA_CROSSBAR configurations are required when the interrupt and DMA-based communication modes are used. Further initialization of the selected IRQ and DMA controllers of the host CPU must be done for full functionality of the McASP DMA and IRQ lines.

24.6.5.1.2 McASP Global Initialization

24.6.5.1.2.1 Main Sequence – McASP Global Initialization for DIT-Transmission

The procedure in Table 24-339 initializes the McASP serializers transmitters to operate in DIT-mode (S/PDIF-transmission protocol) after a power-on reset (POR).

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 24-339. McASP Transmitters Global Initialization for DIT-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 24.6.5.1.2.1.1.	
5. Configure the transmit frame sync generator.	See Section 24.6.5.1.2.1.2.	
6. Configure the transmit clock generator.	See Section 24.6.5.1.2.1.3.	

Table 24-339. McASP Transmitters Global Initialization for DIT-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
7. Configure the TDM sequencer—set all slots active.	MCASP_TXTDM[31:0] XTDMS	0xFFFF FFFF
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. [(3)]	MCASP_XRSRCTLn [1:0] SRMOD	0x1
9. Configure the McASP pins functionality.	See Section 24.6.5.1.2.1.4.	
10. Enable the McASP DIT - transmission mode.	MCASP_TXDITCTL[0] DITEN	0x1[(2)]
11. Configure DIT-specific subframe fields.	See Table 24-344.	
12. Release from reset state the divider that outputs the AHCLKX clock.[(1)]	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKX clock. [(1)]	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKXCTL and MCASP_ACLKXCT registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.
(2) This globally configures all active transmitters to operate in DIT-mode.
(3) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

24.6.5.1.2.1.1 Subsequence – Transmit Format Unit Configuration for DIT-Transmission

The procedure in Table 24-340 configures the transmit frame format unit of the McASP module for a DIT-transmission.

Note

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

Table 24-340. Transmit Format Unit Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_TXFMT[7:4] XSSZ	0xF
IF: the data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_TXMASK[31:0] XMASK	0x-[(1)]
Rotate data right by a multiple-of-4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- [(1)]
ELSE		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_TXMASK[31:0] XMASK	0x-[(1)]
Rotate data right by 0-bit positions.	MCASP_TXFMT[2:0] XROT	0x0
ENDIF		
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

(1) Refer to Section 24.6.4.4.1, *Transmit Fromat Unit* and Section 24.6.4.4.1.2, *DIT-Mode Transmission Data Alignment Settings.*

24.6.5.1.2.1.2 Subsequence – Transmit Frame Synchronization Generator Configuration for DIT-Transmission

The procedure in Table 24-341 configures the transmit frame synchronization generator of the McASP module.

Note

The frame synchronization signal is always rising-edge active and always has a single-bit width.

Table 24-341. Transmit Frame-Synchronization Generator Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_TXFMCTL[15:7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_TXFMCTL[1] FSXM	0x1

24.6.5.1.2.1.3 Subsequence – Transmit Clock Generator Configuration for DIT-Transmission

Note

By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in Table 24-342 configures the transmit clock generator of the McASP module.

Table 24-342. Transmit Clock Generator Configuration in DIT-Mode

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– AHCLKX.	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Set he divisor for the internally generated transmission clock– ACLKX.	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See Section 24.6.4.15.6.1, *Clock Failure Check Startup*.	

24.6.5.1.2.1.4 Subsequence - McASP Pins Functional Configuration

The procedure in Table 24-343 configures the McASP pins for McASP functionality.

Table 24-343. McASP Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins as outputs: AFSX AHCLKX ACLKX Desired i-th McASP data pin AXRi is configured as an output for DIT-transmission.	MCASP_PDIR[28] AFSX; MCASP_PDIR[27] AHCLKX; MCASP_PDIR[26] ACLKX; MCASP_PDIR [i] AXRi	0x1 0x1 0x1 0x1

24.6.5.1.2.1.5 Subsequence – DIT-specific Subframe Fields Configuration

The procedure in Table 24-344 configures the DIT-specific subframe fields as part of the S/PDIF format data.

Table 24-344. DIT-Specific Subframe Fields Configuration

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_TXDITCTL[3] VB	0x-
Configure the valid bit value for even time slots.	MCASP_TXDITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5 MCASP_DITUDRBi[31:0] DITUDRBi, where i = 0 to 5	0x- 0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRAi[31:0], where i = 0 to 5 MCASP_DITCSRBi[31:0], where i = 0 to 5	0x- 0x-

24.6.5.1.2.2 Main Sequence – McASP Global Initialization for TDM-Reception

The procedure in Table 24-345 initializes a McASP serializer n receiver(s) to operate in TDM-mode (the only mode supported by McASP receivers) after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols reception.

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Note

The McASP receivers support only TDM-frames (including 384-TDM frames) reception. DIT-frames reception (i.e. S/PDIF stream) can be implemented indirectly via an external DIR-chip converter with DIT-input and TDM (I2S)-compatible output connected to device McASP receiver input (TDM-only compatible).

Table 24-345. McASP Receivers Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP receive components.	MCASP_GBLCTL[4:0]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[4:0]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the receive format unit.	See Section 24.6.5.1.2.2.1.	
5. Configure the receive frame sync generator.	See Section 24.6.5.1.2.2.2.	
6. Configure the receive clock generator.	See Section 24.6.5.1.2.2.3.	
7. Program all bits -RTDMSk (where k=0 to 31) according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_RXTDM [k] RTDMSk , where k=0 to 31	0x-
8. Configure the desired n-th serializer for receive mode operation. [4]	MCASP_XRSRCTLn [1:0] SRMOD	0x2
9. Configure the McASP pins functionality.	See Section 24.6.5.1.2.2.4.	
10. Optional: Configure a McASP Rx channel for a loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 24.6.4.14.1, *Loopback Mode Configurations*.	0x-[5]
11. Release from reset state the divider that outputs the AHCLKR clock.[1] See also [2].	MCASP_GBLCTL[1] RHCLKRST	0x1
12. Poll the bit to ensure that it is successfully latched in the register. See also [2].	MCASP_GBLCTL[1] RHCLKRST	=0x1
13. Release from reset state the divider that outputs the ACLKR clock. [1] See also [3].	MCASP_GBLCTL[0] RCLKRST	0x1
14. Poll the bit to ensure that it is successfully latched in the register. See also [3].	MCASP_GBLCTL[0] RCLKRST	=0x1

(1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKRCTL and MCASP_ACLKRCTL registers are ignored; hence, the reception clock does not stop during the reset state of the dividers.
(2) This step is necessary even if external high-frequency serial clocks are used.
(3) This step can be skipped if external serial clocks are used and they are running.
(4) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

(5) In this case the receiver clock and frame sync are derived from the McASP transmitter logic, so MCASP_ACLKXCTL[6] ASYNC must be set to 0b0. Neither McASP internal receiver clock and frame sync generators, nor external clock and frame sync source are used.

24.6.5.1.2.2.1 Subsequence – Receive Format Unit Configuration in TDM Mode

The procedure in Table 24-346 configures the receive frame format unit of the McASP module for TDM slots reception.

Table 24-346. Receive Format Unit Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_RXFMT[7:4] RSSZ	0x-[(1)]
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_RXMASK[31:0] RMASK	0x-[(2)]
Select a padding value for masked-out bits.	MCASP_RXFMT[14:13] RPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_RXBUFn which value to be used as a pad value in case MCASP_RXFMT[14:13] RPAD=0x2.	MCASP_RXFMT[12:8] RPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_RXFMT[2:0] RROT	0x- [(3)]
Received stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream reception (MSB-first).	MCASP_RXFMT[15] RRVRS	0x- [(3)]
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream reception.	MCASP_RXFMT[17:16] RDATDLY	0x-
Select to read data from active serializers receive buffers using peripheral (CFG) or DATA port	MCASP_RXFMT[3] RBUSEL	0x-

(1) Refer to Section 24.6.4.4.2, *Receive Format Unit*, regarding options for received TDM-slot sizes.
(2) For more details on Rx masking value, refer to Section 24.6.4.4.2.1, *TDM - Mode Reception Data Alignment Settings*
(3) For more details on rotation and received TDM stream bit order, refer to Section 24.6.4.4.2.1, *TDM - Mode Reception Data Alignment Settings* and Table 24-333, *McASP RFU Settings*.

24.6.5.1.2.2.2 Subsequence – Receive Frame Synchronization Generator Configuration in TDM Mode

The procedure in Table 24-347 configures the transmit frame synchronization generator of the McASP module.

Note

The same bit - MCASP_ACLKXCTL[6] ASYNC which is used to determine if McASP receivers and transmitters work synchronously on the same clock, is also used to define if receiver frame sync is derived from the transmit frame sync generator, or generated independently in the receiver (either inernally or externally sourced). Hence, the settings in below table Table 24-347 have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0.

Table 24-347. Receive Frame-Synchronization Generator Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame. Must be set to 0x2, in case of an I2S-reception. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[15:7] RMOD	0x-[(1)]
Choose the receive frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[4] FRWID	0x-
Select start of received frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[0] FSRP	0x-
IFreceive frame sync - FS is internally generated	Software test condition	

Table 24-347. Receive Frame-Synchronization Generator Configuration for TDM-Reception (continued)

Step	Register/Bit Field/Programming Model	Value
Select internally- generated receive frame sync. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[1] FSRM	0b1
If McASP receiver is required to output internally generated frame, AFSR pin must be set as an output in step 9 of the sequence documented in the Table 24-345. This must not be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSR pin outputting a frame to an external device.	MCASP_PDIR[31] AFSR	0b1
ELSE		
Select externally- generated receive frame sync. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[1] FSRM	0b0
Setup the AFSR pin as input (device level: mcaspi_fsr)	MCASP_PDIR[31] AFSR	0b0
ENDIF		
To generate McASP receive frame sync in receiver logic, select an asynchronous frame sync.	MCASP_ACLKXCTL[6] ASYNC	0b1

(1) Must be set to 0x180 in case of 384-TDM slot frame reception from a DIR component I2S-output. For more details on TDM-frame settings, refer to Section 24.6.4.9.2 .

24.6.5.1.2.2.3 Subsequence – Receive Clock Generator Configuration

The procedure in Table 24-348 configures the receive clock generator of the McASP module.

Note

The settings in below table Table 24-348 have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0 (i.e. receive clock is sourced from the inverted version of the transmit clock). For example, such is the case when McASP loopback mode is used.

Table 24-348. Receive Clock Generator Configuration

Step	Register/Bit Field/Programming Model	Value
To use the McASP receive clock generator, select an asynchronous receiver clock schema (ASYNC=1). Otherwise an inverted version of transmit clock XCLK is used (receiver synchronized with transmitter).	MCASP_ACLKXCTL[6] ASYNC	0b1
IF receive clock - RCLK is internally generated	Software test condition	
The high-speed receive clock - AHCLKR is internally generated based on AUXCLK		
Select an internally-generated high-frequency clock.	MCASP_AHCLKRCTL[15] HCLKRM	0b1
Select the internal high-speed clock source polarity: non-inverted or inverted.	MCASP_AHCLKRCTL[14] HCLKRP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKR in range (1 - 4096).	MCASP_AHCLKRCTL[11:0] HCLKRDIV	0x-
Select an internally-generated receive clock.	MCASP_ACLKRCTL[5] CLKRM	0b1
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Set the divisor for the internally generated receive clock– ACLKR in range (1 - 32).	MCASP_ACLKRCTL[4:0] CLKRDIV	0x-

Table 24-348. Receive Clock Generator Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Optional: If McASP receiver is required to output internally generated clock, ACLKR pin must be set as an output in step 9 of the sequence documented in the Table 24-345. This must not be done in current step because the clock control register - MCASP_ACLKRCTL must be appropriately configured prior to ACLKR pin outputting a receive clock to an external device.	MCASP_PDIR[29] ACLKR	0b1
ELSE		
Select an externally-generated receive clock. Note that in this case the AHCLKR signal path and the CLKRDIV divider are NOT used.	MCASP_ACLKRCTL[5] CLKRM	0b0
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Setup an input directon for the ACLKR pin	MCASP_PDIR[29] ACLKR	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 24.6.4.15.6.1, *Clock Failure Check Startup*.	

24.6.5.1.2.2.4 Subsequence—McASP Receiver Pins Functional Configuration

The procedure in Table 24-349 configures the McASP pins for McASP functionality.

Table 24-349. McASP Receiver Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSR ACLKR Desired n-th McASP data pin AXRn is configured as an input for receiving.	MCASP_PDIR[31] AFSR; MCASP_PDIR[29] ACLKR; MCASP_PDIR[n] AXRn;	0x-(1) 0x- (2) 0x0

(1) See Table 24-347.
(2) For more details on McASP clock configurations, refer to Table 24-348.

24.6.5.1.2.3 Main Sequence – McASP Global Initialization for TDM -Transmission

The procedure in Table 24-350 initializes a McASP serializer n transmitter(s) to operate in TDM-mode after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols transmission.

> **CAUTION**
>
> Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 24-350. McASP Transmitters Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP transmit components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 24.6.5.1.2.3.1.	
5. Configure the transmit frame sync generator.	See Section 24.6.5.1.2.3.2.	

Table 24-350. McASP Transmitters Global Initialization for TDM-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
6. Configure the transmit clock generator.	See Section 24.6.5.1.2.3.3.	
7. Program all bits - XTDMSk, where k=0 to 31, according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_TXTDM [k] XTDMSk, where k=0 to 31[4]	0x-
8. Configure the desired n-th serializer for transmit mode operation. [3]	MCASP_XRSRCTLn[1:0] SRMOD;	0x1
9. Setup all active transmitters to operate in TDM mode.	MCASP_TXDITCTL[0] DITEN	0x0[2]
10. Configure the McASP pins functionality.	See Section 24.6.5.1.2.3.4.	
11. Optional: Configure a McASP Tx channel for loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 24.6.4.14.1, *Loopback Mode Configurations*.	0x-
12. Release from reset state the divider that outputs the AHCLKR clock. See [1]	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKR clock. See [1]	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKX and MCASP_ACLKX registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.
(2) All active transmit channels operate either in TDM mode or in DIT mode depending on DITEN value. There is no option to choose Tx Mode between DIT and TDM separately per serializer transmitter.
(3) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.
(4) Appropriately program in bitfield MCASP_XRSRCTLn [3:2] DISMOD, the desired level (high-impedance state, 0, or 1) at AXRn output, during time of inactive slots. Note, that this setting does NOT apply when all slots are programmed to be active within a frame (in particular DIT-mode).

24.6.5.1.2.3.1 Subsequence – Transmit Format Unit Configuration in TDM Mode

The procedure in Table 24-351 configures the transmit frame format unit of the McASP module for TDM slots transmission.

Table 24-351. Transmit Format Unit Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_TXFMT[7:4] XSSZ	0x-[1]
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_TXMASK[31:0] XMASK	0x-[2]
Select a padding value for masked-out bits.	MCASP_TXFMT[14:13] XPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_TXBUFn which value to be used as a pad value in case MCASP_TXFMT[14:13] XPAD=0x2.	MCASP_TXFMT[12:8] XPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- [3]
transmitted stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream transmission (MSB-first).	MCASP_TXFMT[15] XRVRS	0x- [3]
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream transmission.	MCASP_TXFMT[17:16] XDATDLY	0x-
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

(1) Refer to Section 24.6.4.4.1, *Transmit Format Unit* , regarding options for transmitted TDM-slot sizes.

(2) For more details on Tx masking value, refer to Section 24.6.4.4.1.1, *TDM - Mode Transmission Data Alignment Settings*
(3) For more details on rotation and transmitd TDM stream bit order, refer to Section 24.6.4.4.1.1, *TDM - Mode Transmission Data Alignment Settings* and Table 24-331, *McASP TFU TDM Mode Settings*.

24.6.5.1.2.3.2 Subsequence – Transmit Frame Synchronization Generator Configuration in TDM Mode

The procedure in Table 24-352 configures the transmit frame synchronization generator of the McASP module.

Table 24-352. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame (2 - 32). Must be set to 0x2, in case of an I2S-transmission. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[15:7] XMOD	0x-
Choose the transmit frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[4] FXWID	0x-
Select start of transmit frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[0] FSXP	0x-
IF transmit frame sync - FS is internally generated	Software test condition	
Select internally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[1] FSXM	0b1
If McASP transmitter is required to output internally generated frame, AFSX pin must be set as an output in step 10 of the sequence documented in the Table 24-350. This must NOT be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSX pin outputting a frame sync to an external device.	MCASP_PDIR[28] AFSX	0b1
ELSE		
Select externally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[1] FSXM	0b0
Setup the AFSX pin as input	MCASP_PDIR[28] AFSX	0b0

24.6.5.1.2.3.3 Subsequence – Transmit Clock Generator Configuration for TDM Cases

The procedure in Table 24-353 configures the transmit clock generator of the McASP module.

Table 24-353. Transmit Clock Generator Configuration for TDM Cases

Step	Register/Bit Field/Programming Model	Value
IF transmit clock - XCLK is internally generated	Software test condition	
IF high-speed transmit clock - AHCLKX is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	MCASP_AHCLKXCTL[15] HCLKXM	0b1
Select the high-frequency clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKX in range (1 - 4096).	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-

Table 24-353. Transmit Clock Generator Configuration for TDM Cases (continued)

Step	Register/Bit Field/Programming Model	Value
Optional: If McASP transmitter is required to output internally generated high-frequency clock, AHCLKX pin must be set as an output in step 10 of the sequence documented in the Table 24-350. This must NOT be done in current step because the clock control register - MCASP_AHCLKXCTL must be appropriately configured prior to AHCLKX pin outputting a high-speed clock to an external device.	MCASP_PDIR[27] AHCLKX	0b1
ELSE		
Select an externally-generated high frequency clock (HCLKXDIV divider can not be used).	MCASP_AHCLKXCTL[15] HCLKXM	0b0
Select the high-speed transmit clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Setup an input directon for the AHCLKX pin	MCASP_PDIR[27] AHCLKX	0b0
ENDIF		
Select an internally-generated transmit clock.	MCASP_ACLKXCTL[5] CLKXM	0b1
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL[7] CLKXP	0x-
Set the divisor for the internally generated transmit clock– ACLKX in range (1 - 32).	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated clock, ACLKX pin) must be set as an output in step 10 of the sequence documented in the Table 24-350. This must NOT be done in current step because the clock control register - MCASP_ACLKXCTL must be appropriately configured prior to ACLKX pin outputting a transmit clock to an external device.	MCASP_PDIR[26] ACLKX	0b1
ELSE		
Select an externally-generated transmit clock. Note that in this case the AHCLKX signal path and the CLKXDIV divider are NOT used.	MCASP_ACLKXCTL[5] CLKXM	0b0
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL[7] CLKXP	0x-
Setup an input directon for the ACLKX pin	MCASP_PDIR[26] ACLKX	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 24.6.4.15.6.1, *Clock Failure Check Startup*.	

24.6.5.1.2.3.4 Subsequence—McASP Transmit Pins Functional Configuration

The procedure in Table 24-354 configures the McASP pins for McASP functionality.

Table 24-354. McASP Transmit Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSX AHCLKX ACLKX Desired n-th McASP data pin AXRn is configured as an ouput for transmission.	MCASP_PDIR[28] AFSR; MCASP_PDIR[27] AHCLKR; MCASP_PDIR[26] ACLKR; MCASP_PDIR[n] AXRn	0x-(1) 0x-(2) 0x- (2) 0x1

(1) See Table 24-352.

24.6.5.2 Operational Modes Configuration

24.6.5.2.1 McASP Transmission Modes

24.6.5.2.1.1 Main Sequence – McASP DIT- /TDM- Polling Transmission Method

Figure 24-135 shows the McASP DIT-/TDM- polling method.

Note

- The McASP polling transmission model considers the MPU/DSP as the source of audio data for the McASP transmission buffer.
- The transmit DMA request is disabled and the XDMAERR event is not analyzed.

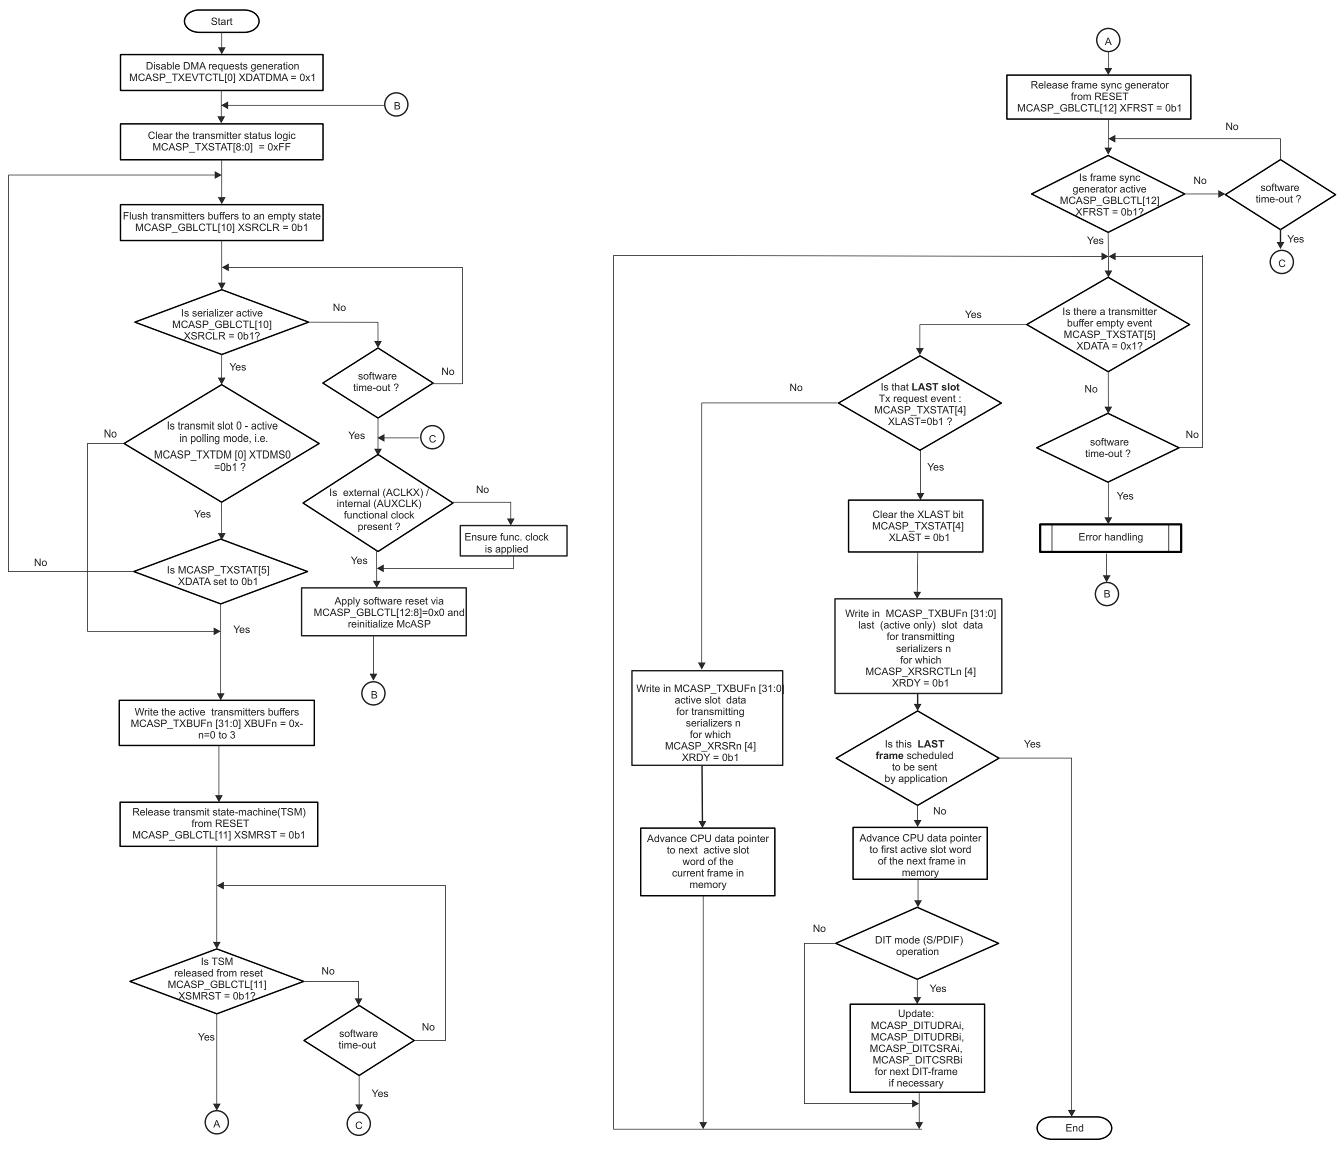

Figure 24-135. McASP DIT- /TDM- Transmission Polling Method

Table 24-355 summarizes the register call for the transmission DIT-/TDM- polling mode.

Table 24-355. Register Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method

Register Name
MCASP_XEVTCTL
MCASP_TXSTAT
MCASP_GBLCTL
MCASP_TXTDM
MCASP_TXBUFn
MCASP_XRSRCTLn
MCASP_DITUDRAi (i=0 to 5)
MCASP_DITUDRBi (i=0 to 5)
MCASP_DITCSRAi (i=0 to 5)
MCASP_DITCSRBi (i=0 to 5)

Table 24-356 summarizes the subprocess call for the DIT-/TDM- transmission polling mode.

Table 24-356. Subprocess Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 24-141

24.6.5.2.1.2 Main Sequence – McASP DIT- /TDM - Interrupt Transmission Method

Figure 24-136 shows the initial setup for interrupt-based transmission.

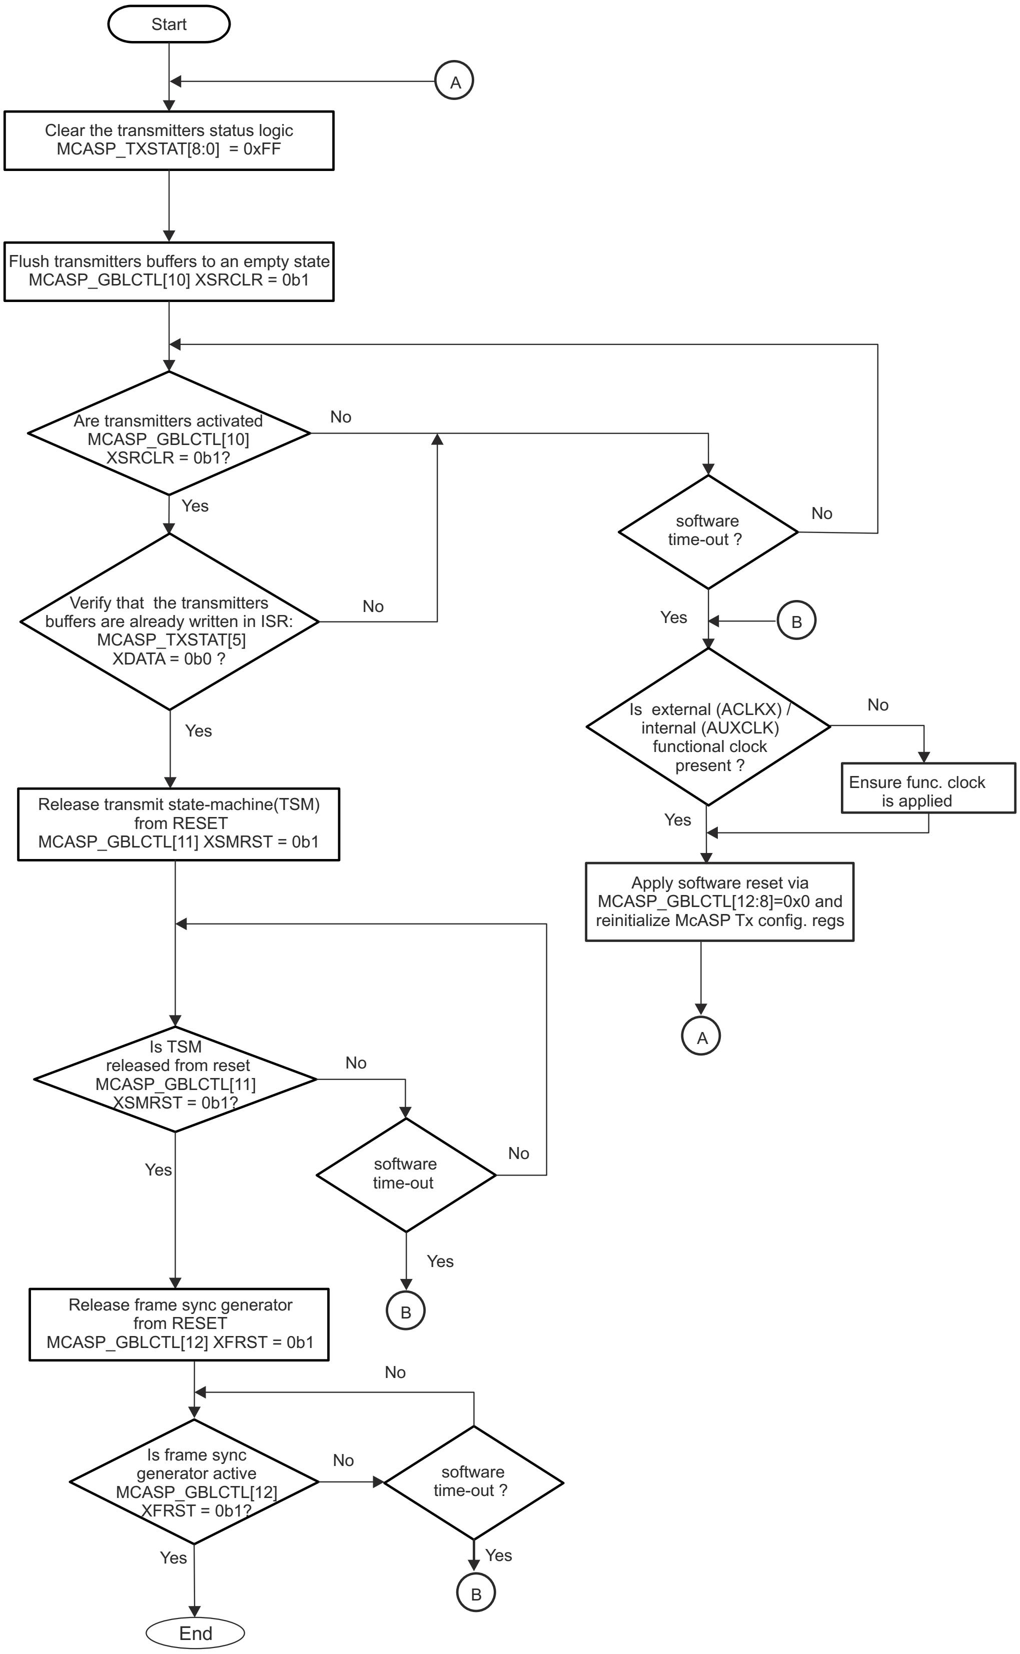

Figure 24-136. Subsequence – DIT-/TDM- Transmission Startup Procedure

Table 24-357 shows the configuration of the McASP using an interrupt method for DIT-/TDM- transmission.

Table 24-357. McASP DIT-/TDM- Interrupt Transmission Model

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update.)	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
IFwrite transfer is through the McASP DATA port (MCASP_TXFMT[3] XBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the *McASP Transmitters Global Initialization* - see Table 24-339)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x0
ENDIF		
DIT/TDM - Transmission Startup Procedure	See Figure 24-136.	

Table 24-358 summarizes the register call to initialize the McASP to transmit using interrupt events.

Table 24-358. Register Call Summary for Subsequence – McASP DIT-/TDM- Transmission Startup Procedure

Register Name	Register Name
MCASP_GBLCTL	MCASP_TXSTAT

24.6.5.2.1.3 Main Sequence –McASP DIT- /TDM - Mode DMA Transmission Method

Table 24-359 shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. Table 24-358 shows the initial setup for DMA - based transmission.

Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

Table 24-359. McASP DMA Transmission Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLX[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_EVTCTLX[5] XDATA	0x0

Table 24-359. McASP DMA Transmission Model with Interrupt Events Servicing (continued)

Step	Register/Bit Field/Programming Model	Value
DMA startup transmission procedure. This procedure is identical than the one shown in Figure 24-136. The only difference is that DMA automatically services all the AXEVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 24-139.	See Figure 24-136.	

24.6.5.2.2 McASP Reception Modes

24.6.5.2.2.1 Main Sequence – McASP Polling Reception Method

Figure 24-137 shows the McASP polling reception method.

Note

The McASP polling reception model considers thedevice CPUs as the accessor of audio data from the McASP receive buffers.

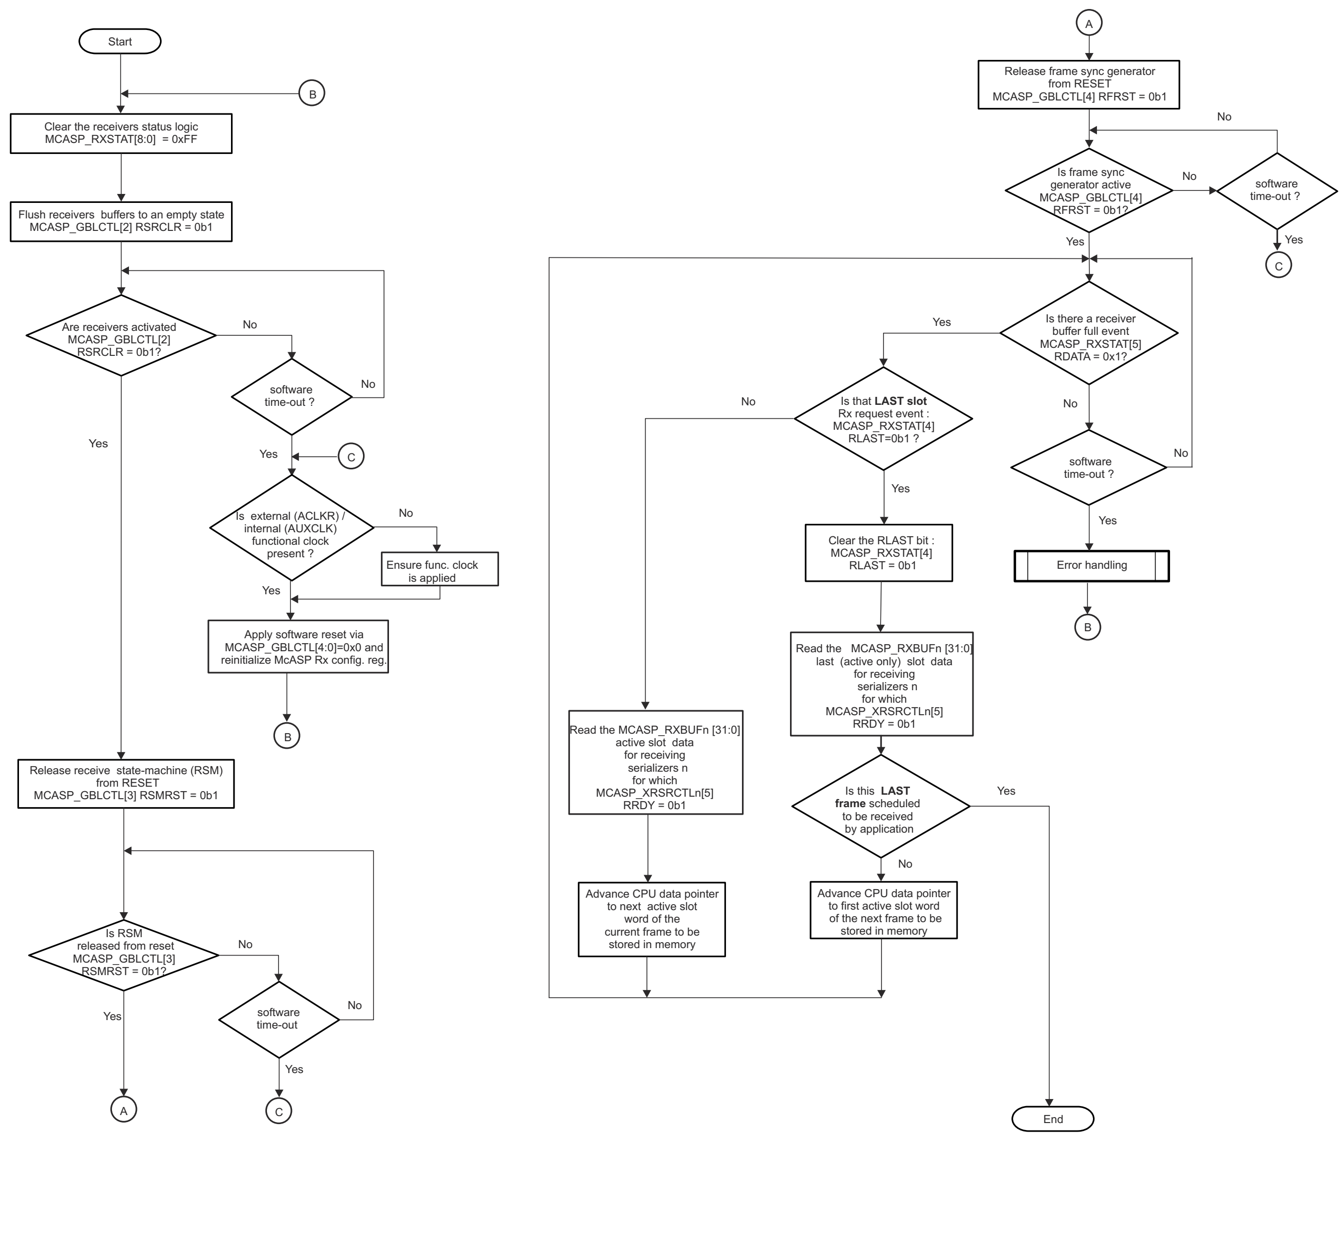

Figure 24-137. McASP Polling Reception Method

Table 24-360 summarizes the register call for the reception polling mode.

Table 24-360. Register Call Summary for Main Sequence – McASP Reception Polling Method

Register Name
MCASP_RXSTAT
MCASP_GBLCTL
MCASP_RXBUFn
MCASP_XRSRCTLn

Table 24-361 summarizes the subprocess call for the polling mode.

Subprocess Name	Cross-Reference
Error handling	Figure 24-142

24.6.5.2.2.2 Main Sequence – McASP TDM - Interrupt Reception Method

Figure 24-138 shows the initial setup for interrupt-based reception.

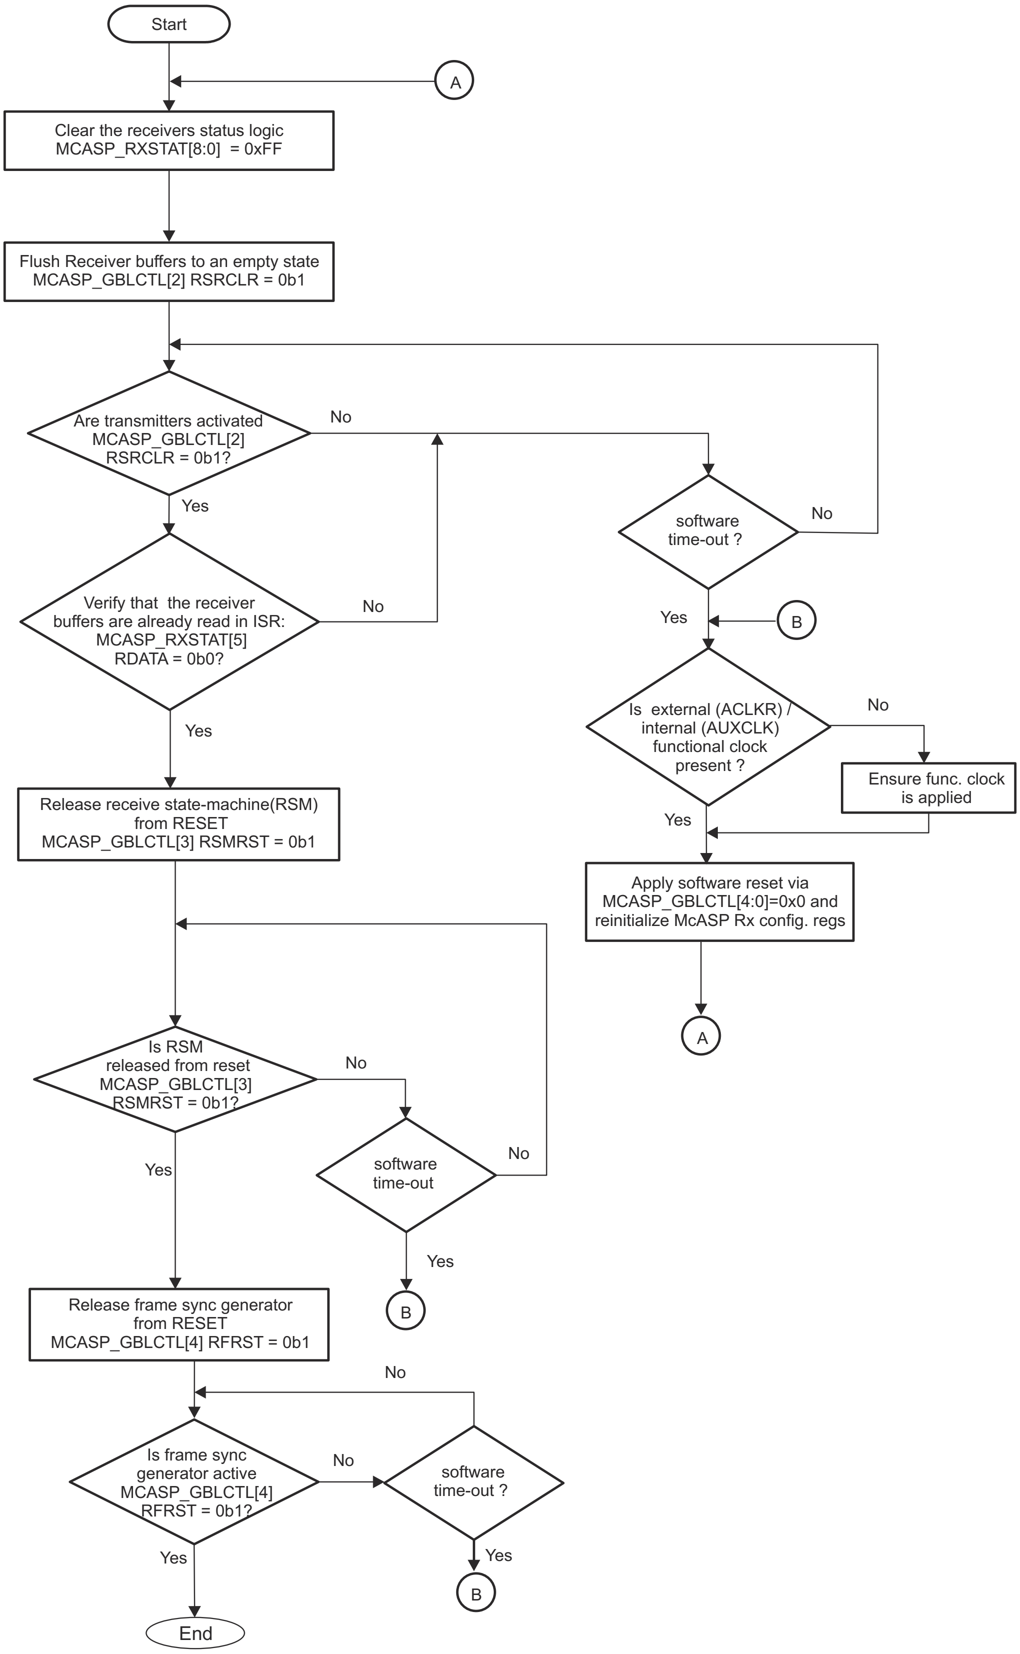

Figure 24-138. Subsequence – TDM - Reception Startup Procedure

Table 24-362 shows the configuration of the McASP using an interrupt method for TDM- reception.

Table 24-362. McASP TDM- Interrupt Reception Model

Step	Register/Bit Field/Programming Model	Value
Disable Rx DMA requests generation.	MCASP_REVTCTL[0] RDATDMA	0x1
Enable the data ready event receive interrupt.	MCASP_EVTCTLR[5] RDATA	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR[2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt	MCASP_EVTCTLR [7] RSTAFRM MCASP_EVTCTLR[4] RLAST	0x1 0x1
IF read transfer is through the McASP DATA port (MCASP_RXFMT[3] RBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the *McASP Receivers Global Initialization for TDM-Mode Operation* - see Table 24-345)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x0
ENDIF		
TDM - Transmission Startup Procedure	See Figure 24-138.	

Table 24-363 summarizes the register call to initialize the McASP to transmit using interrupt events.

Table 24-363. Register Call Summary for Subsequence – McASP TDM- Reception Startup Procedure

Register Name	Register Name
MCASP_GBLCTL	MCASP_RXSTAT

24.6.5.2.2.3 Main Sequence – McASP TDM - Mode DMA Reception Method

Table 24-364 shows the configuration of the McASP using the DMA method for reception. Possible interrupt error event servicing is also considered. Table 24-358 shows the initial setup for DMA - based transmission.

Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

Table 24-364. McASP DMA Reception Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_RXFMT[3] RBUSEL	0x0
Enable the Rx DMA requests generation.	MCASP_REVTCTL[0] RDATDMA	0x0
Enable the Rx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLR[3] RDMAERR	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLR [7] RSTAFRM MCASP_EVTCTLR[4] RLAST	0x1 0x1
Disable the data ready event receive interrupt, as DMA is used to service this request.	MCASP_EVTCTLR[5] RDATA	0x0

Table 24-364. McASP DMA Reception Model with Interrupt Events Servicing (continued)

Step	Register/Bit Field/Programming Model	Value
DMA startup reception procedure. This procedure is identical than the one shown in Figure 24-138. The only difference is that DMA automatically services all the AREVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 24-140.	See Figure 24-138.	

24.6.5.2.3 McASP Event Servicing

24.6.5.2.3.1 McASP DIT-/TDM- Transmit Interrupt Events Servicing

Figure 24-139 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the McASP module.

24.6.6.2 McASP Registers

24.6.6.2.1 MCASP_CFG Register Summary

Table 24-370 to Table 24-373 summarize the MCASP_CFG register mapping.

Table 24-370. MCASP_CFG Register Summary 1

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_CFG L4_PER2 Physical Address

(1) i = 0 to 5
(2) n = 0 to 15

Note

The address locations listed in Table 24-370 to Table 24-373 , *MCASP_CFG Register Mapping Summary*, are relevant for accessing:

- All McASP configuration registers
- MCASP_TXBUFn registers
- MCASP_RXBUFn registers

through the McASP peripheral configuration (CFG) port.

The MCASP_TXFMT[3] XBUSEL bit must be set to 0b1, to allow CFG port write accesses to the McASP XRBUFn buffer. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b1, to allow CFG port read accesses to the McASP XRBUFn buffer.

24.6.6.2.2 MCASP_CFG Register Description

The tables below describe the individual MCASP_CFG register bits.

Note

For all of the below described registers the indexes n and N are applying to serializers (not slots).

Register descriptions cover the superset McASP (16 serializers and all signals pinned out). For the particular McASP instantiation, please refer to *McASP Environment*, and *McASP Integration*.

Table 24-378. MCASP_PDOUT

Address Offset	0x0000 0018		
Physical Address	0x4846 0018	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4 MCASP4_CFG_PER2_L4 MCASP5_CFG_PER2_L4 MCASP6_CFG_PER2_L4 MCASP7_CFG_PER2_L4 MCASP8_CFG_PER2_L4
Description	Pin data output register - holds a value for data out at all times, and may be read back at all times. The value held by MCASP_PDOUT is not affected by writing to MCASP_PDIR and MCASP_PFUNC. However, the data value in MCASP_PDOUT is driven out onto the McASP pin only if the corresponding bit in MCASP_PFUNC is set to 1 (GPIO function) and the corresponding bit in MCASP_PDIR is set to 1 (output). When reading data, it returns the corresponding bit value in MCASP_PDOUT[n]; it does not return the input from the I/O pin. When writing data, writes to the corresponding MCASP_PDOUT[n] bit.		

Table 24-378. MCASP_PDOUT (continued)

PDOUT has these aliases or alternate addresses:

- MCASP_PDSET - when written to at this address, writing a 1 to a bit in MCASP_PDSET sets the corresponding bit in MCASP_PDOUT to 1; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged.
- MCASP_PDCLR - when written to at this address, writing a 1 to a bit in MCASP_PDCLR clears the corresponding bit in MCASP_PDOUT to 0; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged

There is only one set of data-out bits, MCASP_PDOUT[31:0]. The other registers, MCASP_PDSET and MCASP_PDCLR, are just different addresses for the same control bits, with different behaviors during writes.

Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

8	AXR8	Determines drive on AXR8 output pin when the corresponding MCASP_PFUNC[8] and MCASP_PDIR[8] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
7	AXR	Determines drive on AXR7 output pin when the corresponding MCASP_PFUNC[7] and MCASP_PDIR[7] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
6	AXR6	Determines drive on AXR6 output pin when the corresponding MCASP_PFUNC[6] and MCASP_PDIR[6] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
5	AXR5	Determines drive on AXR5 output pin when the corresponding MCASP_PFUNC[5] and MCASP_PDIR[5] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
4	AXR4	Determines drive on AXR4 output pin when the corresponding MCASP_PFUNC[4] and MCASP_PDIR[4] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
3	AXR3	Determines drive on AXR3 output pin when the corresponding MCASP_PFUNC[3] and MCASP_PDIR[3] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
2	AXR2	Determines drive on AXR2 output pin when the corresponding MCASP_PFUNC[2] and MCASP_PDIR[2] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Bits	Field Name	Description	Type	Reset
1	AXR1	Determines drive on AXR1 output pin when the corresponding MCASP_PFUNC[1] and MCASP_PDIR[1] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
0	AXR0	Determines drive on AXR0 output pin when the corresponding MCASP_PFUNC[0] and MCASP_PDIR[0] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Table 24-379. MCASP_PDIN

Address Offset	0x0000 001C		
Physical Address	0x4846 001C	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4 MCASP4_CFG_PER2_L4 MCASP5_CFG_PER2_L4 MCASP6_CFG_PER2_L4 MCASP7_CFG_PER2_L4 MCASP8_CFG_PER2_L4
Description	Pin data input register - holds the state of all the McASP pins. MCASP_PDIN allows reading the actual value of the pin, regardless of the state of MCASP_PFUNC and MCASP_PDIR. Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

Table 24-382. MCASP_GBLCTL

Address Offset	0x0000 0044		
Physical Address	0x4846 0044	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4 MCASP4_CFG_PER2_L4 MCASP5_CFG_PER2_L4 MCASP6_CFG_PER2_L4 MCASP7_CFG_PER2_L4 MCASP8_CFG_PER2_L4
Description	Global transmit control register - provides initialization of the transmit and receive sections. The bit fields in MCASP_GBLCTL are synchronized and latched by the transmitter and receiver corresponding clocks - ACLKX (bits [12:8]) and ACLKR (bits [4:0]), respectively. Before programming MCASP_GBLCTL, ensure that the serial clocks are running. If the corresponding external serial clocks - ACLKX and ACLKR, are not yet running, select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL and ACLKRCTL before programming the MCASP_GBLCTL. Also, after programming any bits in MCASP_GBLCTL, do not proceed until reading back from MCASP_GBLCTL and verifying that the bits in MCASP_GBLCTL are latched.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED	XFRST	XSMRST	XSRCLR	XHCLKRST	XCLKRST	RESERVED	RFRST	RSMRST	RSRCLR	RHCLKRST	RCLKRST

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	RW	0x00000
12	XFRST	Transmit frame-sync generator reset enable bit 0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
11	XSMRST	Transmit state-machine reset enable bit 0x0: The transmit state-machine is held in reset. AXR[n] pin state: If MCASP_PFUNC[n] = 0 and MCASP_PDIR[n] = 1, the corresponding serializer [n] drives the AXR[n] pin to the state specified for inactive time slot. 0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from XBUF[n] to XRSR[n]. The transmit state-machine sets the underrun flag (XUNDRN) in MCASP_XSTAT, if XBUF[n] have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released.	RW	0
10	XSRCLR	Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun occurs. 0x0: The transmit serializer is cleared. 0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in MCASP_XSTAT is set to indicate XBUF is ready to be written.	RW	0
9	XHCLKRST	Transmit high-frequency clock divider reset enable bit 0x0: The transmitter high-frequency clock divider is held in reset and passes through its input as divide-by-1. 0x1: The transmitter high-frequency clock divider is running.	RW	0
8	XCLKRST	Transmit clock divider reset enable bit 0x0: The transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: The transmit clock divider is running.	RW	0
7:5	RESERVED	Reserved	RW	0x0
4	RFRST	Receive frame sync generator reset enable bit. 0x0: Receive frame sync generator is reset. 0x1: Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
3	RSMRST	Receive state machine reset enable bit. 0x0: Receive state machine is held in reset. 0x1: Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.	RW	0

Bits	Field Name	Description	Type	Reset
2	RSRCLR	Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed. 0x0: Receive serializers are cleared. 0x1: Receive serializers are active.	RW	0
1	RHCLKRST	Receive high-frequency clock divider reset enable bit. 0x0: Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1. 0x1: Receive high-frequency clock divider is running.	RW	0
0	RCLKRST	Receive clock divider reset enable bit. 0x0: Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: Receive clock divider is running.	RW	0

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Reserved	RW	0x000 0000

Bits	Field Name	Description	Type	Reset
4	IOLBEN	If DLBEN=0b1, the IOLBEN bit selects between **internal-level (McASP module-level)** and **chip I/O-level** loopback modes. IOLBEN bit value is irrelevant, If DLBEN=0b0. 0x0: McASP internal loopback mode enabled. This selects a direct loopback between corresponding McASP AXRn and AXRn+1 pins, bypassing device pad I/O buffers. 0x1: Chip I/O-level loopback mode enabled. The McASP data is looped back through the device pad I/O buffers.	RW	0
3:2	MODE	Loopback generator mode bits. 0x0: RESERVED 0x1: MODE must be set to 0x1 when McASP operates in loopback mode (DLBEN =0b1). This is necessary to allow transmit clock and frame sync generators to be used by both transmit and receive sections. 0x2, 0x3: Reserved	RW	0x0
1	ORD	Loopback order bit when loopback mode is enabled (DLBEN = 1). 0x0: Odd serializers N + 1 transmit to even serializers N that receive. The corresponding serializers must be programmed properly. 0x1: Even serializers N transmit to odd serializers N+1 that receive. The corresponding serializers must be programmed properly.	RW	0
0	DLBEN	Loop back mode enable bit. 0x0: Loop back mode is disabled (normal McASP operation). 0x1: Loop back is enabled (TDM mode only). Loopback type is selected in IOLBEN bit.	RW	0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x00 0000
8	RERR	RERR bit always returns a logic-OR of: ROVRN | RSYNCERR | RCKFAIL | RDMAERR Allows a single bit to be checked to determine if a receiver error has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	RDMAERR	Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the DMA port in a given time slot than were programmed as receivers. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive DMA error did not occur. 0x1: Receive DMA error did occur.	RW	0

Bits	Field Name	Description	Type	Reset
6	RSTAFRM	Receive start of frame flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new receive frame sync (AFSR) is detected. 0x1: A new receive frame sync (AFSR) is detected.	RW	0
5	RDATA	Receive data ready flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new data in RBUF. 0x1: Data is transferred from XRSR to RBUF and ready to be serviced by the CPUs or DMA. When RDATA is set, it always causes a DMA event (AREVT).	RW	0
4	RLAST	Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. RDATA is also set.	RW	0
3	RTDMSLOT	Returns the LSB of RSLOT. Allows a single read of MCASP_RXSTAT to determine whether the current TDM time slot is even or odd. 0x0: Current TDM time slot is odd. 0x1: Current TDM time slot is even.	RW	0
2	RCKFAIL	Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive clock failure did not occur. 0x1: Receive clock failure did occur.	RW	0
1	RSYNCERR	Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Unexpected receive frame sync did not occur. 0x1: Unexpected receive frame sync did occur.	RW	0
0	ROVRN	Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receiver overrun did not occur. 0x1: Receiver overrun did occur.	RW	0

Description	The current receive TDM time slot register (MCASP_RXTDMSLOT) indicates the current time slot for the receive data frame.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							RSLOTCNT								

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x00 0000
8:0	RSLOTCNT	0x0 - 0x17F: Current receive time slot count. Legal values: 0 to 383 (17Fh). TDM function is not supported for > 32 time slots. However, TDM time slot counter may count to 383 when used to receive a DIR block (transferred over TDM format).	R	0x000

Table 24-396. MCASP_RXCLKCHK

Address Offset	0x0000 0088		
Physical Address	0x4846 0088	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4 MCASP4_CFG_PER2_L4 MCASP5_CFG_PER2_L4 MCASP6_CFG_PER2_L4 MCASP7_CFG_PER2_L4 MCASP8_CFG_PER2_L4
Description	The receive clock check control register (RCLKCHK) configures the receive clock failure detection circuit.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RCNT								RMAX								RMIN								RESERVED				RPS			

Bits	Field Name	Description	Type	Reset
31:24	RCNT	0x0 - 0xFF: Receive clock count value (from previous measurement). The clock circuit continually counts the number of interface clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.	R	0x00
23:16	RMAX	0x00-0xFF: Receive clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in MCASP_RXSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
15:8	RMIN	0x00 - 0xFF: Receive clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00

Description	Transmitter status register - If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes the generation of a new interrupt request.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							XERR	XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR	XUNDRN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN | XSYNCERR | XCKFAIL | XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the DATA port of the McASP in a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0

Bits	Field Name	Description	Type	Reset
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0
5	XDATA	Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect 0x0: XBUF[n] is written and is full 0x1: Data is copied from XBUF[n] to XRSR[n]. XBUF[n] is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).	RW	0
4	XLAST	Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set.	RW	0
3	XTDMSLOT	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even.	R	0
2	XCKFAIL	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred	RW	0
1	XSYNCERR	Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred.	RW	0
0	XUNDRN	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF[n] to XRSR[n], but XBUF[n] has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred.	RW	0

RESERVED																										RRDY	XRDY	DISMOD		SRMOD	

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Reserved	RW	0x0000000
5	RRDY	Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSRn to RBUFn. Read 0x0: Receive buffer (MCASP_RXBUFn) is empty. Read 0x1: Receive buffer (MCASP_RXBUFn) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.	R	0

Bits	Field Name	Description	Type	Reset
4	XRDY	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0). Read 0x0: The transmit buffer (MCASP_TXBUFn) contains data. Read 0x1: The transmit buffer (MCASP_TXBUFn) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.	R	0
3:2	DISMOD	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0). 0x0: Drive on pin is 3-state. 0x1: Reserved 0x2: Drive on pin is logic low. 0x3: Drive on pin is logic high.	RW	0x0
1:0	SRMOD	Serializer mode bit 0x0:The serializer is inactive 0x1:The serializer is operating in transmit mode. 0x2: The serializer is operating in receive mode. 0x3: Reserved	RW	0x0

24.6.6.2.5 MCASP_DAT Register Summary

Table 24-426 to Table 24-429 summarize the MCASP_DAT register mapping.

Table 24-426. MCASP_DAT Register Summary 1

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_DAT L3_MAIN Physical Address
MCASP_RXBUF	R	32	0x0000 0000[1]	0x4580 0000

Table 24-426. MCASP_DAT Register Summary 1 (continued)

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_DAT L3_MAIN Physical Address
MCASP_TXBUF	W	32	0x0000 0000(1)	0x4580 0000

(1) 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP perfomrs accesses to XRBUFn RX/TX buffers through the McASP DATA port.

Table 24-427. MCASP_DAT Register Summary 2

Register Name	Type	Register Width (Bits)	Address Offset	MCASP2_DAT L3_MAIN Physical Address
MCASP_RXBUF	R	32	0x0000 0000(1)	0x45C0 0000
MCASP_TXBUF	W	32	0x0000 0000(1)	0x45C0 0000

(1) 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP perfomrs accesses to XRBUFn RX/TX buffers through the McASP DATA port.

Table 24-428. MCASP_DAT Register Summary 3

Register Name	Type	Register Width (Bits)	Address Offset	MCASP3_DAT L3_MAIN Physical Address	MCASP4_DAT L4_PER2 Physical Address	MCASP5_DAT L4_PER2 Physical Address
MCASP_RXBUF	R	32	0x0000 0000	0x4600 0000	0x4843 6000	0x4843 A000
MCASP_TXBUF	W	32	0x0000 0000	0x4600 0000	0x4843 6000	0x4843 A000

Table 24-429. MCASP_DAT Register Summary 4

Register Name	Type	Register Width (Bits)	Address Offset	MCASP6_DAT L4_PER2 Physical Address	MCASP7_DAT L4_PER2 Physical Address	MCASP8_DAT L4_PER2 Physical Address
MCASP_RXBUF	R	32	0x0000 0000(1)	0x4844 C000	0x4845 0000	0x4845 4000
MCASP_TXBUF	W	32	0x0000 0000(1)	0x4844 C000	0x4845 0000	0x4845 4000

(1) 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP perfomrs accesses to XRBUFn RX/TX buffers through the McASP DATA port.

Note

For MCASP_RXBUF and MCASP_TXBUF buffer accesses through the McASP DATA port, the destination physical address is always the same regardless of current channel index or transfer direction. The MCASP_TXFMT[3] XBUSEL bit must be set to 0b0, to allow write transfers through the DATA port. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b0, to allow read transfers through the DATA port.

Note

The McASP DATA port is exclusively assigned for DMAs/device CPUs accesses to the McASP channels transmit and receive buffer registers. All other McASP module registers must be accessed through the McASP CFG (peripheral) port.

Note

McASP1, McASP2, and McASP3, whose data port are accessible directly via L3_MAIN, do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

24.6.6.2.6 MCASP_DAT Register Description

24.7 SuperSpeed USB DRD

This section describes the SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem of the device.

Note

This chapter describes a module (subsystem) in the superset device. The available number of instances and supported set of features is device part number dependent. Refer to device *Data Manual*, for more information.

24.7.1 SuperSpeed USB DRD Subsystem Overview

SuperSpeed USB DRD Subsystem has four instances in the device providing the following functions:

- USB1: SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem with integrated SS (USB3.0) PHY and HS/FS (USB2.0) PHY
- USB2: High-Speed (HS) USB 2.0 Dual-Role-Device (DRD) subsystem with integrated HS/FS PHY
- USB3: HS USB 2.0 Dual-Role-Device (DRD) subsystem with ULPI (SDR) interface to external HS/FS PHYs
- USB4: HS USB 2.0 Dual-Role-Device (DRD) subsystem with ULPI (SDR) interface to external HS/FS PHYs.

Figure 24-143 shows the USB1 subsystem overview.

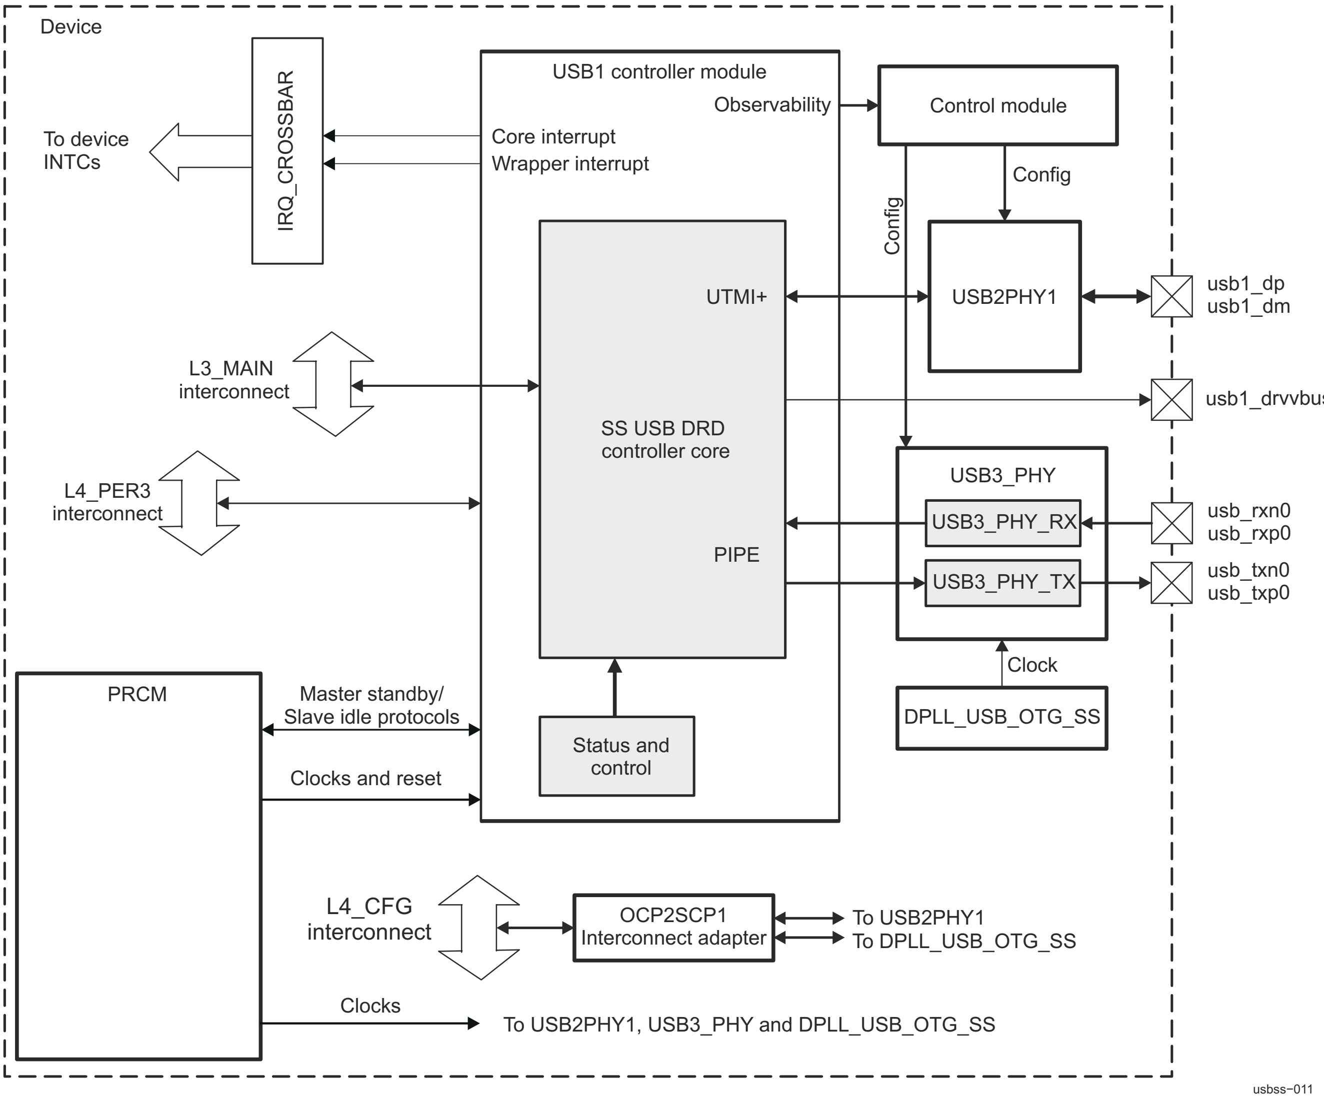

Figure 24-143. USB1 Highlight

Figure 24-144 shows the USB2 subsystem overview.

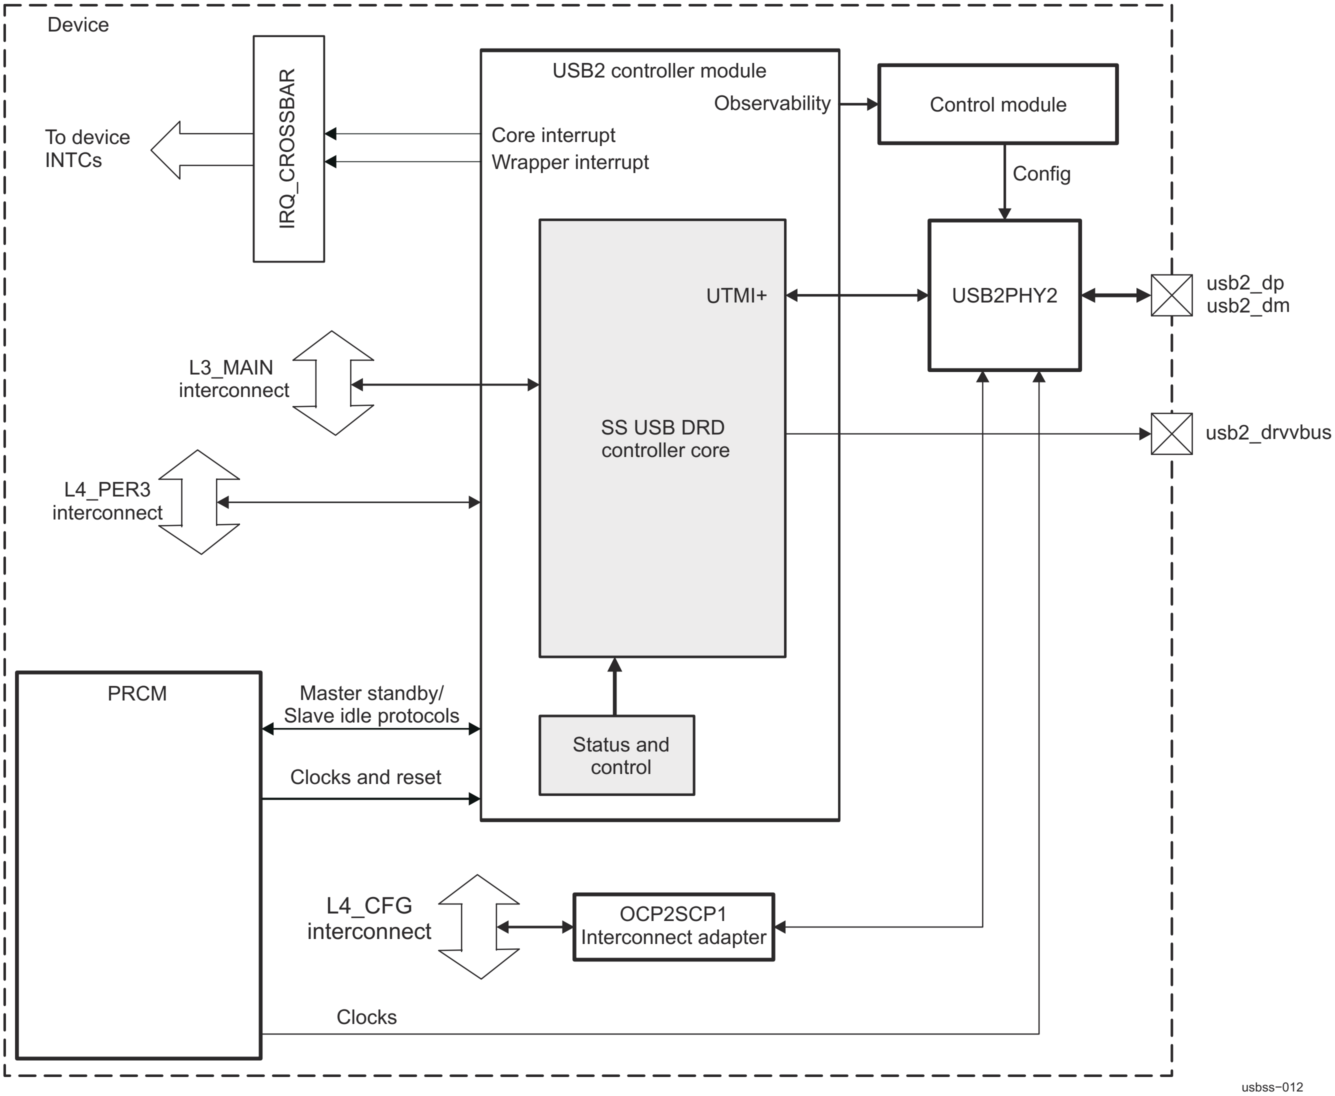

Figure 24-144. USB2 Highlight

Figure 24-145 shows the USB3 and USB4 subsystem overview.

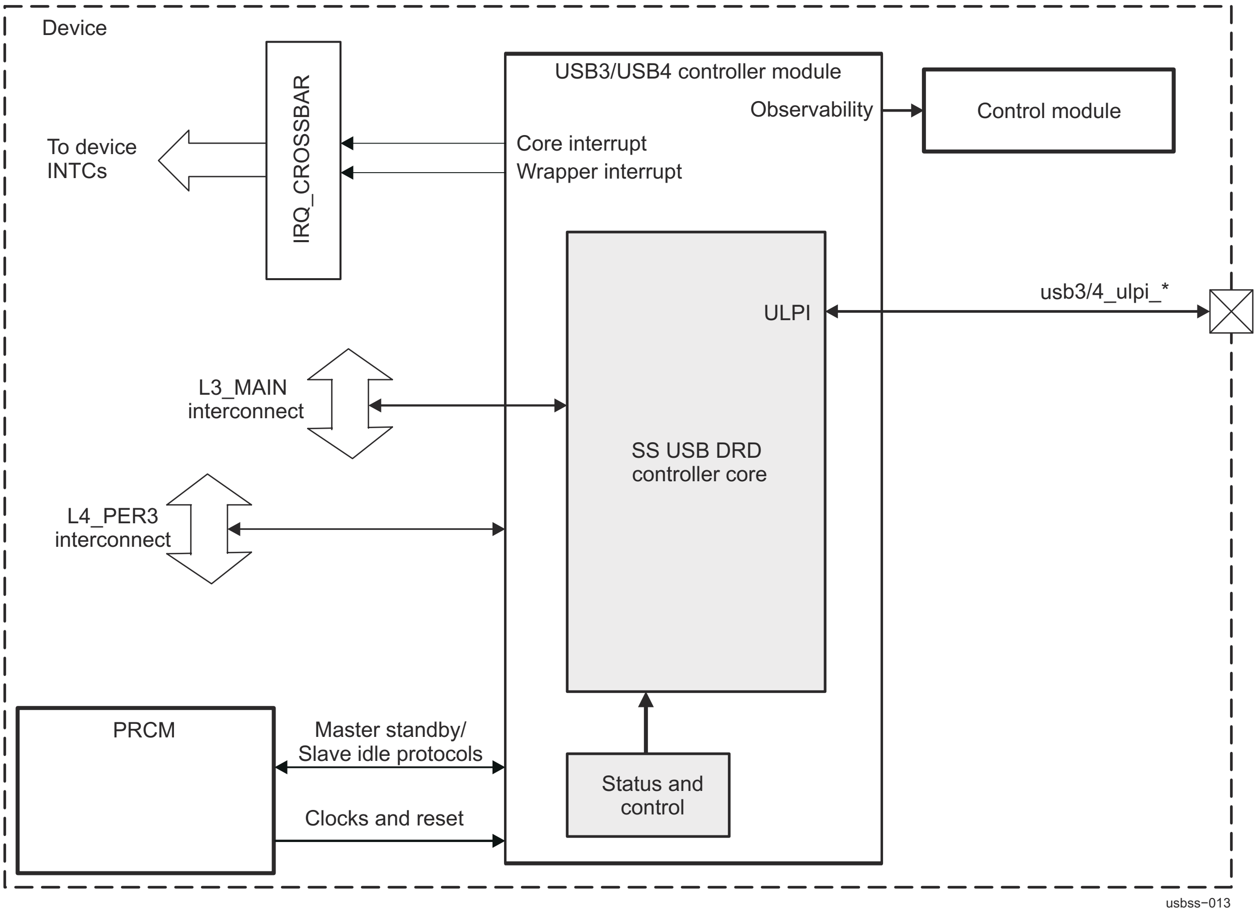

Figure 24-145. USB3 and USB4 Highlight

24.7.1.1 Main Features

SuperSpeed USB DRD Subsystem has the following features:

- Dual-role-device (DRD) capability:
  - Supports USB Peripheral (or Device) mode at speeds SS (5Gbps)(USB1 only), HS (480 Mbps), and FS (12 Mbps)
  - Supports USB Host mode at speeds SS (5Gbps)(USB1 only), HS (480 Mbps), FS (12 Mbps), and LS (1.5 Mbps)
  - USB static peripheral operation
  - USB static host operation
  - Flexible stream allocation
  - Stream priority
  - External Buffer Control
- Each instance contains single xHCI controller with the following features:
  - Internal DMA controller
  - Descriptor caching and data prefetching
  - Interrupt moderation and blocking
  - Power management USB3.0 states for U0, U1, U2, and U3
  - Dynamic FIFO memory allocation for all endpoints
  - Supports all modes of transfers (control, bulk, interrupt, and isochronous)
  - Supports high bandwidth ISO mode
- Connects to an external charge pump for VBUS 5 V generation

- USB-HS PHY (USB2PHY1 and USB2PHY2 for USB1 and USB2, respectively): contain the USB functions, drivers, receivers, and pads for correct D+/D– signalling
- USB3_PHY. The USB3_PHY is embedded in the USB1 subsystem and contains:
  - USB3_PHY_RX deserializer to receive data at SuperSpeed mode
  - USB3_PHY_TX serializer to transmit data at SuperSpeed mode
  - Power sequencer that contains a power control state machine, generating the sequences to power up/down the USB3_PHY_RX/USB3_PHY_TX
  - Dedicated DPLL (DPLL_USB_OTG_SS)

24.7.2 SuperSpeed USB DRD Subsystem Environment

24.7.2.1 SuperSpeed USB DRD Subsystem I/O Interfaces

Figure 24-146 describes the I/O signals of the SuperSpeed USB subsystem interfaces.

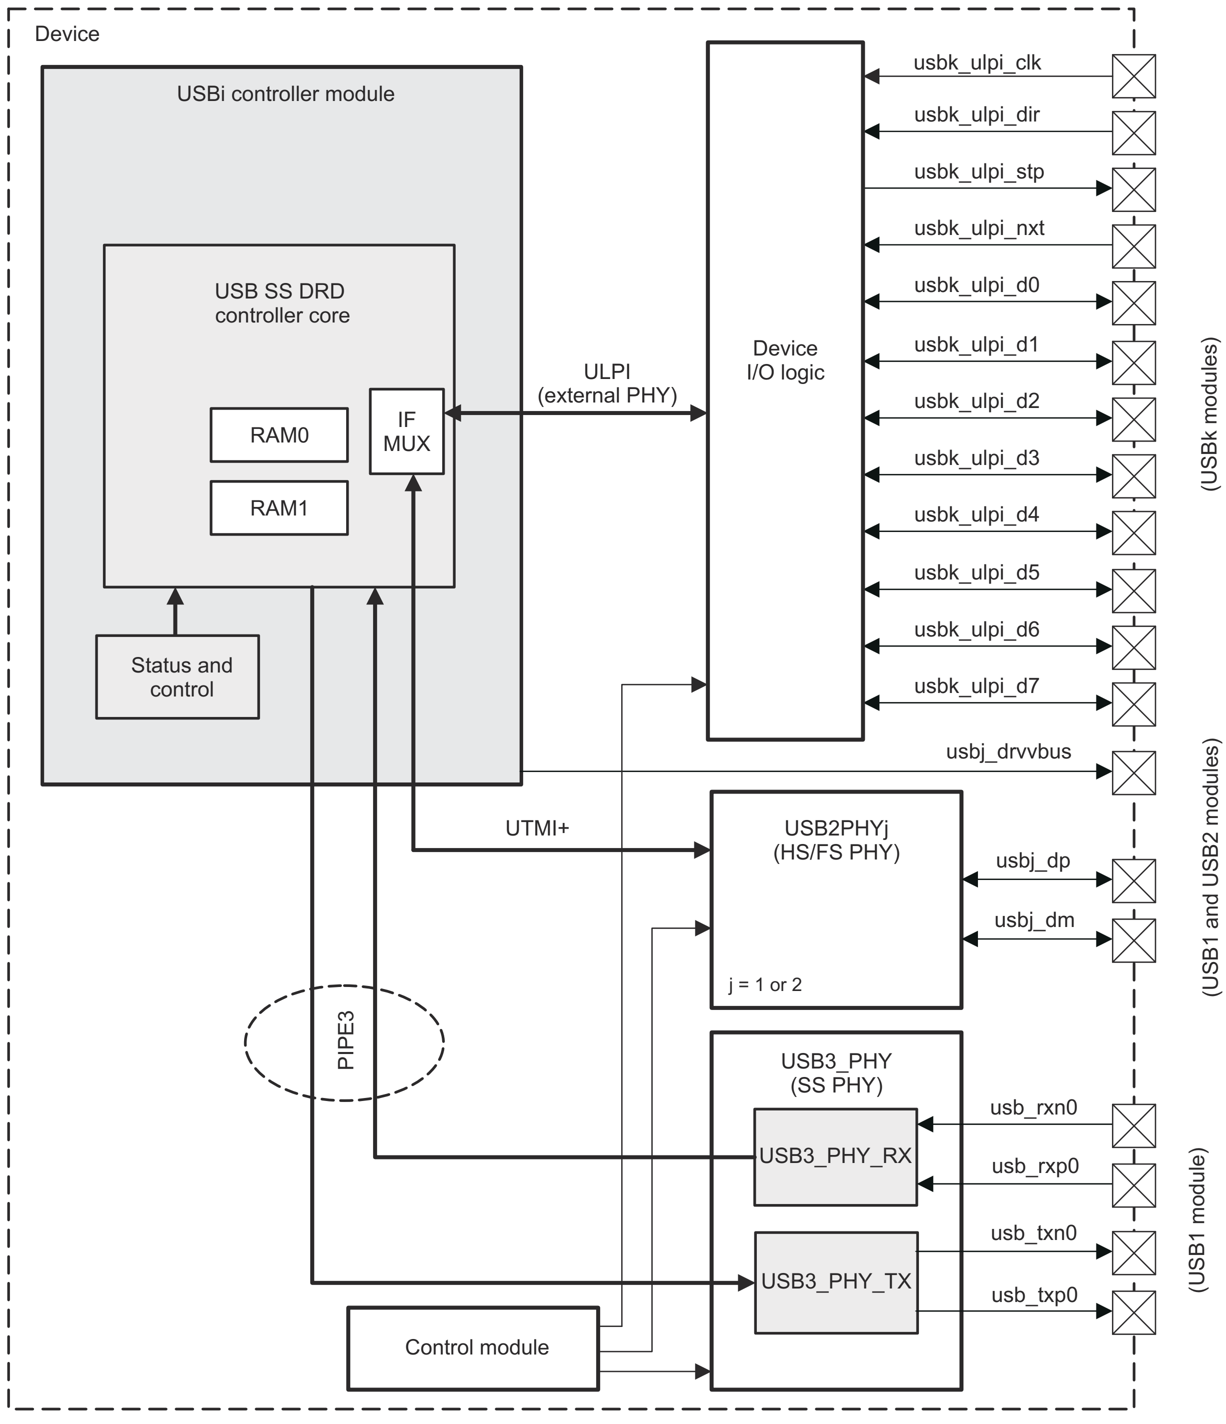

Figure 24-146. SuperSpeed USB Subsystem Environment

i = 1 to 4

k = 3 or 4

Table 24-432 through Table 24-435 describe the I/O signals of the SuperSpeed USB subsystem interfaces shown in Figure 24-146

Table 24-432. USB1 Input/Output Description

Module Pin	Device-Level Signal Name	I/O[(1)]	Description	Reset Value
USB2PHY1				
DRVVBUS	usb1_drvvbus	O	Drive-VBUS enable to external charge pump/power switch	0
DP	usb1_dp	I/O	USB2.0 half-duplex differential pair	HiZ
DM	usb1_dm	I/O		HiZ
USB3_PHY				
TX	usb_txn0	O	USB3.0 transmitter differential pair	HiZ

ULPI_NXT	usb3_ulpi_nxt	I	Next signal control from external transceiver	HiZ
ULPI_DATA0	usb3_ulpi_d0	I/O	Data bit 0 to/from external transceiver	HiZ
ULPI_DATA1	usb3_ulpi_d1	I/O	Data bit 1 to/from external transceiver	HiZ
ULPI_DATA2	usb3_ulpi_d2	I/O	Data bit 2 to/from external transceiver	HiZ
ULPI_DATA3	usb3_ulpi_d3	I/O	Data bit 3 to/from external transceiver	HiZ
ULPI_DATA4	usb3_ulpi_d4	I/O	Data bit 4 to/from external transceiver	HiZ
ULPI_DATA5	usb3_ulpi_d5	I/O	Data bit 5 to/from external transceiver	HiZ
ULPI_DATA6	usb3_ulpi_d6	I/O	Data bit 6 to/from external transceiver	HiZ
ULPI_DATA7	usb3_ulpi_d7	I/O	Data bit 7 to/from external transceiver	HiZ

Table 24-435. USB4 Input/Output Description

Module Pin	Device-Level Signal Name	I/O	Description	Reset Value
ULPI interface				
ULPI_CLK	usb4_ulpi_clk	I	Clock input from external transceiver	HiZ

Table 24-435. USB4 Input/Output Description (continued)

Module Pin	Device-Level Signal Name	I/O	Description	Reset Value
ULPI_DIR	usb4_ulpi_dir	I	Data direction control from external transceiver	HiZ
ULPI_STP	usb4_ulpi_stp	O	Output to external transceiver to stop data stream	1
ULPI_NXT	usb4_ulpi_nxt	I	Next signal control from external transceiver	HiZ
ULPI_DATA0	usb4_ulpi_d0	I/O	Data bit 0 to/from external transceiver	HiZ
ULPI_DATA1	usb4_ulpi_d1	I/O	Data bit 1 to/from external transceiver	HiZ
ULPI_DATA2	usb4_ulpi_d2	I/O	Data bit 2 to/from external transceiver	HiZ
ULPI_DATA3	usb4_ulpi_d3	I/O	Data bit 3 to/from external transceiver	HiZ
ULPI_DATA4	usb4_ulpi_d4	I/O	Data bit 4 to/from external transceiver	HiZ
ULPI_DATA5	usb4_ulpi_d5	I/O	Data bit 5 to/from external transceiver	HiZ
ULPI_DATA6	usb4_ulpi_d6	I/O	Data bit 6 to/from external transceiver	HiZ
ULPI_DATA7	usb4_ulpi_d7	I/O	Data bit 7 to/from external transceiver	HiZ

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers* in *Control Module*.

24.7.2.2 SuperSpeed USB Subsystem Application

24.7.2.2.1 USB3.0 DRD Application

Figure 24-147 shows a typical application using the SuperSpeed USB subsystem. The application represents a full-featured integration and allows all of the capabilities of the controller used.

VBUS sensing can be exported to the external Power-Management IC (PMIC) in case it supports this function. This would eliminate the need for additional components such as level shifters and comparators. In this case, software driver must be modified to be able to react on PMIC interrupts for VBUS-rise and VBUS-fall through the I2C1 interface.

Some PMICs support the VBUS_DETECT output from the VBUS comparator to be muxed directly on their GPIO pin. In this case PMIC VBUS_DETECT can be connected to a SoC GPIO pin, thus, this functionally is identical to Figure 24-147.

See the respective PMIC datasheet for details.

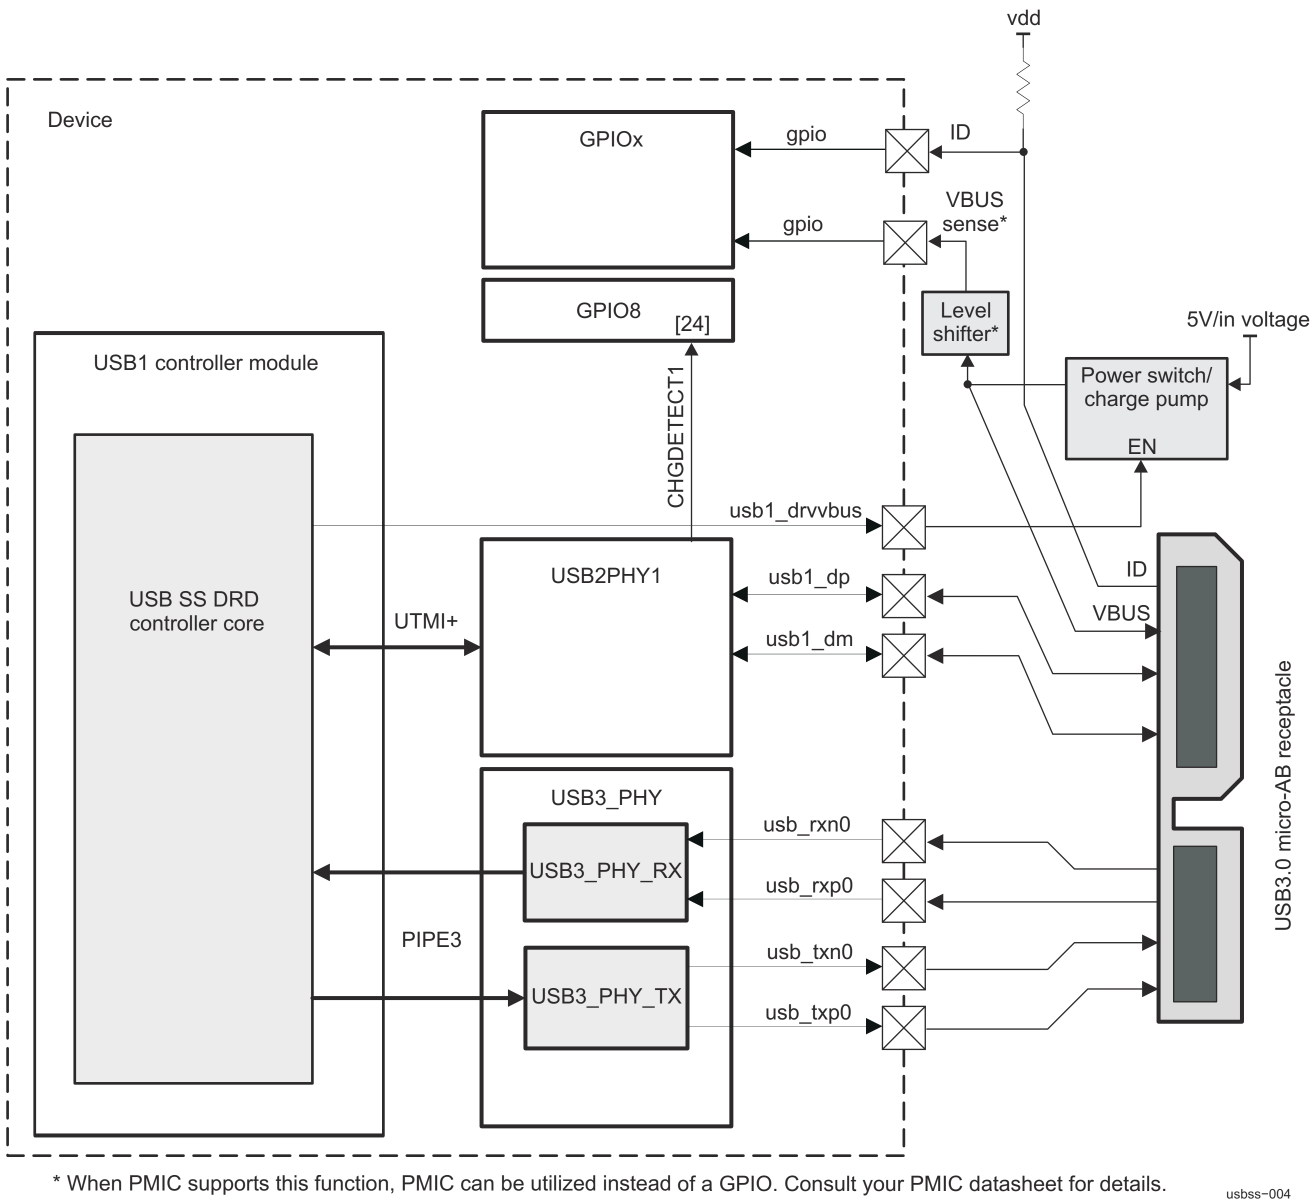

Figure 24-147. SuperSpeed USB Controller Application: USB3.0 DRD

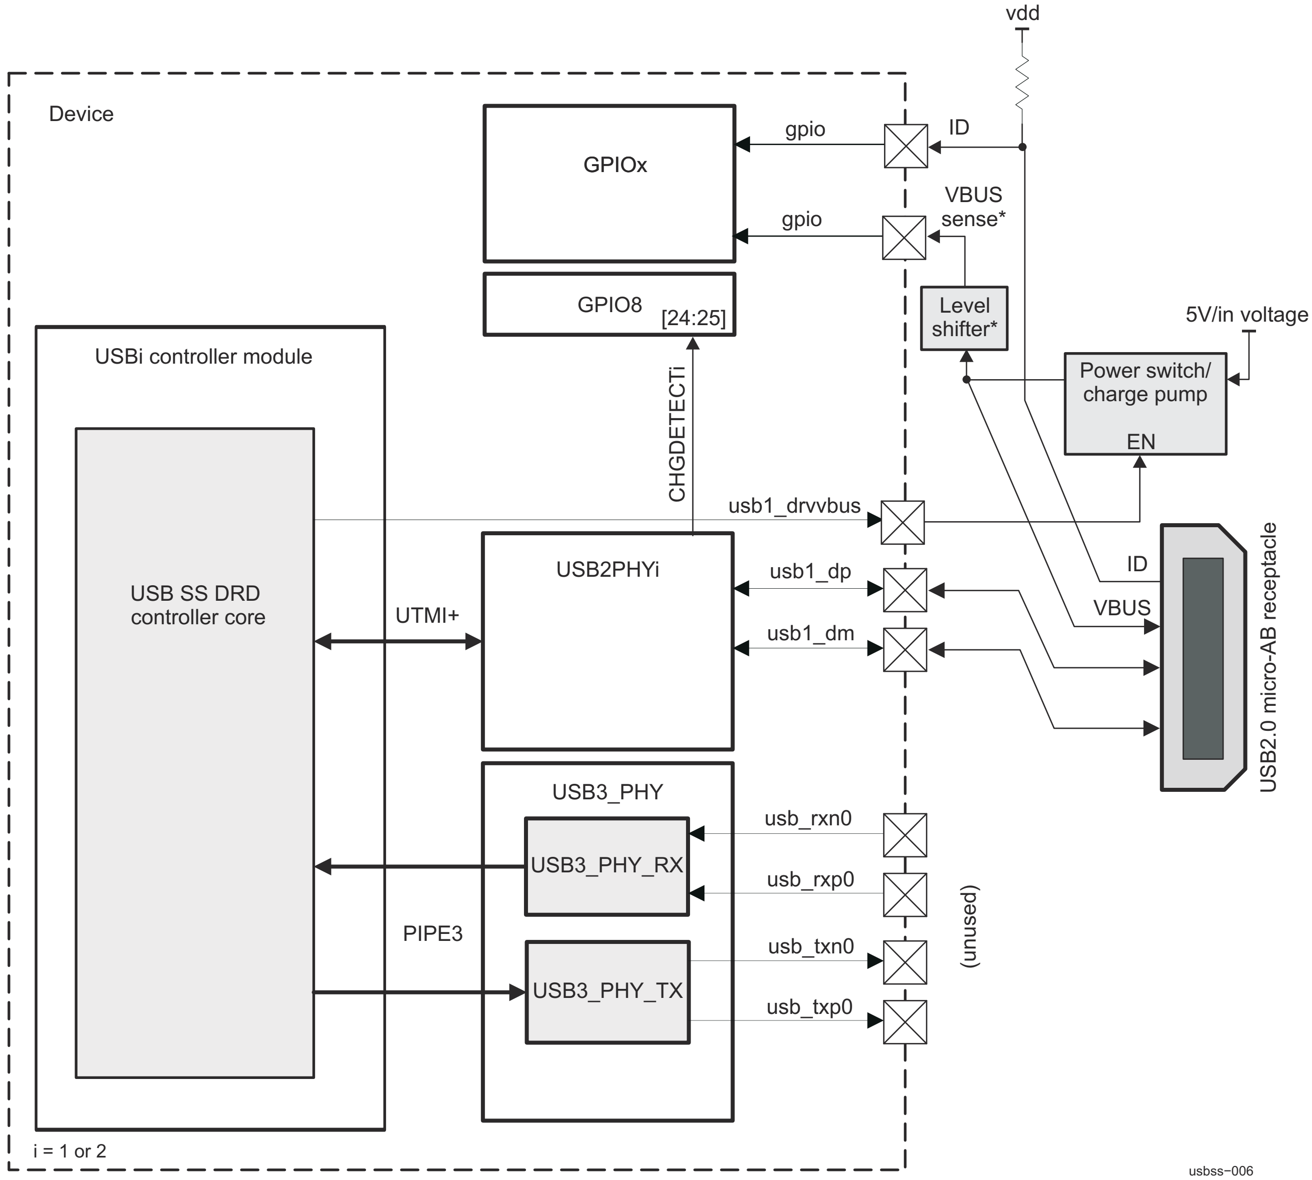
The USB3.0 micro-AB receptacle characterizes a USB3.0 DRD, and allows the following attachments:

- Micro-A-type plugs, to attach to a USB peripheral/hub upstream port (or to another DRD, as host)
- Micro-B-type plugs, to attach to a USB host/hub downstream port (or to another DRD, as peripheral)
- To USB3.0 devices: The USB3.0 micro plug covers all contacts of the receptacle.
- To USB2.0 devices: The USB2.0 micro plug occupies only the wider, USB2.0 half of the receptacle. SuperSpeed signal pairs remain floating.

24.7.2.2.2 USB2.0 DRD Internal PHY

Figure 24-148 shows a USB2.0-only integration in which the USB3.0 capability is not available. Similarly to Figure 24-147, VBUS sensing can be exported to the companion PMIC.



* When PMIC supports this function, PMIC can be utilized instead of a GPIO. Consult your PMIC datasheet for details.

Figure 24-148. SuperSpeed USB Controller Application: USB2.0 DRD (Internal PHY)

The USB2.0 micro-AB receptacle characterizes a USB2.0 DRD and accepts the following:

- Micro-A-type plugs, which attach to a USB peripheral/hub upstream port (or another DRD, as host)
- Micro-B-type plugs, which attach to a USB host/hub downstream port (or another DRD, as peripheral)
- USB2.0 devices only: The USB2.0 micro plug covers all contacts of the receptacle.
- USB3.0 devices: The USB3.0 micro plug is incompatible and the SuperSpeed signal pairs of the cable remain floating.

24.7.2.2.3 USB2.0 DRD External PHY

Figure 24-149 shows an external ULPI PHY IC is used instead of the on-chip UTMI PHY (USB2PHY). Seen from outside the system, both integrations are functionally equivalent. Internally, the functions of the ID and VBUS are taken over by the ULPI PHY. However, power on VBUS can be supplied by an VBUS switch with more power than the ULPI PHY is capable of.

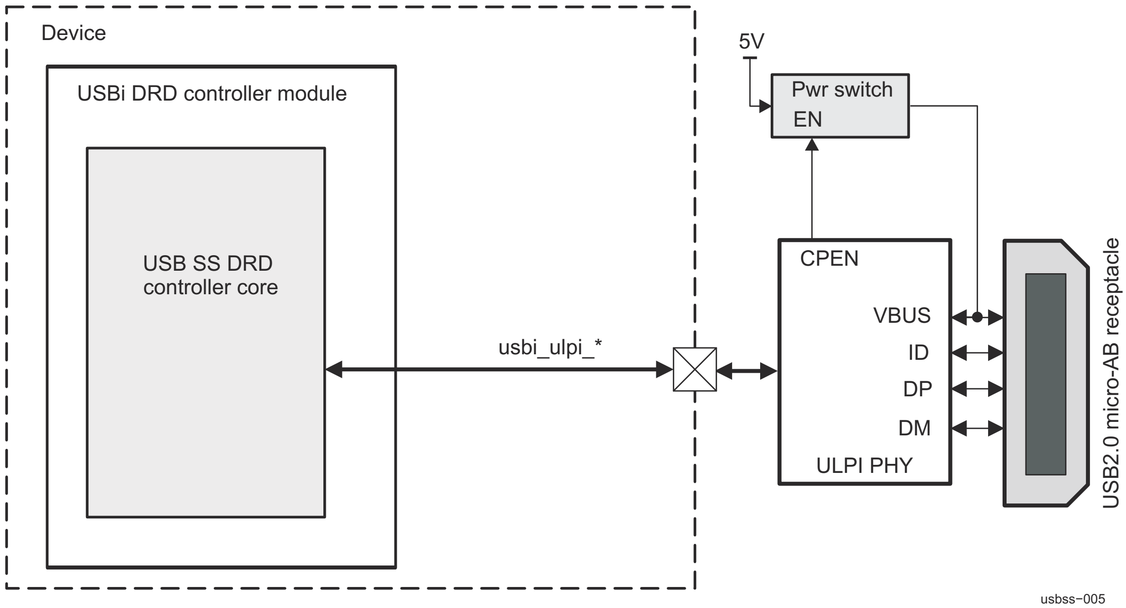


Figure 24-149. SuperSpeed USB Controller Application: USB2.0 DRD (ULPI PHY)

24.7.2.2.4

i = 3 or 4

24.7.2.2.5 Host Mode

In always-host mode:

- ID pin can be omitted. Driver must be set explicitly to operate in host mode
- USB receptacle used must be type-A USB3.0 or USB2.0 respectively.

24.7.2.2.6 Device Mode

In always-device (peripheral) mode

- ID pin can be omitted. Driver must be set explicitly to operate in device mode
- VBUS power switch is not needed. USB devices never drive VBUS
- USB receptacle used must be type-B standard/micro USB3.0 or USB2.0 respectively.

24.7.3 SuperSpeed USB Subsystem Integration

The L3 (master) interconnect generates data traffic within the device. The L4 (slave) interconnect is a configuration port for register setting.

Figure 24-150 shows the SuperSpeed USB subsystem integration in the device.

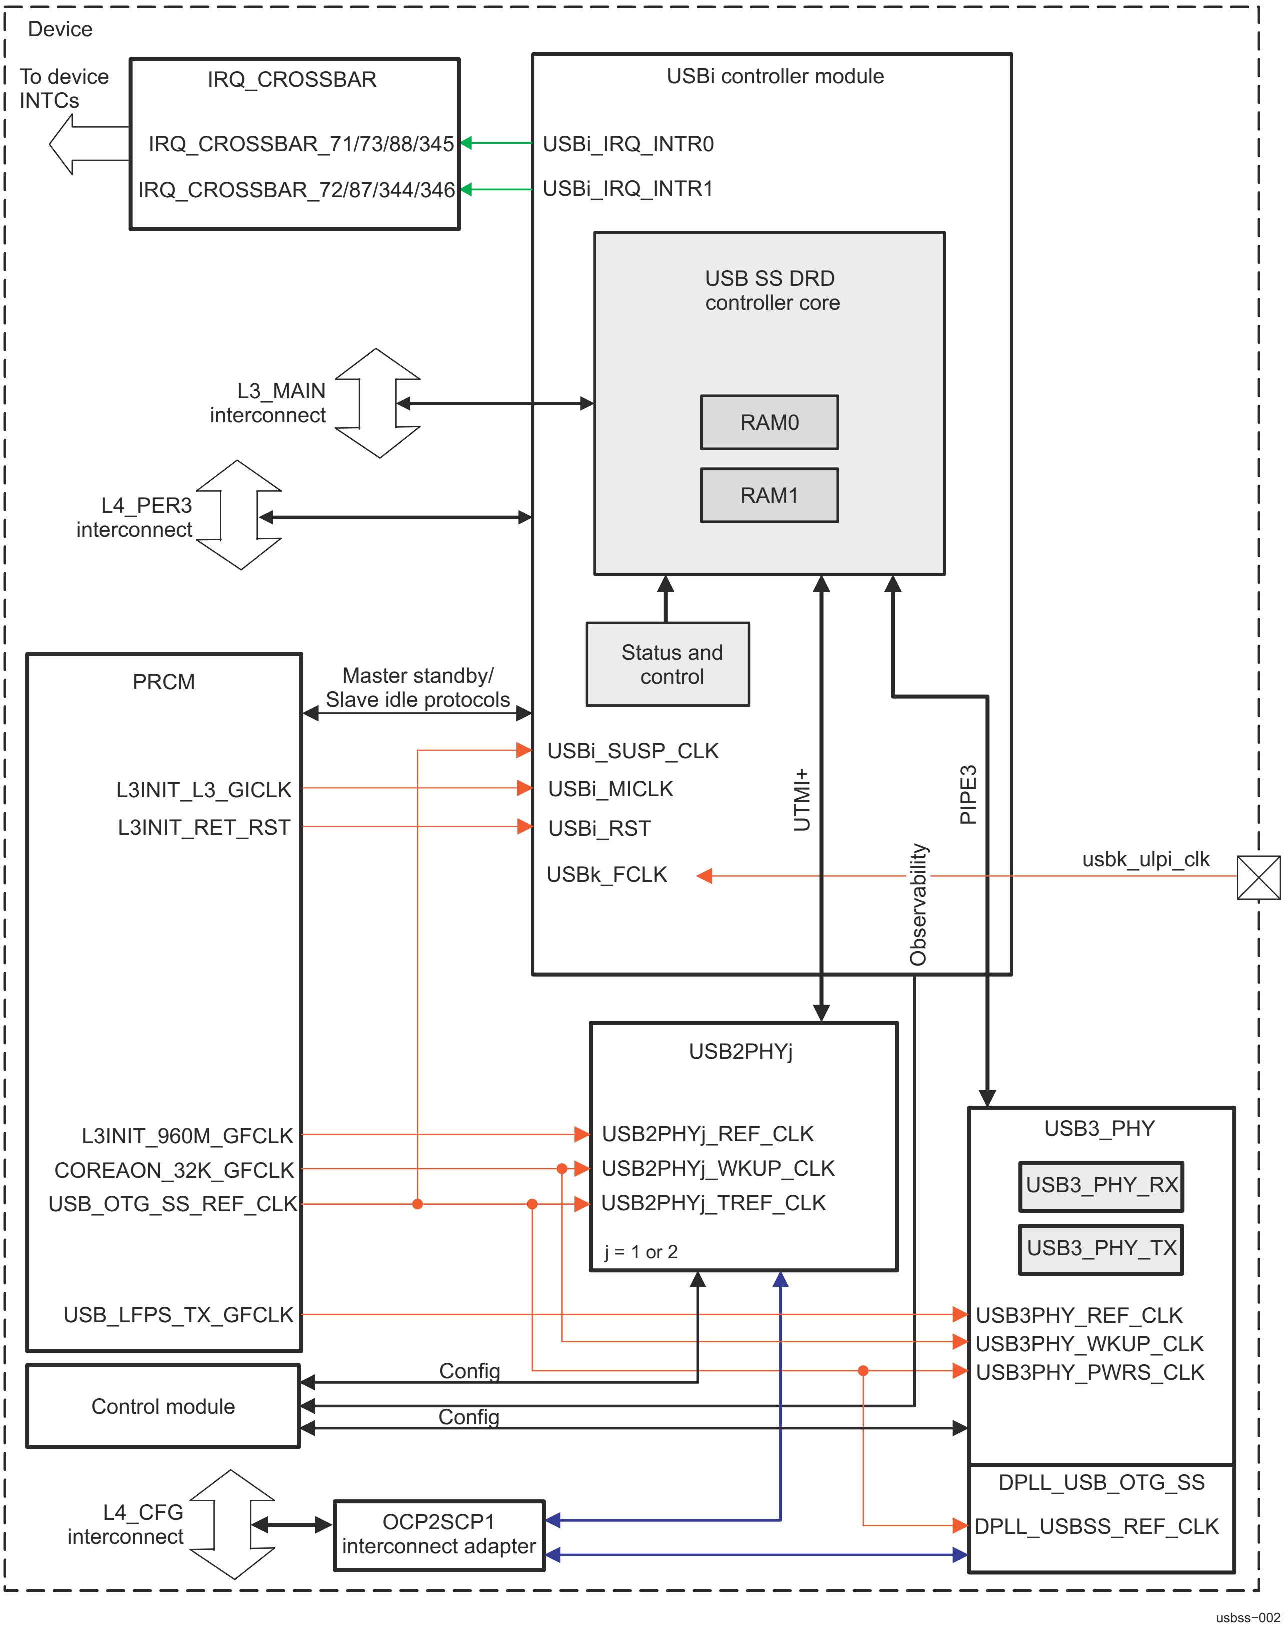

Figure 24-150. SuperSpeed USB Subsystem Integration

i = 1 to 4

k = 3 or 4

Table 24-436 through Table 24-438 summarize the integration of the module in the device.

Table 24-436. SuperSpeed USB Subsystem Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
USB1	PD_L3INIT	L3_MAIN L4_PER3
USB2	PD_L3INIT	L3_MAIN L4_PER3
USB3	PD_L3INIT	L3_MAIN L4_PER3
USB4	PD_L3INIT	L3_MAIN L4_PER3
USB2PHY1	PD_L3INIT	L4_CFG
USB2PHY2	PD_L3INIT	L4_CFG
USB3_PHY	PD_L3INIT	L4_CFG

Table 24-437 lists the clocks provided to the SuperSpeed USB subsystem.

Table 24-437. SuperSpeed USB Subsystem Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
USB1	USB1_FCLK	USB2PHY1_UTMI_CLK	USB2PHY1	60-MHz UTMI clock from PHY
	USB1_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface *CD_L3INIT Clock Domain* in *Power, Reset and Clock Management*.
	USB1_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
USB2	USB2_FCLK	USB2PHY2_UTMI_CLK	USB2PHY2	60-MHz UTMI clock from PHY
	USB2_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface.
	USB2_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
	USB2_125M_CLK	L3INIT_60M_FCLK	PRCM	125-MHz clock for the non-USB3.0 instances.
USB3	USB3_FCLK	OTG_60M_FCLK	usb3_ulpi_clk pad	60-MHz ULPI clock from PHY
	USB3_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface .
	USB3_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
	USB3_125M_CLK	L3INIT_60M_FCLK	PRCM	125-MHz clock for the non-USB3.0 instances.
USB4	USB4_FCLK	OTG_60M_FCLK	usb4_ulpi_clk pad	60-MHz ULPI clock from PHY
	USB4_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface .
	USB4_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
	USB4_125M_CLK	L3INIT_60M_FCLK	PRCM	125-MHz clock for the non-USB3.0 instances.
USB2PHY1	USB2PHY1_REF_CLK	L3INIT_960M_GFCLK	PRCM	Functional REF 960-MHz clock (from the DPLL_USB, PRCM controlled)
	USB2PHY1_WKUP_CLK	FUNC_32K_CLK	PRCM	Wakeup 32-kHz functional clock

Table 24-437. SuperSpeed USB Subsystem Clocks and Resets (continued)

	USB2PHY1_TREF_CLK	USB_OTG_SS_REF_CLK	PRCM	Functional TREF clock derived from SYS_CLK1
USB2PHY2	USB2PHY2_REF_CLK	L3INIT_960M_GFCLK	PRCM	Functional REF 960-MHz clock (from the DPLL_USB, PRCM controlled)
	USB2PHY2_WKUP_CLK	FUNC_32K_CLK	PRCM	Wakeup 32-kHz functional clock
	USB2PHY2_TREF_CLK	USB_OTG_SS_REF_CLK	PRCM	Functional TREF clock derived from SYS_CLK1
USB3_PHY	USB3PHY_REF_CLK	USB_LFPS_TX_GFCLK	PRCM	Fixed-frequency USB3 transmitter REF functional clock

USB4	USB4_RST	L3INIT_RET_RST	PRCM	USB4 controller module hardware retention reset

Table 24-438 lists the interrupt lines that are driven out from the SuperSpeed USB controller modules.

Table 24-438. SuperSpeed USB Subsystem Hardware Requests

		Interrupt Requests		
Module Instance	**Source Signal Name**	**IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
USB1	USB1_IRQ_INTR0	IRQ_CROSSBAR_71	MPU_IRQ_76	USB1 main (core) interrupt request
	USB1_IRQ_INTR1	IRQ_CROSSBAR_72	MPU_IRQ_77 IPU1_IRQ_73 IPU2_IRQ_73	USB1 wrapper interrupt request
USB2	USB2_IRQ_INTR0	IRQ_CROSSBAR_73	MPU_IRQ_78 IPU1_IRQ_74 IPU2_IRQ_74	USB2 main (core) interrupt request
	USB2_IRQ_INTR1	IRQ_CROSSBAR_87	MPU_IRQ_92 IPU1_IRQ_76 IPU2_IRQ_76	USB2 wrapper interrupt request
USB3	USB3_IRQ_INTR0	IRQ_CROSSBAR_88	MPU_IRQ_93 IPU1_IRQ_77 IPU2_IRQ_77	USB3 main (core) interrupt request
	USB3_IRQ_INTR1	IRQ_CROSSBAR_344	-	USB3 wrapper interrupt request
USB4	USB4_IRQ_INTR0	IRQ_CROSSBAR_345	-	USB4 main (core) interrupt request
	USB4_IRQ_INTR1	IRQ_CROSSBAR_346	-	USB4 wrapper interrupt request

Note

The **Default Mapping** column in Table 24-438 shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

24.8 SATA Controller

24.8.1 SATA Controller Overview

The SATA host controller handles data interactions between a local host system memory and a SATA mass storage device with minimal local host (LH) intervention.

In contrast to the parallel 16-bit - ATA (PATA) interface, the SATA interface takes advantage of serial data transmission/reception over a differential pair of conductors. SATA uses the command set from the ATA/ATAPI-6 standard augmented with native command queuing (NCQ) commands optimized for the serialized interface.

The device has one embedded SATA host bus adapter (HBA) controller with a single port. The device SATA host subsystem is composed of several functional components (see Figure 24-151):

- The core component of the SATA host controller subsystem (signified as SATA controller on the Figure 24-151) implements the transport and link layers of the SATA interface protocol, i.e. all SATA media access control (MAC) functionalities.
- SATA_PHY encompasses the physical layer (PHY) components - serializer, de-serializer, etc. which adapt the generated by the SATA controller MAC logic parallel 10-bit output data stream for serial electrical transmission and reception.
- DPLL_SATA is a programmable (through registers of the integrated PLL controller - PLLCTRL_SATA) DPLL clock source that provides a high-speed clock to the SATA_PHY serializer/de-serializer components.
- An L4_CFG interface adapter - OCP2SCP3, which enables accessing the PLLCTRL_SATA registers via L4_CFG interconnect accesses.

For details regarding the device SATA host subsystem components - SATA_PHY , PLLCTRL_SATA, DPLL_SATA and interface adapter), see Section 26.1.1, *SATA PHY Subsystem Overview*, in Chapter 26, *Shared PHY Component Subsystems*.

Figure 24-151 shows an overview of the device-embedded SATA host controller subsystem.

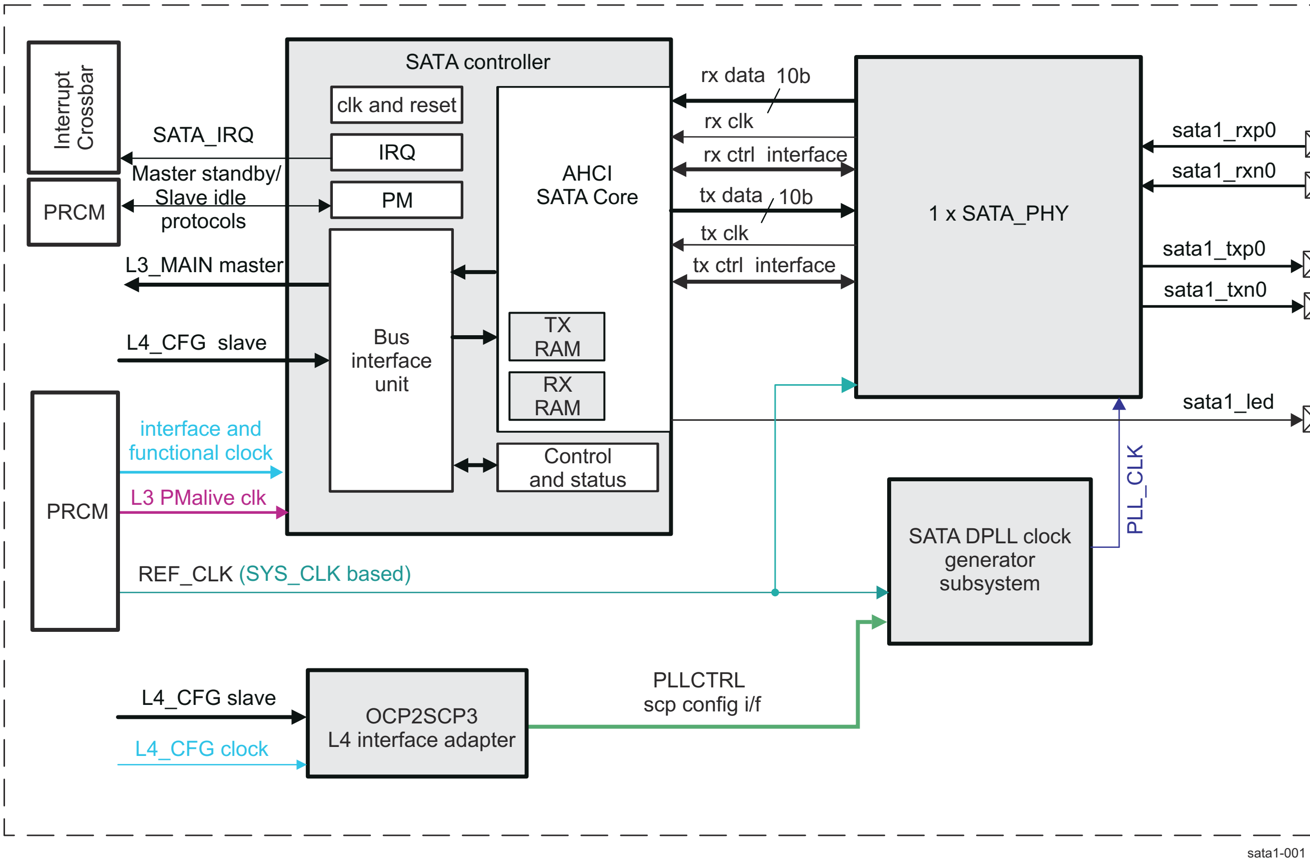

Figure 24-151. SATA Host Controller Subsystem Overview

24.8.1.1 SATA Controller

The SATA controller is the main functional component of the device-embedded SATA (Host Bus Adapter) HBA and is based on advanced host controller interface (AHCI) module. The SATA controller handles data transactions at the link and transport layers of the SATA interface using the advanced host controller interface (AHCI) mechanism. The SATA controller core engine is a generation 2-compliant host (supporting 3 Gbps transfer speed) with integrated DMA and FIFO RAM buffers.

The SATA controller AHCI-based interactions involve extensive DMA processing of both data and command transfers, reducing much of the user overhead associated with standard ATA task file register servicing. The SATA HBA port programmable DMA acts as a master on the device L3_MAIN interconnect, which facilitates direct command/data transfers between host system memory and attached SATA storage devices.

The SATA controller has a slave configuration port accessible on the device L4_CFG interconnect. This port provides the user with an appropriate register interface for HBA setup, control and status, interrupt settings, DMA configuration, etc.

24.8.1.1.1 AHCI Mode Overview

The SATA core supports the AHCI hardware mechanism, which provides the user software with a suitable HBA register interface to manage SATA interface operations. Generally, the AHCI introduces a system memory structure that includes some generic control and status area and a list of command entries (which can have a depth from 1 up to 32 entries) assigned per HBA port. Each of the command list entries contains information necessary to program a SATA device and pointers to data transfer descriptors.

The AHCI mode of operation disregards the master/slave communication model. A certain SATA AHCI host controller port establishes a point-to-point connectivity with only a single SATA peripheral device at a time, which is always a master device.

24.8.1.1.2 Native Command Queuing

The SATA AHCI engine supports NCQ and is capable of command queued protocol interactions with NCQ-compliant SATA mass storage devices. The NCQ commands generated by a SATA HBA port are loaded into command queues maintained at the peripheral device. The commands are stored in a queue and subsequently fetched and processed by peripheral device controller in sequences, which imply more native and highly-optimized for the device order of execution. The synchronization between an NCQ-aware SATA HBA and an NCQ-aware peripheral storage device involves implementation of the so called FPDMA queued command protocol, which ensures that HBA posts NCQ commands to the target SATA device in its demanded NCQ order.

24.8.1.1.3 SATA Transport Layer Functionalities

The SATA controller handles all of the transport layer functions of the SATA protocol. During reception it receives a frame information structure (FIS) from its link layer through the RX FIFO, decodes the type, and routes it to the proper location through the port DMA. During transmission it transfers a FIS constructed by the port DMA to the link layer through the TX FIFO. It also passes link layer errors and checks for transport layer errors to pass up to the system. The transport layer also contains the TX and RX FIFOs. These FIFOs are used as asynchronous data buffers between the serial domain and the bus clock domain. The size of these FIFOs affects the subsystem ability to buffer data before flow control must be asserted. It also affects the maximum transaction size that can be programmed into the port DMA.

24.8.1.1.4 SATA Link Layer Functionalities

The link layer maintains the link and supports all SATA link layer functionality, including:

- Out-of-band (OOB) transmit signaling
- Frame negotiation and arbitration
- Envelope framing/deframing
- Cyclic redundancy check (CRC) calculation (receive and transmit)
- 8b/10b encoding/decoding
- Flow control
- Frame acknowledgment and status
- Data width conversion
- Data scrambling/descrambling
- Primitive transmission
- Primitive detection and dropping
- Power management

24.8.1.2 SATA Controller Features

This section describes the features supplied by the SATA controller module. The SATA controller complies with the following standards:

- *Serial ATA Standard* specification (revision 2.6)
- *Serial ATA Advanced Host Controller Interface* specification (revision 1.1). The device SATA host controller also complies with the *Serial ATA Advanced Host Controller Interface* specification (revision 1.3), excluding support for the port multiplier FIS-based switching feature.

The main features of the SATA host controller are:

- Serial ATA 1.5-Gbps and 3-Gbps speeds (SATA-1 and SATA-2)
- Integrated RxFIFO and TxFIFO RAM data buffers
- Support of all SATA power management features
- AHCI support of 64-bit addressing mode (see device limitation note below)
- HBA port associated Internal DMA engine
- Hardware-assisted NCQ for up to 32 entries
- Command completion coalescing (CCC) interrupts
- Support of port multiplier with command-based switching
- Activity LED generation

Additionally, link layer supports:

- 8b/10b encoding and decoding functionality
- RX elasticity buffer
- TX OOB sequence generation
- RX OOB sequence generation

The differences between the SATA host controller and a standard SATA host controller defined by the *Serial ATA Gold Standard* specification (v2.6) are:

- Staggered spin-up is not supported (only one HBA AHCI port embedded).
- Only one port is supported by the device-embedded SATA HBA from up to 32 possible, according to the standard.
- The SATA controller is AHCI-mode compliant only and does not support standard ATA legacy modes of operation.
- Cold presence detection signals are not available. The SATA controller targets support for permanently attached SATA drives only.

The following features are NOT supported by the SATA host subsystem:

- Far-end analog loopback
- Cold presence detect (CPD) signal is not available at the system level. As a consequence, the SATA device hot-plug operation is not supported.
- Mechanical presence switch signal is not available at system level.
- Message signaled interrupts
- PHY layer functionalities of SATA controller are not integrated. These are assigned to the SATA_PHY transceiver integrated at the device level (outside SATA controller module itself).

The SATA controller master (DMA) interface features:

- 32-bit data
- 36 bits of the AHCI master address bus (byte-aligned addressing) implemented in the device. See device limitation note below.
- 1-bit tag-ID port, but the tag value is 1 on all accesses (that is, the feature is not used)
- Sequential burst support (16 x 32 bit – Dwords)

Note

Even though the SATA AHCI Controller supports 64-bit -addressing mode, only 36-lower bits of the 64-bit address bus are integrated (meaningful) in the device. This defines a 64-GiB AHCI master address space.

The SATA controller slave interface features:

- 32-bit data, 13-bit (byte-aligned) address
- Single access (no burst support)
- All accesses are expected to be 4 bytes wide, 32-bit aligned.

Note

Accesses smaller than 4 bytes wide (that is, byte enable patterns different from 4’b1111) are functional and do not generate an error. Misaligned addresses do not generate an error.

As can be seen in Figure 24-151, the SATA Controller has all events merged to a single interrupt output - SATA_IRQ, mapped to the device Interrupt Crossbar.

24.8.2 SATA Controller Environment

Apart from the SATA communication-dedicated electrical connections to the SATA_PHY component, there is an additional SATA-defined-led drive generation signal that can be output at the device pad: *spi1_cs[1]* . For more information about this signal pad configuration register mapping, see *Pad Configuration Registers* in *Control Module*. For more details regarding the behavior of activity LED generation, see Section 24.8.4.10, *Activity LED Generation Functionality*.

Table 24-439. SATA Controller I/O Signals

Module Pin Name	Device Level Signal Name	I/O[(1)]	Description	Reset Value
TXP[(2)]	sata1_txp0	O	TXP output of the SATA PHY differential transmission line	0
TXN[(2)]	sata1_txn0	O	TXN output of the SATA PHY differential transmission line	0
RXP[(2)]	sata1_rxp0	I	RXP input of the SATA PHY differential reception line	Hi-Z
RXN[(2)]	sata1_rxn0	I	RXN input of the SATA PHY differential reception line	Hi-Z
ACT0_LED	sata1_led	O	HBA port activity LED indication	Hi-Z

(1) I = Input; O = Output
(2) These signals are part of the interface between SATA PHY serializer / de-serializer and the externally attached SATA storage device.

Note

The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the sections *Pad Configuration Rregisters*, and *Control Module Register Manual*, in *Control Module*, for more information.

The Figure 24-152 shows the SATA host controller subsystem environment summarizing the interface signals exported directly from SATA controller at the device boundary, as well as those exported after SATA_PHY processing at the device boundary. For more information on the interface between the SATA controller and SATA_PHY , see Chapter 26, *Shared PHY Component Subsytsems*.

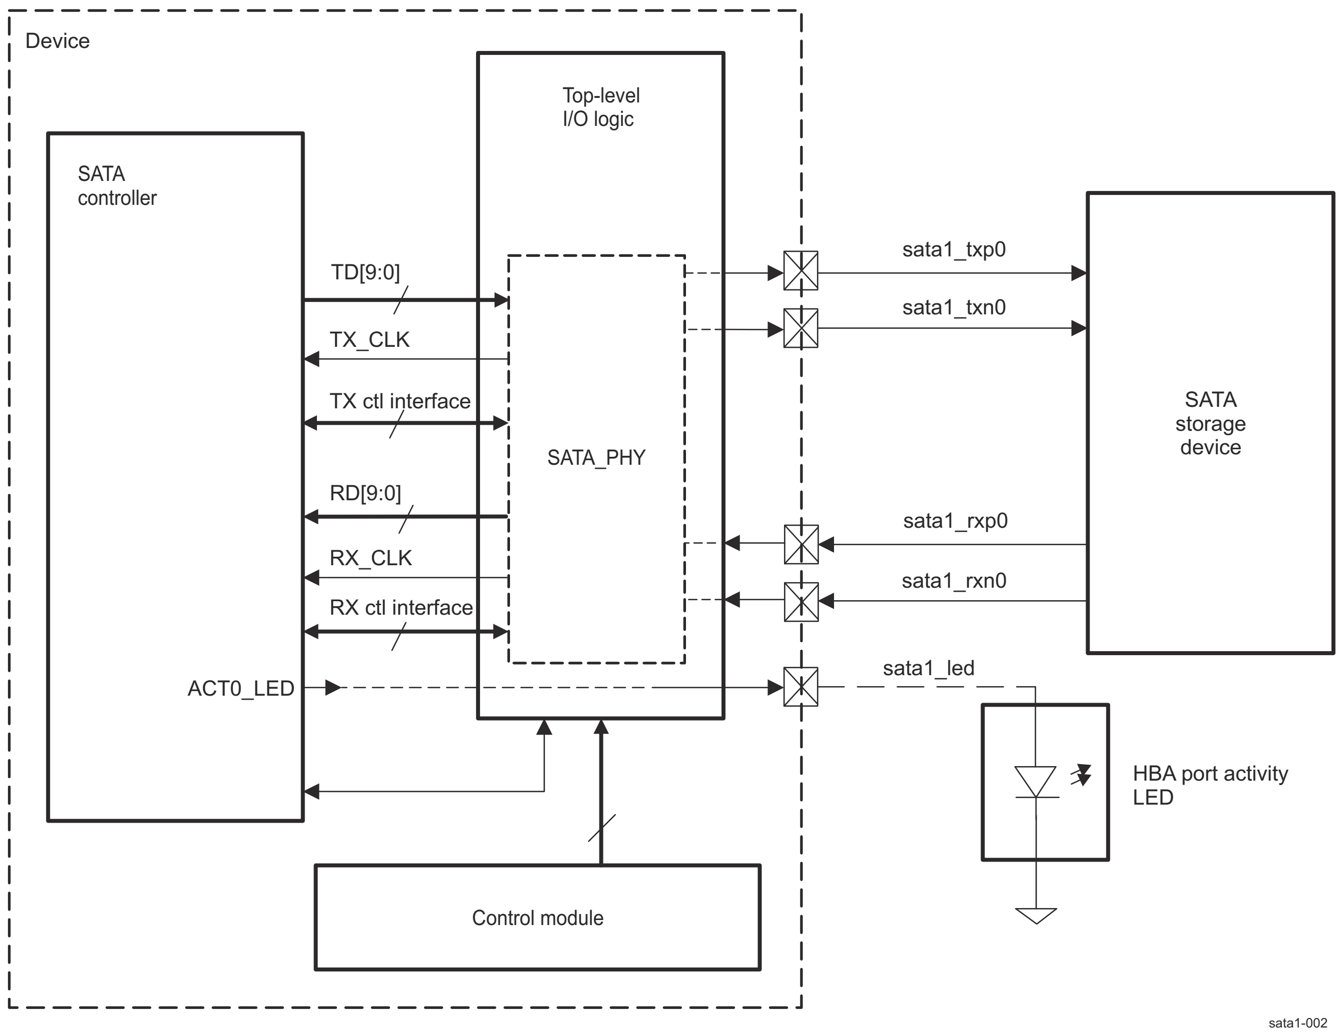

Figure 24-152. SATA Subsystem Environment

24.8.3 SATA Controller Integration

This section describes the SATA AHCI host controller integration in the device, including information about clocks, resets, and hardware requests. Figure 24-153 shows the SATA controller integration.

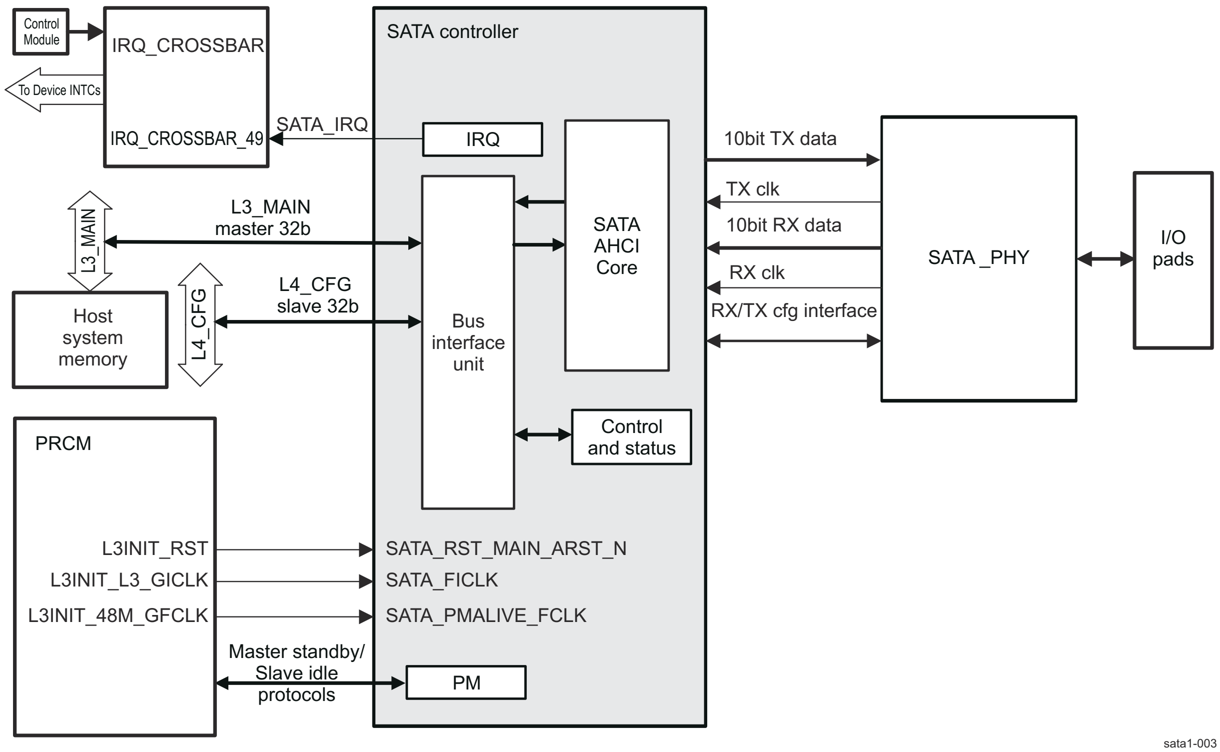

Figure 24-153. SATA Controller Integration

SATA controller integration includes these features:

- A single functional and interface clock (SATA_FICLK, shared between the master and the slave interfaces)
- A functional always-on clock (SATA_PMALIVE_FCLK to support entrance into and exit from the SATA defined low-power modes)
- A single hardware nonretention reset input (SATA_RST_MAIN_ARST_N)
- Master standby and slave idle protocols with the power, reset, and clock management (PRCM) module
- A single interrupt request generation line (SATA_IRQ, mapped to IRQ_CROSSBAR_49 line of IRQ CROSSBAR)
- No DMA or wakeup requests generation to surrounding modules
- L3_MAIN master interface
- L4_CFG-configuration slave interface

The SATA encoded symbol transmission/decoded symbol reception relies on two serial clocks , which are supplied indirectly from the DPLL_SATA through the SATA_PHY component.

Note

For more information about the slave idle protocol and the wakeup request, see *Module-Level Clock Management* in *Power, Reset, and Clock Management*.

Table 24-440 through Table 24-442 summarize the integration of the module in the device.

Table 24-440. SATA Controller Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect

Table 24-440. SATA Controller Integration Attributes (continued)

SATA	PD_L3INIT	L4_CFG L3_MAIN

Table 24-441. SATA Controller Clocks and Resets

Table 24-442. SATA Controller Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
SATA	SATA_IRQ	IRQ_CROSSBAR_49	MPU_IRQ_54 DSP1_IRQ_80 DSP2_IRQ_80	SATA Controller IRQ line

Note

The "**Default Mapping**" column in Table 24-442 *SATA Controller Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

- For a description of the interrupt source, see *Interrupt Requests*.

Note

- The SATA HBA does not generate DMA and wakeup hardware requests to the surrounding modules integrated in the device

24.8.4 SATA Controller Functional Description

24.8.4.1 SATA Controller Block Diagram

Figure 24-154 shows a block diagram of the SATA host controller.

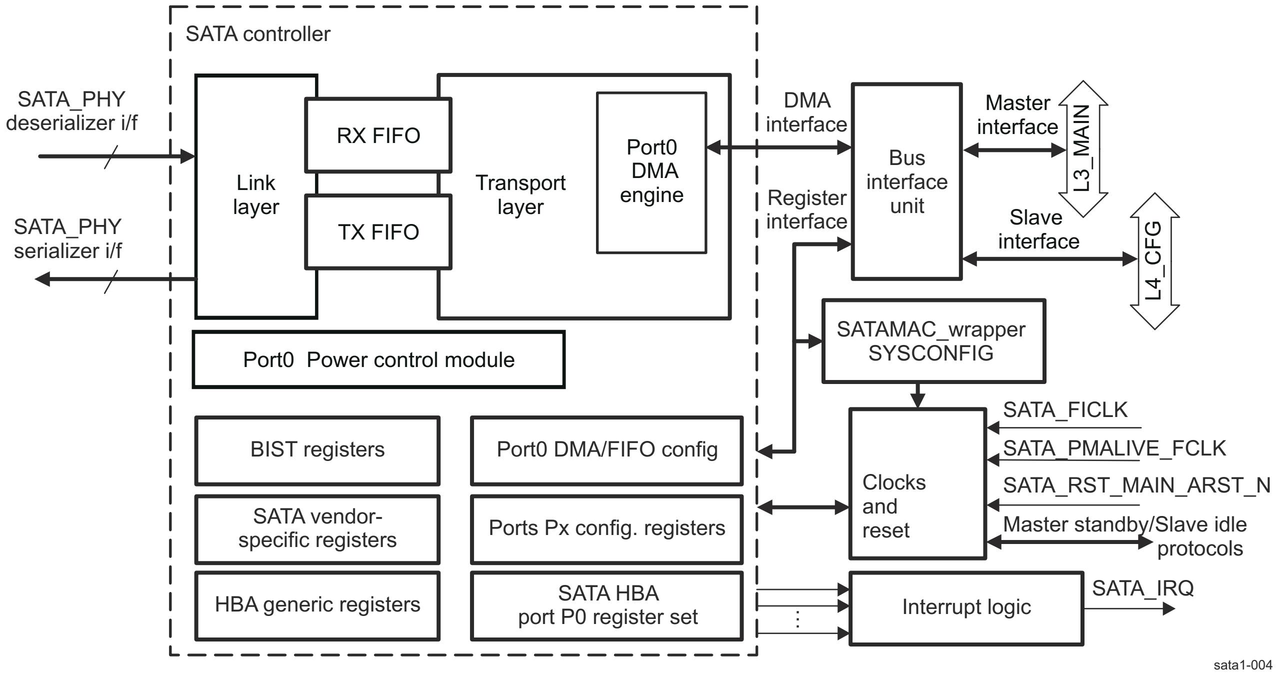

Figure 24-154. SATA Controller Functional Block Diagram

The SATA HBA port-associated DMA is a master on the device L3_MAIN interconnect. For a write to the attached storage device, this port reads FISs from the host system memory and pushes them into the transmit FIFO. When frame Dwords are received at RxFIFO, this interface is used to write the data out to the dedicated host system memory area. For details about DMA features and operation, see Section 24.8.4.8, *DMA Port Configuration*.

The SATA controller has a configuration slave interface used to read and write all system registers. The slave interface includes the following functions:

- Configuring the SATA AHCI core (and indirectly, to a certain extent, the SATA_PHY physical component)
- Configuring the DMA for transmit and receive operations
- Initiating write transfers to the attached storage device
- Responding to interrupts and reads

Both the slave and master interface of the SATA host controller share the same functional and interface clock, that is, operate on the same frequency (see also Section 24.8.3, *SATA Controller Integration*).

A bus interface unit adapts the SATA controller master and slave buses to the corresponding L3_MAIN and L4_CFG device interconnects.

Note

The **SATA controller AHCI Core registers** are part of the instance signified as **DWC_ahsata** inside the Section 24.8.6.1, *SATA Controller Instance Summary*.

24.8.4.2 SATA Controller Link Layer Protocol and Data Format

One of the main tasks of the SATA HBA Link layer is to perform a parallel 8-bit FIS data to a 10-bit parallel code conversion (8b/10b encoding) . The encoded stream, which is a sequence of 10-bit parallel-encoded characters, is subsequently passed to the SATA_PHY serializer component to adapt to a serial 10-bit character transmission to the SATA peripheral device. For more details, see Section 26.1.1, *SATA PHY Subsystem Overview*, and Section 26.1.4, *SATA PHY Subsystem Functional Description,* in Chapter 26, *Shared PHY Component Subsystems*.

One of the main tasks of the SATA HBA Link receiver is to perform a 8b/10b decoding, in which process the parallel 10-bit characters coming out from the SATA_PHY de-serializer are decoded to parallel data or control bytes. The received symbols with invalid codes are rejected by the link layer and corresponding illegal reception errors are generated. For more details regarding the SATA_PHY de-serializer, see Section 26.1.1, *SATA PHY Subsystem Overview*, and Section 26.1.4, *SATA PHY Subsystem Functional Description,* in Chapter 26, *Shared PHY Component Subsystems*.

There are also other data process stages at the link layer, such as CRC calculation, scrambling/descrambling, primitive insertion/detection, etc. Figure 24-155 shows the primary stages of link Dword data processing.

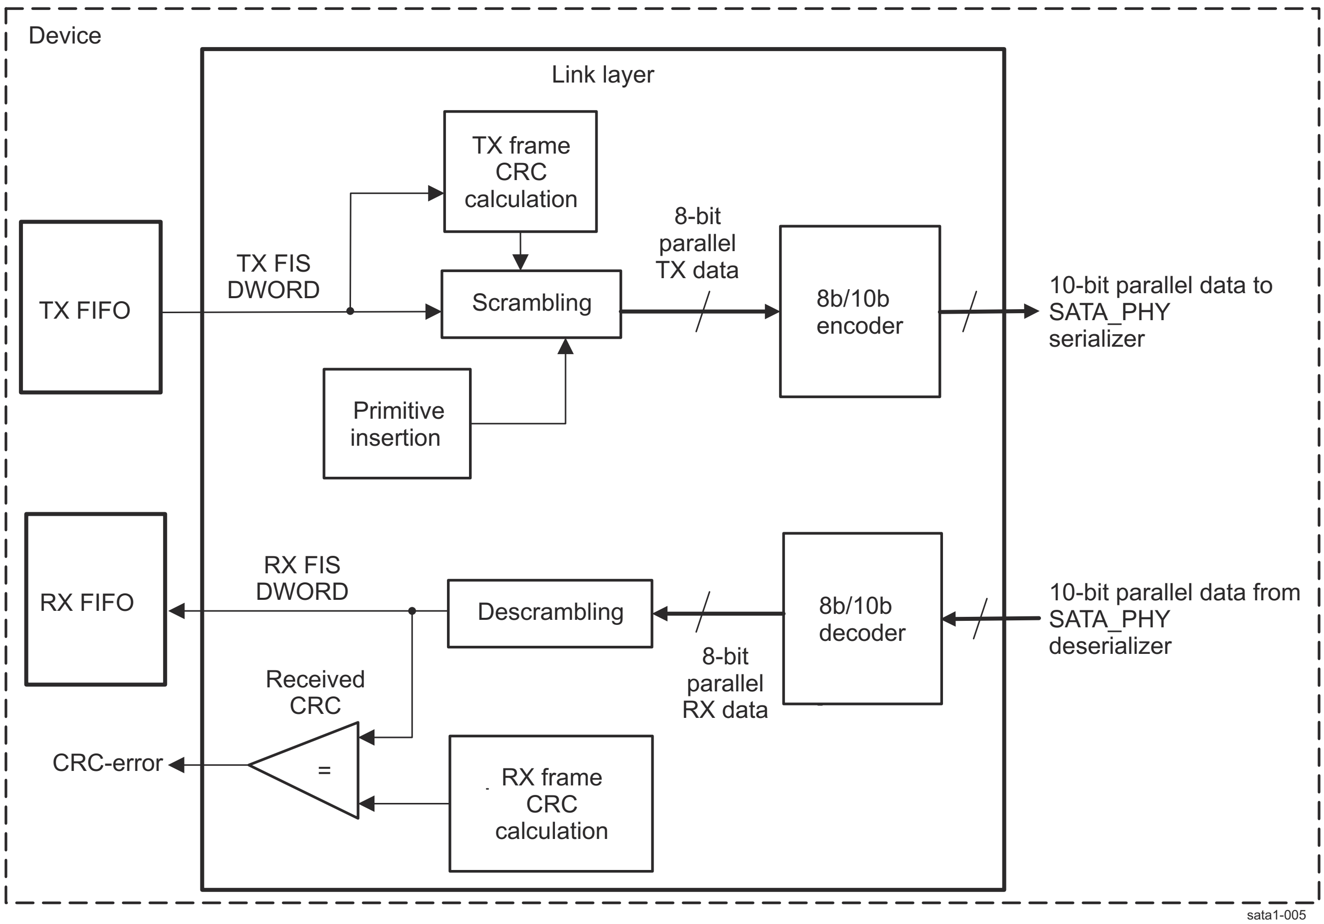

Figure 24-155. Simplified Schema of Link Dword Processing

24.8.4.2.1 SATA 8b/10b Parallel Encoding/Decoding

The input to the link coder logic is a parallel (unencoded) data byte and an associated control variable: Z with two possible values (K, D). The Z value signifies the byte to be encoded either as a control character (K value) or a data character (D value). The data byte (ABCDEFGH, where A matches the least significant bit [LSB]) is divided into two asymmetric portions: a 5-bit one ABCDE (range: 0 to 31) and a 3-bit one FGH (range: 0 to 7).

The encoding process is performed in two stages. At the first stage, the 5-bit portion is converted to a 6-bit subblock (abcdei); at the second stage, the 3-bit portion is converted to a 4-bit subblock (fghj). An additional parameter called running disparity (rd) is taken into account during code calculation at both the character transmission and reception link sides. It introduces code correlation between adjacent bytes so that the current subblock code can depend on the code of the previous subblock and its associated rd output value. As a consequence, depending on the input rd parameter and the 8b/10b encoded value, the encoding/decoding lookup tables might have two different entries for the same byte.

The 10-bit parallel-encoded character is passed to the 10-bit data input of the SATA_PHY serializer component, which further transmits it serially in a LSB to most significant bit (MSB) order (abcdeifghj). The receiver link receives and decodes the sequence in the same LSB to MSB order (abcdeifghj). While SATA encoder takes the full range of a data byte (0–255) encoding values, it uses only two values to encode control characters. For more information on the 8b/10b encoding/decoding process, see the SATA standard specification.

24.8.4.2.2 SATA Stream Dword Components

The basic unit of SATA information is Dword – a double sized word (32 bits). An encoded Dword has a 40-bit length (4 x 10 bits), but, for simplicity, unencoded Dword lengths are considered here. Each Dword is serially transmitted or received by the SATA_PHY components in LSB character to MSB character order.

- Primitives

  The shortest meaningful component of the SATA stream is the primitive, which consists of a single Dword. Different types of primitive characters are inserted into the SATA stream to maintain synchronization between the host and the SATA peripheral device. Primitives convey real-time state information regarding the SATA communication channel itself. For example, the SATA link layer generates primitives to perform flow control, synchronize power management state transitions, frame enveloping, etc. The transport layer is not aware of the lower level primitive Dwords. They are subject to processing only to the link layer.
- Primitive handshakes

  In some cases, the transmitter of a primitive can require that the receiver send an acknowledge Dword to confirm primitive reception, which is a primitive handshake.

  The first byte of a primitive Dword is always a control character (or Z = K) with two possible encodings. The remaining three data bytes (Z = D) contain the function of the primitive. According to the SATA standard, the transmitter and the receiver are not required to match the number of primitives sent and received.

  Table 24-443 briefly summarizes the primitives used by SATA.

Table 24-443. SATA Primitives Summary

Primitive Name	Short Description
ALIGNp	Sent in pairs to PHY component to readjust its internal operations
CONTp	After CONTp insertion, previous primitives are repeated continuously until a different primitive is inserted
DMATp	terminates DMA data transmission
EOFp	End of frame
HOLDp	Inserted to hold data when transmitter doesn't have data ready to transmit
HOLDAp	Acknowledges a HOLDp primitive
PMACKp	Acknowledges a power management request
PMNAKp	A power management request denial
PMREQ_Pp	Power management request to PARTIAL state
PMREQ_Sp	Power management request to SLUMBER state
R_ERRp	Reception error occurred
R_IPp	Current node is receiving data
R_OKp	Reception without error
R_RDYp	Receiver is ready for reception

Table 24-443. SATA Primitives Summary (continued)

Primitive Name	Short Description
SOFp	Start of frame
SYNCp	Synchronization primitive
WTRMp	Transmitter inserts this primitive while waiting to get the reception status from receiver
XRDYp	Transmitter has data ready for transmission

- SATA data frames

  SATA data frames incorporate data FISs constructed at the transport layer along with some primitives (see Figure 24-156). The maximum number of Dwords between SOFp to EOFp does not exceed 2064 Dwords, including the FIS type and CRC fields described here.
- Frame FIS components

  The FIS (Frame Information Structure) contents of a frame incorporate the Dwords that correspond to SATA target data structures. FIS Dwords are output from transport layer TxFIFO to the transmitter link 8b/10b encoder during transmission. In the case of reception, the FIS content is obtained at transport layer RxFIFO after being successfully decoded by the receiver link logic. The commands and data embedded into Frame FISs are generated/interpreted at a higher transport level of the SATA controller and are user software-accessible in the host system memory.
- CRC

  The CRC is the last Dword in a frame, immediately following the last FIS Dword of the frame and preceding the EOFp primitive. The 32-bit CRC calculation is performed only on the FIS Dwords of the frame contents, so that frame-inserted primitives such as HOLDp, CONTp, etc., are not taken into account. The CRC is aligned on a Dword boundary. CRC code computation expects an input of an even number of words and should be Dword-multiple. If an FIS block contains an odd number of words, the last FIS word is padded with 0s to a full Dword before the CRC is calculated.
  – During transmission: The CRC Dword is calculated on original FIS contents, before scrambling and serial 8b/10b encoding are performed.
  – During reception: The CRC Dword is calculated on the 8b/10b decoded and subsequently descrambled 8-bit FIS Dword contents. It is then compared to the CRC received from the source to perform error check analysis.
- Frame embedded primitives

  The beginning of a frame is marked with a SOFp primitive, and the end is marked with an EOFp primitive. Some primitives, such as HOLDp and HOLDAp acknowledge, can be inserted into frames between data FISs.
- SATA data stream

  As shown in Figure 24-156, the SATA data stream is composed of frames carrying the target data/command contents combined with various primitives generated to maintain consistency of transfers over the SATA interface.

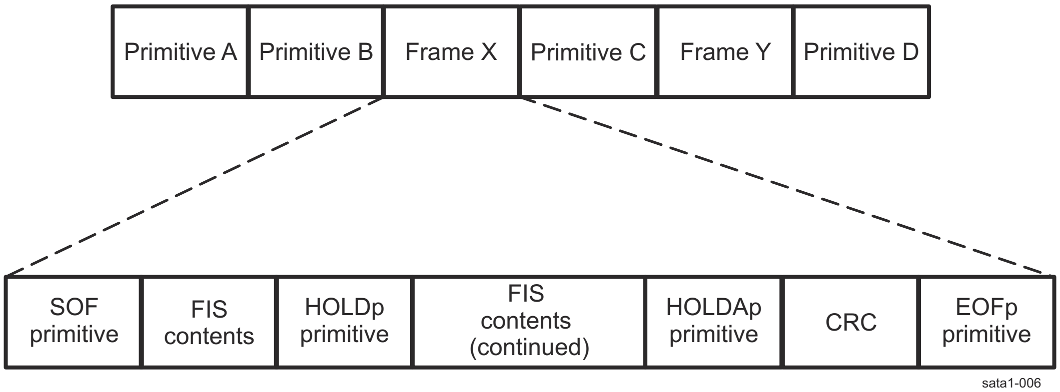

Figure 24-156. SATA Data Stream Components

24.8.4.2.3 Scrambling/Descrambling Processing

The contents of a frame are scrambled before being passed to the link 8b/10b encoder. Scrambling is performed on Dword quantities by XORing the data to be transmitted with the output of a linear feedback shift register (LFSR). All data words between the SOFp and EOFp are scrambled, including the CRC. Figure 24-155 shows the basic flow.

The SATA controller (as defined by the SATA standard) performs scrambling/descrambling processing for EMI reduction purposes. Two scramblers are instantiated within the SATA controller: The first, the data payload scrambler, scrambles FIS data payload contents (including the calculated CRC Dword); the second, the repeated primitive suppression scrambler, scrambles only the repeated primitive stream contents.

The scrambling runs as follows: A certain data payload Dword located between SOFp and EOFp is XORed with the data payload scrambler output. The resulting scrambled Dword is submitted to the 8b/10b encoder for transmission.

On reception, the Dword is decoded using a 10b/8b decoder, the scrambler output is XORed with the resulting Dword, and the resulting Dword is presented to the link layer. It is then used for CRC computation. The CRC Dword is scrambled in the same way as data payload characters.

For details on the scrambling/descrambling feature, see the *SATA Standard Specification* (rev.2.6).

24.8.4.3 Resets

24.8.4.3.1 Hardware Reset

The module is reinitialized in hardware upon activation of PRCM.L3INIT_RST reset signal (for more information about hardware reset, see Section 24.8.3, *SATA Controller Integration*).

For more information on the PRCM.L3INIT_RST hardware reset signal, refer to *Reset Domains*, in *Power, Reset, and Clock Management*.

This reset normally occurs on device power up or during a system bus failure. All components of the SATA AHCI core are initialized, including the HBA port and generic registers. The bus interface unit (BIU) and SATA AHCI core wrapper components are also impacted.

24.8.4.3.2 Software Initiated Resets

The SATA controller supports three levels of software reset, each of which has different impact over the SATA HBA hardware components and AHCI interface registers:

- Software reset (least intrusive)
- Port reset
- HBA reset (most intrusive)

Note

It is recommended that user software always starts with the least intrusive reset approach. Software chooses the next most intrusive reset only if the less intrusive reset does not succeed in clearing the condition.

24.8.4.3.2.1 Software Reset

Software reset impacts only the attached to the HBA port SATA peripheral device, without affecting the established communication between physical layers or HBA engine.

To issue a software reset, the user must prepare two H2D register FISs into the emptied command list of the port. The first FIS must have bits SRST = 0b1 and C = 0b0. The first FIS corresponding command header bits C and R are set as follows: C = 0b1 and R = 0b1.The second FIS has bits SRST = 0b0 and C = 0b0. The second FIS corresponding command header bits C and R are set as follows: C = 0b0 and R = 0b0.

However, steps must be taken before issuing the software reset to the peripheral device attached to the port. For details on software reset, see the AHCI specification.

24.8.4.3.2.2 Port Reset

The port reset (also known as COMRESET) must be applied when the HBA port does not function properly after a software reset is issued to the port. The effect is that the SATA HBA port is reinitialized and communication between the phy layers of both the SATA host and the SATA target device is reestablished.

To trigger a COMRESET sequence on the SATA interface, user software must write 0x1 to the SATA_PxSCTL[3:0]DET bit field. The host receives a COMINIT signal sequence, indicating that the peripheral device has successfully reestablished communication. For more information on port reset, see the AHCI specification (revision 1.1).

Note

The port reset (COMRESET) method is the preferred AHCI mechanism for error recovery and should be used instead of the software reset.

24.8.4.3.2.3 HBA Reset

Software can globally reset the SATA controller, if a port reset does not clear the conditions successfully. On HBA reset, all SATA AHCI core interface registers are reset, **excluding those from the hardware initialization domain** - the SATA_PxCLB, SATA_PxCLBU, SATA_PxFB and SATA_PxFBU registers. All state machines that relate to data transfers and queuing return to IDLE state, and the port is reinitialized by sending COMRESET. The global reset is triggered when user software sets the SATA_GHC[0]HR = 0b1 bit. The HBA indicates that global reset is finished, deasserting the SATA_GHC[0]HR bit to 0b0 in hardware. Hence, user software must poll the HR bit to detect this condition. For more information, see the mentioned AHCI standard specification.

24.8.4.4 Power Management

The device SATA host controller subsystem power management can be identified at the following levels:

- SATA controller low power-management features (defined also in the SATA standard specification, revision 2.6)
- Master standby and idle slave protocols established between SATA controller and the device PRCM through a SATA AHCI core wrapper interface (signified as SATAMAC_wrapper instance inside the Section 24.8.6.1, *SATA Controller Instance Summary*).

This section describes the relationships that exist between both levels of SATA Controller power management.

24.8.4.4.1 SATA Specific Power Management

The SATA controller core supports both PARTIAL and SLUMBER low-power states, as described in the SATA standard specification (revision 2.6). These modes allow power savings by powering down part of SATA_PHY and gating off the clocks to the link layer. The port power control module is used to enter and exit these modes, which can have the normal functional clocks gated off.

24.8.4.4.1.1 PARTIAL Power Mode

In the PARTIAL power state, the SATA_PHY component transmits electrical IDLE to the device and the receiver is left on to receive OOB signals. This mode can also be used to support near-end analog loopback, if a device is attached.

24.8.4.4.1.2 Slumber Power Mode

In the SLUMBER power state, the transmitter is completely turned off. This allows for greater power savings but near-end analog loopback cannot be performed and there is a longer latency to exit the mode.

24.8.4.4.1.3 Software Control over Low Power States

The user has manual control over low power states through the SATA_PxCMD [31:28]ICC register bit field. This works if the link is in IDLE state; otherwise, writes to this field are ignored.

24.8.4.4.1.4 Aggressive Power Management

Low power modes can be initiated by software when there are no pending transactions, but the SATA AHCI core also supports aggressive power management. In this mode, the subsystem automatically initiates the PARTIAL or SLUMBER state when there are no inflight commands. This is useful for power savings, but the price is increased latency if a low-power mode is entered and a transfer request is made. Software enables aggressive link-layer power management by setting the SATA_PxCMD[26]ALPE bit to 0x1. The link aggressive power management state (PARTIAL or SLUMBER) is selected using the SATA_PxCMD[27]ASP bit.

24.8.4.4.2 Master Standby and Slave Idle Management Protocols

The master standby and slave idle protocols are implemented between the PRCM and SATA controller, with mode settings located in the SATAMAC_wrapper register (SATA_SYSCONFIG).

- The standard idle request/acknowledge handshake is associated with the L4_CFG slave port. The default idle mode is smart-idle, as indicated by the power-on reset (POR) value: SATA_SYSCONFIG[3:2]IDLEMODE = 0x2.

  Note

  No other mode is expected to be required in normal operation: no-idle and force-idle are used for debugging only. Because the module is not capable of asynchronous wakeup, the smart-idle/wakeup (IDLEMODE = 0x3) is strictly equivalent to smart-idle.

- The standby/wait handshake is associated with the L3_MAIN master port. Software is responsible to keep the DMA operations and the standby status in sync.

The default standby mode is smart-standby, as indicated by the POR value: SATA_SYSCONFIG[5:4]STANDBYMODE = 0x2. However, the SATA controller hardware does not provide any indication about DMA activity that could be used to drive the standby dynamically (that is, the smart mode): Smart-standby is therefore strictly equivalent to the force-standby mode (that is, the module remains in or goes to permanent standby).

The standby control procedures are therefore software-driven.

To exit standby:

1. Change the standby mode to no-standby by setting SATA_SYSCONFIG[5:4] = 0x1.
2. Optional: Confirm the SATA controller standby status through the PRCM. For more information, see *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
3. Only then, enable the controller DMA (AHCI list processor). For more information, see the AHCI specification.

To enter standby:

1. Disable the controller DMA (AHCI list processor). For more information, see the AHCI specification.
2. Ensure all pending transactions have completed. For more information, see the AHCI specification.
3. Change the standby mode to smart-standby (or force-standby) by setting SATA_SYSCONFIG[5:4] = 0x2.

CAUTION

The software is responsible to keep the DMA operations and the standby mode status in sync.

Note

Because the standby exit is software driven, it is by definition synchronous: the asynchronous wakeup is never activated, which means that the smart-standby and smart-standby/wakeup are equivalent (as well as force-standby).

Note

For more information on the SATA Controller master standby and slave idle management protocols with the device PRCM , see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

24.8.4.4.3 Clock Gating Synchronization

The bus clock can also be gated off in either the PARTIAL or SLUMBER state, if the software guarantees there is nothing in flight, the clock can be stopped and started without glitches, and the clock can be restarted quickly when activity is initiated from the device side.

The following steps outline the procedure to stop the clock:

1. Put the link in a low power state (either PARTIAL or SLUMBER)
   - SATA MAC link layer can enter low power either manually see Section 24.8.4.4.1.3, *Software Control over Low Power States*) or automatically (see Section 24.8.4.4.1.4, *Aggressive Power Management*)
   - If there is no device attached (making it impossible to enter a low power state), the SATA_SYSCONFIG[16] OVERRIDE0 override bit can be set to 0b1 to stop the interface/functional clock (SATA_FICLK) and save power.
2. Initiate the clock stopping procedure.

CAUTION

If a SATA drive attached to the SATA HBA port has not entered a low power state (PARTIAL or SLUMBER), the user must not set the SATA_SYSCONFIG[16]OVERRIDE0 bit; otherwise, the link layer can be ruined, resulting in indeterminate SATA controller behavior.

24.8.4.4.4

Table 24-444. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	SATA_SYSCONFIG [3:2]IDLEMODE bit field	The available modes are: Force-idle, no-idle, and smart-idle wakeup disabled modes are available.
Master standby modes	SATA_SYSCONFIG [5:4]STANDBYMODE bit field	The available modes are: Force-standby, no-standby, smart-standby wakeup disabled
Clock-gate overriding mode	SATA_SYSCONFIG [16]OVERRIDE0 bit field	Clock stopping override function. Should not be applied when attached to port SATA peripheral device has not entered a Low-power mode.

For more information on the L3INIT_L3_GICLK functional clock gating in the device PRCM , refer to *Clock Domain-Level Clock Management*, in the chapter, *Power, Reset and Clock Management*.

24.8.4.5 Interrupt Requests

This section describes all of the conditions that can generate an interrupt. Each condition is subject to the masking capabilities described in Section 24.8.4.5.4, *Interrupt Condition Control*.

24.8.4.5.1 Interrupt Generation

Both level and pulse interrupts are available. Exercise care when using the pulse interrupt. Because of the synchronization and interrupt aggregation from the internal core, clearing one interrupt as another interrupt occurs can prevent a new pulse from being generated. A new pulse is generated only if the first interrupt is completely cleared (that is, the level interrupt goes away) before the new interrupt event occurs. Thus, an interrupt can occur after the register write is issued to clear the first interrupt but before the interrupt is fully cleared. In this case, a new pulse is not issued and the level interrupt remains asserted. After issuing the write to clear an interrupt, software must read the interrupt status registers to ensure that a new interrupt has not occurred.

24.8.4.5.2 Levels of Interrupt Control

The AHCI directs that interrupts be indicated in a two-tier structure and thus associated with different HBA ports. Considering the device SATA HBA single-port implementation for the first tier, only the SATA_IS[0] IPS bit should be considered. It indicates if the only port available to the user (HBA port 0) has pending interrupts.

For the second tier, the SATA_PxIS register (where x = 0) indicates which specific interrupt condition(s) occurs to trigger an interrupt on port 0. In most cases, software writes 0x1 (Write One to Clear) to clear these bits, and then writes 0x1 to the SATA_IS [0]IPS bit to clear the interrupt. However, some interrupts in the SATA_PxIS register have alternate methods of being cleared (for details, see Section 24.8.6.2.2, *DWC_ahsata Register Description*). Section 24.8.4.5.3, *Interrupt Events Description*, describes all interrupt generating conditions.

Figure 24-157 shows the SATA controller two-tier interrupt propagation structure. Besides SATA_IS[0], which gates all interrupts at the port 0 level, the tier 1 interrupt is globally gated by the SATA_GHC[1] IE bit.

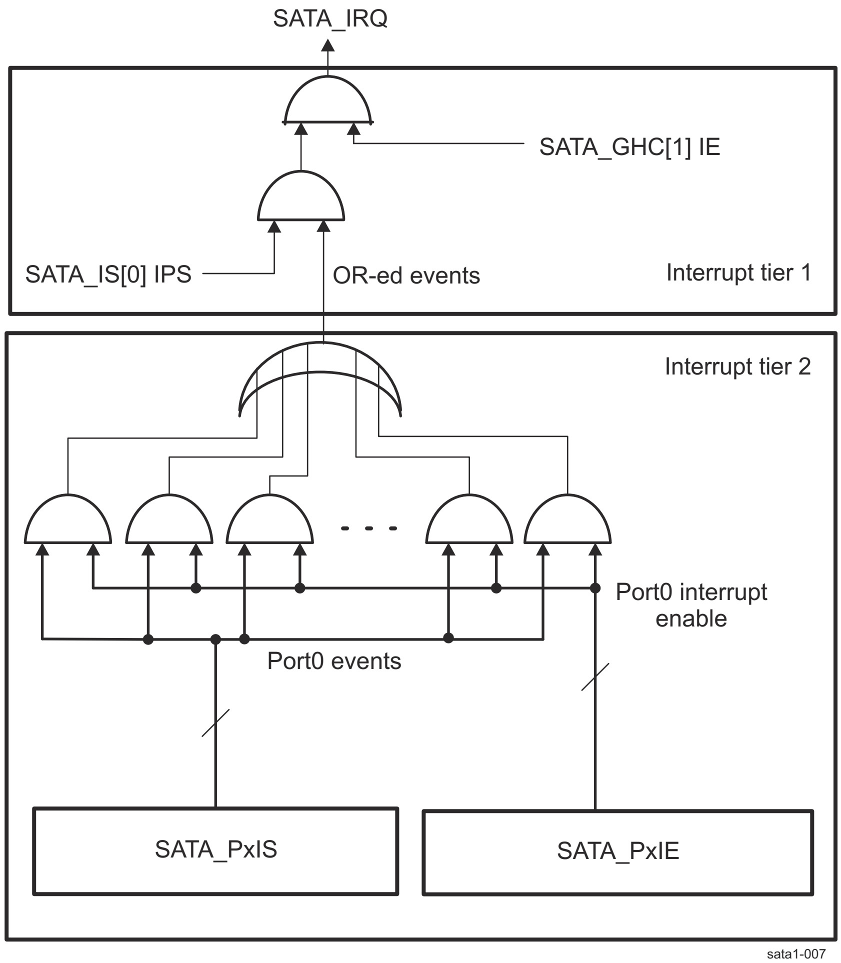

Figure 24-157. SATA Controller Interrupt Propagation Schema

Note

Regardless of the device SATA controller single HBA port implementation, user software must read/write the tier 1 SATA_IS[0] IPS register bit to process interrupts.

24.8.4.5.3 Interrupt Events Description

This section describes the different events that are reflected in the SATA_PxIS register and that cause SATA_IRQ interrupt generation, if enabled, in the SATA_PxIE register. For more information regarding SATA_IRQ handling at the IRQ CROSSBAR subsystem, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

24.8.4.5.3.1 Task File Error Status

This event is registered whenever the SATA_PxTFD[7:0] STS bit field is updated by the device and the error bit SATA_PxTFD[0]STS_ERR is set. SATA_PxTFD[7:0] STS is updated when a new register FIS, PIO setup FIS, or set device bits FIS is received from the device.

24.8.4.5.3.2 Host Bus Fatal Error

This event is registered whenever an error is received by the SATA controller internal DMA master port from the configuration slave port.

24.8.4.5.3.3 Interface Fatal Error Status

This event is registered if an error is generated on the interface. The following conditions can cause this:

- SYNC escape during an H2D register or data FIS transmission
- One of the following errors during a data FIS transfer:
  - Protocol (SATA_PSERR[10] ERR_P)
  - CRC (SATA_PSERR[21] DIAG_C)
  - Handshake (SATA_PSERR[22] DIAG_H)
  - SATA_PHY not ready (SATA_PSERR[9] ERR_C)
- Unknown FIS received with a good CRC, but length greater than 64 bytes
- Physical region descriptor (PRD) table byte count of 0

Note

This is a fatal error in which the DMA is in an error state until software clears the SATA_PxCMD[0] ST bit or resets the interface with a port or global reset. For more information about software-initiated resets, see Section 24.8.4.3.2, *Software Initiated Resets*.

24.8.4.5.3.4 Interface Non-Fatal Error Status

This event is registered on the following error conditions:

- One or more of the following errors are registered during a non-data FIS transfer:
  - Protocol (SATA_PSERR[10] ERR_P)
  - CRC (SATA_PSERR[21] DIAG_C)
  - Handshake (SATA_PSERR[22] DIAG_H)
  - SATA_PHY not ready (SATA_PSERR[9] ERR_C)
- Command list underflow during a read operation when software builds a command table that has more total bytes than the transaction given to the device

---

Note

The conditions previously described are non-fatal and the SATA host controller continues to operate normally.

24.8.4.5.3.5 Overflow Status

This event is registered if command list overflow is detected during read or write when software builds a command table with fewer total bytes than the transaction given to the device.

Note

This is a fatal error in which the DMA is in an error state until software clears the SATA_PxCMD[0] ST bit or resets the interface with a port or global reset. For more information about software-initiated resets, see Section 24.8.4.3.2, *Software Initiated Resets*.

24.8.4.5.3.6 Incorrect Port Multiplier Status

This event is registered when the SATA controller receives a FIS from a device with a PM field not matching what is expected. The SATA_PxIS[23] IPMS event corresponding bit can be set during device enumeration, but software should ignore it until enumeration is finished.

24.8.4.5.3.7 PHYReady Change Status

This event is registered when the status of PHYReady changes. Its corresponding status bit (SATA_PxIS[22] PRCS) reflects the SATA_PxSERR[16]DIAG_N bit.

24.8.4.5.3.8 Port Connect Change Status

This event is registered when there was a change in the current connect status as reflected by the SATA_PxSERR[26]DIAG_X bit.

24.8.4.5.3.9 Descriptor Processed

This event is registered when a transaction completes. Its corresponding flag (SATA_PxIS[5] DPS) is set whenever a PRD with the I bit set transfers all of its data.

Note

The PRD interrupt is an opportunistic interrupt and should not be used to definitely indicate the end of a transfer. Two PRD interrupts can happen close in time so that the second interrupt is missed while the first PRD interrupt is being cleared.

When a PRD entry is exhausted, the HBA can be directed to generate an interrupt through the I bit in the PRD entry (although a PRD is not considered exhausted until all data FISs that transfer data pointed to by that PRD entry is complete). For example, if the data FIS is 8 KiB, and this is covered by three PRD entries, the data is not considered valid at the end of the first or second PRD because the CRC has not been checked, even though the data has been copied to memory or to the device. Therefore, if the I bit is set in the PRD entry, the HBA must hold onto it internally and not set PxIS.DPS until the data FIS is complete and the CRC is correct. Once correct, PxIS.DPS can be set and, if PxIE.DPE and GHC.IE are set, the HBA generates an interrupt.

Conversely, if the PRD entry is 16 KiB and two 8 KiB Data FISS are used to transfer all of the data pointed to by the PRD entry, the PRD interrupt associated with that PRD entry is not signaled until after the second data FIS transfer completes successfully.

24.8.4.5.3.10 Unknown FIS Interrupt

This status event indicates that an unknown FIS is received and copied into system memory.

24.8.4.5.3.11 Set Device Bits Interrupt

This status event indicates that a Set Device Bits FIS is received with the I bit set and copied to system memory.

24.8.4.5.3.12 DMA Setup FIS Interrupt

This status event indicates that a DMA Setup FIS is received with the I bit set and copied into system memory.

24.8.4.5.3.13 PIO Setup FIS Interrupt

This status event indicates that a PIO Setup FIS with the I bit set is copied into system memory and the data related to that FIS is transferred.

24.8.4.5.3.14 Device to Host Register FIS Interrupt

This status event indicates that a D2H Register FIS is received with the I bit set and copied to system memory.

24.8.4.5.4 Interrupt Condition Control

There are several ways for software to control the conditions causing a non - command completion coalescing **(non-CCC)** SATA_IRQ interrupt assertion. The SATA_GHC[1] IE register bit serves as a global mask. If it is 0x0, all interrupts are masked. If it is 0x1, interrupts not masked by the SATA_IS (all interrupts for port 0) and SATA_PxIE registers can trigger an interrupt. The SATA_PxIE register matches the SATA_PxIS register bit for bit. If the corresponding bit in the SATA_PxIE register is set to 0x1, the interrupt is unmasked. If the corresponding is 0x0, the interrupt is masked off.

Table 24-445 summarizes the SATA controller interrupt status bits and their corresponding interrupt enable bits at the second tier of the SATA controller interrupt generation schema.

Table 24-445. Interrupt Events Summary

Event Status Flag	Interrupt Event Mask	Mapped to Interrupt Output	Brief Interrupt Event Description
SATA_PxIS [30]TFES	SATA_PxIE [30]TFEE	SATA_IRQ	Task File Error
SATA_PxIS [29]HBFS	SATA_PxIE [29]HBFE	SATA_IRQ	Host Bus Fatal Error
SATA_PxIS [27]IFS	SATA_PxIE [27]IFE	SATA_IRQ	Interface Fatal Error
SATA_PxIS [26]INFS	SATA_PxIE [26]INFE	SATA_IRQ	Interface Non-Fatal Error
SATA_PxIS [24]OFS	SATA_PxIE [24]OFE	SATA_IRQ	Overflow
SATA_PxIS [23]IPMS	SATA_PxIE [23]IPME	SATA_IRQ	Incorrect Port Multiplier
SATA_PxIS [22]PRCS	SATA_PxIE [22]PRCE	SATA_IRQ	Phy Ready Change
SATA_PxIS [6]PCS	SATA_PxIE [6]PCE	SATA_IRQ	Port Connect Change
SATA_PxIS [5]DPS	SATA_PxIE [5]DPE	SATA_IRQ	Descriptor Processed
SATA_PxIS [4]UFS	SATA_PxIE [4]UFE	SATA_IRQ	Unknown FIS Received
SATA_PxIS [3]SDBS	SATA_PxIE [3]SDBE	SATA_IRQ	Set Device Bits FIS Received
SATA_PxIS [2]DSS	SATA_PxIE [2]DSE	SATA_IRQ	DMA Setup FIS Received
SATA_PxIS [1]PSS	SATA_PxIE [1]PSE	SATA_IRQ	PIO Setup FIS Received
SATA_PxIS[0]DHRS	SATA_PxIE [0]DHRE	SATA_IRQ	Device to Host Register FIS Received

Note

To ensure normal generation of the standard (single-event driven, non-CCC) interrupts described in Table 24-445, the user must ensure that the CCC feature is disabled (that is, the SATA_CCC_CTL[0] EN bit is set to 0x0).

24.8.4.5.5 Command Completion Coalescing Interrupts

The SATA controller supports CCC, which can be thought of as interrupt pacing. Instead of being generated for every command completed, an interrupt can be triggered based on a certain number of commands completed and/or a timer time-out. This significantly reduces the load on the CPU by not allowing software to receive an interrupt every time a command is processed. Software can thus queue many commands or wait for many received FISes and process them as a batch. All CCC functions are controlled by the SATA_CCC_CTL, SATA_CCC_PORTS, and SATA_TIMER1MS registers. Setting SATA_CCC_PORTS[0]PRT = 0x1 makes the only available SATA controller HBA port 0 - CCC-aware. The SATA_CCC_CTL register can be used to program CCC logic to trigger an interrupt whenever a certain number of commands are complete and/or a timeout value (as specified by the TV field of SATA_CCC_CTL and SATA_TIMER1MS registers) occurs. For specific programming instructions, see the SATA_CCC_CTL description.

24.8.4.5.5.1 CCC Interrupt Based on Expired Timeout Value

To trigger a CCC interrupt on a port after an elapsed timer value, the following programming sequence must be implemented by user software:

1. Software disables the CCC feature, clearing SATA_CCC_CTL[0] EN to 0b0.
2. Software sets SATA_CCC_PORTS[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets SATA_CCC_CTL[15:8] CC = 0x0, which provides that the expired timeout trigger condition is selected.
4. Software defines the 1-ms time-based unit by loading an appropriate number of interface/functional clock cycles into the 20-bit SATA_TIMER1MS[19:0] TIMV bit field. For example, its reset value of 0x186A0 (100 000 x SATA_FICLK cycles) provides that a 1-ms timeout base will be generated if SATA_FICLK = 100 MHz.
5. Software chooses the timeout value as the number of 1-ms intervals through the 16-bit SATA_CCC_CTL[31:16]TV bit field.
6. Software enables the CCC-interrupt feature, asserting SATA_CCC_CTL[0] EN bit to 0b1.

Assertion of bit SATA_CCC_CTL[0] EN to 0x1 is required to start the 1MS TIMER after the above described configuration steps are completed.

Note

On CCC event configuration, the CCC feature should be disabled (that is, SATA_CCC_CTL[0] EN should be kept at 0b0).

Note

Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the SATA_CCC_CTL[7:3] INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA_IS[0] IPS bit is set to 0x1.

24.8.4.5.5.2 CCC Interrupt Based on Completion Count

If the desired method to receive an interrupt is based on the completion of a certain number of commands, the following settings must be performed:

1. Software disables the CCC feature, clearing SATA_CCC_CTL[0] EN to 0b0.
2. Software sets SATA_CCC_PORTS[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets SATA_CCC_CTL[15:8] CC! = 0x0 to the desired number (1–255) of commands to be completed. The CC! = 0x0 provides that the count completion condition is selected.
4. Software enables the CCC-interrupt feature, asserting the SATA_CCC_CTL[0] EN bit to 0b1.

Note

On CCC event configuration , the CCC feature should be disabled (that is, SATA_CCC_CTL[0] EN should be kept at 0b0).

Note

Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the SATA_CCC_CTL [7:3]INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA_IS[0] IPS bit is set to 0x1.

24.8.4.6 System Memory FIS Descriptors

The SATA AHCI mode supports a command list of from 1 up to 32 entries (command slots) assigned to HBA port 0, which should be allocated and built into host system memory by user software. After receiving command/data messages from the attached port 0 SATA mass-storage drive, the HBA extracts the FIS Dwords, sorts them out, and stores them into different areas of RX FIS-allocated host system memory.

24.8.4.6.1 Command List Structure Basics

Each command list entry has an associated command header (CH) that takes 32 bytes in host system memory, from which only the first 4 Dwords (16 bytes) are used. The CH contains different fields that detail the direction of transfer (H2D or D2H), type of command (ATA/ATAPI), reset behavior, PM ID, byte count and byte length of the PRD table, etc.

A command list slot CH specifies the base address of the underlying command table and information about the associated command FIS length. The command table in system memory has three main areas:

- A 64-byte command FIS area in which the user loads the command-associated FIS contents
- An ATAPI area in which a 12- or 16-byte ATAPI command is loaded, if specified in the CH (through bit A)
- A PRD table area that allows up to 65535 data descriptor entries

An entry of a PRD table (that is, a scatter/gather list item) specifies descriptor parameters of a data block transfer handled by the HBA port DMA.

Figure 24-158 shows the interrelations between the FIS-related structures that user software must allocate and build into the host system memory.

For details on command and data structures in host system memory, see the AHCI and SATA standard specifications.

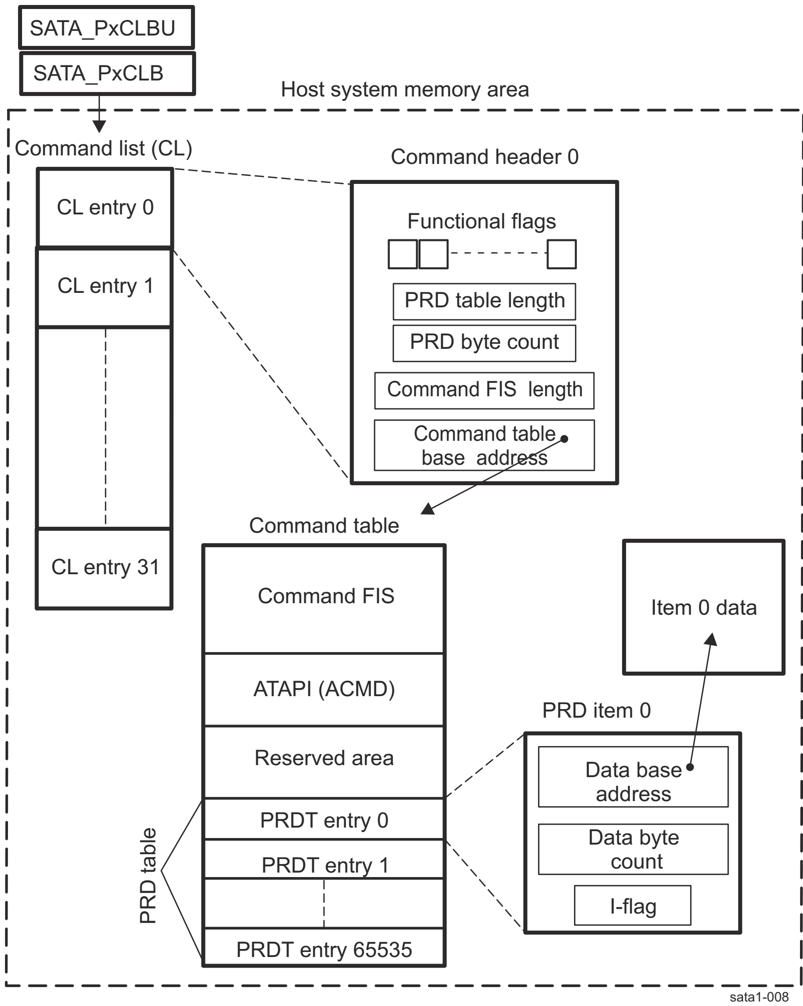

Figure 24-158. Command List Descriptor Structures

After allocating the necessary portions for the CL, command slots underlying data descriptors, and received FISs into host system memory, the base addresses of these memory locations must be provided by user software to the HBA through the hardware init domain registers: SATA_PxCLB (command list base address - lower bits), SATA_PxCLBU (command list base address-upper bits), SATA_PxFB (received FISs system memory area base address-lower bits) and SATA_PxFBU (received FISs system memory area base address-upper bits) . Thus, the command and data DMA engines can access the transfer context programming structures.

Note

SATA_PxCLBU / SATA_PxFBU registers store the upper half of the native 64-bit AHCI addresses. Because only 36-lower bits of the AHCI 64-bit address bus are integrated in the device, actually only the 4-lower bits within SATA_PxCLBU / SATA_PxFBU are meaningful. **The remaining 28-bits must be always written to '0'-s in the descriptors (SATA_PxCLBU[31:4]=0x0 / SATA_PxFBU[31:4]=0x0) .**
Default value for the SATA_PxCLBU / SATA_PxFBU registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the SATA_PxCLB / SATA_PxFB registers.

24.8.4.6.2 Supported Types of Commands

The following types commands are supported:

- Standard serial ATA nonqueued commands set.

  As opposed to NCQ, these commands are serviced, acknowledged one by one after a successful completion. The nonqueued SATA CL entries can take advantage of the PRD prefetching option indicated by the P flag in the corresponding CH (for more information, see the SATA specification). The ATA legacy commands are not supported by the SATA AHCI core.
- ATAPI commands

  ATAPI commands are supported by the SATA HBA engine. A request for an ATAPI command service is indicated by setting CH bit A to 0b1. The ATAPI command that the user builds into the ATAPI area of the command table can be 12 or 16 bytes in length and is indicated by the PIO Setup FIS sent by the SATA peripheral storage device requesting the ATAPI command. In addition, the SATA controller supports ATAPI active-LED generation (See Section 24.8.4.10, *Activity LED Generation Functionality*).
- NCQ-commands

  NCQ-commands are supported by the SATA controller HBA engine, the execution of which can be greatly facilitated by the CCC interrupt feature (for more information, see Section 24.8.4.5.5, *Command Completion Coalescing Interrupts*). As described in Section 24.8.1.1.2, *Native Command Queuing*, the NCQ commands have FPDMA queued command protocol mechanism, which implies that they are treated in a different way then standard SATA commands. The AHCI interface register set include specific registers, such as SATA_PxSACT, etc., to make the HBA aware of the outstanding NCQ slots in a command list. As opposed to standard nonqueued commands, NCQ commands are acknowledged before their actual completion, which accelerates the CL servicing for NCQ slots. The queue tag of the command requested by the SATA peripheral device is indicated to the HBA port by the TAG field in a DMA Setup FIS that an attached SATA peripheral device sends to the SATA controller host . The HBA then uses the tag value to index the NCQ commands updated by user software in the command list. The NCQ command descriptors are not allowed to use the prefetching option in CH because their order of execution is determined by the SATA target device.

24.8.4.6.3 Received FIS Structures

After stream decoding and primitive removal by the link layer, the validated FIS Dwords are extracted from the RxFIFO buffer by the transport layer DMA, and the original SATA storage drive FIS structures are recovered to a dedicated host system memory space. The DMA stores the received FISs into different memory areas based on FIS type. The unknown FIS reception is legal to HBA, as long as the length of the unknown FIS does not overrun the 64-byte size limit of the FIS descriptors. For details on received FISs memory area organization, see the AHCI and SATA standard specifications.

24.8.4.6.4 FIS Descriptors Summary

The FISs that encapsulate SATA target commands and data contents can be divided into:

- FISs transmitted from the host to an attached SATA peripheral device (H2D FISs)
- FISs sent by an attached SATA peripheral device to the host (D2H FISs)

The H2D FISs are constructed by user software into system memory. he H2D FIS types are:

- H2D Register FIS
- H2D DMA Setup FIS
- H2D Data FIS

The D2H FISs are constructed by the attached SATA peripheral device transport layer. The D2H FIS types are as follows:

- D2H Register FIS
- D2H DMA Setup FIS
- PIO Setup FIS
- DMA Activate FIS
- Set Device Bits FIS
- D2H Data FIS

For details on different type of FIS contents, see the SATA standard specification (revision 2.6).

24.8.4.7 Transport Layer FIS-Based Interactions

24.8.4.7.1 Software Processing of the Port Command List

After user software instantiates the CL structures in host system memory, it must maintain them appropriately. The command list is advanced when the BSY, DRQ, and ERR bits of a serial ATA device task file are cleared, which is communicated through a D2H register FIS to HBA port. The HBA port 0 hardware clears the corresponding to the i-th completed command: SATA_PxCI [i] CI (SATA_PxCI [TAG] CI for NCQ) bit to notify user software that the next command FIS can be advanced into the CL. The software then builds the command slot components: CH fields, command table, and associated PRD data descriptors in system memory. Software asserts the SATA_PxCI[i+1] CI (or SATA_PxCI[TAG] CI bit for an NCQ indicated command) to activate the prepared CL command, which is possible only when SATA_PxCMD[0] ST = 0x1. The nonqueued commands in the CL are processed in ascending order of slots (linear processing). The SATA_PxCMD [12:8]CCS read-only field indicates the CL index of the command currently being issued by the HBA port.

The processing of NCQ command slots invokes additional register update/check steps. Before setting the SATA_PxCI[TAG] CI bit to 0b1 and posting an active NCQ command to the SATA HBA port, software must indicate an NCQ outstanding command at the position defined by the SATA peripheral device queue TAG by setting SATA_PxSACT[TAG] DS = 0x1. After the queued command is posted, the peripheral SATA device sends a Set Device Bits FIS to the HBA port to clear the SATA_PxSACT bits corresponding to the successfully completed NCQ commands.

Command-list processing is initially triggered by software setting SATA_PxCMD[0] ST = 0x1, which requires certain conditions to be satisfied.

Note

There are some restrictions to setting SATA_PxCMD[0] ST to 0x1. For more information, see the AHCI specification (revision 1.1).

The SATA controller is capable of command list override (CLO) operation. CLO is activated by setting SATA_PxCMD[3] CLO = 0b1, which is expected only when SATA_PxCMD[0] ST = 0x0 (that is, the command list is not processed by the HBA) to avoid HBA-indeterminate behavior. As a consequence of a CLO operation, the SATA_PxTFD register STS_DRQ and STS_BSY flags are cleared. For example, CLO is necessary when the DRQ and BSY flags cannot be cleared by HBA before issuing a software reset (because of some hang condition). For more information on CLO behavior, see the AHCI standard specification.

24.8.4.7.2 Handling the Received FIS Descriptors

The HBA DMA facilitates the reception of the D2H FISs into host system memory. The reception is enabled by the user setting SATA_PxCMD[4] FRE to 0b1. The software is allowed to change the SATA_PxFB / SATA_PxFBU contents and thus move the FIS reception area to different system memory locations, if SATA_PxCMD[14] FR is cleared, which occurs after software writes SATA_PxCMD[4] FRE = 0b0. In this case, further FIS reception is blocked when the internal RxFIFO becomes full. Before setting SATA_PxCMD[4] FRE to 0x1, the user software must ensure that a valid address is programmed into the SATA_PxFB / SATA_PxFBU registers.

Note

The HBA port stores the unknown FISs (up to 64 bytes) in system memory but does not have a specified behavior to indicate an error condition on reception. The unknown FISs must be handled specifically by user software.

24.8.4.8 DMA Port Configuration

The SATA controller handles all data operations on its port with an internal DMA integrated in SATA AHCI core.

The SATA controller DMA transfers all information between system memory and the attached SATA peripheral device, as well as configuration and status FISs. The transmit and receive DMA data paths are independently programmable.

The burst size in both directions is fixed to 16 Dwords. The DMA issues transactions of this size or smaller (in Dword increments), depending on programmed transaction size.

Note

If the programmed transaction size is lower than 16-Dwords (burst size), then the DMA maxes out at transaction size.

The user can also separately program the transaction size for receive and transmit channels by setting the SATA_PxDMACR[7:4] RXTS and SATA_PxDMACR[3:0] TXTS bit fields. The transaction size is the minimum amount of data on which the DMA works. For example, if a FIS comes from the device to the host, the DMA does not begin transferring data into system memory until there is at least SATA_PxDMACR[7:4] RXTS number of Dwords in the receive FIFO. During transmit, the DMA reads data from system memory in SATA_PxDMACR[3:0] TXTS Dword increments to put into the transmit FIFO. Transactions can be broken up into multiple bursts of 16 Dword - size, crossing of a 1-KiB boundary (boundary between 1-KiB address blocks in memory), or end-of-frame. RXFIFO and TXFIFO transaction sizes are limited to maximum half the size of the integrated RXFIFO and TXFIFO buffers. For more information on maximum transaction sizes and RXFIFO/ TXFIFO depths, see the SATA_PxDMACR and SATA_PPARAMR descriptions.

24.8.4.9 Port Multiplier Operation

The SATA controller HBA port supports connection to a bunch of maximum 15 devices through a port multiplier (PM). The communication mechanism is based on PM command-based switching.

24.8.4.9.1 Command-Based Switching Mode

In this mode of operation, user software must initiate transfers to different PM ports so that multiple commands are not outstanding to different devices connected to the PM extension ports.

24.8.4.9.1.1 Port Multiplier NCQ and Non-NCQ Commands Generation

The PM port command servicing order depends on the type of commands in the CL:

- Non-queued command generation to PMs

  When processing commands that are non-queued, the HBA executes each command entry in its entirety before moving to the next entry in the command list. The next entry can include a command to a different PM device port. Because the HBA operates in the order of its command list, system software must not fill the list in sequential order with commands to a single device; otherwise, another device might get starved. For more information, see the AHCI standard specification.
- NCQ command generation to PMs

  Because the SATA controller supports command-based switching only, system software must only add NCQ commands to the command list that target a single port behind the PM, wait for the commands to finish

(SATA_PxSACT bits all cleared), and then add commands for a different port. For more information, see the AHCI standard specification.

24.8.4.9.2 Port Multiplier Enumeration

To enumerate PM devices, a software reset should be issued by SATA controller to the PM port #0xF (this is a point of connection for the PM or a single endpoint device). The software must prepare two H2D Register FISs into the host system memory for a software reset with the PM-port select (PMP) field set to 0xF. To ensure reliable PM device enumeration, software must also perform a CLO operation. For more information, see the AHCI standard specification.

24.8.4.10 Activity LED Generation Functionality

The HBA port drives the device-level sata1_led signal that is active on the following conditions (see also Table 24-439):

- If (SATA_PxCI [31:0]! = 0x0 or SATA_PxSACT[31:0]! = 0x0) and SATA_PxCMD[24] ATAPI = 0b0 (for active nonATAPI commands indication)
- If (SATA_PxCI [31:0]! = 0x0 or SATA_PxSACT[31:0]! = 0x0) and SATA_PxCMD[24] ATAPI = 0b1 and SATA_PxCMD[25] DLAE = 0b1 (for active ATAPI commands indication)

When SATA_PxCI and SATA_PxSACT are cleared to 0x0, the LED on the sata1_led signal-associated pad is driven off.

24.8.4.11 Supported Types of SATA Transfers

SATA controller AHCI mode defines two types of transfers between the host system memory and a SATA peripheral device: DMA and PIO data transfers. Whether the transaction is of a DMA type or PIO type, the HBA fetches and stores data to memory, offloading the CPU. No register is implemented for direct user access to the data port.

PIO transfers specified by PIO Setup FISs are strongly discouraged because of their limited support of error indication. PIO commands use is limited to only few cases in which commands support only PIO mechanism, such as execution of the IDENTIFY DEVICE command and ATAPI command transfers in which the PACKET command is invoked. The SATA controller AHCI mechanism allows multiple DRQ blocks of data per PIO command.

24.8.4.11.1 Supported Higher Level Protocols

The following DMA, PIO, FPDMA-queued, and ATAPI command/data protocols are supported by the SATA controller AHCI engine:

- Standard SATA command-related
  - Nondata command protocol
  - PIO write protocol
  - PIO read protocol
  - DMA write protocol
  - DMA read protocol
- NCQ command-related
  - Write FPDMA-queued protocol
  - Read FPDMA-queued protocol
- ATAPI PACKET command-related
  - PACKET Nondata command protocol
  - PACKET PIO read/write protocol
  - PACKET DMA read/write protocol

24.8.4.12 SATA Controller AHCI Hardware Register Interface

Table 24-446 summarizes the SATA host controller subsystem registers and divides them into functional categories.

Table 24-446. Summary of SATA Host Subsystem Functional Registers

Register	Functional Category	Brief Register Description
SATA_SYSCONFIG	Device-level registers (wrapper of SATA AHCI core)	TI wrapper idle/standby power management configuration register
SATA_CDRLOCK [3]		TI wrapper register which defines default delay of received data valid information.
SATA_IDR	SATA vendor-specific (VS) register	TI high lander identification register
SATA_CAP	SATA controller generic registers	SATA HBA capabilities set 1
SATA_CAP2		SATA HBA capabilities set 2
SATA_VS		SATA HBA register showing supported AHCI specification revision
SATA_GPARAM1R		SATA HBA global parameters set 1
SATA_GPARAM2R		SATA HBA global parameters set 2
SATA_GHC		SATA HBA global AHCI settings
SATA_PPARAMR	SATA HBA ports-related registers	SATA HBA port x[1] parameter settings
SATA_PI		Enables SATA HBA port x[1] functionalities
SATA_IS		Enables all SATA HBA port x[1] associated interrupts (first tier of interrupt schema)
SATA_CCC_PORTS		Enables SATA CCC feature for the port x[1]
SATA_CCC_CTL		CCC feature parameters control and status
SATA_TIMER1MS		Time base for 1-ms unit of CCC timeout
SATA_PxCLB	SATA HBA Port Px[1] SATA Specification- defined Functional Registers	CL base address (lower-half of AHCI 64-bit address)
SATA_PxCLBU		CL base address (upper-half of AHCI 64-bit address) [2]
SATA_PxFB		Received FISs base address (lower-half of AHCI 64-bit address)
SATA_PxFBU		Received FISs base address (upper-half of AHCI 64-bit address)[2]
SATA_PxIE		Port x[1] non-CCC interrupt enable
SATA_PxIS		Port x[1] non-CCC interrupt event status
SATA_PxCMD		Port x[1] command register
SATA_PxTFD		Port x[1] task file data register
SATA_PxSIG		Port x[1] associated SATA signature register
SATA_PxSSTS		Port x[1] SStatus SATA register (See the SATA standard specification.)
SATA_PxSCTL		Port x [1]SControl SATA register (See the SATA standard specification.)
SATA_PxSERR		Port x [1]SError SATA register (See the SATA standard specification.)
SATA_PxSACT		Port x[1] SActive SATA register (See SATA standard specification.)
SATA_PxCI		Port x [1]command activation/completion indication register
SATA_PxSNTF		Port x[1] SNotification register (See the SATA standard specification.)
SATA_OOBR		OOB detection counters setup
SATA_PxDMACR	Non-standard Port Px[1] Control register	Port x[1] associated DMA configuration register

Table 24-446. Summary of SATA Host Subsystem Functional Registers (continued)

Register	Functional Category	Brief Register Description
SATA_TESTR	SATA HBA BIST related registers	Test/normal mode switching
SATA_BISTAFR		BIST FIS-activate register
SATA_BISTCR		BIST control register
SATA_BISTFCTR		BIST FIS count register
SATA_BISTSR		BIST status register
SATA_BISTDECR		BIST Dword error count register

(1) x = 0, as only SATA HBA port 0 is implemented
(2) Only the 4-lower bits meaningful in the device, the others must be kept at '0'
(3) Under normal conditions, the user is supposed to keep this register at its default (power-on-reset) value.

24.8.5 SATA Controller Low Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the SATA host controller.

24.8.5.1 Global Initialization

24.8.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements to initialize the surrounding modules when the SATA host controller is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SATA host controller (for more information, see Section 24.6.3 and Section 24.6.2). Table 24-447 describes the global initialization of surrounding modules.

Table 24-447. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled (see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*).
Control Module	Module-specific pad muxing and other PHY power configurations must be set in the control module (see *Pad Configuration Registers* and *Control Module Register Manual*, in *Control Module*).
IRQ_CROSSBAR	IRQ_CROSSBAR must be configured to enable the interrupt from the SATA controller (see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*).
L4_CFG and L3_MAIN interconnects	For more information about the interconnect configuration, see *L3_MAIN Interconnect Agents* and *L4 Interconnect*, in *Interconnect.*

Note

The MPU INTC configuration is required when using the interrupt communication mode.

24.8.5.1.2 SATA Controller Global Initialization

24.8.5.1.2.1 Main Sequence SATA Controller Global Initialization

Table 24-448 describes the procedure to initialize the SATA host controller after a POR.

Table 24-448. SATA Controller Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the OCP2SCP3 adapter for PLLCTRL_SATA.	See Section 26.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 26, *Shared PHY Component Subsystems*.	-
Configure the DPLL_SATA.	See Section 26.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 26, *Shared PHY Component Subsystems*.	-
Configure the SATA_PHY.	See Section 26.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 26, *Shared PHY Component Subsystems*.	-

Table 24-448. SATA Controller Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Perform all firmware capability writes. [(1)]	See Section 24.8.5.1.2.2, *SubSequence – Firmware Capability Writes*.	-
Set up all appropriate structures in memory per the AHCI standard specification.	See Section 24.8.4.6, *System Memory FIS Descriptors*. See also the AHCI standard specification.	-
Write a valid CL memory base address to the SATA_PxCLB register.	SATA_PxCLB [31:10] CLB	CL Base address (lower-half)
	SATA_PxCLBU [3:0] CLBU	CL Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Write a valid Rx FIS memory base address to the SATA_PxFB register.	SATA_PxFB [31:8] FB	Rx FIS Base address (lower-half)
	SATA_PxFBU [3:0] FBU	Rx FIS Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Issue a software type of reset depending on the error condition.	See Section 24.8.4.3.2, *Software Initiated Resets*.	-
Set the appropriate bits in the SATA_PxCMD register.	See Section 24.8.4.7.1, *Software Processing of the Port Command List*. See also the AHCI standard specification.	-
Program the SATA_PxSCTL register to configure SATA interface capabilities.	See the AHCI standard specification.	-
Program the SATA_PxDMACR register.	See Section 24.8.4.8, *DMA Port Configuration*.	-
Enable the interrupts at port 0.	SATA_IS[0] IPS	0x1
Enable the involved port 0 specific interrupts.	See Section 24.8.4.5.2, *Levels of Interrupt Control*, and Section 24.8.4.5.4, *Interrupt Condition Controll*.	-
Enable the FIS reception in the SATA_PxCMD register.	SATA_PxCMD[4] FRE	0x1
Spin up the device (if required).	See the AHCI standard specification and the SATA standard specification.	-

(1) This step has an effect only on hardware initialization.

Note

The SATA AHCI Controller always manipulates 64-bit memory pointers, and the master interface has 64-bit addresses, but the actual AHCI master interface integration in the device uses ONLY the 36-lower bits. In that case, even though the AHCI support indicates “64-bit” in the SATA_CAP[31] S64A, ONLY the 4-lower bits (SATA_PxCLBU [3:0] / SATA_PxFBU [3:0]) are meaningful in the device.**The upper 28 bits of the address, i.e.** SATA_PxCLBU [31:4] / SATA_PxFBU [31:4] **, must be always SW-programmed to '0'.**

Note

Default value of the SATA_PxCLBU / SATA_PxFBU registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the SATA_PxCLB / SATA_PxFB registers.

24.8.5.1.2.2 SubSequence – Firmware Capability Writes

Table 24-449 lists the firmware capability write sequence by which SATA HBA initialization is performed.

Note

In the following sequence, SATA controller accesses hardware initialization domain registers that can be written only one time after POR.

Table 24-449. Firmware Capability Writes

Step	Register/Bit Field/Programming Model	Value
Disable the staggered spin-up support feature.(1)	SATA_CAP[27] SSS	0x0
Enable the SATA controller port 0.	SATA_PI[0] PI	0x1
Disable the mechanical presence detect feature.(1)	SATA_CAP[28] SMPS	0x0
Disable the external signal-only connector.(1)	SATA_PxCMD[22:21] ESP	0x0
Disable the cold presence detect feature.(1)	SATA_PxCMD[20] CPD	0x0
Disable support for the mechanical presence switch.	SATA_PxCMD[19] MPSP	0x0
Disable the hot-plug-capable port feature.	SATA_PxCMD[18] HPCP	0x0
If PM is attached:		
Set the SATA_PxCMD [17] PMA bit to notify HBA that the PM is attached to HBA port 0.	SATA_PxCMD[17] PMA	0x1
ELSE		
Clear the SATA_PxCMD[17] PMA bit as a notification that a single-target SATA device is attached to port 0.	SATA_PxCMD[17] PMA	0x0

(1) It makes no sense to enable staggered spin-up because only one HBA port is used.

24.8.5.1.3 Issue Command - Main Sequence

The procedure in Table 24-450 prepares a command list entry and issues its corresponding command.

Table 24-450. Prepare and Issue a Command

Step	Register/Bit Field/Programming Model	Value
Build command header and command table into host system memory.	For details, see Section 24.8.4.6.1, *Command List Structure Basics*.	-
Create the command corresponding PRD table.		
Queue the command to the command list.	See Section 24.8.4.7.1, *Software Processing of the Port Command List*.	-
Set the SATA_PxCMD[0] ST bit to direct the DMA to start processing the CL.	SATA_PxCMD[0] ST	0x1(1)
IF a nonNCQ command is issued:		
Set the corresponding SATA_PxCI.CI bit to activate a command already prepared in the i-th slot of the CL .	SATA_PxCI[i] CI	0x-
ELSE		
Indicate the NCQ slot positions through the SATA_PxSACT register. For details on TAG tracking, see Section 24.8.4.7.1.	SATA_PxSACT[TAG] DS	0x-
Set the corresponding SATA_PxCI.CI bit to activate the NCQ command already prepared in the i-th slot of the CL.	SATA_PxCI[TAG] CI	0x-

(1) See the AHCI standard specification for important restrictions when PXCMD[0] ST can be software-asserted to 1.

24.8.5.1.4 Receive FIS—Main Sequence

The procedure in Table 24-451 is used to handle a FIS reception.

Table 24-451. FIS Reception

Step	Register/Bit Field/Programming Model	Value
Read SATA_PxIS to determine the type of FIS.	For more information, see Section 24.8.4.7.2, *Handling the Received FIS Descriptors*.	-

Bits	Field Name	Description	Type (1)	Reset
31:21	RESERVED		R	0x000
20	FERLB	Far-end retimed loopback Write 0x0: No action Write 0x1: Puts the DWC_ahsata link into far-end retimed mode without the BIST activate FIS, regardless of whether the device is connected or disconnected (link in NOCOMM state) Read 0x0: Read returns 0	WO	0
19	RESERVED		R	0
18	TXO	Transmit only 0x0: No action 0x1: Initiate transmission of one of the noncompliant patterns defined by the SATA_BISTCR.PATTERN value when the device is disconnected.	W	0
17	CNTCLR	Counter clear Clears BIST error count registers Write 0x0: No action Write 0x1: Clear SATA_BISTFCTR, SATA_BISTSR, and SATA_BISTDECR registers Read 0x0: Read returns 0	WO	0
16	NEALB	Near-end analog loopback This mode should be initiated in the PARTIAL or SLUMBER power state or with the device disconnected from the port PHY (link NOCOMM state). BIST Activate FIS is not sent to the device in this mode. Write 0x0: No action Write 0x1: Places the port PHY in near-end analog loopback mode. SATA_BISTCR.PATTERN bit field contains the appropriate pattern.	WO	0

Bits	Field Name	Description	Type[(1)]	Reset
15	LLB	Lab Loopback Mode Masks out phy_sig_det from the OOB detector in BIST Loopback Mode. To exit BIST Loopback mode, clear the register bit then issue COMRESET / receive COMINIT.	RW	0
14	RESERVED		R	0
13	ERRLOSSEN	Always keep this bit at default value.	RW	0
12	SDFE	Signal detect feature enable Not affected by global reset or port reset 0x0: Link layer feature to handle unstable/absent phy_sig_det signal is disabled. 0x1: Link layer feature to handle unstable/absent phy_sig_det signal is enabled.	RW	0
11	RESERVED	Only write 0 into this reserved field to avoid undefined results.	RW	0
10	LLC_RPD	Link layer control, repeat primitive drop In normal mode, the function can be changed only during port reset (SATA_PxSCTL.DET = 0x1). 0x0: Repeat primitive drop function disabled in normal mode, enabled in BIST mode 0x1: Repeat primitive drop function enabled in normal mode, disabled in BIST mode	RW	1
9	LLC_DESCRAM	Link layer control, descrambler In normal mode, the function can be changed only during port reset (SATA_PxSCTL.DET = 0x1). 0x0: Descrambler disabled in normal mode, enabled in BIST mode 0x1: Descrambler enabled in normal mode, disabled in BIST mode	RW	1
8	LLC_SCRAM	Link layer control, scrambler In normal mode, the function can be changed only during port reset (SATA_PxSCTL.DET = 0x1). Hardware–cleared (enabled) when the port enters a responder far-end transmit BIST mode with scrambling enabled (SATA_BISTAFR.PD = 0x80). 0x0: Scrambler disabled in normal mode, enabled in BIST mode. 0x1: Scrambler enabled in normal mode, disabled in BIST mode.	RW	1
7	RESERVED		R	0
6	ERREN	Error enable Allow or filter (disable) PHY internal errors outside the FIS boundary to set corresponding SATA_PxSERR bits 0x0: Filter errors outside the FIS; allow errors inside the FIS. 0x1: Allow errors outside or inside the FIS.	RW	0
5	FLIP	Flip disparity Change disparity of the current test pattern to the opposite each time its state is changed by software.	RW	0
4	PV	Pattern version Selects either short or long version of the SSOP, HTDP, LTDP, LFSCP, COMP pattern 0x0: Short pattern version 0x1: Long pattern version	RW	0

Bits	Field Name	Description	Type(1)	Reset
3:0	PATTERN	Pattern Defines one of the listed SATA-compliant patterns for far-end retimed/ far-end analog/ near-end analog initiator modes, or noncompliant patterns for transmit-only responder mode when initiated by software writing to the SATA_BISTCR.TXO bit 0x0: Simultaneous switching outputs pattern (SSOP) 0x1: High transition density pattern (HTDP) 0x2: Low transition density pattern (LTDP) 0x3: Low frequency spectral component pattern (LFSCP) 0x4: Composite pattern (COMP) 0x5: Lone bit pattern (LBP) 0x6: Mid-frequency test pattern (MFTP) 0x7: High frequency test pattern (HFTP) 0x8: Low frequency test pattern (LFTP)	RW	0x0

(1) WO = A write-only accessible bit field

Table 24-464. SATA_BISTFCTR

Address Offset	0x0000 00A8		
Physical Address	0x4A14 00A8	**Instance**	DWC_ahsata
Description	BIST frame-information-structure CounT register Received BIST FIS count in the loopback initiator far-end retimed, far-end analog, and near-end analog modes. Updated each time a new BIST FIS is received. Reset by global reset, port reset (COMRESET), or by writing 1 to SATA_BISTCR.CNTCLR Does not roll over and freezes when the FFFF_FFFFh value is reached. It takes approximately 65 hours of continuous BIST operation to reach this value.		
Type	R

Bits	Field Name	Description	Type	Reset
31	CPDS	Cold port detect status Set when the pX_cp_det input changes its state due to the insertion or removal of a device Valid only if the port supports cold presence detection as indicated by the SATA_PxCMD.CPD bit set to 1. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
30	TFES	Task file error status Set whenever the SATA_PxTFD.STS register is updated by the device and the error bit (bit 0) is set. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
29	HBFS	Host bus fatal error status Set when master (DMA) detects an ERROR response from the slave Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
28	HBDS	Host bus data error status This bit is always cleared to 0. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
27	IFS	Interface fatal error status This bit is set when any of the following conditions is detected: 1) SYNC escape is received from the device during H2D register or data FIS transmission. 2) One or more of the following errors are detected during data FIS transfer: - 10B to 8B Decode Error (SATA_PxSERR.DIAG_B) - Protocol (SATA_PxSERR.ERR_P) - CRC (SATA_PxSERR.DIAG_C) - Handshake (SATA_PxSERR.DIAG_H) - PHY not ready (SATA_PxSERR.ERR_C) 3) Unknown FIS is received with good CRC, but the length exceeds 64 bytes. 4) PRD table byte count is 0. 5) DMA setup FIS is received with a TAG corresponding to inactive (SATA_PxSACT bit is cleared) command slot. Port DMA transitions to a fatal state until the software clears SATA_PxCMD.ST bit or resets the interface by way of port reset or global reset. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
26	INFS	Interface nonfatal error status Set when any of the following conditions is detected: 1) One or more of the following errors are detected during nondata FIS transfer: - 10b to 8b decode error (SATA_PxSERR.DIAG_B) - Protocol (SATA_PxSERR.ERR_P) - CRC (SATA_PxSERR.DIAG_C) - Handshake (SATA_PxSERR.DIAG_H) - PHY not ready (SATA_PxSERR.ERR_C) 2) Command list underflow during read operation (that is, DMA read) when the software builds a command table that has more total bytes than the transaction given to the device. In both cases port operation continues normally. When an error is detected during nondata FIS transmission, this FIS is retransmitted continuously until it succeeds, or until the software times out and resets the interface. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
25	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
24	OFS	Overflow status Set when command list overflow is detected during read or write operation when the software builds command table that has fever total bytes than the transaction given to the device. Port DMA transitions to a fatal state until the software clears SATA_PxCMD.ST bit or resets the interface by way of port reset or global reset. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
23	IPMS	Incorrect PM status FIS received from a device in which the PM field did not match what was expected May be set during enumeration of devices on a PM due to the normal PM enumeration process Must be used only after enumeration is complete on the PM Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
22	PRCS	PhyRdy change status Reflects the state of SATA_PxSERR.DIAG_N To clear this bit, clear the SATA_PxSERR.DIAG_N bit to 0. Read 0x1: Internal pX_phy_ready signal changed state Read 0x0: Internal pX_phy_ready signal has not changed state since its last reset.	R	0
21:8	RESERVED		R	0x0000
7	DMPS	Device mechanical presence status Set when the pX_mp_switch input changes its state as a result of a mechanical switch attached to this port opening or closing Valid only when SATA_CAP.SMPS and SATA_PxCMD.MPSP are set Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
6	PCS	Port connect change status This bit reflects the state of the SATA_PxSERR.DIAG_X bit. Cleared only when SATA_PxSERR.DIAG_X is cleared Read 0x1: Change in current connect status Read 0x0: No change in current connect status	R	0

Bits	Field Name	Description	Type	Reset
5	DPS	Descriptor processed A PRD with the I bit set has transferred all of its data. Note. This is an opportunistic interrupt and must not be used to definitively indicate the end of a transfer. Two PRD interrupts could occur close enough together that the second interrupt is missed when the first PRD interrupt is cleared. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
4	UFS	Unknown FIS interrupt An unknown FIS was received and has been copied into system memory. Cleared to 0 by the software clearing the SATA_PxSERR.DIAG_F bit to 0. Note: The UFS bit does not directly reflect the SATA_PxSERR.DIAG_F bit. SATA_PxSERR.DIAG_F bit is set immediately when an unknown FIS is detected, whereas the UFS bit is set when that FIS is posted to memory. The software should wait to act on an unknown FIS until the UFS bit is set to 1 or the two bits may become out of sync. Read 0x1: IRQ event active Read 0x0: Event inactive	R	0
3	SDBS	Set device bits interrupt A Set Device Bits FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
2	DSS	DMA setup FIS interrupt A DMA Setup FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
1	PSS	PIO setup FIS interrupt A PIO Setup FIS is received with the I bit set, copied into system memory, and the data related to the FIS is transferred. Note: This bit is set even when the data transfer resulted in an error. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
0	DHRS	Device to host register FIS interrupt A D2H register FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Table 24-480. SATA_PxIE

Address Offset	0x0000 0114		
Physical Address	0x4A14 0114	**Instance**	DWC_ahsata
Description	Port interrupt enable Enables and disables the reporting of the corresponding interrupt to system software When a bit is set (1), SATA_GHC.IE = 1, and the corresponding interrupt condition in SATA_PxIS is active, then the SATA controller interrupt output is asserted. When a bit is cleared (0), interrupt sources are still reflected in the status registers. Reset on global reset

Bits	Field Name	Description	Type	Reset
31:28	ICC	Interface communication control Control of power management states of the interface If the link layer is in the L_IDLE state, writes cause the port to request a transition to a given interface state. If the link layer is not in the L_IDLE state, writes have no effect. When a nonreserved, non-0 (No-Op) value is written, the core performs the action and clears the field back to 0 (Idle) Write 0x0: No-Op Read 0x0: Port is ready to accept a new interface control command, although the transition to the previously selected state might not have occurred yet. 0x1: Active 0x2: PARTIAL. SATA device can reject the request and the interface then remains in its current state. 0x6: SLUMBER. SATA device can reject the request and the interface then remains in its current state.	RW	0x0
27	ASP	Aggressive SLUMBER/PARTIAL 0x0: If SATA_PxCMD.ALPE = 1, the port aggressively enters the PARTIAL state when it clears the SATA_PxCI register and the SATA_PxSACT register is cleared when it clears the SATA_PxSACT register and SATA_PxCI is cleared. 0x1: If SATA_PxCMD.ALPE = 1, the port aggressively enters the SLUMBER state when it clears the SATA_PxCI and the SATA_PxSACT register is cleared or when it clears the SATA_PxSACT register and SATA_PxCI is cleared.	RW	0
26	ALPE	Aggressive link power management enable 0x0: Aggressive power management state transition is disabled. 0x1: Port aggressively enters a lower link power state (PARTIAL or SLUMBER) based on the setting of SATA_PxCMD.ASP.	RW	0
25	DLAE	Drive LED on ATAPI enable 0x0: LED is never enabled. 0x1: Port asserts the pX_act_led output when commands are active and SATA_PxCMD.ATAPI = 1.	RW	0
24	ATAPI	Device is ATAPI Used by the port to determine whether or not to assert pX_act_led output when commands are active. 0x0: Connected device is not an ATAPI. 0x1: Connected device is an ATAPI.	RW	0
23	APSTE	Auto PARTIAL to SLUMBER transition enable 0x0: No automatic transition from PARTIAL to SLUMBER 0x1: Link layer transitions from its PARTIAL power management state to SLUMBER state automatically, whether host software-, port (aggressive)-, or device-initiated.	RW	0
22	FBSCP	FIS-based Switching Capable Port May only be set to ? 1? if CAP.SPM = CAP.FBSS = 1 (not the case). Writable once after power up, read-only afterwards. 0x0: port does not support FIS-based switching. 0x1: Port supports Port Multiplier FIS-based switching.	RW	0x0

Bits	Field Name	Description	Type	Reset
21	ESP	External SATA port Writable once after power up, read-only afterward 0x0: Port signal-only connector is not externally accessible. 0x1: Port signal-only connector is externally accessible. SATA_CAP.SXS is also set to 1. Mutually exclusive with SATA_PxCMD.HPCP	RW	0x0
20	CPD	Cold presence detect Writable once after power up, read-only afterward 0x0: Platform does not support cold presence detection on this port. 0x1: Platform supports cold presence detection on this port. SATA_PxCMD.HPCP should be set to 1.	RW	0
19	MPSP	Mechanical presence switch attached to port Writable once after power up, read-only afterward 0x0: Platform does not support a mechanical presence switch on this port. 0x1: Platform supports a mechanical presence switch attached to this port. SATA_PxCMD.HPCP should be set to 1.	RW	0
18	HPCP	Hot plug capable port Writable once after power up, read-only afterward 0x0: Port signal and power connectors are not externally accessible. 0x1: Port signal and power connectors are externally accessible through a joint signal-power connector for blindmate device hot plug.	RW	0
17	PMA	PM attached Software is responsible for detecting the presence of a PM. There is no autodetection. 0x0: No port Multiplier is attached to this Port 0x1: Port Multiplier is attached to this Port	RW	0
16	CPS	Cold presence state Reports whether a device is currently detected on this port as indicated by the pX_cp_det input state (assuming SATA_PxCMD.CPD = 1). Read 0x1: Device detected Read 0x0: No device detected	R	0
15	CR	Command list running For details, see the AHCI state-machine in Section 5.3.2 of the AHCI specification. Read 0x1: Command list DMA engine for this port is running. Read 0x0: Command list is stopped for this port.	R	0
14	FR	FIS receive running For details, see Section 10.3.2 of the AHCI specification. Read 0x1: FIS receive DMA engine for the port is running. Read 0x0: FIS receive DMA engine for the port is stopped.	R	0

Bits	Field Name	Description	Type	Reset
13	MPSS	Mechanical presence switch state Reports the state of a mechanical presence switch attached to this port as indicated by the pX_mp_switch input state (assuming SATA_CAP.SMPS = 1 and SATA_PxCMD.MPSP = 1) Cleared to 0 when SATA_CAP.SMPS = 0 Read 0x1: Switch is open. Read 0x0: Switch is closed.	R	0
12:8	CCS	Current command slot This field is valid when SATA_PxCMD.ST is set to 1 and is set to the command slot value of the command currently issued by the port. When SATA_PxCMD.ST transitions from 1 to 0, this field is reset to 0x00. After SATA_PxCMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command is issued, the highest priority slot to issue from next is SATA_PxCMD.CCS + 1. For example, after the port issues its first command, if CCS = 0x00 and SATA_PxCI is set to 0x3, the next command issued is from command slot 1.	R	0x00
7:5	RESERVED		R	0x0
4	FRE	FIS receive enable Must not be set until SATA_PxFB / SATA_PxFBU is programmed with a valid pointer to the FIS receive area Base can be moved after clearing FRE and waiting for FR to clear to 0. 0x0: Received FISes are not accepted by the port, except for the first D2H register FIS after the initialization sequence, and no FISes are posted to the FIS receive area. 0x1: Port can post received FISes into the FIS receive area pointed to by SATA_PxFB and SATA_PxFBU.	RW	0
3	CLO	Command list override Write 0x0: No effect Write 0x1: Request to clear SATA_PxTFD.STS_BSY and SATA_PxTFD.STS_DRQ to 0. Use only immediately prior to setting SATA_PxCMD.ST bit to 1 from a previous value of 0. Any other case results in indeterminate behavior. Read 0x1: Override is active, SATA_PxTFD.STS_BSY and SATA_PxTFD.STS_DRQ are being cleared. Read 0x0: Override is inactive.	RW	0
2	POD	Power-on device Writable if SATA_PxCMD.CPD = 1 (cold presence detection enabled), otherwise read-only -1. 0x0: Disabled 0x1: Port asserts the pX_cp_pod output pin so that it can be used to provide power to a cold-presence detectable port.	RW	0

Bits	Field Name	Description	Type	Reset
1	SUD	Spin-up device Writable if SATA_CAP.SSS = 1 (staggered spin-up supported), else read-only 1. Read-only-0 on power-up until SATA_CAP.SSS bit is written with the required value. 0x0: Clearing the bit from 1 to 0 causes no action on the interface. 0x1: On edge-detect from 0 to 1, the port starts a COMRESET initialization sequence to the device.	RW	0
0	ST	Start 0x0: Port does not process the command list. On transition from 1 to 0, the SATA_PxCI register is cleared by the port on transition to an IDLE state. 0x1: Port processes the command list. On transition from 0 to 1, the port starts processing the command list at entry 0. SATA_PxSERR must be cleared prior to setting ST to 1. For important restrictions on when ST can be set to 1, See Section 10.3.1 of the AHCI specification.	RW	0

Table 24-485. SATA_PxSCTL

Address Offset	0x0000 012C		
Physical Address	0x4A14 012C	**Instance**	DWC_ahsata
Description	Port SATA control Control of SATA interface capabilities. Writes to this register result in action taken by the port PHY interface. Reads from the register return the last value written to it. Reset on global reset. Wait for at least seven periods of the slower clock (OCP or parallel serdes clock) between writes, due to the internal clock domain crossing between the transport (OCP) and link (serdes I/F) layers.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												PMP				SPM				IPM				SPD				DET			

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x000
19:16	PMP	PM port: This field is not used by the AHCI.	R	0x0
15:12	SPM	Select power management: This field is not used by the AHCI.	R	0x0
11:8	IPM	Interface power management transitions allowed: Indicates which power states the HBA is allowed to transition to. If an interface power management state is disabled, the HBA is not allowed to initiate that state and the HBA must PMNAK_P any request from the device to enter that state. The two MSBs are always 2'b00 (not writable), as for all unreserved field values. 0x0: No interface power management state restrictions 0x1: Transitions to the PARTIAL state disabled 0x2: Transitions to the SLUMBER state disabled 0x3: Transitions to both PARTIAL and SLUMBER states disabled	RW	0x0
7:4	SPD	Speed allowed: Highest allowable speed of the interface The two MSBs are always 2'b00 (not writable), as for all unreserved field values. 0x0: No speed negotiation restrictions 0x1: Limit speed negotiation to generation 1 communication rate. 0x2: Limit speed negotiation to a rate not greater than generation 2 communication rate.	RW	0x0
3:0	DET	Device detection initialization: Controls the HBA device detection and interface initialization. Can be modified only when SATA_PxCMD.ST = 0. Must have a value of 0x0 when SATA_PxCMD.ST = 1. MSB is always 1'b0 (not writable), as for all unreserved field values. 0x0: No device detection or initialization action requested 0x1: Perform interface communication initialization sequence to establish communication. This is functionally equivalent to a hard reset and results in the interface being reset and communications reinitialized. While this field is 1h, COMRESET is transmitted on the interface. Software must leave the DET field set to 1h for a minimum of 1 ms to ensure that a COMRESET is sent on the interface. 0x4: Disable the serial ATA interface and put PHY in offline mode.	RW	0x0

Table 24-486. SATA_PxSERR

Address Offset	0x0000 0130		
Physical Address	0x4A14 0130	**Instance**	DWC_ahsata
Description	Port SATA error Detected interface errors accumulated since the last time it cleared. When set, indicates that the corresponding error condition became true one or more times since the last time cleared. Write 1 to a bit to clear it. Cleared by global reset or port reset (COMRESET).		
Type	RW

DS																															

Bits	Field Name	Description	Type	Reset
31:0	DS	Device status: Field is bit-significant. Each bit corresponds to the TAG and command slot of a native queued command, where bit 0 corresponds to TAG 0 and command slot 0. Set by Software prior to issuing a native queued command for a particular command slot. Prior to writing SATA_PxCI[TAG] to 1, software sets DS[TAG] to 1 to indicate that a command with that TAG is outstanding. The device clears bits by sending a set device bits FIS to the port. The port clears bits in this field that are set to 1 in the SActive field of the set device bits FIS. The port only clears bits that correspond to native queued commands completed successfully. Write only when SATA_PxCMD.ST bit is set to 1. Cleared when SATA_PxCMD.ST is written from 1 to 0. Not cleared by a port reset (COMRESET) or a software reset.	RW	0x0000 0000

RESERVED	OVERRIDE0	RESERVED	STANDBYMODE	IDLEMODE	RESERVED

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0000

Bits	Field Name	Description	Type	Reset
16	OVERRIDE0	Override for clock stopping. Normally the functional clock can be stopped only if the link is put into PARTIAL or SLUMBER power state. However, if there is no device attached (such as in a removable media situation) or the device is not started, the user can stop the functional clocks but not be able to enter a low-power state. In this case, software can set the OVERRIDE bit to 1, removing the requirement for a low-power state WARNING: If there is a device attached, the OVERRIDE bit is used, and the functional clock is stopped when the link is not in a low-power state it ruins the link and causes undetermined behavior. A port reset or full SATASS reset might be required to recover. 0x0: Normal mode 0x1: Override mode	RW	0
15:6	RESERVED		R	0x000
5:4	STANDBYMODE	Configuration of the local initiator-state management mode. By definition, the initiator can generate a read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: Local initiator is unconditionally placed in STANDBY state. Backup mode, for debug only 0x1: No-standby mode: local initiator is unconditionally placed out of STANDBY state. Backup mode, for debug only. 0x2: Smart-standby mode: Local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. The IP module does not generate (initiated-related) wakeup events. 0x3: Smart-Standby wakeup-capable mode: Local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. The IP module can generate (master related) wakeup events when in STANDBY state. Mode is relevant only if the appropriate IP module mwakeup output is implemented.	RW	0x2

Bits	Field Name	Description	Type	Reset
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, the target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: The local target IDLE state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the internal requirements of th e IP module. Backup mode, for debug only. 0x1: No-idle mode: The local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: The local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the internal requirements of the IP module. IP module does not generate (IRQ- or DMA-request-related) wakeup events. 0x3: Smart-idle wakeup-capable mode: The local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the internal requirements of the IP module. IP module can generate (IRQ- or DMA-request-related) wakeup events when in IDLE state. Mode is only relevant if the appropriate IP module swakeup output(s) is (are) implemented.	RW	0x2

(1) Under normal conditions, this bitfield must be kept at its default (power-on-reset) value.

24.9 PCIe Controller

This section describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) Controller which provides a high-speed glueless serial interconnect to peripherals utilizing high bandwidth applications.

24.9.1 PCIe Controller Subsystem Overview

The Peripheral Component Interconnect Express (PCIe) module is a multi-lane I/O interconnect that provides low pin-count, high reliability, and high-speed data transfer at rates of up to 5.0 Gbps per lane, per direction, for serial links on backplanes and printed wiring boards. It is a 3-rd Generation I/O Interconnect technology succeeding PCI and ISA bus that is designed to be used as a general-purpose serial I/O interconnect. It is also used as a bridge to other interconnects like SATA, USB2/3.0, GbE MAC, and so forth.

The device instantiates two PCIe subsystems (PCIe_SS1 and PCIe_SS2) . The PCIe controller is capable to operate either in Root Complex (RC) or in End Point (EP) PCIe mode. The device PCIe_SS1 controller supports up to two 16-bit data lanes on its PIPE port. The device PCIe_SS2 controller supports only one 16-bit data lane on its PIPE port.

When the PCIe_SS1 controller PIPE port is configured to operate in a single-lane mode, it operates on a single pair of PCIe PHY serializer and deserializer - PCIe1_PHY_TX/PCIe1_PHY_RX. When PCIe_SS1 PIPE is configured to operate in dual-lane mode, it operates on two pairs of PCIe PHY serializer and deserializer - PCIe1_PHY_TX/PCIe1_PHY_RX and PCIe2_PHY_TX/PCIe2_PHY_RX, respectively. The single-lane PCIe_SS2 controller PIPE port (if enabled) can operate only on the PCIe2_PHY_TX/PCIe2_PHY_RX pair. Hereby, if PCIe_SS2 controller is used, the PCIe_SS1 can operate only in a single-lane mode on the PCIe1_PHY_TX/PCIe1_PHY_RX. In addition, PCIe PHY subsystem encompasses a PCIe PCS (physical coding sublayer), a PCIe power management logic, APLL, a DPLL reference clock generator and an APLL clock low-jitter buffer. For more details on PCIe PHY subsystem, please refer to Section 26.4, *PCIe Shared Phy Subsystem*.

- The PCIe Controller implements the transport and link layers of the PCIe interface protocol.
- PCIe PCS (a physical coding sublayer component) converts a 8-bit portion of parallel data over a PCIe lane to a 10-bit parallel data to adapt the process of serialization and deserialization in the TX/RX PHYs to various requirements. At the same time it transforms the transmission rate to maintain the PCIe Gen2 bandwidth (5 Gbps) on both sides (PCIe controller and PHY).
- A multiplexer logic which adds flexibility to connect a PCIe controller hardware mapped PCS logic output to a single (for the single-lane PCIe_SS2 controller) or to a couple (for the 2-lane PCIe_SS1 controller) of PHY ports at a time
- Physical layer (PHY) serializer/deserializer components with associated power control logic, building the so called PMA (physical media attachment) part of the PCIe_PHY transceiver, as follows:
  – PCIe physical port 0 associated serializer (TX) - PCIe1_PHY_TX and deserializer (RX) - PCIe1_PHY_RX
  – PCIe physical port 1 associated serializer (TX) - PCIe2_PHY_TX and deserializer (RX) - PCIe2_PHY_RX
- DPLL_PCIe_REF is a DPLL clock source, controlled from the device PRCM, that provides a 100-MHz clock to the PCIe PHY serializer/deserializer components reference clock inputs.
- Both the PCIe_SS1 and PCIe_SS2 share the same APLL (APLLPCIe) which by default multiplies the DPLL_PCIe_REF (typically 100 MHz or 20 MHz) clock to 2.5 GHz.
- The APLLPCIe low-jitter buffer (ACSPCIE) and additional logic takes care to provide the PCIe APLL reference input clock.

Figure 24-159 shows an overview of a device PCIe subsystem with its integrated components.

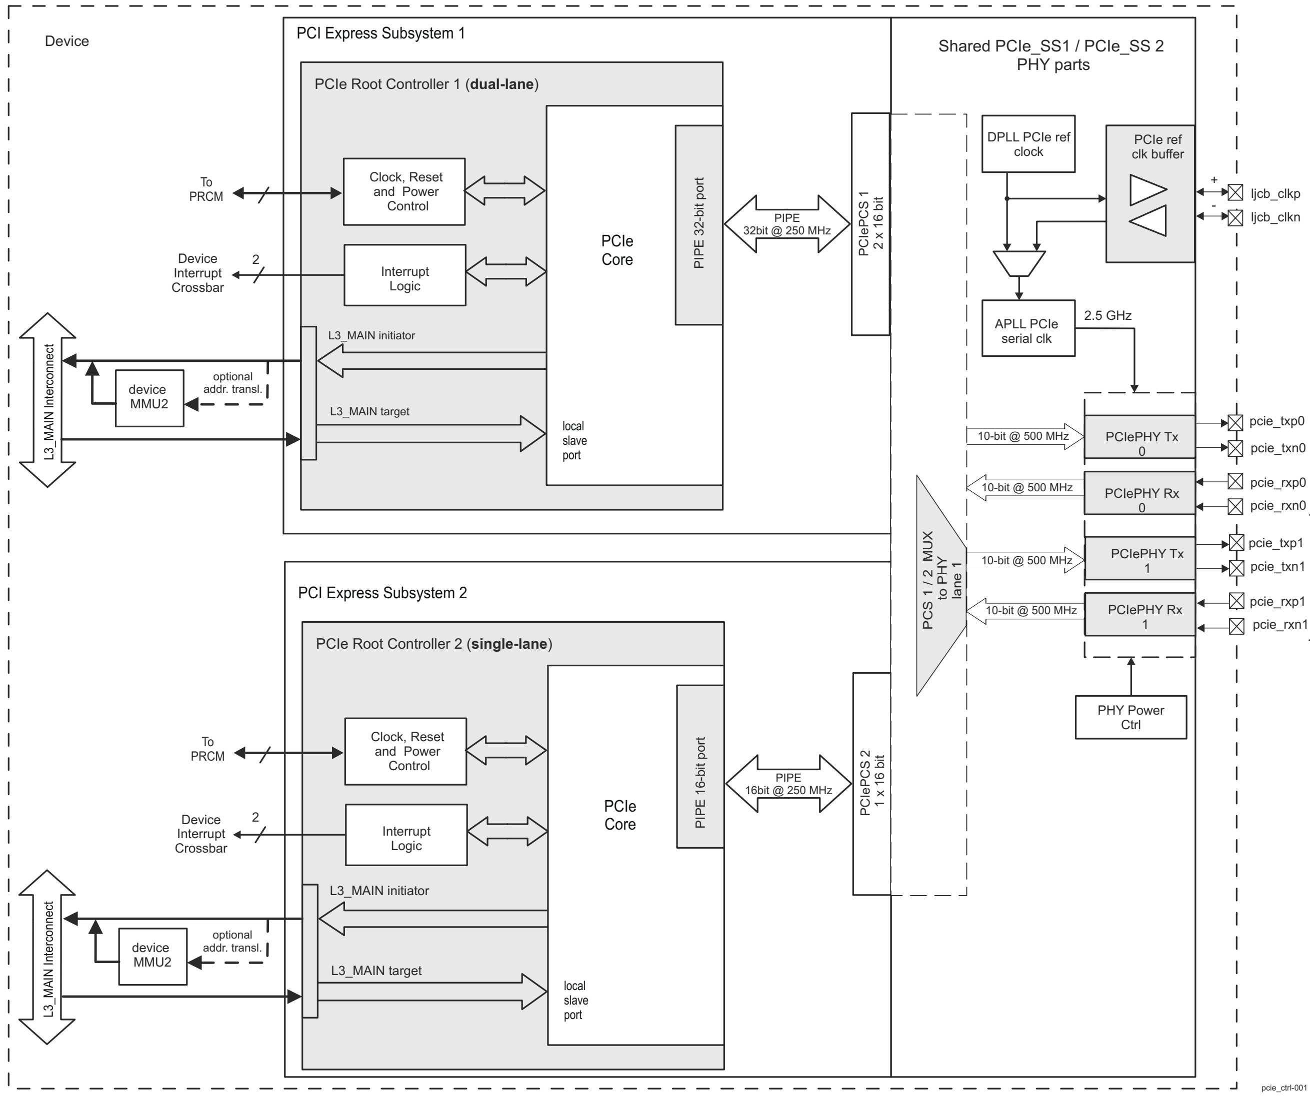

Figure 24-159. PCIe Controller Subsystem Overview

24.9.1.1 PCIe Controllers Key Features

This section describes the features supplied by the PCIe controller modules (including PCIe at device level). The PCIe_SS1 and PCIe_SS2 controllers comply with the following standards:

- PCI Local Bus Specification revision 3.0
- PCI Express Base 3.0 Specification, revision 1.0.

At system level the device supports PCI express interface in the following configurations:

- Each PCIe subsystem controller has support for PCIe Gen2 mode (5.0 Gbps per lane) and Gen1 mode (2.5 Gbps per lane).
- One PCIe (PCIe_SS1) operates as Gen2 2-lanes supporting in either root-complex (RC) or end-point EP.
- Two PCIe (PCIe_SS1 and PCIe_SS2) operates Gen2 1-lane supporting either RC or EP with the possibility of one operating in Gen1 and one in Gen2.
- PCIe_SS1 can be configured to operate in either 2-Lane (dual lane) or 1-Lane (single lane) mode, as follows:
  - Single Lane - lane 0 mapped to the PCIe port 0 of the device
  - Flexible dual lane configuration - lanes 0 and 1 can be swapped on the two PCIe ports
- PCIe_SS2 can only operate in 1-Lane mode, as follows:

  – Single Lane - lane 0 mapped to the device PCIe port 1

When PCie_SS1 is configured to operate in dual-lane mode, PCIe_SS2 is not available.

The main features of a device PCIe controller are:

- 16-bit operation at 250 MHz on PIPE interface (per 16-bit lane)
- One master port on the L3_MAIN supporting 32-bit address and 64-bit data bus.
- PCIe_SS1/PCIe_SS2 master port dedicated MMU (device MMU2) on L3_MAIN path, to which PCIe traffic can be optionally mapped.
- One slave port on the L3_MAIN supporting 29-bit address and 64-bit data bus.
- Maximum outbound payload size of 64 Bytes (the L3 Interconnect PCIe1/2 target ports split bursts of size >64 Bytes to the into multiple 64 Byte bursts)
- Maximum inbound payload size of 256 Bytes (internally converted to 128 Byte - bursts)
- No remote read request size limit: implicit support for 4 KiB-size and greater
- Support of EP legacy mode
- Support of inbound I/O accesses in EP legacy mode
- PIPE interface features fixed-width (16-bit data per lane) and dynamic frequency to switch between PCIe Gen1 and Gen2.
- Ultra-low transmit and receive latency
- Automatic Lane reversal as specified in the PCI Express Base 3.0 Specification, revision 1.0 (transmit and receive)
- Polarity inversion on receive
- Single Virtual Channel (VC0) and Single Traffic Class (TC0)
- Single Function in End point mode
- Automatic credit management
- ECRC generation and checking
- All PCI Device Power Management D-states with the exception of $D3_{cold}$/L2 state
- PCI Express Active State Power Management (ASPM) state L0s and L1 (with exceptions)
- PCI Express Link Power Management states except for L2 state
- PCI Express Advanced Error Reporting (AER)
- PCI Express messages for both transmit and receive
- Filtering for Posted, Non-Posted, and Completion traffic
- Configurable BAR filtering, I/O filtering, configuration filtering and completion lookup/timeout
- Access to configuration space registers and external application memory mapped registers through ECAM mechanism.
- Legacy PCI Interrupts reception (RC) and generation (EP)
- 2× hardware interrupts per PCIe_SS1and PCIe_SS2 controller mapped via the device Interrupt Crossbar (IRQ_CROSSBAR) to multiple device host (MPU, DSP, and so forth) interrupt controllers in the device
- MSIs generation and reception
- PCIe_PHY Loopback in RC mode

24.9.2 PCIe Controller Environment

The below Table 24-494 shows the device integrated PCI Express subsystem interface signals to external PCIe devices.

Table 24-494. PCIe_SS I/O Signals

1 (B1)	1	PCS1 (MAC B) lane 0	PCS1 (MAC B) lane 1

(1) See CTRL_CORE_PCIE_CONTROL register in *CTRL_MODULE_CORE Registers*

For more information on the interface between PCIe_SS controller and PCIe_PHY, see Section 26.4.4.1, *PCIe Shared PHY Subsystem Block Diagram*, and Section 26.4.4, *PCIe Shared PHY Subsystem Functional Descriptions* in Section 26.4, *PCIe Shared PHY Subsystem*.

24.9.3 PCIe Controllers Integration

This section describes the PCIe controllers integration in the device, including information about clocks, resets, and hardware requests. Figure 24-160 shows the PCIe controllers integration.

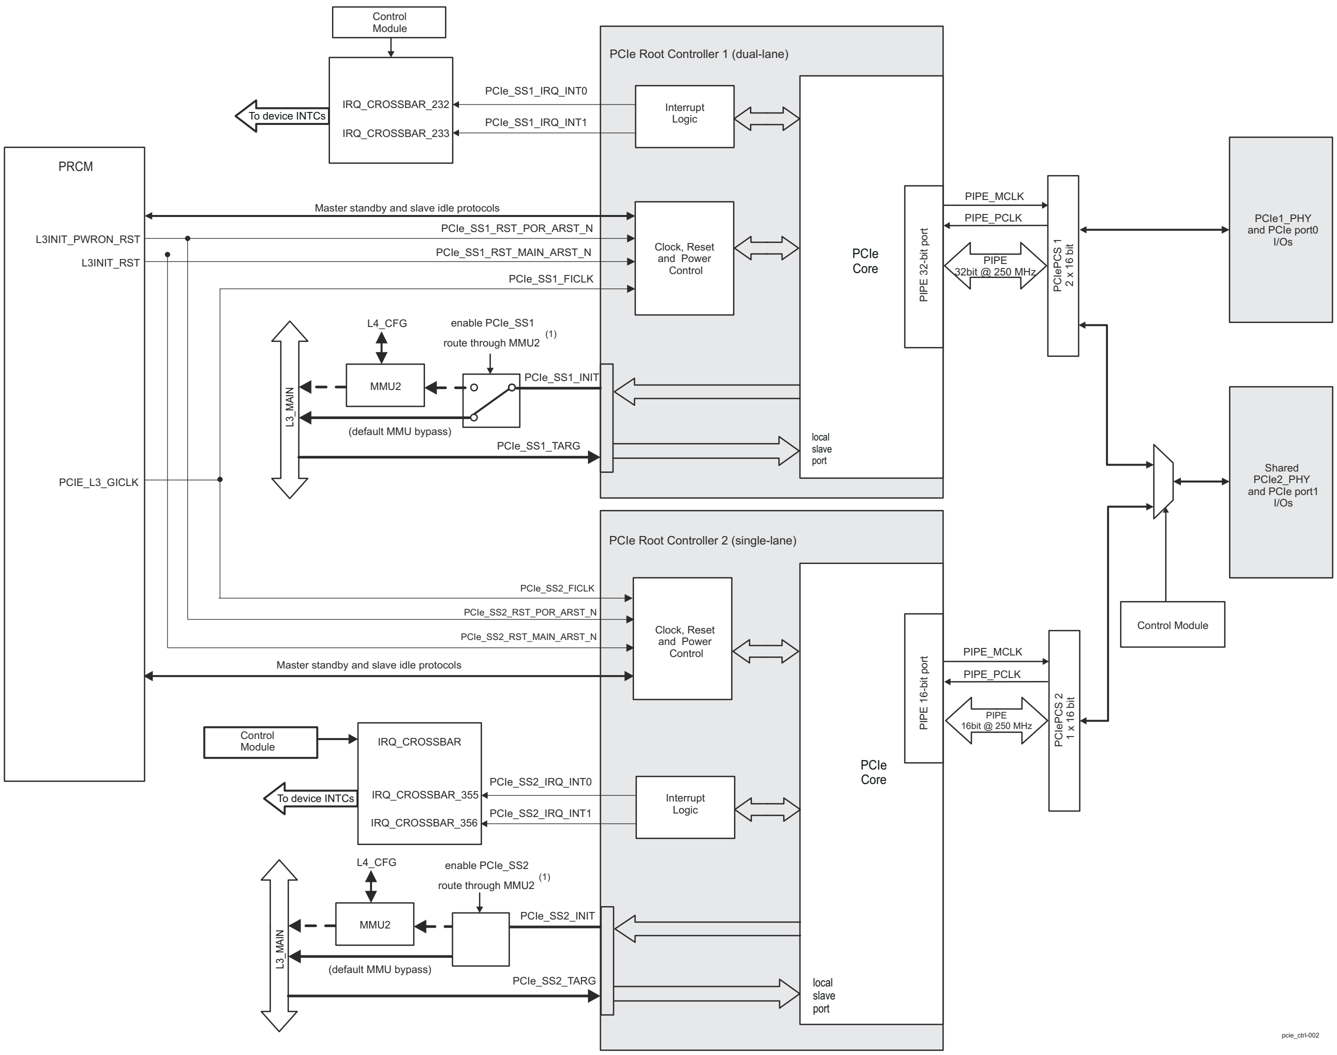

Figure 24-160. PCIe Controllers Integration

Note

By default, the traffic from the PCIe_SS1 and PCIe_SS2 controller master (initiator) port - PCIe_SS1_INIT/PCIe_SS2_INIT to the L3_MAIN interconnect, bypasses the device MMU2. Mapping the PCIe traffic from the PCIe master port to MMU2 on the L3_MAIN path is enabled via a bit in the device Core Control Module. For more details, refer to the Section 24.9.4.3.1.1.

PCIe controller integration includes these features:

- A single interface/functional clock (PCIe_SS_FICLK, shared between the master and the slave interfaces)
- A couple of functional clocks:
  - A PCIE controller clock input which receives the PIPE_PCLK generated by the assocaited PCIe PHY PCS logic
  - A PCIE controller clock output PIPE_MCLK which mirrors PIPE_PCLK back to the PCIe PHY PCS component

- Two hardware non-retention resets - PCIe_SS_RST_POR_ARST_N and PCIe_SS_RST_MAIN_ARST_N by PRCM
- Master standby and slave idle protocols with the power, reset, and clock management (PRCM) module
- Two interrupt request lines (per each PCIe controller):
  - PCIe_SS1_IRQ_INT0/PCIe_SS2_IRQ_INT0 - a main interrupt line
  - PCIe_SS1_IRQ_INT1/PCIe_SS2_IRQ_INT1 - a MSI interrupt line
- No DMA requests generation to surrounding modules
- One 64-bit data/32-bit address master port on the L3_MAIN interconnect (with an option to pass the PCIe initiator traffic to L3_MAIN through device MMU2). For details, refer to the Section 24.9.4.3.
- One 64-bit data/29-bit address slave port on the L3_MAIN interconnect (No MMU included on the slave address path). For details, refer to the Section 24.9.4.3.

For more details on the MMU2 integration in the device, refer to the Section 20.2, *MMU Integration* of the Chapter 20, *Memory Management Units*.

Note

For more information about the slave idle protocol and the wakeup request, see *Module-Level Clock Management* in *Power, Reset, and Clock Management*.

Table 24-496 through Table 24-498 summarize the integration of the module in the device.

Table 24-496. PCIe Controllers Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
PCIe_SS1	PD_L3INIT	L3_MAIN
PCIe_SS2	PD_L3INIT	L3_MAIN

Table 24-497. PCIe Controllers Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
PCIe_SS1	PCIe_SS1_FICLK	PCIE_L3_GICLK	PRCM	PCIe_SS1 root controller interface and functional clock (shared between slave and master ports)
PCIe_SS2	PCIe_SS2_FICLK	PCIE_L3_GICLK	PRCM	PCIe_SS2 root controller interface and functional clock (shared between slave and master ports)
Resets				
PCIe_SS1	PCIe_SS1_RST_POR_ARST_N	L3INIT_PWRON_RST	PRCM	A nonretention hardware power-on reset to the PCIe_SS1 controller
	PCIe_SS1_RST_MAIN_ARST_N	L3INIT_RST	PRCM	A nonretention hardware main reset to the PCIe_SS1 controller
PCIe_SS2	PCIe_SS2_RST_POR_ARST_N	L3INIT_PWRON_RST	PRCM	A non-retention hardware power-on reset to the PCIe_SS2 controller

Table 24-498. PCIe Controllers Hardware Requests (continued)

Interrupt Requests				
Module Instance	**IRQ Source Name**	**IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
	PCIe_SS1_IRQ_INT1	IRQ_CROSSBAR_233	N/A	PCIe_SS1 controller MSI interrupt request.
PCIe_SS2	PCIe_SS2_IRQ_INT0	IRQ_CROSSBAR_355	N/A	PCIe_SS2 controller main interrupt request
	PCIe_SS2_IRQ_INT1	IRQ_CROSSBAR_356	N/A	PCIe_SS2 controller MSI interrupt request.

Note

The **Default Mapping** column in Table 24-498, *PCIe Controller Hardware Requests* shows the default mapping of the IRQ sources listed in column **IRQ Source Name** to a certain interrupt line of one of the device interrupt controllers. These IRQ sources can also be mapped to other interrupt lines of each device interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*. For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

No DMA requests are generated by the PCIe controller to the surrounding modules.

For more details on interrupt request management at the PCIe subsystem local level, refer to the Section 24.9.4.6, *PCIe Controller Interrupt Requests*.

24.9.4 PCIe SS Controller Functional Description

24.9.4.1 PCIe Controller Functional Block Diagram

This section describes how the overall PCI express functionality is implemented by the current controller, both as EP and as RC, and how each type of traffic is transmitted and received.

The PCI express interface allows memory-mapped read and write transactions to be performed across different partners of the same PCIe fabric. Locally the device local PCIe system is composed of the PCIe_SS controller itself, device local hosts (such as MPU, DSP, and so forth), device DMAs (EDMA, and so forth) and device system memory (EMIFs SDRAM), connected to the PCIe controller via L3_MAIN interconnect.

Figure 24-161 summarizes the functional components of the PCIe_SS controller, as well as the connectivity between PCIe_SS and other components (MMU2, IRQ_CROSBBAR, PRCM, and so forth) within the device.

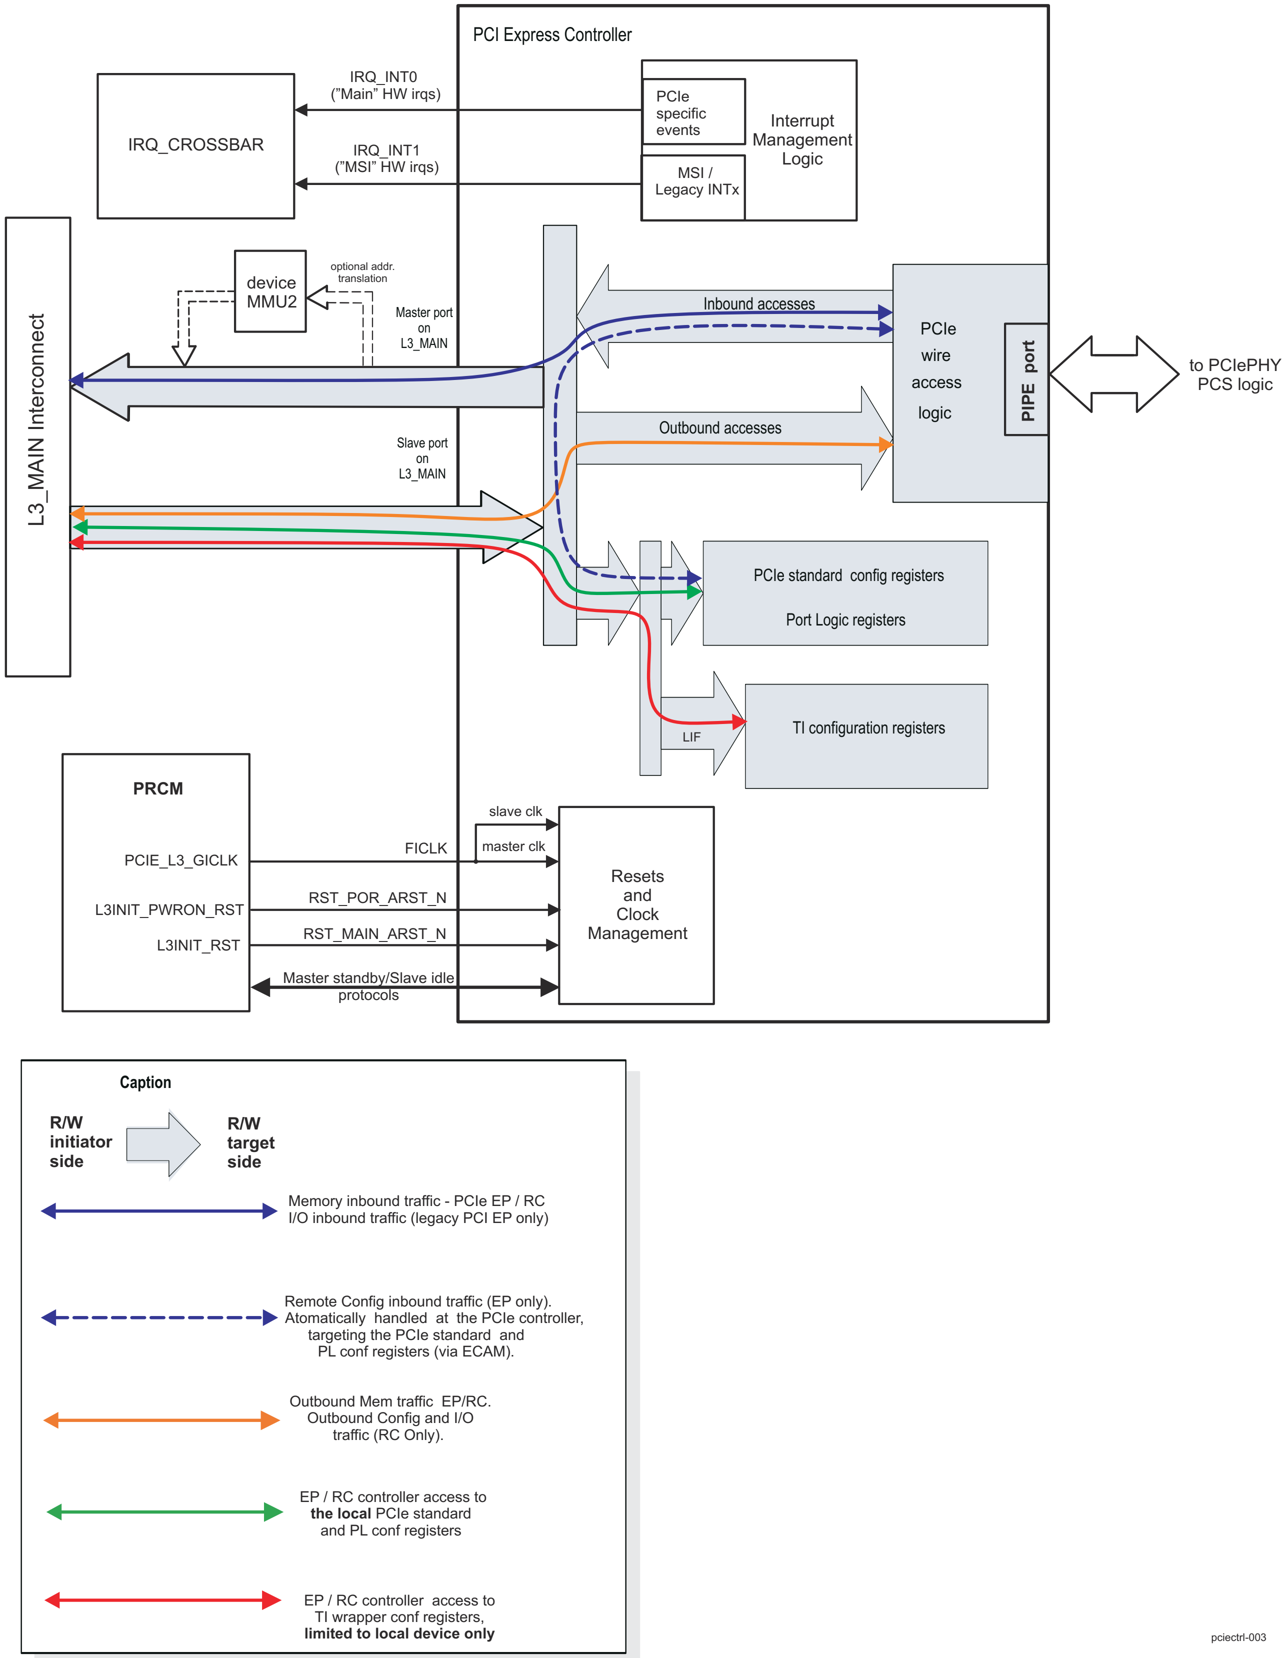

Figure 24-161. PCIe Controller Functional Block Diagram

24.9.4.2 PCIe Traffics

Most of the accesses (Memory-space) are typically flowing straight through the controller, from PCIe bus to L3_MAIN or the other way. However, some transactions are accesses to the PCIe device's configuration registers:

- The source of those accesses is either the local running application, through the PCIe slave port, or a distant PCIe device on the bus, as an inbound transaction from the PCIe wire. Access may or may not be possible depending on the mode of operation (see also transfer descriptions on the Figure 24-161).
- The destination of those accesses is either the PCIe controller core, for the PCIe-standard configuration registers and the non-standard port logic (PL) registers, or the TI wrapper configuration registers accessed over the local interface (LIF).

Figure 24-161 also gives a simplified view of the accesses allowed by device PCIe controller.

On the right hand side of the diagram is the PCIe_PHY (PCS+PMA), itself connected to the PCIe wires. The same structure is expected in the link partner on the other side of the link. Each partner can initiate and complete transactions on the link, using a packet-based protocol. Each lane is a full-duplex serial channel, that is, packets can be exchanged in both directions simultaneously. When more than one lane is used, each packet is transmitted in parallel over all active lanes.

The bidirectional accesses, initiated from components on the PCIe bus (fabric) to/from the device local PCIe subsystem are identified as *Inbound traffic*, while the bidirectional accesses, initiated by device local PCIe system to/from the PCIe bus are identified as *Outbound traffic*.

Note that there are two ways to transmit data from the local PCIe system to a distant PCIe partner:

- **Outbound write accesses**, locally initiated by, for example, a local DMA accessing controller through the PCIe slave port, connected on L3_MAIN, to push data towards a distant PCIe partner.
- **Inbound read accesses**, remotely initiated by, for example, a distant DMA though the PCIe wire, and issued on the PCIe master port, connected on L3_MAIN, to fetch data from the local memory.

Likewise, there are two ways for the local PCIe system to receive data from a distant PCIe partner:

- **Outbound read accesses**, locally initiated by, for example, a local DMA accessing the PCIe slave port, connected on L3_MAIN, to fetch data from a distant PCIe partner.
- **Inbound write accesses**, remotely initiated by, for example, a distant DMA though the PCIe wire, and issued on the PCIe master port towards the local system memory.

Note

Inbound PCIe I/O transfers are supported by the PCIe controller only in EP mode (typically for legacy PCI - EPs).

24.9.4.3 PCIe Controller Ports on L3_MAIN Interconnect

The PCIe controller to L3_MAIN connectivity is illustrated, on the left-hand side of the Figure 24-161. Read/write accesses from external PCIe components to the device local system memory on L3_MAIN are performed through the PCIe_SS master (initiator) port - PCIe_SS_INIT. The addresses issued on this port are by default directly routed to the L3_MAIN, but they can be optionally routed to and further translated by the device memory management unit - MMU2 before they reach the L3_MAIN target. For more details on MMU port, refer to Section 24.9.4.3.1.1.

On the other hand, the device local hosts (MPU, DSP, and so forth) initiate accesses to the PCIe controller local registers and PCIe bus remote devices via a PCIe_SS slave (target) port - PCIe_SS_TARG on the L3_MAIN. No MMU is included on the slave path. The slave interface has two uses: manage the local PCIe controller, and carry outbound PCIe traffic, that is initiated locally by PCIe hosts (MPU, DSP, DMAs, and so forth) within the device.

24.9.4.3.1 PCIe Controller Master Port

The PCIe controller master port (using AXI protocol with an adapter to the device L3_MAIN interconnect) has the following key fetures:

- 64-bit data, 32-bit address bus width
- Up to 16 simultaneous outstanding transactions, on up to 16 different IDs (4-bit ID port) total for read and write ports together, as follows:
  – Posted incoming PCIe transactions are all mapped to AXI ID 0, which ensures that they are executed in order. This includes all high-bandwidth writes, which are memory-type - posted.
  – Non-posted incoming PCIe transactions are mapped to AXI ID 1 and above. This includes the high-bandwidth memory-type reads.
- uses the same clock source as the PCIe slave port, but potentially on a different divider ratio
- PCIe master port, does not use a disconnect interface, because unlike the PCIe slave port, it is expected to be always active when the PCIe controller has to initiate a transaction over the device L3_MAIN.
- The PCIe controller maximum inbound payload size is 256 Bytes. The PCIe master port burst maximum length is 16 words (16 x 64-bit data words = 128 Bytes per burst). Hence a 256 Byte inbound data payload is converted by the PCIe master port to 2 max-sized bursts (128 Byte each) towards the device L3_MAIN interconnect PCIe slave port which is 128 Byte-burst compatible.
- Only incremental bursts (INCR) are supported by the PCIe controller master port.
- Non-aligned bursts can be generated - bursts that are not aligned with their own size: a burst-aligned portion of 2^N-bytes aligned burst starts on a byte address multiple of 2^N, that is a byte address with the N LSBs at '0').

The PCIe memory space supports a 64-bit address mode but in the device PCIe controller, the AXI master port address size is restricted to 32 bits.

Note

A PCIe controller remains fully functional, and able to receive transactions from , for example, anywhere within the 64-bit PCIe memory space, as long as they are correctly remapped by the inbound address translation unit (ATU) to a 32-bit L3_MAIN space address (device L3_MAIN 4 GiB - memory space). The limitation is that the range addressable by the PCIe master is reduced, and that regions larger than 2^{32} bytes (4GiB) total, cannot be mapped to the AXI master port on L3_MAIN.

24.9.4.3.1.1 PCIe Controller Master Port to MMU Routing

A standalone MMU2 module is included at the system level, primarily for use by the PCIe_SS1 and PCIe_SS2 controller. This provides several benefits including protection of the MPU host memory regions from corruption by PCIe_SS1 and PCIe_SS2 accidental accesses.

PCIe controller initiated (by remote side) traffic can be optionally routed through the MMU2 as controlled by a Control Core Module register bit. The PCIe_SS1 and PCIe_SS2 routing allows these sub-systems to be used to perform transfers.

Note

By default, the CTRL_MODULE_CORE instance located CTRL_CORE_CONTROL_IO_1[20] MMU2_DISABLE bit is set to 0b0 and the MMU2 is functionally enabled. Despite this, the PCIe_SS1 and PCIe_SS2 controller traffic still bypasses this MMU.
In order, for PCIe_SS1 and PCIe_SS2 master traffic
to be routed through the MMU2, the CTRL_MODULE_CORE
bits: CTRL_CORE_SMA_software_7[13] PCIE_SS1_MMU_ROUTE_ENABLE and
CTRL_CORE_SMA_software_7[12] PCIE_SS2_MMU_ROUTE_ENABLE, must be set to 0b1 by user software.

Accesses are directed to the MMU2 by the L3_MAIN switch fabric through the use of a 33-rd address bit. For the PCIe_SS1 and PCIe_SS2 master port, the value of the 33rd bit is actually defined by the above mentioned control module CTRL_CORE_SMA_software_7 register bits. For descriptions of the CTRL_CORE_SMA_software_7 register bitfields related to MMU2 route controls, refer to the *Control Module Register Manual*, in the chapter, *Control Module*.

For more information on device MMU2 functionality and register settings, refer to the *MMU Functional Description* and *MMU Register Manual*, in the chapter, *Memory Management Units*, respectively.

24.9.4.3.2 PCIe Controller Slave Port

The PCIe controller slave port gives access to two internal targets: the local target, to manage the local controller, and the outbound window, which forwards accesses onto the PCIe wire.

The PCIe slave port (using AXI protocol with an adapter to the device L3_MAIN interconnect) has the following key features:

- **64-bit data, 29-bit address** bus width
- Up to 16 simultaneous outstanding transactions, up to 16 different IDs (4-bit ID port).
- Uses the same clock source as the PCIe controller master port, but potentially on a different divider ratio.
- Supports L3_MAIN disconnect protocol
- Exclusive and locked accesses are not supported for read and write port

PCIe Controller slave port purposes are:

- **Configuration and management of the PCIe controller:**
  - This low-bandwidth activity accesses the device PCIe controller local configuration/status registers, the Port Logic registers and the PCIe controller wrapper TI-specific registers.
  - The L3_MAIN base address corresponding to the PCIe_SS1 controller local configuration/status registers (DIF access targets) is 0x5100_0000. For the PCIe_SS2 controller local configuration/status registers (DIF access targets), the L3_MAIN base address is 0x5180_0000.
  - Bursts are not supported when accessing these registers.
- **Outbound PCIe traffic**:
  - This activity can consume the entire bandwidth available on the PCIe wires (up to 1 Gbyte/s in each direction for 2-lane, Gen2 operation), in concurrence with the AXI master ports' operation (that carries inbound PCIe traffic).
  - PCIe controller maximum outbound payload size is 64 Bytes (the L3 Interconnect PCIe1/2 target ports split bursts of size > 64 Bytes to the into multiple 64 Byte bursts). Only bursts of incremental type (INCR) are supported on the PCIe controller slave port.
  - Non-aligned bursts can be generated.
  - All outbound traffic activities are mapped within a device L3_MAIN space region which is 256 MiB in size.
  - For the PCIe_SS1 controller the PCIe outbound window is mapped within range 0x2000_0000 - 0x2FFF_FFFF of the device L3_MAIN memory space. For the PCIe_SS2 controller the PCIe outbound window is mapped within range 0x3000_0000 - 0x3FFF_FFFF (256 MiB) of the device L3_MAIN memory space.

Note

The PCIe controller remains fully functional, and able to send transactions to, for example, anywhere within the 64-bit PCIe memory space, with the appropriate remapping of the 28-bit address by the outbound address translation unit (iATU). The limitation is that the total size of addressed PCIe regions (in config, memory, IO spaces) must be less than 2^{28} bytes.

24.9.4.3.3

Note

Because only incremental burst mode is supported, the PCIe addresses can not be in a cacheable memory space. Subsequently, cache coherence protocol is not involved, and the PCIe controller is not expected to receive coherent PCIe TLPs (NS=0). For safety purpose, the PCIe controller coherent feature must be permanently disabled (and this applies for the device by default) by keeping PCIECTRL_TI_CONF_SYSCONFIG[16] MCOHERENT_EN at value 0b0. In that case, inbound coherent PCIe TLPs (that means with NS=0) proceed normally, but coherence will not be guaranteed by the device.

24.9.4.4 PCIe Controller Reset Management

The PCIe controller has two hardware reset inputs - a hardware **main** and **fundamental** resets which are asynchronous and active low.

In addition, a number of internal reset conditions can cause some sections of the controller to reset, depending on the power transitions and configuration. All reset conditions and categories are described below.

24.9.4.4.1 PCIe Reset Types and Stickiness

Three types of reset conditions are defined by the PCI standard. Each reset condition listed below falls into one of these categories. The same reset condition can take different types depending on the usecase:
- Cold reset condition: upon device power-up.
- Warm reset condition: does not follow a device power-up.
- Hot reset condition: transmitted over the PCIe link.

A reset including the physical layer (PCIe_PHY) is **called a fundamental reset**. According to the PCI Express Base 3.0 Specification, revision 1.0, it clears the programming registers non-sticky bits, and may clear or may not clear the sticky bits as well, depending on a Vaux power supply. If Vaux integrated in a PCIe subsystem, it is enabled via PM specific sticky bits - PM_CSR[8] PME_EN and DEV_CAS[10] AUXPM_EN register bits.

CAUTION

No Vaux power supply source is defined in hardware for the device integrated PCIe_SS. Subsequently, all PCIe bits defined by the PCIe standard or device specific implementation as "sticky", are reset along with the "non-sticky" bits upon a PCIe fundamental reset assertion. Because it is mandatory to communicate the permanent Vaux absence to the device PCIe EP/RC controller, the EP/RC DEV_CAS[10] AUXPM_EN (or PM_CSR[8] PM_EN) and PCIECTRL_TI_CONF_PM_CTRL [11] AUX_PWR_DET bits have to be always software written ‘0’ during initialization.

A function-level reset (FLR) impacts only one of the EP device’s functions.

Note

The device PCIe controller supports only a single function, so it does not support FLR.

24.9.4.4.2 PCIe Reset Conditions

24.9.4.4.2.1 PCIe Main Reset

Main hardware reset: Assertion of the reset signal on the main hardware reset input of the PCIe subsystem unconditionally brings the entire PCIe controller back to its default state. The main HW reset impacts both non-sticky and sticky bits of the PCIe controller.

Note

The PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE (RC/EP) bitfield and the remaining TI wrapper configuration registers (PCIe_SS_TI_CONF) are sensitive to main hardware reset only.

24.9.4.4.2.1.1 PCIe Subsystem Cold Main Reset Source

The cold main reset has as a source - the device PRCM L3INIT_PWRON_RST power-on reset. For more information on the PCIe controller hardware reset inputs see Section 24.9.3, *PCIe Controller Integration*).

The L3INIT_PWRON_RST assertion by PRCM resets all PCIe controller registers including the TI wrapper configuration registers (note that the PCIe device type in the PCIECTRL_TI_CONF_DEVICE_TYPE register is reset by default to "Root Complex").

For more information on the PRCM.L3INIT_PWRON_RST hardware reset, refer to *Reset Domains*, in *Power, Reset, and Clock Management*.

24.9.4.4.2.1.2 PCIe Subsystem Warm Main Reset Sources

The warm main reset of the PCIe controller is sourced by the device PRCM L3INIT_RST output. For more information on the PCIe controller hardware reset inputs see Section 24.9.3, *PCIe Controller Integration*). For more information on the PRCM.L3INIT_RST hardware reset, refer to *Reset Domains*, in *Power, Reset, and Clock Management*.

The L3INIT_RST main reset is tiggered from different warm reset sources within the PD_L3INIT power domain (global warm software reset, MPU watchdog reset, and so forth).

Software triggered main reset to PCIe controller : To the above group of PRCM warm main reset sources, there is also a software-triggered reset which can be asserted locally and independently to each of the PCIe_SS1 and PCIe_SS2 in the PD_L3INIT domain. The main software reset is triggered via assertion of bit:

- RM_PCIESS_RSTCTRL[0] RST_LOCAL_PCIE1 for the device PCIe_SS1 controller
- RM_PCIESS_RSTCTRL[1] RST_LOCAL_PCIE2 for the device PCIe_SS2 controller

The software (warm) reset completion triggered through device PRCM is flagged in the *Write-one to Clear* PRCM register:

- RM_PCIESS_RSTST[0] RST_LOCAL_PCIE1 for the device PCIe_SS1 controller
- RM_PCIESS_RSTST[1] RST_LOCAL_PCIE2 for the device PCIe_SS2 controller

The user software running on PCIe controller is supposed to clear the reset status bit upon reset completion event via writing 0b1 to RM_PCIESS_RSTST[0] RST_LOCAL_PCIE1 and RM_PCIESS_RSTST[1] RST_LOCAL_PCIE2 bit in PRCM.

For more details on above PCIe controller software reset bits, refer to the *PRCM Register Manual*, in the *Power, Reset and Clock Management*

Note

The warm main reset (icluding PCIe subsystem software reset) from PRCM impacts all PCIe core register bits (sticky and non-sticky) and the PCIe TI wrapper configuration registers (PCIe_SS_TI_CONF). Note that the PCIe device type in the PCIECTRL_TI_CONF_DEVICE_TYPE register is reset by default to "Root Complex".

For more details on sticky/non-sticky bits behaviour refer to the PCI Express Base 3.0 Specification, revision 1.0.

24.9.4.4.2.2 PCIe Standard Specific Resets to the PCIe Core Logic

Fundamental hardware reset - This reset impacts all non-sticky PCIe core bits. It is automatically triggered:

- upon a software initiated device type change in the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE (to RC/EP)

- upon exitting certain low-power modes
- upon PCIe controller's main power supply (Vmain) being powered-up or Vmain detected below a defined threshold by the PCIe RC. This is a cold fundamental reset.

Note

All (sticky and non-sticky bits) of the PCIe controller core are reset upon fundamental hardware reset assertion because of Vaux not implemented. Hereby all PCIe core registers have to be re-initialized from scratch after a PCIe fundamental reset.

Hardware fundamental reset operation: The hardware fundamental reset is an input to the PCIe core, to be controlled by the local PCIe software driver. Its impact is conditional: a fundamental reset clears the entire controller (including the PCIe_PHY part), with the following exceptions:

- DEVICE_TYPE register (unconditional) and all other PCIe_SS_TI_CONF registers
- PCIe link PM FSM, if the module is out of "IDLE"

The fundamental reset is applied to PCIe core in the following two cases :

- After reprogramming the device type (to EP or RC) in the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE bitfield, to latch in the new type and clear the programming registers. Remain out of idle and clear PCIECTRL_TI_CONF_PM_CTRL[11] AUX_PWR_DET to 0 beforehand, in order to reset also the sticky bits.
- L3 exit at initial power-up unless the restart is already initiated by the other side of the link

---

Note

The TYPE value ("EP", "legacy EP" or "RC") has to be read back by software until desired type-value is seen. This insures that the fundamental reset triggered by "TYPE" change has completed successfully. The user software must not change the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE register value during PCIe core operation.

Note

The fundamental hardware reset does not impact the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE (RC/EP) bitfield and the remaining TI wrapper configuration registers (PCIe_SS_TI_CONF). These can be reset only by a PCIe main reset input assertion.

PCIe link-down reset condition - When the PCIe link has gone down and goes up again, namely transitions from D3cold/L3 back to D0, the PCIe core auto-applies this **internal fundamental reset** and reports it on IRQ event (PCIECTRL_TI_CONF_IRQSTATUS_MAIN[11] LINK_REQ_RST) after link-up.

PCIe hot-reset condition - As defined by the PCIe standard: reset condition propagated in-band (over the PCIe wire) from an upstream port to a downstream port, using the TS1 and TS2 OS (see the PCI Express Base 3.0 Specification, revision 1.0). Requires the link to be already powered and up. The hot reset causes the link to go down and up again, causing a link-down reset condition, and as such is a fundamental reset.

The hot reset sequence can be tracked in the LTSSM by the transition to "hot reset" state, then on to "detect" and the rest of the link-up sequence.

- When RC, a hot reset is generated by writing the bit “Secondary Bus Reset” of the PCIe standard “Bridge Control Register” - BRIDGE_INT [22] SEC_BUS_RST bit .
- When EP, a host reset is automatically processed by the controller hardware.

PCIe soft reset condition - As defined by the PCIe standard: When the D-state of a device is changed from $D3_{hot}$ to D0 by software, namely by the RC doing a remote CFG write to the EP (EP) PM_CSR [1:0] PWR_STATE register, the EP device reacts depending on its DIF CS (local) setting of the no-soft-reset (NSR) bit (EP) PM_CSR [3] NSR:

- If bit NSR=0, the soft reset is applied, and the device transitions to the $D0_{unitialized}$ state (see Figure 24-162). Non-sticky bits are reset.
- If bit NSR=1, the soft reset is inhibited, the device transitions directly to the $D0_{active}$ state (see Figure 24-162), no reset is applied. Full context is retained, including non-sticky bits.

Note

The soft reset is a hot reset. The soft reset is not a fundamental reset; that means that it does not reset the PHY, only the programming registers.

24.9.4.5 PCIe Controller Power Management

This section is a brief summary of the supported power modes and power transitions, as well as the consequences (clock gating, power gating, resets, and so forth) on the PCIe controller.

24.9.4.5.1 PCIe Protocol Power Management

The power state of a PCIe controller port is described by four different FSMs, each running at a different level of the protocol, each with its own independent state. The FSMs are covered in Section 24.9.4.5.1.1 through Section 24.9.4.5.1.2.

Table 24-499summarizes the typical power stable state combinations, namely the combinations of states the controller can settle into, after a number of potential transitions and transient states, and assuming that the lowest power state possible is used.

The PCIe standard defined optional gating of the reference clock on PCIe_PHY PLL input (and therefore of the PIPE clock) when in L1-state is not supported. As shown in the Table 24-499, the PIPE clock is always running while link is in L1.

Table 24-499. Power States Summary

Device D-state	Link L-state	PHY LTSSM state	PIPE power down	PIPE clock(1)	Vmain	LP_CLK(4) (auxiliary clock)	Slave Idle	Master Standby
D0_uninitialized(2)	LDn	Detect	P1	OFF	don't care	ON	1	1
D0_uninitialized	L0	n/a	P0	ON	ON	ON	0	1
D0_active	L0	L0	P0	ON	ON	ON	0	0/1(3)
D0_active	L0s	L0s	P0s	ON	ON	ON	0	0/1(3)
D0_active	L1	L1	P1	ON	ON	ON	0	0/1(3)
D1	L1	L1	P1	ON	ON	ON	0	1
D2	L1	L1	P1	ON	ON	ON	0	1
D3_hot	L1	L1	P1	ON	ON	ON	0	1
D3_cold	L3	n/a	P2	OFF	OFF	OFF	1	1

(1) The PIPE clock activity, as visible from the PCIe core boundary, implies the activity of the high-speed PLL it is derived from, which implies the activity of the reference clock on the PLL input.
(2) Default controller state after reset. Not a real PCIe state.
(3) Master standby value depends on the PCI express application (MSE, ISE, and so forth)
(4) See Section 24.9.4.5.2

24.9.4.5.1.1 PCIe Device/function power state (D-state)

The function power state machine is the highest-level PM FSM in a PCIe device. The power state control bitfield is part of standard PCIe register bitfield- (EP)PM_CSR/(RC)PM_CSR [1:0] PWR_STATE.

Note

A Vaux power source is not tied to the PCIe core, that is why the state D3_cold with Vaux switched-on is unsupported by the PCIe PM FSM.

Note

The six available D-states are, by order of decreasing power: D0_uninitialized (default), D0_active, D1, D2, D3_hot, D3_cold. Note that the function power state Cfg field - is only 2 bit, encoding only 4 combinations: D0, D1, D2, D3. The difference between uninitialized and active (D0), and between hot and cold (D3) is implicit.

The eventual (“stable” or “quiescent”) power state of a PCIe link (link state) is determined by the D-state of the downstream device. For the current controller, it means that the D-state determines the link state in EP type mode, but not in RC type mode.

Note also that the device may go through a number of transient link states before entering/after exiting its quiescent link state, so that a device, for example, in D3_hot may be consuming maximum instantaneous power .

D0_uninitialized is the function’s default state, entered after powerup and/or reset. It is used by the RC software to enumerate the function (Cfg transactions). Mem and IO transaction are disabled. It can only be entered though a reset, partial or total. Together with D0_active, it is the highest-power D-state.

D0_active is the function’s active state, where all Memory and I/O transactions take place. By definition, a function transitions from D0_uninitialized to D0_active after the RC software enables Memory and I/O transactions, either as completer ("Cfg" write 0b1 to memory space enable: MSE/IO space enable: ISE) or as requester ("Cfg" write 1 to bus master enable: BME). D0_active can be exited to/entered from D1, D2, or D3_hot by the RC software writing to the function’s (EP)PM_CSR[1:0] PWR_STATE power state. Together with D0_uninitialized, it is the highest-power D-state.

D1 and D2 are two optional states, with reduced power compared to D0. Both operate the same way, and have the same action on lower-level PM FSM, with D1 expected to have a faster wakeup and D2 a lower power. Both are supported by the current controller. D1 and D2 can be exited to/entered from D0_active, D1, D2, or exited to D3_hot , by the RC software writing to the function’s (EP)PM_CSR[1:0] PWR_STATE power state bitfield. The current controller supports D1 and D2 but a fully compliant implementation also depends on the system providing the right combination of HW and software.

D3_hot is a lower-power state (compared to D0, D1, D2). It can be entered from D0_active, D1, or D2 by the RC software writing to the function’s (EP)PM_CSR[1:0] PWR_STATE. Transition to D3_hot is typically continued to D3_cold and main power (VMAIN) shutdown. It can also be exited to D0 by the RC writing (0b00) to the (EP)PM_CSR[1:0] PWR_STATE. The state transition to either D0_active or D0_uninitialized depends on the NSR value written in the bit (EP)PM_CSR[3] NSR (No_Soft_Reset bit) of 0b1 (that means - function is not reset) or 0b0 (that means - function is reset, link is restarted and must be reconfigured) respectively.

D3_cold is the lowest-power state, defined by the VMAIN being turned off. It it typically entered from D3_hot as shown in the figure below, but any turn-off request will actually place the function in that state. It can only be exited to D0_uninitialized, by restoring VMAIN and after resetting the function, totally or partially (see link states below).

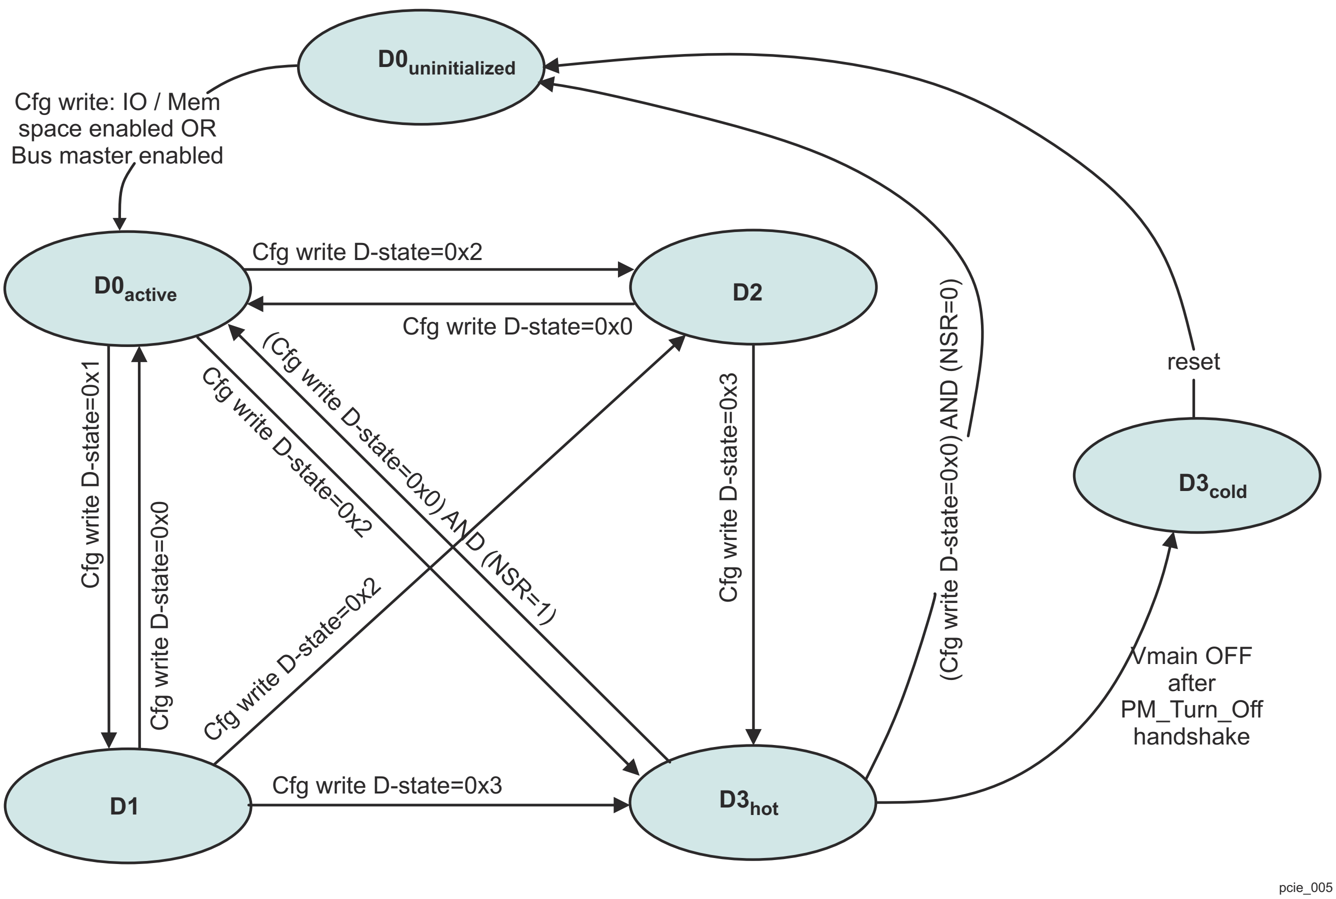

Figure 24-162. PCIe D-state (function power state) FSM diagram

The Figure 24-162 shows the state transitions in the power state. NSR is the “No_Soft_Reset” bit in the function’s (EP)PM_CSR configuration register. NSR advertizes the ability of the device to go into D3_hot while retaining its register settings (when 1), or conversely, the inability to do so and the reset of those setting upon D3_hot exit (when 0).

NSR is read-only to the RC software over Cfg accesses, but it can be set by the EP's local software over DIF (CS access) prior to enumeration. The controller shall apply the NSR to itself accordingly.

Most function power state transitions are done explicitly by the RC-side software writing into the EP function’s (EP)PM_CSR[1:0] PWR_STATE, over the PCIe wire. This is one of the two PM control mechanisms of PCIe, the other one being ASPM . The remaining function power state transitions are caused by resets.

The D-state of a device sets the link power state (L-state) for the PCIe link above. In other words, the L-state of a PCIe link (connecting an upstream device, closer to the RC, and a downstream device, closer to an EP) is set by the downstream device.

24.9.4.5.1.2 PCIe Controller PIPE Powerstate (Powerdown Control)

The PIPE interfaces the MAC, or controller, above PIPE in the protocol hierarchy and the PHY, or transceiver, below PIPE. The current controller implementation has a PIPE interface at its boundary.

> **CAUTION**
>
> The physical layer as defined by the PCIe standard extends into the PCIe MAC layer, to include, for example, the LTSSM, so that “physical layer” and PHY do not coincide, with the latter included in the former.

The PIPE interface has its own power state, driven by the PCIe controller towards PCIe_SS PHY on a 2-bit powerdown signal, depending on the PM state machines above. It has four states: P0, P0s, P1, P2:

- **P0 (pipe_powerdown = 0b00):** active state, for high-speed (HS) data transmission and reception. Used for L0 link state.
- **P0s (pipe_powerdown = 0b01):** active HS receiver, suspended transmitter. Used for L0s link state.
- **P1 (pipe_powerdown = 0b10):** Suspended HS receiver and transmitter, but PIPE clock still running.
- **P2 (pipe_powerdown = 0b11):** Suspended HS receiver and transmitter, PIPE clock stopped - asynchronous mode.

24.9.4.5.2 PCIE Controller Clocks Management

24.9.4.5.2.1 PCIe Clock Domains

The controller has two main clock domains: the L3_MAIN bridge (ports) and the PCIe core.

The L3_MAIN bridge runs on a single clock. That same clock is used to run both the PCIe controller master and slave ports. It can be divided, with independently ratios for master and slave. However, both sides are typically expected to run at the same speed, as both are capable of the same performance.

There is an auxiliary clock - LP_CLK which is a PCIe_SS internal low-power clock, used when pipe clock is stopped. It is assumed to be always available when the module is not idle.

The PCIe core runs on the PIPE clock whenever that clock is provided by the relevant PCIe_PHY. When the PCIe link is in a low-power state and the PIPE clock is not available, the core splits in two sub-domains:

- Most of the core stops
- A small “auxiliary” part of the core (which includes the configuration registers) switches to a low-power clock LP_CLK
- The two subdomains can still be considered synchronous despite their different clocking scheme, since they are either running on the same clock, or one of the subdomain clocks is stopped.

24.9.4.5.2.2 PCIe Controller Idle/Standby Clock Management Interfaces

A PCIe controller has two clock management (CM) interfaces with device PRCM:

- A master port clock management interface based on master standby protocol with the device PRCM
- A slave port clock management interface based on slave idle protocol with the device PRCM

The PCIe wrapper logic located register PCIECTRL_TI_CONF_SYSCONFIG[3:2] IDLEMODE and PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE bitfields are used to software configure the idle / standby CM behaviour locally for the PCIe_SS controller. The Table 24-500, shows the available CM options.

Table 24-500. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	PCIECTRL_TI_CONF_SYSCONFIG [3:2] IDLEMODE bit field	The available modes are: Force-Idle, No-Idle, wakeup-disabled Smart-Idle and wakeup-capable Smart-Idle.
Master standby modes	PCIECTRL_TI_CONF_SYSCONFIG [5:4] STANDBYMODE bit field	The available modes are: Force-Standby, No-Standby, wakeup-disabled Smart-Standby and wakeup-capable Smart-Standby.

For more information on the PCIeSS functional clock gating in the device PRCM (clock PCIE_L3_GICLK), refer to *Clock Domain-Level Clock Management*, in the chapter, *Power, Reset and Clock Management*.

The relations between the PCIeSS master (standby)/slave (idle) behaviour to various PCIe protocol link power management features are covered in the Section 24.9.4.5.2.2.1 and Section 24.9.4.5.2.2.2, respectively.

24.9.4.5.2.2.1 PCIe Controller Master Standby Behavior

As a master (initiator) on the device L3_MAIN interconnect, the PCIe controller supports the standby protocol over the standard three signals: mstandby/mwait/mwakeup. The behavior of that interface can be configured in the PCIeSS controller wrapper (PCIe_SS_TI_CONF) register - PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE bitfield.

The standby protocol notifies the local system if inbound PCIe transactions are likely to be routed to the controller's master port.

Note

Note that CFG-type transactions are typically not part of the PCIe controller master port transfers: in RC mode they are only outbound, and in EP mode they are processed inside the controller.

Automatic mode (default): most operations are expected to take place in "smart-standby" mode. In that mode, the master standby interface is automatically managed by the PCIe status, featuring (Mstandby = 0) if (D-state=$D0_{active}$ and MSE=1 that is bit (RC) STATUS_COMMAND_REGISTER/(EP) STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN) :

- D-state = D0_active indicates that the link is up, that data can be exchanged. It's also a condition for memory-type transactions to take place.
- The Memory Space Enable bit (RC) STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN, indicating that the RC has enumerated the PCIe fabric and configured the memory space for operation, before EP writing the MSE bit in the local CFG register - (EP) STATUS_COMMAND_REGISTER via DIF CS access.

In automatic (smart-standby) mode, the standby is therefore controlled remotely by the RC software, which sets both the D-state and the MSE.

Note that the master does not go to standby during ASPM (so called active state power management) transitions to L0s or L1 on the link, as it remains in "D0_active" during that time. Although the physical layer is partially or fully stopped during L0s and L1, the short restart time of a few microseconds does not justify a transition to standby by the master. In other words, the master goes or doesn't go to standby after a link layer transition to L1, depending on the cause, if a transition in "D-state" or "ASPM" occured, respectively.

More generally, the link state is not directly correlated to the automatic standby state of the master:

- Master in standby (mstandby=1): link can be in L0 (link startup), L1 (D1, D2, D3hot), L3 (D3cold)
- Master out of standby (mstandby=0): link can be in L0, L0S/L1 (ASPM)

The "Mstandby" status depends on the possibility of transactions, not on actual transactions. The master may remain out of standby indefinitely without any transaction, and an incoming transaction shall not cause the master to exit standby. The latter is an error case which occurance is prevented in hardware.

The mwait=0 handshake, eventually returned after the mstandby=0 transition, should prevent the master from issuing transactions until the system is ready. However, no back-pressure can actually be applied to the PCIe to prevent inbound accesses after, for example, MSE has been set. It is assumed that there will be sufficient time for the mwait to transition, that is typically for the system to reopen the path to its local memory, before the first inbound transaction is routed to the master.

When the PCIe local controller itself is in RC mode, note that the D-state may remain D0active even after the has gone down. It is therefore advised to use the clearing of the local MSE bit to set the master in standby. Alternatively, the RC can be placed in D3hot mode, or the standby can be forced (to mstandby = 1) by setting the standbymode to "force-standby". Whatever the method, the RC is aware of the state of the entire PCIe fabric, and is expected to put its master in standby in full knowledge of the situation.

For more information on the PCIe Controller Standby Management Protocol with the device PRCM , see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

Manual control, EP type: When incoming transactions are not memory-type (e.g.: IO type), the master is capable of issuing transactions while the automatic out-of-standby conditions above are not met.

Note

In the EP, non-memory type transaction cases, it is the user software responsibility to manually force the master out of standby via setting the bit PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE = 0x1, that means - "No-Standby", before the first transaction, and to return it to automatic mode via setting PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE = 0x2, that means - "Smart-Standby" after the last transaction.

For instance, an EP shall have to monitor the ISE (IO space enable) bit and the link status, and set the PCIECTRL_TI_CONF_SYSCONFIG [5:4] STANDBYMODE bitfield accordingly if EP is configured to have an IO BAR.

24.9.4.5.2.2.2 PCIe Controller Slave Idle/Disconnect Behavior

As a target of the device L3_MAIN bus (with target being the PCIe controller slave port on L3_MAIN respectively), the controller supports the "Idle" protocol. The behaviour of that interface can be configured in the PCIeSS controller wrapper register - PCIECTRL_TI_CONF_SYSCONFIG[3:2] IDLEMODE bitfield.

Additionally, the slave port clock management supports a disconnect protocol which is controlled automatically.

The idle transition of the PCIe controller is strictly synchronized to PIPE clock. The PRCM places the PCIe controller to an "Idle state" before PCIePCS generated PIPE clock is stopped due to some reason: g.h. PCIe PHY low power transition with gating local PLL clocks, the APLL_PCIe clock or gating PCIeREF_DPLL clock. The IDLE state is automatically maintained by PRCM during periods in which PIPE clock is stopped.

PCIe controller transitions to IDLE initiated by the system PRCM are strictly synchronized with the PCIe operational state. The PRCM allows the PCIe controller to be brought out of "IDLE" state, only if the generation of the PIPE clock is enabled by configuring the high-frequency PLL (source of the PIPE clock) and the 100 MHz PCIe reference clock scheme (source of the high-frequency clock). For more details on the PCIe PLL and PHY related clocks, refer to the Section 26.4, *PCIe Shared PHY Susbsystem* in the chapter, *Shared PHY Component Subsystems* .

CAUTION

All accesses to the device PCIe controller on its slave port, namely to the local target configuration PL/PCIe standard/wrapper registers or to the PCIe bus, require the PIPE clock to be running. The presence of the PCIe interface clock - PCIE_L3_GICLK is not sufficient to perform such accesses.

24.9.4.5.2.2.2.1 PCIe Controller Idle Sequence During D3cold/L3 State

When the link of a RC enters L3 mode, the PIPE interface must go to P2 mode for power saving. The PCIe controller maintains the PIPE interface in P1 mode (PIPE clock running) and the internal registers accessible until the system requests entry into "Idle", and only then transition to P2: it is the device PRCM responsibility to Idle the module (PCIECTRL_TI_CONF_SYSCONFIG [3:2] IDLEMODE set to 0x2 - *Smart Idle mode* should be selected), in order to reach a low-power state. Transitioning to "P2", stops the PIPE clock and makes the register inaccessible, which in turn corresponds to an "IDLED" and disconnected from L3_MAIN PCIe slave port.

Note

The "L3" state can only be exited when the RC re-enabling the Vmain power supply, and reconfiguring all PCIe registers from scratch: In both EP and RC cases, the system should detect Vmain power assertion, apply a fundamental reset, then bring the module out of "IDLE" and restart the link normally. All registers are reset.

24.9.4.6 PCIe Controller Interrupt Requests

In the rest of this section, and for clarity:

- "**Interrupts**" refer by default to the virtual interrupt lines emulated by the PCIe protocol using either the PCI legacy or PCIe Message-Signaled Interrupts (MSI) methods, and used for non-PCIe purposes by the system.
- "**Hardware interrupts**" refer to the actual interrupt signals coming out of the current PCIe controller, and used to manage various events of the PCIe protocol, including PCI interrupts.

Each PCIe controller has two **hardware interrupt lines** described in Table 24-501 and Table 24-503, which are level-sensitive. PCIe pulse interrupts are unsupported in the device.

The main HW interrupt line - PCIe_SS1_IRQ_INT0/PCIe_SS2_IRQ_INT0 receives all interrupt events related to the control of the PCIe operation, including power management and errors.

The MSI HW interrupt line - PCIe_SS1_IRQ_INT1/PCIe_SS2_IRQ_INT1 receives all interrupt events propagated by a remote EP over the PCIe interface, for specific (non-PCIe) applicative purposes, in conjunction with the PCIe transactions. This includes the legacy interrupts (INTx) as well as the Message Signaled Interrupts (MSI) proper, as defined by the PCIe standard.

Note

MSI-X is unsupported by PCIe controller.

The difference between the two hardware interrupt types - "main" and "MSI" is that the main interrupt events are used by the PCIe interface, whereas the MSI interrupt uses the PCIe interface.

Note

Incoming MSI events only exist in RC mode when MSI events are received over the PCIe wire. In EP mode, other mechanisms allow controller to generate (transmit) of the same type of interrupt events onto the PCIe bus.

The main interrupt events are further divided into PCI management and error events. The MSI interrupts are divided into legacy and MSI proper. Each of these four categories of events is described in Section 24.9.4.6.1 and Section 24.9.4.6.2.2.

24.9.4.6.1 PCIe Controller Main Hardware Management

24.9.4.6.1.1 PCIe Management Interrupt Events

The events described here trigger the main interrupt line. Each status bit is set to one by a specific PCIe event, and must be cleared by the local SW.

CFG_MSE_EVT: (EP mode) PCIe controller’s Memory Space Enable (MSE) config bit has been set by the RC software - written to 1 by a configuration write. This notifies the local EP that incoming memory-type PCIe transactions may now target the local function, over the AXI master port.

CFG_BME_EVT: (EP mode) PCIe controller’s Bus Master Enable (BME) config bit has been set by the RC software - written to 1 by a configuration write. This allows the local EP to initiate (outgoing) PCIe transactions, over the AXI slave’s outbound window.

LINK_UP_EVT: Link layer has successfully booted and reached L0active state. Data can be transmitted and received over the PCIe wire.

LINK_REQ_RST: Link-down reset was triggered (by link-down condition). Non-sticky bits have been reset.

PM_PME: (RC mode) PCIe controller has received a power management event PM message on its PCIe downstream port, requesting wakeup.

PME_TO_ACK: (RC mode) PCIe controller has received a Turn-Off Acknowledge PM message on its PCIe downstream port, acknowledging a previously transmitted turnoff message (PME_Turn_Off).

PME_TURN_OFF: (EP mode) PCIe controller has received a Turn-Off PM message on its PCIe upstream port, requesting an acknowledge (PME_TO_Ack) and the transition of the link to L2/L3

24.9.4.6.1.2 PCIe Error Interrupt Events

The events described here trigger the main interrupt line.

ERR_COR: (RC mode) Correctable Error message received on PCIe downstream port.

ERR_NONFATAL: (RC mode) Uncorrectable Error message received on PCIe downstream port.

ERR_FATAL: (RC mode) Fatal Error message received on PCIe downstream port.

ERR_SYS: (RC mode) Either of the three error messages above (correctable, non-fatal, fatal) was reported and enabled in the root control register.

ERR_ECRC: End-to-end CRC error detected.

ERR_AXI: AXI slave error caused by response table overflow. This error is not supposed to happen.

24.9.4.6.1.3 Summary of PCIe Controller Main Hardware Interrupt Events

Table 24-501 describes the events, related to control of the PCIe interface operation itself, including power management, reset and error handling, that trigger the "main" hardware interrupt line.

Table 24-501. PCIe Main Hardware Interrupt Events Summary

Event Status and Clear	Interrupt Enable	Interrupt Disable	Mapping	Description
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[14] CFG_MSE_EVT	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[14] CFG_MSE_EVT_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[14] CFG_MSE_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	CFG "Memory Space Enable" change event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[13] CFG_BME_EVT	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[13] CFG_BME_EVT_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[13] CFG_BME_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	CFG "Bus Master Enable" change event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[12] LINK_UP_EVT	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[12] LINK_UP_EVT_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[12] LINK_UP_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Link-up state change" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[11] LINK_REQ_RST	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[11] LINK_REQ_RST_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[11] LINK_REQ_RST_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Link Request Reset" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[10] PM_PME	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[10] PM_PME_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[10] PM_PME_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Power Management PME message received" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[9] PM_TO_ACK	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[9] PM_TO_ACK_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[9] PM_TO_ACK_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Power Management acknowledge" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[8] PM_TURNOFF	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[8] PM_TURNOFF_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[8] PM_TURNOFF_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Power Management Turn-off" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[5] ERR_AER	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[5] ERR_AER_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[5] ERR_AER_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"ECRC Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[4] ERR_AXI	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[4] ERR_AXI_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[4] ERR_AXI_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"AXI tag lookup fatal error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[3] ERR_COR	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[3] ERR_CORR_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[3] ERR_CORR_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Correctable Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[2] ERR_NONFATAL	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[2] ERR_NONFATAL_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[2] ERR_NONFATAL_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Non-Fatal Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[1] ERR_FATAL	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[1] ERR_FATAL_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[1] ERR_FATAL_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Fatal Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[0] ERR_SYS	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[0] ERR_SYS_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[0] ERR_SYS_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"System Error" event

Note

While the PCIECTRL_TI_CONF_IRQSTATUS_MAIN register is updated only if corresponding interrupt is enabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN register, the PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN register always provides the Legacy/MSI event status regardless of an interrupt being enabled or disabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN register.

24.9.4.6.2 PCIe Controller Legacy and MSI Virtual Interrupts Management

The PCIe protocol uses TLPs to create "virtual" interrupt lines across the PCIe fabric. Interrupts do not constitute a separate transaction type like Mem, Cfg, I/O, and so forth, but reuse the existing types.

24.9.4.6.2.1 Legacy PCI Interrupts (INTx)

Legacy PCI interrupts are supported over PCIe by dedicated message codes (posted-write in Msg space) that flag the assertion or deassertion of one of four "virtual" interrupt lines (or pins): INTA, INTB, INTC, INTD. They can only be sent by EPs, and routed to/received by the RC.

PCIe controller supports single-function mode and can send only INTA when configured as EP.

Note

Use of legacy PCI interrupt is exclusive with use of MSI (defined in Section 24.9.4.6.2.1.2). MSI should be the preferred method whenever possible.

24.9.4.6.2.1.1 Legacy PCI Interrupt Events Overview

Legacy INTx (with x= A/B/C/D) are interrupt events inherited from PCI, where each was implemented on a physical bus wire. The RC can allocate each line to a given EP function, which is then allowed to assert/deassert that line (and only that line). PCI legacy interrupt events are mapped on the MSI interrupt line of PCIe controller. For more details, refer to Section 24.9.4.6.2.1.2 and Section 24.9.4.6.2.1.3.

The controller HW shall both set and clear the IRQ status bit according to the assert and deassert messages received over the PCIe wire, respectively. In other words, the legacy interrupt status bit do not need to be cleared by the local software after processing.

Typical legacy interrupt service routine (ISR) on the RC-configured PCIe controller is:

- Remote EP function transmits an "assert INTx" message. Value of x (within A/B/C/D) was previously assigned by the RC software using configuration accesses.
- "assert INTx" message is routed up the PCIe topology to the RC (local controller)
- PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit INTx goes to 1
- MSI interrupt line is asserted
- software reads PCIECTRL_TI_CONF_IRQSTATUS_MSI status register. The asserted bit (A,B,C,D) allows to determines the EP function that generated the event.
- software accesses this EP function over PCIe to process the interrupt: ad-hoc service routine
- As a result of the processing, remote EP function transmits the "deassert INTx" message
- software clears the PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit INTx to 0.
- MSI interrupt line is deasserted, assuming there is no other asserted event.

24.9.4.6.2.1.2 Legacy PCI Interrupt Transmission (EP mode only)

Writing 0b1 to TI wrapper register PCIECTRL_TI_CONF_INTX_ASSERT[0] ASSERT_F0 bit sends an ASSERT message on the "interrupt pin" specified in the config header space.

Writing 0b1 to TI wrapper register PCIECTRL_TI_CONF_INTX_DEASSERT[0] DEASSERT_F0 bit will send a DEASSERT message on the "interrupt pin" specified in the config header space.

A status of the virtual "interrupt line" is available by reading out either bitfield.

Note

This status is just a local record of the last message sent, it is not the result of any feedback from the PCIe fabric, since messages are posted, no response is generated. For that reason, the PCIe protocol does not guarantee the coherence between assertion and deassertion INTx messages, that means that it's up to the application to ensure that the INTx assertion has been seen by the RC before sending the deassertion, and vice versa.

CAUTION

The operations above should only be used when in EP mode, and will produce undefined results if applied to an RC-configured controller.

24.9.4.6.2.1.3 Legacy PCI Interrupt Reception (RC mode only)

The reception of either of the 8 INTX message codes (ASSERT/DEASSERT of INTA/B/C/D) shall assert/deassert the corresponding HW interrupt event in status register:

- PCIECTRL_TI_CONF_IRQSTATUS_MSI[0] INTA
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[1] INTB
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[2] INTC
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[3] INTD

This implies that the status of an asserted event does not need to be cleared locally (by software writing 1 to the PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[n] INTx_EN bit, where n=0 to 3 and x=A, B, C, D, respectively) as it is expected to be cleared remotely over PCIe, by the EP function.

Note

The RC does not keep track of the INTx requester, even though the information is available in the incoming TLP's RequesterID: each legacy interrupt is expected to be used by only one EP function, known apriori by the RC.

When messages are posted, there is no response generated by the RC.

INTx messages can only be received (and the corresponding HW interrupts asserted) when in RC mode.

Note

The HW interrupts have to be maintained disabled when in EP mode.

24.9.4.6.2.2 PCIe Controller Message Signaled Interrupts (MSI)

Message Signal Interrupts are the preferred option to map interrupt over PCIe. It allows up to 32 interrupts vectors/events to be triggered by each EP function. MSI interrupts are implemented memory-space (posted) writes, 1-DWORD long. They should only be sent by EPs to the RC.

Note

While legacy PCI interrupts are mapped onto PCIe messages (Msg), the Message Signaled Interrupts are mapped onto PCIe memory writes (MWr), not onto messages.

Use of MSI is exclusive with use of legacy PCI interrupts (defined above).

An MSI is a memory (posted) write done by an EP to a mailbox in the RC. The data size is always 32 bit, the address and the data are programmed by the RC during PCIe enumeration, into the EP function's MSI capability descriptor (in the EP function's PCI config space).

Like legacy PCI interrupts, MSI does pass any status information to the RC, other than the interrupt vector (event) itself: the data payload of the write access is used exclusively to identify the interrupt's requester and its vector. The exchange of status information is outside the scope of MSI.

Note

Unlike the legacy PCI interrupts, MSI does not emulate an interrupt "level" that is either high or low, gets asserted or deasserted. Each MSI interrupt vector corresponds to a univocal event, that does not get "cleared" later on.

Note

The device integrated PCIe controller does not support extended MSI-X message signaled interrupts.

24.9.4.6.2.2.1 PCIe Specific MSI Interrupt Event Overview

MSI are interrupts designed specifically for PCIe, unlike the legacy PCI events seen in the Section 24.9.4.6.2.1. They are mapped on the MSI interrupt line of PCIe controller, using a single status bit in the PCIECTRL_TI_CONF_IRQSTATUS_MSI register. The "MSI controller" decodes and records each received MSI write as a specific "vector" coming from a specific EP function. Each application assigns a dedicated meaning to a given vector. Each function can use up to 32 vectors, as configured by the RC. MSI vectors can only be "asserted" by the EP function, unlike PCI legacy events that can be asserted and deasserted. In other words, the local software has to "clear" the asserted vector before it can be reused.

The PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit MSI must remain set as long as a vector is still set. Once the last vector has been cleared, the MSI bit must be cleared by software.

See also Section 24.9.4.6.2.2.3.

Typical MSI interrupt service routine on the RC-configured PCIe controller:

1. Software reads PCIECTRL_TI_CONF_IRQSTATUS_MSI status register, and identifies an (unspecified) MSI event, as opposed to a PCI legacy event.
2. Software clears PCIECTRL_TI_CONF_IRQSTATUS_MSI[4] MSI.
3. Software reads PCIECTRL_PL_MSI_CTRL_INT_STATUS_N and identifies EP functions that raised MSI.
4. Software clears PCIECTRL_PL_MSI_CTRL_INT_STATUS_N status bit.
5. Software calls the EP function specific interrupt handlers for each of the vectors.
6. Repeat steps 3 to 5 until PCIECTRL_PL_MSI_CTRL_INT_STATUS_N reads 0.
7. Exit MSI IRQ handler, only if PCIECTRL_PL_MSI_CTRL_INT_STATUS_N is 0.

24.9.4.6.2.2.2 PCIe Controller MSI Transmission Methods (EP mode)

There are two methods for MSI transmission: hardware and software. MSI transmission applies only to EP configured local PCIe system.

24.9.4.6.2.2.2.1 PCIe Controller MSI transmission, hardware method

The device PCIe controller (EP) transmits an MSI by writing 0b1 to the TI config wrapper register PCIECTRL_TI_CONF_MSI_XMT[0] MSI_REQ_GRANT bit. The other fields indicate function number, TC, vector, for the MSI. The address, data (potentially modulated by the vector) are automatically extracted from the EP function's MSI capability descriptor, previously programmed by the remote RC during enumeration.

For status, PCIECTRL_TI_CONF_MSI_XMT[0] MSI_REQ_GRANT can be polled. The bit remains HIGH (0b1) following a request (write to 0b1) and goes back LOW (0b0) once the MSI transmit request has been granted.

Note

Bit PCIECTRL_TI_CONF_MSI_XMT[0] MSI_REQ_GRANT reflects only the PCIe local status, that is a confirmation that the MSI has been transmitted. Since the MSI is a posted write, there is no way for the EP to ensure that it has been correctly received by the RC.

24.9.4.6.2.2.2.2 PCIe Controller MSI transmission, software method

Alternatively, an MSI can also be sent as a SW-composed memory write (MWr). MSI address and data shall be taken from the local EP function's MSI capability descriptor, where they were programmed by the RC at enumeration, along with the "multiple message enabling". If more than one vector is enabled, MSI data can be modulated accordingly. Furthermore, the transaction shall match the mandatory characteristics of an MSI MWr access, as follows :

- Header attribute bits ATTR = 2'b00 (no snoop = 0, relaxed ordering = 0)
- 1 DWORD long
- First byte enable: 0b0000
- Last byte enable: 0b0011 (16 bits of data)

Such a SW-generated MSI can be scheduled at the end of a series of memory transactions (MRd/MWr), with the PCI transaction ordering rules guaranteeing that the MSI will not overtake the other transactions.

24.9.4.6.2.2.3 PCIe Controller MSI Reception (RC mode)

Unlike legacy PCI interrupts, MSI must be configured by the RC in each function before use. Depending on its reception capacities, the RC can enable between 1 and 32 vectors (individual events) per MSI-enabled EP function.

The current RC implementation supports MSI reception for up to 8 different EP functions, with up to the protocol's maximum (32) vectors a piece, all mapped to a single MSI address. MSI reception is handled by the "MSI controller" though non-standard "port logic" (PL) registers (mapped in the PCI config space): For more details see the PCIe controller port logic associated PCIECTRL_PL_MSI_CTRL_x registers in the Section 24.9.7.5.1.

The reception of MSI implicitly requires the MSI mailbox address (in PCI memory space) to be routed to the RC: refer to Section 24.9.4.7, *PCIe Controller Address Spaces and Address Translation* for that. The MSI address (32-bit or 64-bit) is programmed in dedicated PCIe PL registers.

The MSI message data (MWr DWORD) is encoded as follows for the current RC. This encoding shall be used by the RC to configure the remote EP discovered at enumeration.

Table 24-502. MSI Message Data Encoding (RC)

Bit range	Size	Value	Comment
31:16	16	0x0000	Reserved as per PCI standard
15:8	8	0x00	Unused, always zero
7:5	3	0 to 7	Identifier of EP function in MSI controller (8 possible values)
4:0	5	0 to 31	Interrupt vector for the EP (32 possible values)

An inbound access recognized as MSI is terminated inside the controller, and does not appear on the PCIe controller's master port like other inbound memory writes in the same range.

24.9.4.6.3 PCIe Controller MSI Hardware Interrupt Events

Table 24-503 describes the events, related to non-PCIe interrupts (PCI legacy and PCIe MSI interrupts), which trigger the "MSI" hardware interrupt line.

Table 24-503. MSI Hardware Interrupt Events Summary

Event Status and Clear[(1)]	Interrupt Enable Bit	Interrupt Disable Bit	Mapping	Description
PCIECTRL_TI_CONF_IRQSTATUS_MSI[0] INTA	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[0] INTA_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[0] INTA_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	Legacy interrupt caused by EP sending inband ASSERT/ DEASSERT event on virtually emulated by PCIe pin INTA. Typically set and cleared by the remote EP, without local software intervention.
PCIECTRL_TI_CONF_IRQSTATUS_MSI[1] INTB	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[1] INTB_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[1] INTB_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[2] INTC	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[2] INTC_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[2] INTC_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[3] INTD	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[3] INTD_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[3] INTD_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[4] MSI	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[4] MSI_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[4] MSI_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	MSI interrupt status. It is cleared by clearing all vectors in the MSI controller (PL) registers.

(1) The MSI hardware interrupts have to be maintained disabled when in EP mode.

Note

While the PCIECTRL_TI_CONF_IRQSTATUS_MSI register is updated only if corresponding interrupt is enabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MSI register, the PCIECTRL_TI_CONF_IRQSTATUS_RAW_MSI register always provides the Legacy/MSI event status regardless of an interrupt being enabled or disabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MSI register.

24.9.4.7 PCIe Controller Address Spaces and Address Translation

The PCIe controller acts as a general-purpose bridge between the device local PCIe system and the PCIe fabric. Both are address-based mappings, and the bridging requires address translation between the different spaces.

The Table 24-504 lists the memory-mapped spaces interconnected by each of the PCIe_SS1 and PCIe_SS2 controllers. For each address space (row), the local PCIe subsystem (including the PCIe core) provides “entry points” (4th column) to inject transactions into the specified space, and ”exit points” (5th column) to receive transactions from the specified space.

Table 24-504. PCIe_SS Address Space Map

Space name	Address width	Size (bytes)	Entry point	Exit point	Comments
Device L3_MAIN memory space visible through PCIe controller's master port	32-bit	4 GiB	iATU IBR output	device system RAM, miscellaneous modules	Accessed over PCIe controller initiator (master) port; Includes the outbound window below.
PCIe_SS controller outbound window in device	28-bit	256 MiB	Device CPU hosts (MPU, DSPs, and so forth) of PCIe subsystem on device L3_MAIN interconnect	iATU OBR input	Mapped within PCIe controller target (slave) port, the outbound window is itself remapped within the device L3_MAIN memory space (256 MiB sized region).
PCIe memory space	32-bit/64-bit[(1)]	4 GiB/16 EiB	ATU OBR output (mem mode)	ATU IBR input (mem mode)	Contains all memory BARs
PCIe I/O space	32-bit	4 GiB	ATU OBR output (I/O mode)	ATU IBR input (I/O mode)	Contains all I/O BARs
PCIe config space (ECAM)	28-bit	256 MiB	ATU OBR output (configuration mode)	Configuration registers inside PCIe controller	Contains the PCIe-standard configuration spaces for EP functions (a 4 KiB- descriptor per function).

(1) Regarding the PCIe address space shared between all devices identified on the PCIe fabric, the local PCIe controller OBR iATU output generates a 32-bit address (it addresses a total of 4 GiB external PCIe space), while the IBR iATU input receives accesses from within a total of 16 ExaBytes of external PCIe space (a 64-bit address).

By definition, an iATU (Address Translation Unit) has an input (the space the access originates from) and an output (the space the access is headed for), with the required address translation taking place in the middle. An iATU inbound region (IBR) routes from PCIe (input) to device L3_MAIN space (output), an iATU outbound region (OBR) routes from the L3_MAIN space (input) to the PCIe (output).

Table 24-505summarizes the action of the different ATU regions. It contains the same information as the table above, organized differently. Note that inbound regions are not required to managed incoming configuration accesses, which are completed automatically by the PCIe controller hardware.

PCIe controller core outbound and inbound ATUs define:

- 16 outbound iATU regions
- 4 inbound iATU regions

Table 24-505. Address Translation Unit Region Access Summary

ATU region direction	ATU region type	Source space	Destination space
Outbound (OBR)	Memory	PCIe controller outbound window	PCIe memory space
Inbound (IBR)	Memory	PCIe memory space	Device PCIe subsystem space
Outbound (OBR)	I/O	PCIe controller outbound window	PCIe I/O space
Inbound (IBR)	I/O	PCIe I/O space	Device PCIe subsystem space
Outbound (OBR)	Configuration	PCIe controller outbound window	PCIe Cfg space

In a read/write access to an iATU outbound region (input), which is mapped in the PCIe controller target's 256 MiB-wide outbound window, do not confuse:

- Physical address accessed in the device L3_MAIN address space - 4 GiB
- Physical address within the PCIe_SS1/PCIe_SS2 controller target (slave) port:
  – PCIe outbound window - Cfg ; Memory and I/O space accessible within (0x2000_0000 - 0x2FFF_FFFF)/ (0x3000_0000 - 0x3FFF_FFFF)
  – PCIe controller local configuration/status registers accessible within (0x5100_0000 - 0x517F_FFFF)/ (0x5180_0000 - 0x51FF_FFFF)
- Address offset within the outbound window (0 - 256 MiB)

CAUTION

In the calculation of an ATU outbound region translation, the input is the address offset within the outbound window, ranging from 0x0000_0000 (0 bytes) to 0x0FFF_FFFC (256 MiB – 4 Bytes), they are the third and last address type in the list above.

PCI express is an interconnect that propagates read/write accesses from/to systems beyond the local device PCIe subsystem. The figure below shows such a link, where the transaction initiator (PCIe requester device, on the left) and the transaction target (PCIe completer device, on the right) are two instances of the PCIe controller subsystem, connected over the PCI express fabric (in the middle). The physical routing of the transaction over the PCIe topology (through switches) is implicit and transparent for addresses. A simplified chain of address translation is represented for each PCIe transaction type (Configuration, Memory or IO).

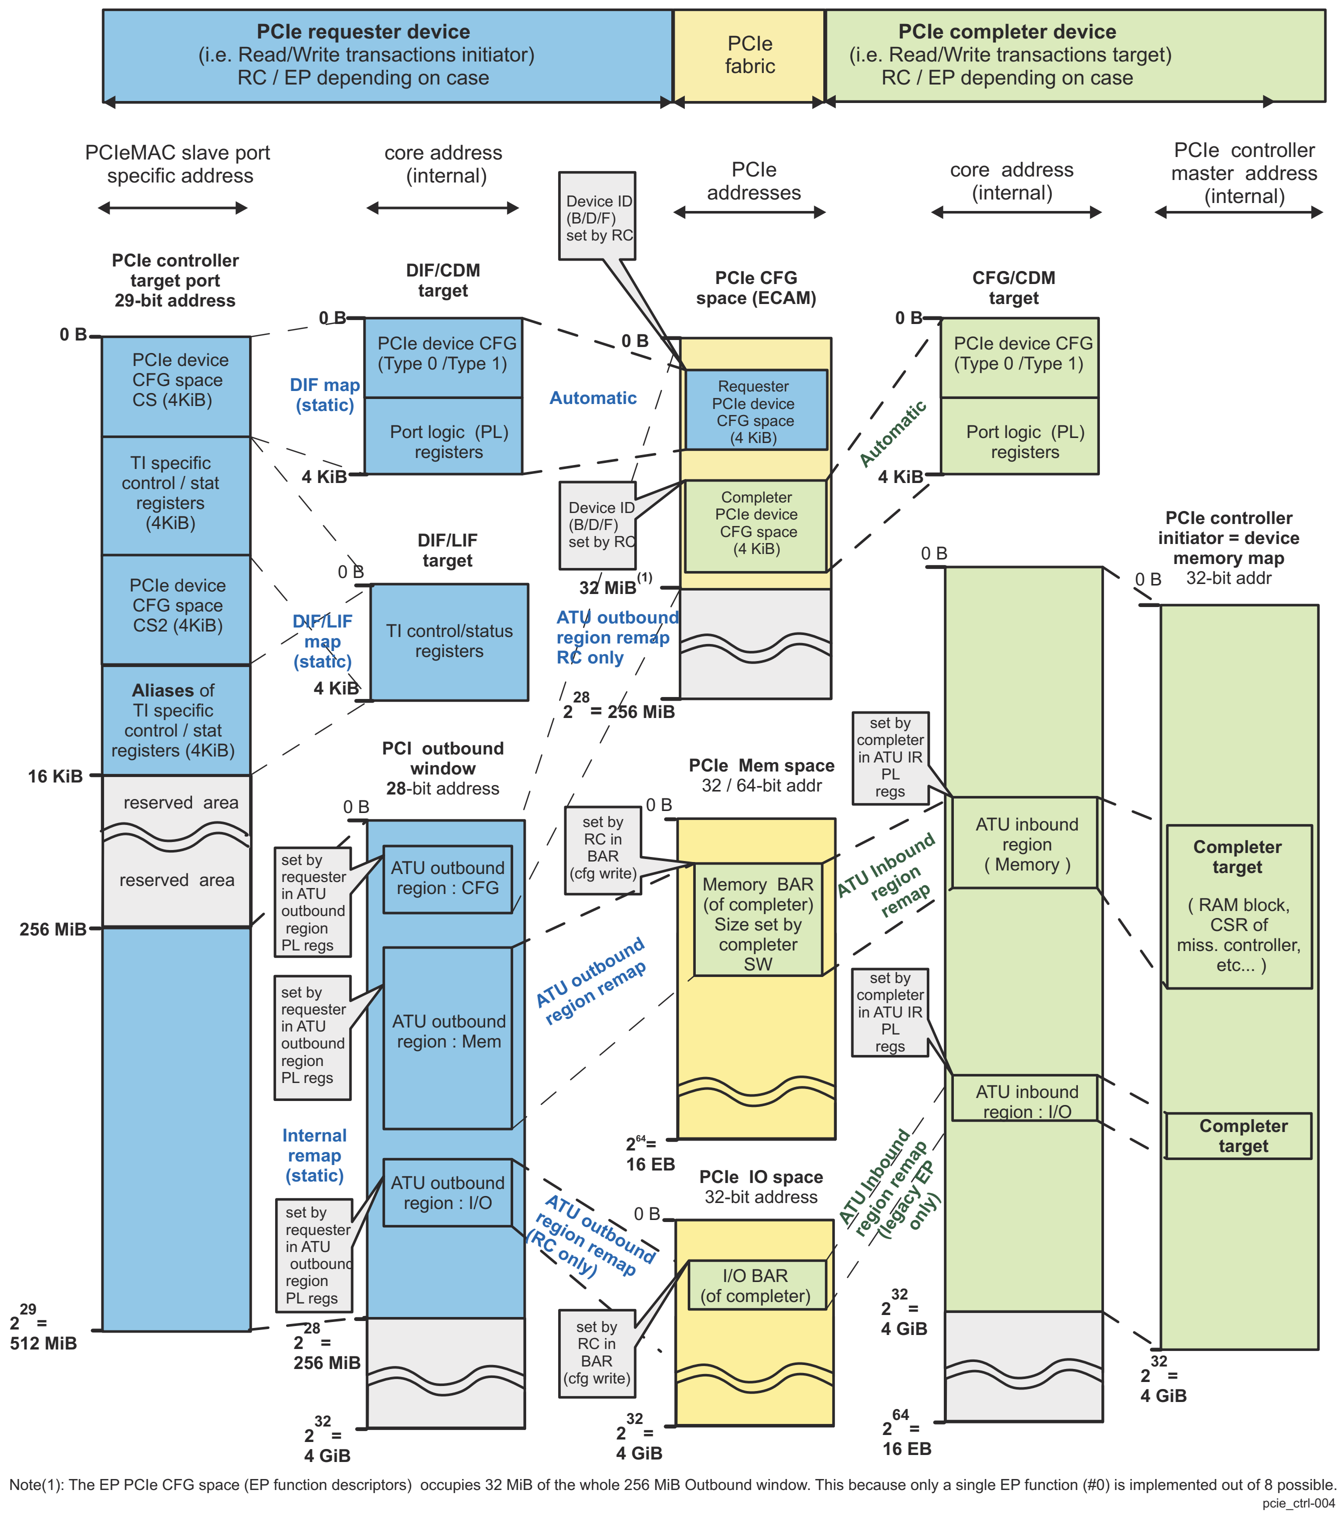

Figure 24-163. PCIe Core to PCIe Core Address Mapping and Translation

Note

There is a difference between requester/completer and RC/EP relationships, an EP device can be either the requester or the completer in a memory transaction.

24.9.4.8 PCIe Traffic Requesting and Responding

The PCIe wire can carry several types of packet-based traffic. The current chapter details how the current controller can be requester and completer of each type:

- **Requester:** initiates and transmits an outbound request, receives a response if required by (non-posted) request type.
- **Completer:** receives and processes an inbound request, generates and transmits a response if required by (non-posted) request type.

24.9.4.8.1 PCIe Memory-type (Mem) Traffic Management

The bulk of PCIe traffic is expected to take place in the memory (MEM) space, making use of large TLP/large L3_MAIN interface bursts.

Before PCI activity starts, one or several BAR of each device (EP function or RC) shall be initialized in Memory mode, as described in the Section 24.9.4.9.3, *Base Address Registers (BAR) Initialization*.

The following fields shall be set, using (CS) access (they are RO over PCI) :

- BARn[0]= "space decoder" shall be set to 0 = MEM space. This is the default setting for all BAR.
- BARn[2:1] = "type" shall be configured to either 32 or 64-bit. In the latter case, BARn+1 above shall contain the 32-bit upper part of the BAR base address.
- BARn[3] = "prefetchable" (P)

The BAR shall be enabled, using (CS2) access to BARn[0]:

- Write 1: BARn is enabled, can be configured by the RC writing to the MSBits of the BARn base address field.
- Write 0: BARn is disabled: register is read-only and return 0 over PCIe.

As part of the standard enumeration process, the RC then maps all the Memory BARs it finds (while discovering the connected EP functions) into the memory address space (32 or 64-bit address), using Cfg accesses over the PCIe wire. Optionally, the RC can also configure its own two BAR, over the DIF interface.

Once that process is complete, memory requests can take place point-to-point, that means that the requests can be initiated by any device (EP or RC) towards any other device function.

24.9.4.8.1.1 PCIe Memory Requesting

An ATU outbound region can then be programmed to remap the desired parts of the memory space (which correspond to BARs on other devices) into the local controller target's outbound window, accessed through the L3_MAIN slave port.

Alternatively, the iATU can be bypassed, and the outgoing access forwarded to the PCIe wire without address translation. In that *pass-through* mode, the PCIe address is equal to the 28 LSBits of the PCIe controller target address, that is, the address offset within the 256 MiB-wide outbound window. This gives access to the lowest 256 MiB of the PCIe memory space, from 0x0 to 0x0FFF_FFFC.

The forwarded PCIe TLPs shall have the following (hardcoded) header field values:

- TYPE = 0 = MRd/ MWr (Memory read or write)
- EP (poisoned bit) = 0 (not poisoned)
- ATTR (Attributes) = 2b01:
  - ATTR[1] = RO (relaxed ordering) = 0
  - ATTR[0] = NS (no snoop) = 1
- TC (traffic class) = 0

Initiators in the device local PCIe subsystem (typically CPUs or DMA) can then access memory space by initiating read/write accesses on the controller's slave port over L3_MAIN, either to the range of an enabled ATU outbound region, for the translated mode (with all TLP fields configurable), or outside any enabled ATU outbound region, for the pass-through mode (with the TLP fields hardcoded as explained above).

24.9.4.8.1.2 PCIe Memory Responding

An ATU inbound region can be programmed in BAR matching mode to remap (part or all of) each memory BAR to the controller's inbound window (this means to translate their address to the memory space of the device chip), and issue them on the PCIe controller's master port towards L3_MAIN. BAR matching mode is expected to be the most common method for an EP. In that mode, the ATU can be set up before enumeration - before the BAR's actual range (offset) is configured by the remote RC.

Alternatively, the ATU inbound region can be programmed in address matching mode. In that case, any access routed to the device (EP or RC) and matching the range specified in the ATU is remapped to the controller's inbound window (this means to translate their address to the memory space of the device), and issued on the master port towards L3_MAIN.

Address matching is the preferred method for an RC, which would route any access outside its base/limit range, as defined in its PCIe standard (Type-1) configuration space, and independently of any BAR so that BAR matching is not possible. In that case, only space not already taken up by a BAR can be used. Note the setup of an address matching iATU inbound region can only be done after enumeration, that is, after the RC has discovered and mapped all enabled Memory BAR of all EP functions to their address.

Finally, in case an incoming access does not match any enabled ATU inbound region (BAR or address matching), the transaction is just passed through untranslated, that is, with the address unchanged and the TLP attributes stripped off. This is not expected to be commonly used.

Incoming memory requests (to the local EP's Memory BAR) shall then cause the master port on L3_MAIN to access a given address range of the local system (potentially the entire 32-bit address range).

24.9.4.8.2 PCIe Configuration Type (Cfg) Traffic Management

Configuration (Cfg) traffic is not symmetrical: it can only be requested by the RC, and completed (in the case of PCIe controller) by the EP. It is used by the RC for the enumeration of the fabric: EP, functions, switches.

Note

The RC cannot use configuration traffic over the PCIe wire to access its own 4 KiB configuration space. To do that, it uses DIF accesses (CS) with bit PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN = 0b0.

24.9.4.8.2.1 RC Self-configuration (RC Only)

Like any other device on the PCIe fabric, the RC has its own 4-KiB configuration space, where RC local configuration registers are stored.

Note

Since the RC configuration registers are programmed by the RC itself, no remote access over the PCIe wire (Cfg TLP) is required. Local DIF accesses (CS) are used instead.

However, some register fields normally defined as read-only by the PCI standard are actually programmable over DIF (see Section 24.9.4.9.2), which may cause a standard software driver to fail. In that case, the CS-writability of those fields has to be disabled by reprogramming the located in the PCIe controller port logic bit PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN to 0b0. Note that this is normally done after CS-writable fields have been configured by the non-standard initialization "firmware", thus making the RC's configuration space PCI compliant.

The Section 24.9.4.8.2.2 and Section 24.9.4.8.2.3 only covers configuration of an EP function by an RC, using actual Configuration TLPs (transport layer packets).

24.9.4.8.2.2 Configuration Requests over PCIe (RC Only)

After coming out of reset, the PCI fabric is enumerated by the RC through configuration (Cfg) transactions to the switches and EP present in the topology. The enumeration process is covered by the PCI and PCIe standards - for more details refer to the PCI Express Base 3.0 Specification, revision 1.0.

Configuration transactions are created by an outbound ATU region set up to translate the PCIe controller slave port accesses into Cfg TLP on the PCIe wire.

- The L3_MAIN interconnect port (read or write) determines the TLP type (CfgRd/CfgWr)
- The data is passed unchanged from the L3_MAIN interconnect to the PCI world (write) and reciprocally (read)
- The entire PCI configuration space can be mapped as a standard, contiguous block, as specified in the **Enhanced Configuration Access Mechanism (ECAM)**. The ATU maps this 256 MiB block at a programmable base address within the controller slave port's 256 MiB "outbound window", using the ATU "Cfg shift" feature.
- The other parameters are programmed beforehand in the ATU's configuration registers (IATU_*)

The (28-bit) address offset within the 256 MiB ECAM block is the concatenation of :

- **Cfg register address** (Offset[11:0] = 12-bit = 4 KiB configuration space per EP function)
- **Function number** (Offset[14:12] =3 bit = 8 functions per PCIe EP)
- **Device number** (Offset[19:15] = 5 bit = 32 devices per bus, always 0 for PCIe controller itself)
- **Bus number** (Offset[27:20] = 8-bit = 256 busses in the PCIe fabric)
- Total for ECAM: 8 + 5 + 3 + 12 = 28-bit offset, or 256 x 32 x 8 x 4 KiB = 256 MiB

Note

The device PCIe controller itself supports only one function in EP mode. On the PCIe fabric, however when in RC mode, the PCIe controller may need to configure up to 8 functions per EP (potentially for all 65536 EPs). Hence the ECAM config. space visible to RC is 256 MiB in size.

A Cfg read access to the Vendor ID register is used by the RC to detect the presence of a function. If that specific read (address 0x000 in the 4-KiB PCI config space) fails with an UR PCIe response (Unsupported Request: no function present), the PCIe controller shall return a correct response to L3_MAIN with data 0xFFFF. This indicates the absence of the function to the application, without triggering an error on L3_MAIN.

24.9.4.8.2.3 Configuration Responding over PCIe (EP Only)

As an EP, the device only expects to receive (and never transmit) configuration transactions, and expects those to be CFG0 and not CFG1.

Incoming Cfg accesses with the appropriate Target ID are automatically routed to the targeted EP function's 4-KiB PCI configuration space, which contains both the PCI standard registers (header, descriptors, extende descriptors, and so forth) and the PL registers. The request read/write complete automatically, with no transaction appearing on the PCIe controller master port. Since Cfg accesses are non-posted, each incoming request shall generate a response.

Note

An ATU inbound region is also capable of processing incoming Cfg transactions, and translating them into read/write accesses on the master port towards L3_MAIN. However, this method is not expected to be used, and automatic completion –described above– is expected to be used instead.

24.9.4.8.3 PCIe I/O-type (IO) traffic management

I/O traffic is not symmetrical: it can only be requested by the RC, and responded to by the EP. It is a mostly deprecated feature of PCI, and could be replaced by Memory traffic. However, it is still required by the standard for a PCIe RC. It is supported by the current controller in both RC (requester) and **legacy EP mode (completer)**.

24.9.4.8.3.1 PCIe I/O requesting (RC only)

As part of the standard enumeration process, the RC maps all the I/O BARs it finds (while discovering the connected EP functions) into the 4 GiB I/O address space (32-bit address).

An ATU outbound region shall then be programmed to map a zone of the I/O space into the controller target's outbound window, accessed through the slave port.

Initiators in the RC host (typically a local CPU) can then access I/O space by initiating (1 DWORD) read/write accesses to the ATU region's range on the controller's slave port on L3_MAIN.

Note

There is NO specific hardware mechanism to notify the RC that it is allowed to issue I/O requests, since that configuration decision comes from the RC in the first place.

24.9.4.8.3.2 PCIe IO BAR initialization before enumeration (EP only)

Before PCI enumeration, each BAR can be initialized/enabled individually for IO space, using the DIF access (CS or CS2). The size of an enabled IO BAR (that is, the number of writable bits in the base address) is fixed to 256 bytes, that is, a mask of 0xFF that is, the writable BAR base address range for the RC is BARn[31:8], while BARn[7:0] is read-only.

In (CS) access, the BARn[0] "space decoder" field becomes RW and shall be written to 1 = IO space

In (CS2) access, BARn[0] becomes a write-only BAR enable :

- Write '1': BARn is enabled, can be configured by the RC writing to the MSBits of the BARn base address field.
- Write '0': BARn is disabled: register is read-only and return 0x0 over PCIe.

24.9.4.8.3.3 PCIe I/O responding (PCI legacy EP only)

I/O support is permitted only for the "legacy EP" type, that is, EP's side it is required that PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE has been preliminary set to 0x1 by EP's local software. Before PCI activity starts, one or several BAR of the EP function shall be enabled in I/O mode, to get enumerated by the RC as per the PCI standard.

An iATU (internal address translation unit) inbound region can be programmed in **BAR matching mode** to map the BAR to the controller's inbound window (that is, translate their address to the memory space of the SoC), and issue them on the PCIe master port towards device L3_MAIN.

BAR matching mode is expected to be the most common method for an EP. In that mode, the iATU can be set up before enumeration, that is, before the BAR's actual range (offset) is configured by the remote RC.

Alternatively, the ATU inbound region could be programmed in address matching mode. However, a valid I/O access coming into an EP is necessarily within a BAR, so BAR matching should be used. Additionally, BAR matching can be configured before enumeration, that is, before the RC has mapped the I/O BAR to their actual address.

Incoming I/O requests to the local EP's IO BAR shall then cause the PCIe master port to access a given address range of the local system (potentially the entire 32-bit address range), in 32-bit read/write accesses.

24.9.4.8.4 PCIe Message-type (Msg) traffic management

Most messages are generated and received automatically by logic in the controller HW, and do not require any specific intervention from the user.

The application can transmitted the following power management messages by writing to the TI configuration wrapper instance PCIECTRL_TI_CONF_PM_CTRL register:

- PCIECTRL_TI_CONF_PM_CTRL [0]PME_TURN_OFF: (power management event, turn off) request from RC to turn off, broadcasted downstream.

- PCIECTRL_TI_CONF_PM_CTRL[1] PM_PME: (power management event): request from EP to wake up, routed upstream towards RC.

No dedicated logic exists in the controller to support vendor-defined messages.

The ATU is capable of generating (outgoing) messages, and receiving (incoming) ones, by translating them from read/write accesses on the PCIe controller slave port, or to read/write accesses on the PCIe controller master port, respectively. However, this functionality is not required for standard PCI operation.

24.9.4.9 PCIe Programming Register Interface

PCI is an memory-mapped, dynamically reconfigurable interconnect protocol, so that the same physical register may be accessed in several different ways. The current chapter targets to describe only the statically-mapped programming registers of the local PCIe controller, accessed over the local AXI slave.

They are composed of:

- **PCIe-standard configuration registers:** by definition accessible over the PCIe wire through the PCIe configuration (and extended configuration - ECAM) space. Those registers are different depending on the selected mode (Type-0: EP or Type1: RC).
- **Port Logic (PL) registers:** non-standard user-accessible registers for additional PCIe functionality. They are also accessible over PCIe wire, in the configuration (ECAM) space.
- **TI-specific control and status registers:** more non-standard registers, accessible only locally. These are associated with the PCIe controller wrapper level functional control and status.

24.9.4.9.1 PCIe Register Access

The Table 24-506 summarizes how the resources of the local controller can be accessed. Note that the rightmost column represent accesses to the PCIe controller hosts system memory.

Table 24-506. Summary of Access Types related to PCIe Controller Local Resources

Access	PCIe standard configuration registers	Port Logic (PL) registers	TI-specific registers	System memory available to PCIe
Local DIF access (over PCIe controller target (slave) port, from device host CPUs and DMAs)	Yes[(1)] (CS or CS2)	Yes	Yes	No
Remote PCIe config (Cfg) transaction (over PCIe wire)	EP: Yes[(1)] RC: No[(2)]	EP: Yes RC: No[(2)]	No	No
Remote PCIe Memory transaction (over PCIe wire)	No	No	No	Yes (iATU)
Remote PCIe IO transaction (over PCIe wire)	No	No	No	EP: Yes (iATU) RC: No[(3)]

(1) 1. Read and writes to PCIe standard configuration registers (in PCIe config space, address 0x0 to 0x700) will give different results depending on the access method (DIF CS/CS2, PCIe): see [(1)].
(2) 2. PCIe Cfg transactions can only be issued by the RC (to an EP): A RC cannot receive one.
(3) 3. PCIe IO transactions can only be issued by the RC (to an EP): A RC cannot receive one.

24.9.4.9.2 Double Mapping of the PCIe Local Control Registers

Each local programming register is mapped twice inside the controller's local target, with an offset of 0x1000 (4 KiB) between the two mappings.

The "low" mapping is the Data Interface (DIF) chip-select (CS) access. In DIF CS mode, some fields that are read-only (RO) over PCI become writable if PL bit PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN=0b1 (default). This access is used by the local host (e.g. BIOS) for the initialization of the PCI device, prior to PCI protocol startup (LTSSM enable). Fields and registers that are CS-sensitive are labeled (CS) in the Section 24.9.7.

The "high" mapping is the Data Interface (DIF) chip-select-2 (CS2) access. In DIF CS2 mode, some fields that are read-only (RO) over PCI or in DIF CS mode, become writable if PL bitfield

PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN=0b1 (default). This access is also used by the local host for further initialization of the PCI device. Fields and registers that are CS2-sensitive are labeled (CS2) in the tables below.

Note

The following important notes on accesses must be considered by user for device PCIe controller:

- If PCIe_SS_PL_CONF instance located bitfield PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN is cleared to 0b0, the "CS and CS2-sensitive" fields become read-only (RO) again, that is, they revert to the behaviour defined in the PCI/PCIe standards.
- The standard PCI configuration registers (header, descriptors, extended descriptors) are the only ones that can change their behaviour in CS and CS2 access.
- The port logic (PL) registers and the PCIe controller wrapper TI configuration registers are not affected by the CS: for those, the two mappings have the same properties, that is, they are perfect aliases
- For an RC, which by definition cannot access its own (locally stored) configuration registers over the PCIe wire, the DIF access is the only alternative. The PCIe controller must present a PCI-standard-compliant type-1 configuration space to the RC software driver, that is, with none of the read-only bits actually writable, as follows:
  – the DIF CS access should be used
  – PL bitfield PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN should be cleared to 0b0 (after a pre-initialization, if required)

24.9.4.9.3 Base Address Registers (BAR) Initialization

The 6 base address registers ((EP) BAR0 through (EP) BAR5) supported in EP mode (Type0), get discovered and configured by the RC during PCI enumeration, as per the PCIe standard. Via the PCIe ECAM (enhanced configuration access) mechanism the **RC** maps a remote EP function's BAR registers in 64-bit PCIe memory space and software run on RC access them as the PCIECTRL_EP_PCIEWIRE_BAR0 through PCIECTRL_EP_PCIEWIRE_BAR5 registers. Note that the configuration space of the RC (Type1 registers) also contains two BARs ((RC) BAR0 and (RC) BAR1), but they are not expected to be used.

Before enumeration, BARs can be initialized by the local software, using DIF access (CS or CS2), to modify the properties seen by the RC at enumeration. The following can be configured in each BAR: enabling, IO or memory type, size (mask width). Even BAR numbers (0,2,4) can also be paired with the BAR number above (1,3,5) to create a single, 64-bit address (memory).

Note

If PCIe_SS_PL_CONF instance located register PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN bit is cleared, most BAR fields become read-only again, behaving like in over-the-wire PCI Cfg writes by the RC. Only the BAR base address (MSbits) is still writable. The size/mask, type, and enabling become read-only.

Table 24-507. PCIe Default BAR Configuration

	Enabled(1)	Space(2) BARn[0]	Type(2) BARn[2:1]	Prefetch(2) BARn[3]	Mem Size(1) (M-bit mask)	I/O Size (M-bit mask)
(EP) BAR0	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	1 MiB (20-bit)	256 Bytes (8-bit)
(EP) BAR1	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)
(EP) BAR2	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	1 MiB (20-bit)	256 Bytes (8-bit)
(EP) BAR3	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)
(EP) BAR4	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	4 KiB (12-bit)	256 Bytes (8-bit)
(EP) BAR5	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)

(1) reprogrammable with DIF (CS2) access

(2) reprogrammable with DIF (CS) access

The Table 24-508 and Table 24-509 describe how a memory and IO BAR can be accessed, respectively. A single address of the PCIe config space is accessed for a given BAR, with each line of the table showing a different mode: read vs. write; PCIe Cfg access vs. DIF (CS) access vs. DIF (CS2) access.

"M" is the width of the BAR mask in bits, with 2^M the BAR size in bytes. Bits M and above are writable by the RC over the PCIe wire to set the BAR base address, as follows:

- The value of M for a Memory BAR varies from 4 (2^4=16 Byte = minimum size) to 32 (2^{32} = 4 GiB for a 32-bit BAR, potentially more for a 64-bit BAR) depending on the BAR and on the configuration.
- The current implementation forces M=8 for an I/O BAR, that is, an IO BAR has a fixed size of 2^8=256 bytes, the maximum allowed by the PCIe protocol.

Table 24-508. BARn Register Access Methods (Mem BAR)

Method	BAR[31:M][1]	BAR[M-1:4]	BAR[3]	BAR[2:1]	BAR[0]
PCI read	Base address readout	Read returns zero	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder"[2]
PCI write	Base address write	No effect (masked = R/O)	No effect	No effect	No effect
CS read	Base address readout	Read returns zero (masked)	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder"[2]
CS write	Base address write	No effect (masked = R/O)	Write "Prefetchable"	Write "Type"	Write "space decoder"[2]
CS2 read	Base address readout	Read returns zero (masked)	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder"[2]
CS2 write	Write 0 to unmask (Sets M)	Write 1 to mask (Sets M)	Write 1	Write 1	Write "BAR enable"

(1) For M=32, the BAR mask is 32-bit wide, the BAR size is 4 GiB and the column disappears.
(2) Space decoder is Memory = 0 in this table.

Table 24-509. BARn Register Access Methods (IO BAR)

Method	BAR[31:8]	BAR[7:2]	BAR[1]	BAR[0]
PCI read	Base address readout	Read returns zero	Read out 0 (reserved bit)	Read out 1 "space decoder"[1]
PCI write	Base address write	No effect (masked = R/O)	No effect	No effect
CS read	Base address readout	Read returns zero (masked)	Read out 0 (reserved bit)	Read out 1 "space decoder"[1]
CS write	Base address write	No effect (masked = R/O)	Write 0 No effect	Write "space decoder"[1]
CS2 read	Base address readout	Read returns zero (masked)	Read out 0 (reserved)	Read out 1 "space decoder"[1]
CS2 write	Write 0. No effect in fixed-sized I/O BAR	Write 1. No effect in fixed-sized I/O BAR	Write 0 No effect	Write "BAR enable"

(1) Space decoder is I/O = 1 in this table.

24.9.5 PCIe Controller Low Level Programming Model

24.9.5.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the PCIe_SS1 and PCIe_SS2 controllers are used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the PCIe_SS (for more information, see PCIe Controllers Integration and PCIe Controllers Environment). Table 24-510 describes the global initialization of the surrounding modules.

Table 24-510. Global Initialization of the PCIe Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.)
Control Module	Module configuration must be done in control module. See *CTRL_MODULE_CORE Registers* and Table 24-495, *PCIe Port Configuration*
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to map the interrupts from the PCIe Controllers to a certain device processor INTC via the IRQ_CROSSBAR module. For more details on IRQ_CROSSBAR programming, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
(Optional) A local INTC	The local interrupt controller must be configured to enable the interrupt once IRQ output is mapped on INTC via the IRQ_CROSSBAR. See *Interrupt Controllers*.
L4 and L3_MAIN interconnects	For more information about the interconnect configuration, see *L3_MAIN Interconnect Agents*, and *L4 Interconnect Overview*, in *Interconnects*.
(Optional) Device MMU2	For more information on the configuration for routing the PCIe_SS1,2 master port traffic through the device MMU2, see Section 24.9.4.3.1.1, as well as Chapter 20, *Memory Management Units*.

Note

The interrupt configuration is required when using interrupt communication mode.

24.9.5.2 Main Sequence of PCIe Controllers Initalization

Note

This section aims to describe only the basic steps that must be followed by PCIe application software in order for a PCIe RC or EP type device to initialize, establish PCIe connectivity and interact with devices on the PCIe fabric. For this reason, it focuses on settings of the PCIe controllers wrapper registers (and not on PCI/PCIe standard and non-standard (PL) registers), through which PCIe application interacts with PCIe devices.

Table 24-511. Main Sequence PCIe Controller Global Initialization

RC and/or EP Initialization Step[1]	Register/Bit Field/Programming Model	Value
1. Initialize the DPLL_PCIe_REF (clock source, dividers, power dependencies) in PRCM	Refer to Section 26.4.5	
2. Assert a local software main reset to the PCIe_SS1,2 controllers	PRCM.RM_PCIESS_RSTCTRL[0] RST_LOCAL_PCIE1 PRCM.RM_PCIESS_RSTCTRL[1] RST_LOCAL_PCIE2	0b1
3. Poll main reset completion status for the PCIe_SS1,2 controllers	PRCM.RM_PCIESS_RSTST[0] RST_LOCAL_PCIE1 PRCM.RM_PCIESS_RSTST[1] RST_LOCAL_PCIE2	=0b1
4. Perform tuning of the PCIe PHY	Refer to Section 26.4.5	
IF: required operation mode for PCIe controller is “RC”	Software Test Condition	
5. Select RC type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x4 (default)
6. Poll to insure a fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x4

Table 24-511. Main Sequence PCIe Controller Global Initialization (continued)

RC and/or EP Initialization Step[1]	Register/Bit Field/Programming Model	Value
7. Make sure LTSSM_EN is kept by RC's software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize RC PCIe controller's core registers.	See Table 24-513	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ msi status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. [optional step] Enable INTx (x=A,B,C,D) interrupts reception (generated from legacy EPs to RC) but disable MSI interrupts reception at the same time. OR Enable the MSI interrupts reception (MSI interrupts are generated to RC from PCIe EPs only) but disable the INTx interrupts reception at the same time	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI [3:0] INTx_EN	0x-
	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4] MSI_EN	0b1
	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI [4] MSI_EN	0b1
	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [3:0] INTx_EN	0xF
ELSE IF: required operation mode for PCIe controller is "PCIe EP"		
5. Select "PCIe EP" type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x0
6. Poll to insure fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x0
7. Make sure LTSSM_EN is kept by EP's software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize EP PCIe controller's core registers	See Table 24-512	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable –PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ msi status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. Disable both INTx (x=A,B,C,D) and MSI interrupts reception.	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4:0]	0x1F
ELSE:		
5. Select "PCI Legacy EP " type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x1
6. Poll to insure fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x1
7. Make sure LTSSM_EN is kept by EP's software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize EP controller local registers via DIF CS/CS2 accesses	See Table 24-512	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. Disable both INTx (x=A,B,C,D) and MSI interrupts reception	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4:0]	0x1F
ENDIF		

Table 24-511. Main Sequence PCIe Controller Global Initialization (continued)

RC and/or EP Initialization Step[(1)]	Register/Bit Field/Programming Model	Value
13. PCIe (RC/EP) controller enables the link. It is supposed that all active EPs attached on the PCIe fabric synchronously enable their LTSSM engine with the RC.	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b1
14. Local CPU polls until the PCIe Controller link is up (that is, brought into L0- power state)	PCIECTRL_TI_CONF_PHY_CS[16] LINK_UP	=0b1
15. If PCIECTRL_TI_CONF_IRQSTATUS_MAIN[3] LINK_UP_EVT has been enabled in step (10), this means it should be cleared	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[12] LINK_UP_EVT	0b1
16. RC host starts link training sequence, negotiation with EPs, enumeration of the EPs, and initializes the descriptors per each of the discovered EP functions. Example: RC Initializes the MSI message vectors table per each of the EPs. RC maps the EPs global PCIe Memory per each EP function appropriately initializing the BARn registers MSB part.		
17. [RC only] **IF:** an EP is a requester, the RC remotely enables its BME bit via an ECAM access to the EP's command /status register.	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_R EGISTER[2] BUSMASTER_EN	0b1
18. [RC only] **IF:** an EP is a completer, the RC remotely enables its MSE (for Mem transfers) or ISE bits (for legacy I/O transfers) via an ECAM access to the EP's command/status register.	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_R EGISTER[1] MEM_SPACE_EN OR PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_R EGISTER[0] IO_SPACE_EN	0b1
19. [EP only] Before EP's application generates a request (that is, requester EP), the EP application must insure that its local BME_EVT status has already been asserted to 0b1 by the RC host controller.	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[13] BME_EVT_MSG OR PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN[13] BME_EVT_MSG	=0b1
The EP must locally clear the BME interrupt, writing BME_EVT_MSG flag to 0b1 (Wr1toClr).	Wr1ToClr PCIECTRL_TI_CONF_IRQSTATUS_MAIN[13] BME_EVT_MSG	0b1
20. [RC only] Before RC application initiates a request to an completer EP function with a *Memory type BAR*, the RC must check that EP's MEM_SPACE_EN flag has already been asserted by the RC host. This is done via an ECAM remote access by RC to EP's command/status register. [EP Only] The EP's CPU is notified about remote MEM_SPACE_EN flag assertion in a dedicated bit that can be enabled to generate an interrupt. The interrupt flag is cleared via writing to 0b1 (Wr1ToClr).	PCIe_SS1,2_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_R EGISTER[1] MEM_SPACE_EN	=0b1
	The EP application may receive an interrupt (if enabled – see step 10) indicated in the PCIECTRL_TI_CONF_IRQSTATUS_MAIN[14] MSE_EVT_MSG. Or poll this in PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN[14] MSE_EVT_MSG.	0b1
20. [RC only] Before RC application initiates a request to a completer EP function with an *I/O type BAR*, the RC must check that EP's IO_SPACE_EN flag has already been asserted by the RC host. This is done via an ECAM remote read access by RC to EP's command/status register.	PCIe_SS1,2_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_R EGISTER[0] IO_SPACE_EN	=0b1
[EP Only] Unlike Mem type EPs, there is no interrupt event to notify the EP about its ISE flag being asserted by the RC. So, to be aware of an incoming transaction, I/O legacy EP must poll local IO_SPACE_EN flag until its asserted by RC to 0b1.	PCIECTRL_EP_DBICS_STATUS_COMMAND_REGIS TER[0] IO_SPACE_EN	=0b1

Table 24-511. Main Sequence PCIe Controller Global Initialization (continued)

RC and/or EP Initialization Step(1)	Register/Bit Field/Programming Model	Value
[EP Only] 21. IF IO_SPACE_EN bit has been set to '1' for a legacy EP, user must force the legacy EP master port out-of-standby (before first transaction). There is no automatical standby generation for I/O transfers.	PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE	0x1

(1) Unless a step is not marked as "[EP Only]" or "[RC Only]", the initialization step should be considered as applicable in both EP and RC modes of PCIe controller.

Table 24-512. Local EP (Type 0) PCIe Standard and Port Logic Registers Initialization Subsequence

8.1 Initialize PCI standard configuration header registers via corresponding DIF CS/CS2 accesses. Example: BAR MASK0 – BAR MASK5 (that must be entirely initialized by the EP, and LSB part of the BAR0 – BAR5 registers)	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.2 Initialize the RC PCIe capability registers via corresponding DIF CS/CS2 accesses.	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.3 Initialize the RC PCIe Port Logic registers. Example: iATU settings of internal local address ranges, link settings – link powers, timings, and so forth		

Table 24-513. RC (Type 1) PCIe Standard and Port Logic Registers Initialization Subsequence

RC must enable write operation to be able to configure its own PCIe standard and PL registers.	PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN	0b1
8. 1 Initialize RC PCI standard configuration header registers via corresponding DIF CS/CS2 accesses. (Example: RC BAR 0,1 and BAR MASK0,1 registers.)	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.2 Initialize the RC PCIe capability registers via corresponding DIF CS/CS2 accesses.	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.3 Initialize the RC PCIe Port Logic registers. Example: iATU settings of internal local address ranges, link settings – link power, timings, and so forth Prepare the MSI vectors, Setup of the MSI, others.		
Disable write operation in RC PCIe standard and PL registers.	PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN	0b0

Note

When the PCIe_SS1 controller is configured to operate in two lane mode, by default lane 0 is mapped to the PCIe1_PHY (device PCIe PHY port 0), and lane 1 is mapped to the PCIe2_PHY (device PCIe PHY port 1). The PCIe_SS1_TI_CONF wrapper located software control - PCIECTRL_TI_CONF_PHY_CS[0] REVERSE_LANES allows user software to swap mapping of the PCIe_SS1 controller lane 0 and lane 1 on the two device PCIe PHY ports (swapping the RX and TX paths simultaneously with polarity of an individual lane unchanged). Note that the identical control is not functional in the PCIe_SS2_TI_CONF, because the PCIe_SS2 can operate in a single lane mode only, and (if selected) its lane 0 is always mapped to the PCIe PHY port 1 (that is, PCIe2_PHY).

24.9.6 PCIe Standard Registers vs PCIe Subsystem Hardware Registers Mapping

The below tables provide the PCIe/PCI standard logical registers versus PCIe controller hardware registers mapping in the device.

Table 24-514. PCIe Type-0 (EP) Configuration Standard Capability Registers vs PCIe Controller Hardware Registers Mapping

PCIe Standard Register Name	PCIe_SS1_EP_CFG_PCIe and PCIe_SS2_EP_CFG_PCIe Corresponding Register(1)	PCIe_SS1_EP_CFG_DBICS and PCIe_SS2_EP_CFG_DBICS Corresponding Register(2)	PCIe_SS1_EP_CFG_DBICS2 and PCIe_SS2_EP_CFG_DBICS2 Corresponding Register(3)

PCIe_SS2_RC_CFG_DBICS2	0x5180 1000	128 Bytes
PCIe_SS2_TI_CONF	0x5180 2000	332 Bytes

(1) ECAM_Param_Base_Addr = 0x0000_0000 to 0x0FFF_F000

Note

The *ECAM_Param_Base_Addr* variable is the 16-bit **base address** (this address is 4 KiB-aligned with value in the range: 0x0000_0000 - 0x0FFF_F000) of the relevant EP function descriptor (relevant EP's function PCIe standard and PL configuration registers) **in a contiguous 256-MiB ECAM space** (0x0000_0000 - 0x0FFF_FFFF). For more information on the PCIe ECAM configuration space mapping mechanism, refer to the section *PCI Express Enhanced Configuration Access Mechanism (ECAM)*, in the *PCI Express Base 3.0 Specification, Revision 1.0*.

For information on the EP's function PL register offsets and descriptions, refer to the Section 24.9.7.5.

24.9.7.2 PCIe_SS_EP_CFG_PCIe Registers

Note

This section describes the PCIe EP mode (PCIe type-0) standard configuration registers as they are accessed over PCIe wire logic and not via DIF CS/CS2 accesses. These register names are prefixed with "PCIECTRL_EP_PCIEWIRE".

24.9.7.2.1 PCIe_SS_EP_CFG_PCIe Register Summary

Table 24-520. PCIe_SS1_EP_CFG_PCIe Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	PCIe_SS1_EP_CFG_PCIe Physical Address
PCIECTRL_EP_PCIEWIRE_DEVICE_VENDORID	R	32	0x0	ECAM_Param_Base_Addr(1) + 0x2000 0000

Table 24-520. PCIe_SS1_EP_CFG_PCIe Registers Mapping Summary (continued)

PCIECTRL_EP_PCIEWIRE_LNK_CAS_2	RW	32	0xA0	ECAM_Param_Base_Addr(1) + 0x3000 00A0

(1) ECAM_Param_Base_Addr = 0x0000_0000 to 0x0FFF_F000

Note

The *ECAM_Param_Base_Addr* variable is the 16-bit base address (this address is 4 KiB-aligned with value in the range: 0x0000_0000 - 0x0FFF_F000) of the relevant EP function descriptor (relevant EP's function PCIe standard and PL configuration registers) in a contiguous 256-MiB ECAM space (0x0000_0000 - 0x0FFF_FFFF). For more information on the PCIe ECAM configuration space mapping mechanism, refer to the section *PCI Express Enhanced Configuration Access Mechanism (ECAM)*, in the *PCI Express Base 3.0 Specification, Revision 1.0*.

For information on the EP's function PL register offsets and descriptions, refer to *PCIe_SS_PL_CONF Registers*.

24.9.7.3 PCIe_SS_EP_CFG_DBICS Registers

Note

This section describes the PCIe EP mode (PCIe type-0) standard configuration registers as they are locally accessed within the DIF CS space. These register names are prefixed with "PCIECTRL_EP_DBICS".

24.9.7.3.1 PCIe_SS_EP_CFG_DBICS Register Summary

Table 24-548. PCIe_SS1_EP_CFG_DBICS Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	PCIe_SS1_EP_CFG_DBICS Physical Address
PCIECTRL_EP_DBICS_DEVICE_VENDORID	RW	32	0x0	0x5100 0000

RESERVED	LINK_EQ_REQ	EQ_PH3	EQ_PH2	EQ_PH1	EQ_COMPLETE	DEEMPH_LEVEL	COMPL_PRST_DEEPH	COMPL_SOS	ENT_MOD_COMPL	TX_MARGIN	SEL_DEEMP	HW_AUTO_SP_DIS	ENTR_COMPL	TRGT_LINK_SPEED

Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x0
21	LINK_EQ_REQ	Link Equilization Request	RW Wr1toClr	0x0
20	EQ_PH3	Equalization Ph3 Success, Gen3 Only	R	0x0
19	EQ_PH2	Equalization Ph2 Success, Gen3 Only	R	0x0
18	EQ_PH1	Equalization Ph1 Success, Gen3 Only	R	0x0
17	EQ_COMPLETE	Equalization Complete, Gen3 Only	R	0x0
16	DEEMPH_LEVEL	Current De-emphasis Level	R	0x1
15:12	COMPL_PRST_DEEPH	Compliance Pre-set/ De-emphasis	RW	0x0
11	COMPL_SOS	Compliance SOS	RW	0x0
10	ENT_MOD_COMPL	Enter Modified Compliance	RW	0x0
9:7	TX_MARGIN	Transmit Margin	RW	0x0
6	SEL_DEEMP	Selectable De-emphasize	R	0x0
5	HW_AUTO_SP_DIS	Hardware Autonomous Speed Disable	R	0x0
4	ENTR_COMPL	Enter Compliance	RW	0x0
3:0	TRGT_LINK_SPEED	Target Link Speed	RW	0x1

24.9.7.4 PCIe_SS_RC_CFG_DBICS Registers

Note

This section describes the PCIe RC mode (PCIe type-1) standard configuration registers as they are locally accessed within the DIF CS space. These register names are prefixed with "PCIECTRL_RC_DBICS".

24.9.7.4.1 PCIe_SS_RC_CFG_DBICS Register Summary

Table 24-580. PCIe_SS1_RC_CFG_DBICS Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	PCIe_SS1_RC_CFG_DBICS Physical Address
PCIECTRL_RC_DBICS_DEVICE_VENDORID	RW	32	0x0000 0000	0x5100 0000
PCIECTRL_RC_DBICS_STATUS_COMMAND_REGISTER	RW	32	0x0000 0004	0x5100 0004

24.9.7.5 PCIe_SS_PL_CONF Registers

Note

The Section 24.9.7.5.1 lists the implementation-specific (that is, not PCIe-standard) “port logic” - PL registers, mapped in the 4-KiB PCIe configuration space along with the PCIe-standard registers already described. Unlike the standard registers, port logic (PL) registers are not affected by the device type (Type-0/EP vs. Type-1/RC).

Note

Besides at the (DIF CS space) physical addresses listed in below tables, the PCIe PL configuration registers are also locally accessible (aliased) at the (DIF CS2 space) base address 0x5100_1700 (PCIe_SS1) and 0x5180_1700 (PCIe_SS2), without any difference in PL registers behaviour between CS and CS2 spaces. There is also no difference in PL registers behaviour between PCIe wire remote accesses and local (DIF CS,CS2) accesses.

24.9.7.5.2 PCIe_SS_PL_CONF Register Description

Table 24-613. PCIECTRL_PL_LAT_REL_TIM

Address Offset	0x0000 0000		
Physical Address	0x5100 0700 0x5180 0700	**Instance**	PCIe_SS1_PL_CONF PCIe_SS2_PL_CONF
Description	Ack Latency and Replay Timer Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REPLAY_TIME_LIMIT																ACK_LATENCY_TIME_LIMIT															

Bits	Field Name	Description	Type	Reset
31:16	REPLAY_TIME_LIMIT	The replay timer expires when it reaches this limit; The core initiates a replay upon reception of a Nak or when the replay timer expires; The default value depends on number of bytes (NB) per cycle, which is defined by the maximum core base frequency of the device PCIe core, corresponding to 250 MHz for PCIe-Gen2 (5 Gbps) operation. The default is then updated based on the Negotiated Link Width and Max_Payload_Size; Note: If operating at 5 Gb/s, then the rounded-up value of an additional (153/CX_NB) cycles is added, where CX_NB correspond to the number of PCIEPCS 8-bit input symbols per single 16-bit lane, that is, CX_NB=2. This means at 5Gbps, 77 extra cycles should be considered for the replay time limit. This is for additional internal processing for received TLPs and transmitted DLLPs.	RW	0xc0

Bits	Field Name	Description	Type	Reset
15:0	ACK_LATENCY_TIME_LIMIT	The Ack/Nak latency timer expires when it reaches this limit; The default value depends on number of bytes (NB) per cycle, which is defined by the maximum core base frequency of the device PCIe core, corresponding to 250 MHz for PCIe-Gen2 (5 Gbps) operation. The default is then updated based on the Negotiated Link Width and Max_Payload_Size. Note: If operating at 5 Gb/s, then the rounded-up value of an additional (51 /CX_NB) cycles is added, where CX_NB correspond to the number of PCIEPCS 8-bit input symbols per single 16-bit lane, that is, CX_NB=2. This means at 5Gbps, 26 extra cycles should be considered for the acknowledge latency time limit. This is for additional internal processing for received TLPs and transmitted DLLPs.	RW	0x40

24.9.7.6 PCIe_SS_EP_CFG_DBICS2 Registers

Note

This section describes the PCIe EP mode (PCIe type-0) standard configuration registers as they are locally accessed within the DIF CS2 space. These register names are prefixed with "PCIECTRL_EP_DBICS2".

24.9.7.6.1 PCIe_SS_EP_CFG_DBICS2 Register Summary

Table 24-654. PCIe_SS1_EP_CFG_DBI_CS2 Registers Mapping Summary

4	ENTR_COMPL	Enter Compliance	RW	0x0
3:0	TRGT_LINK_SPEED	Target Link Speed	RW	0x1

24.9.7.7 PCIe_SS_RC_CFG_DBICS2 Registers

Note

This section describes the PCIe RC mode (PCIe type-1) standard configuration registers as they are locally accessed within the DIF CS2 space. These register names are prefixed with "PCIECTRL_RC_DBICS2".

24.9.7.7.1 PCIe_SS_RC_CFG_DBICS2 Register Summary

Table 24-682. PCIe_SS1_RC_CFG_DBI_CS2 Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	PCIe_SS1_RC_CFG _DBICS2 Physical Address
PCIECTRL_RC_DBICS2_DEVICE_VENDORID	RW	32	0x0000 0000	0x5100 1000
PCIECTRL_RC_DBICS2_STATUS_COMMAND_REGISTER	RW	32	0x0000 0004	0x5100 1004

Table 24-687. PCIECTRL_RC_DBICS2_BIST_HEAD_LAT_CACH

Address Offset	0x0000 000C		
Physical Address	0x5100 100C 0x5180 100C	**Instance**	PCIe_SS1_RC_CFG_DBICS2 PCIe_SS2_RC_CFG_DBICS2
Description	BIST, Header Type, Latency Timer, Cache Line Size		
Type	RW		

31:24	23	22:16	15:8	7:0
BIST	MFD	HEAD_TYP	MSTR_LAT_TIM	CACH_LN_SZE

Bits	Field Name	Description	Type	Reset
31:24	BIST	BIST	R	0x0
23	MFD	MultiFunction Device	R	0x0
22:16	HEAD_TYP	Header Type Read 0x0: EP header (Type0) Read 0x1: RC header (Type1)	R	0x1
15:8	MSTR_LAT_TIM	Master Latency Timer, Not Applicable for PCIe hence hardwired to 0	R	0x0
7:0	CACH_LN_SZE	Cache Line Size, No impact on write, write is allowed only for legacy purpose	RW	0x0

Table 24-688. PCIECTRL_RC_DBICS2_BAR0_MASK

Address Offset	0x0000 0010		
Physical Address	0x5100 1010 0x5180 1010	**Instance**	PCIe_SS1_RC_CFG_DBICS2 PCIe_SS2_RC_CFG_DBICS2
Description	Base Address Register 0 Mask (CS2 mode only) Write 1 to BAR[0] to enable the BAR Write ones to BAR[M-1:1] for a 2**M byte BAR Reads like in CS mode		
Type	RW		

31:1	0
BAR_MASK	BAR_ENABLED

Bits	Field Name	Description	Type	Reset
31:1	BAR_MASK	Write 1 to unmask/0 to mask the BAR address bit (CS2 only)	RW	0xFFFF
0	BAR_ENABLED	BAR enabled (CS2 only)	RW	0x1

Table 24-689. PCIECTRL_RC_DBICS2_BAR1_MASK

Address Offset	0x0000 0014

Table 24-689. PCIECTRL_RC_DBICS2_BAR1_MASK (continued)

Physical Address	0x5100 1014 0x5180 1014	**Instance**	PCIe_SS1_RC_CFG_DBICS2 PCIe_SS2_RC_CFG_DBICS2
Description	Base Address Register 1 Mask (CS2 mode only) Write 1 to BAR[0] to enable the BAR Write ones to BAR[M-1:1] for a 2**M byte BAR If BAR0 is in 64-bit mode, contains the upper bits of BAR0 mask Reads like in CS mode		
Type	RW		

31–1	0
BAR_MASK	BAR_ENABLED

Bits	Field Name	Description	Type	Reset
31:1	BAR_MASK	Write 1 to unmask/0 to mask the BAR address bit (CS2 only)	RW	0xFFFF
0	BAR_ENABLED	BAR enabled (CS2 only)	RW	0x1

Table 24-690. PCIECTRL_RC_DBICS2_BUS_NUM_REG

Address Offset	0x0000 0018		
Physical Address	0x5100 1018 0x5180 1018	**Instance**	PCIe_SS1_RC_CFG_DBICS2 PCIe_SS2_RC_CFG_DBICS2
Description	Bus Number Registers		
Type	RW		

31–24	23–16	15–8	7–0
SEC_LAT_TIMER	SUBORD_BUS_NUM	SEC_BUS_NUM	PRIM_BUS_NUM

Bits	Field Name	Description	Type	Reset
31:24	SEC_LAT_TIMER	Secondary Latency Timer, Not Applicable for PCI Express hence hardwired to 0	R	0x0
23:16	SUBORD_BUS_NUM	Subordinate Bus Number	RW	0x0
15:8	SEC_BUS_NUM	Secondary Bus Number	RW	0x0
7:0	PRIM_BUS_NUM	Primary Bus Number	RW	0x0

Table 24-691. PCIECTRL_RC_DBICS2_IOBASE_LIMIT_SEC_STATUS

24.9.7.8 PCIe_SS_TI_CONF Registers

24.9.7.8.1 PCIe_SS_TI_CONF Register Summary

Note

Though the PCIe controller wrapper TI configuration registers are also accessible (aliased) at base address 0x5100_3000 (PCIe_SS1) and 0x5180_3000 (PCIe_SS2), the preferable base addresses to access them are the ones used in above table, that is, 0x5100 2000 and 0x5180 2000. These registers are visible only within the device L3_MAIN space.

Table 24-713. PCIe_SS1_TI_CONF Registers Mapping Summary

24.9.7.8.2 PCIe_SS_TI_CONF Register Description

Table 24-715. PCIECTRL_TI_CONF_REVISION

Address Offset	0x0000 0000		
Physical Address	0x5100 2000 0x5180 2000	**Instance**	PCIe_SS1_TI_CONF PCIe_SS2_TI_CONF
Description	IP Revision Identifier		
Type	R		

31–0
REVISION

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision	R	0x-(1)

(1) TI Internal data.

Table 24-716. PCIECTRL_TI_CONF_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x5100 2010 0x5180 2010	**Instance**	PCIe_SS1_TI_CONF PCIe_SS2_TI_CONF
Description	Controls various parameters of the master and slave interfaces.		
Type	RW		

31–17	16	15–6	5–4	3–2	1–0
RESERVED	MCOHERENT_EN	RESERVED	STANDBYMODE	IDLEMODE	RESERVED

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
16	MCOHERENT_EN	Allows the no-snoop (NS) attribute of inbound PCIe TLPs to be passed to SoC system bus (AXI) master as a 'coherent' inband flag. 0x0: DIS AXI not coherent 0x1: EN AXI coherent = not(PCIE "NS") that is, cache-coherence is preserved	RW	0x0
15:6	RESERVED		R	0x0
5:4	STANDBYMODE	PM mode of local initiator (master); Initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode = Initiator is unconditionally placed in standby state. 0x1: No-standby mode = initiator is unconditionally placed out of standby state. 0x2: Smart-standby mode = initiator's standby state depends on internal conditions, that is, the module's functional requirements. Asynchronous wakeup events cannot be generated. 0x3: Smart-Standby, wakeup-capable mode = initiator's standby state depends on internal conditions, ie the module's functional requirements. Asynchronous wakeup events can be generated.	RW	0x2
3:2	IDLEMODE	PM mode of local target (slave); Target shall be capable of handling read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode = local target's idle state follows (acknowledges) the system's idle requests unconditionally, regardless of the IP module's internal requirements. 0x1: No-idle mode = local target never enters idle state. 0x2: Smart-idle mode = local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. Module shall not generate (IRQ- or DMA-request-related) wakeup events. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.	RW	0x2
1:0	RESERVED		R	0x0

Table 24-717. PCIECTRL_TI_CONF_IRQ_EOI

Address offset	0x18		
Physical Address	0x5100 2018 0x5180 2018	**Instance**	PCIe_SS1_TI_CONF PCIe_SS2_TI_CONF
Description	Software End-Of-Interrupt: Allows the generation of further pulses on the interrupt line, if an new interrupt event is pending, when using the pulsed output. Unused when using the level interrupt line (depending on module integration).		
Type	RW		

31–4	3–0
RESERVED	LINE_NUMBER

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x000 0000

Bits	Field Name	Description	Type	Reset
3:0	LINE_NUMBER	Write the IRQ line number to apply software EOI to it. Write 0x0: software EOI on main interrupt line Read 0x0: Read always returns zeros Write 0x1: software EOI on message-signalled (MSI) interrupt line	RW	0x0

Table 24-718. PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN

Address Offset	0x0000 0020		
Physical Address	0x5100 2020 0x5180 2020	**Instance**	PCIe_SS1_TI_CONF PCIe_SS2_TI_CONF
Description	Raw status of 'main' interrupt requests; Set even if event is not enabled. Write 1 to set the (raw) status, mostly for debug (regular status also gets set).		
Type	RW W1toSet

24.10 DCAN

This chapter describes the controller area network modules (DCAN) in the device.

24.10.1 DCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time applications. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The device supports two DCAN modules, referred to as DCAN1 and DCAN2, connecting to the CAN network through external (for the device) transceivers. The DCAN modules support bit rates up to 1 Mbit/s and are compliant to the CAN 2.0B protocol specification

Figure 24-164 shows the DCAN1 module highlights.

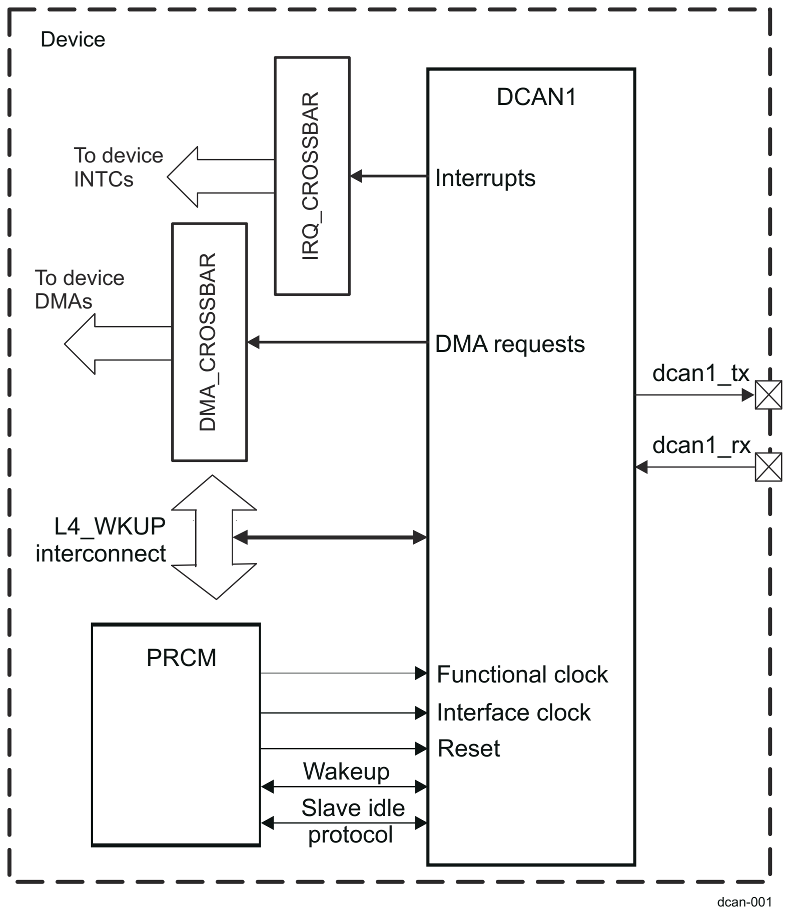

Figure 24-164. DCAN1 Overview

Figure 24-165 shows the DCAN2 module highlights .

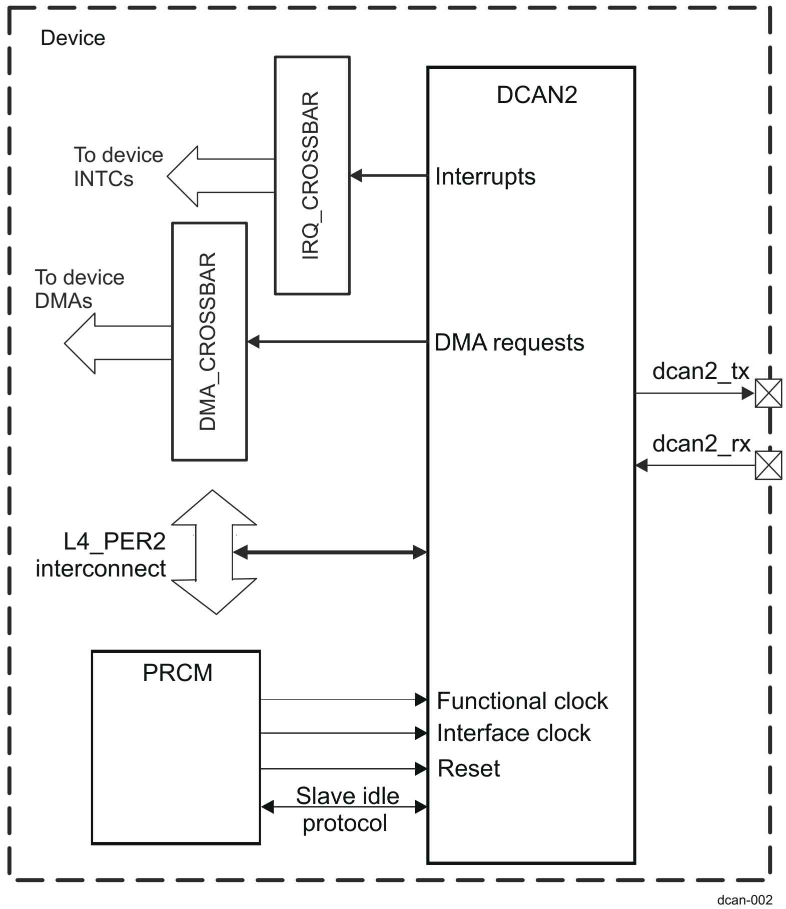

Figure 24-165. DCAN2 Overview

24.10.1.1 Features

The DCAN module implements the following features:

- Support for CAN protocol version 2.0 part A, B
- Bit rates up to 1 Mbit/s
- 64 message objects in a dedicated message RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM parity check mechanism
- Direct access to message RAM during test mode
- Support for two interrupt lines: Level 0 and Level 1, plus separate parity error interrupt line
- Local power down and wakeup support
- Automatic message RAM initialization
- Support for DMA access

24.10.2 DCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the DCAN.

Figure 24-166 shows an overview of a typical DCAN application.

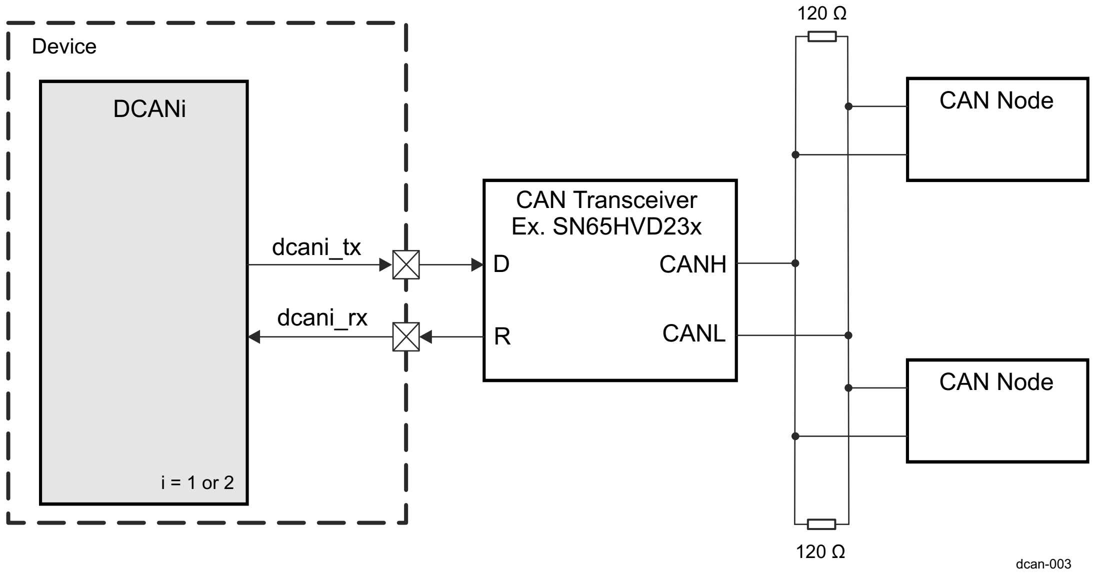

Figure 24-166. DCAN Typical Application

Table 24-736 describes the external signals of the DCAN1 module .

Table 24-736. DCAN2 I/O Description

Module Signal	Device Signal	I/O[(1)]	Description	Value at Reset
CAN_RX	dcan2_rx	I	Serial data input from external CAN tranceiver	HiZ
CAN_TX	dcan2_tx	O	Serial data output to external CAN tranceiver	1

(1) I = Input; O = Output

Table 24-737 describes the external signals of the DCAN2 module .

Table 24-737. DCAN1 I/O Description

Module Signal	Device Signal	I/O[(1)]	Description	Value at Reset
CAN_RX	dcan1_rx	I	Serial data input from external CAN tranceiver	HiZ
CAN_TX	dcan1_tx	O	Serial data output to external CAN tranceiver	1

(1) I = Input; O = Output

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers* of *Control Module*.

24.10.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using NRZ encoding and has two states:
  – Recessive state (logic 1)

  - Dominant state (logic 0)
- The network is multimaster. When two or more nodes attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost
- The message transmission is multicast. Data messages transmitted are identifier based, not address based
- Content of message is labeled by the identifier that is unique throughout the network (for example, rpm, temperature, position, pressure, etc.)
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is)
- Data is transmitted and received using message frames, consisting of:
  - Arbitration field
  - Control field
  - Data field (0 ÷ 8 bytes)
  - CRC field
  - ACK field.

24.10.3 DCAN Integration

Figure 24-167 shows the integration of the DCAN1 module in the device.

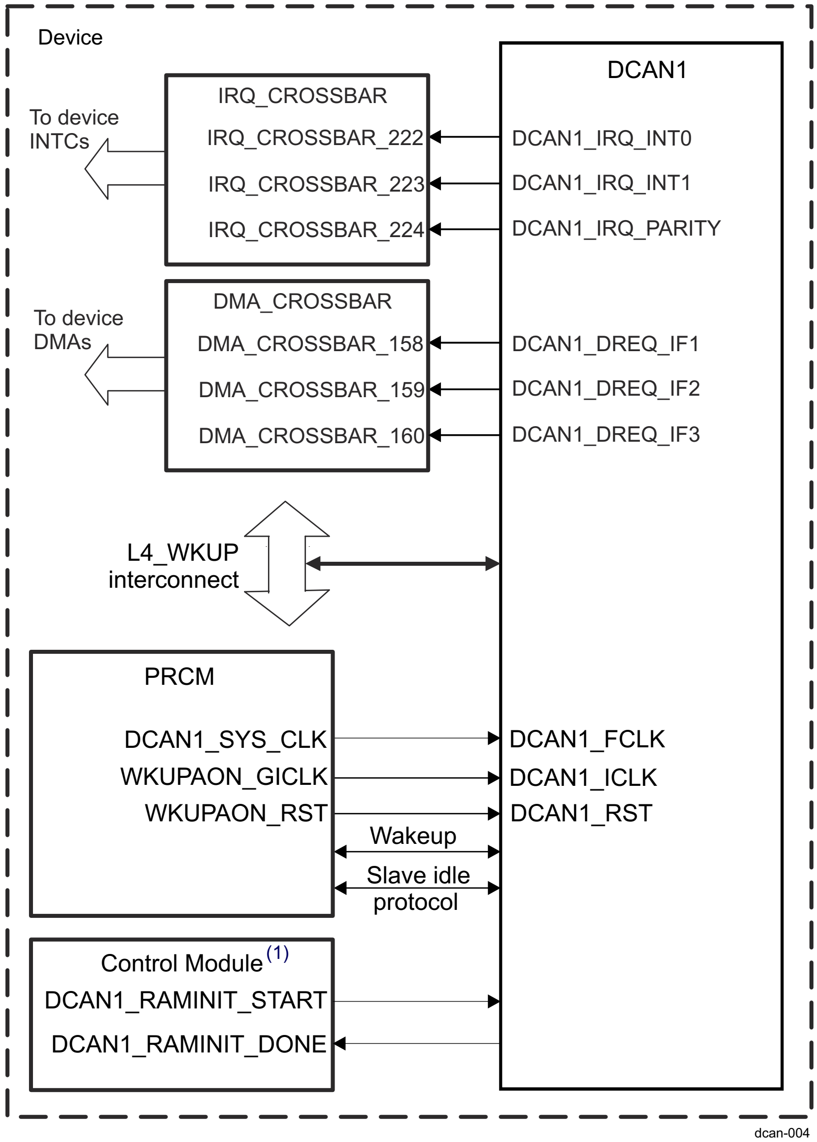

Figure 24-167. DCAN1 Integration

(1) For more information on DCAN RAM Initialization see Section 24.10.4.12.1.3, *DCAN RAM Hardware Initialization*

Figure 24-168 shows the integration of the DCAN2 module in the device .

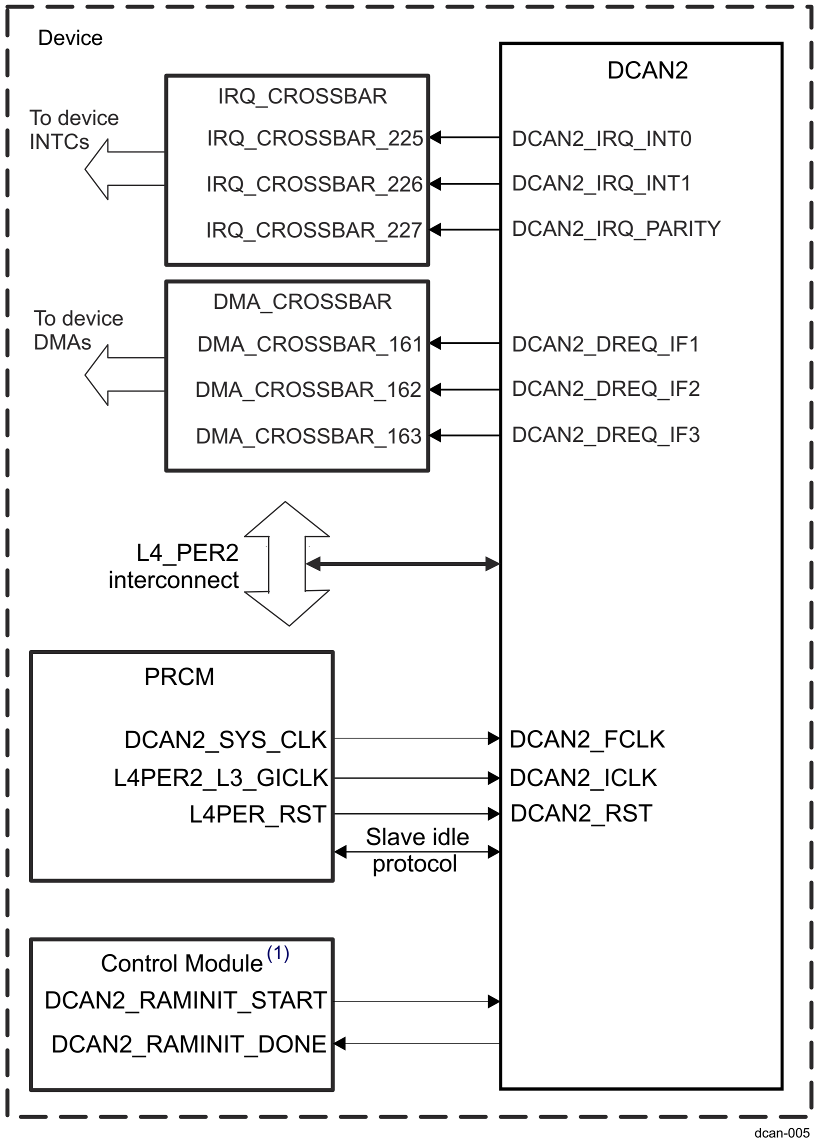

Figure 24-168. DCAN2 Integration

(1) For more information on DCAN RAM Initialization see Section 24.10.4.12.1.3, *DCAN RAM Hardware Initialization*

Table 24-738 through Table 24-740 summarize the integration of the DCAN modules in the device.

Table 24-738. DCAN Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
DCAN1	PD_WKUPAON	Yes	L4_WKUP
DCAN2	PD_COREAON	No	L4_PER2

DCAN2	DCAN2_DREQ_IF1	DMA_CROSSBAR_161	-	DMA request for IF1 register set
	DCAN2_DREQ_IF2	DMA_CROSSBAR_162	-	DMA request for IF2 register set
	DCAN2_DREQ_IF3	DMA_CROSSBAR_163	-	DMA request for IF3 register set

Note

DCAN has no default IRQ mappings through the IRQ_CROSSBAR. For DCAN, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.

Note

For the description of the interrupt source, see Section 24.10.4.2, *Interrupt Functionality*.

24.10.4 DCAN Functional Description

The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 24-169 shows the DCAN block diagram and its features are described below.

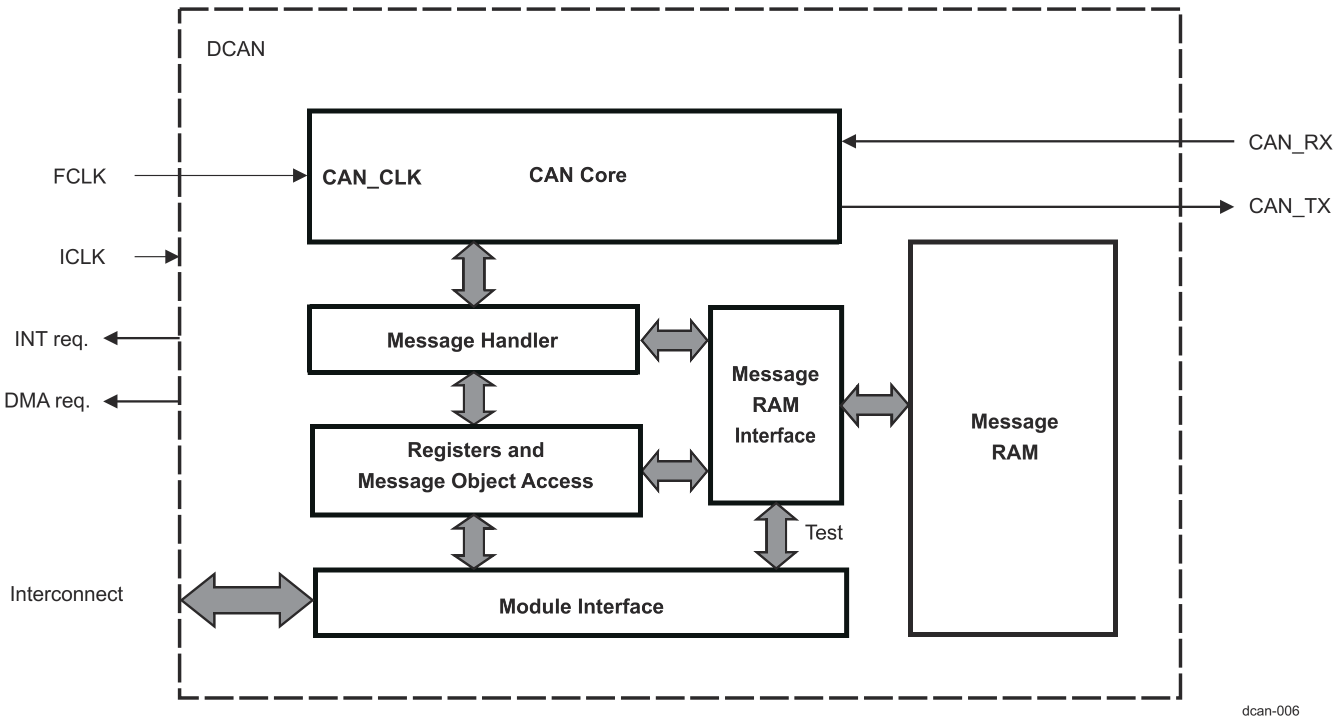

Figure 24-169. DCAN Block Diagram

CAN Core: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

Message Handler: The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

Message RAM: The DCAN enables a storage of 64 CAN messages.

Message RAM Interface: Three interface register sets control the MPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in Section 24.10.4.8.12, *Reading From a FIFO Buffer*.

The interface registers have the same word-length as the message RAM.

Registers and Message Object Access: Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either MPU or DMA.

Module Interface: The DCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.

Clocking: Two clocks are provided to the DCAN module: the peripheral synchronous clock (interface clock [ICLK]) and the peripheral asynchronous clock (functional clock [FCLK]) .

24.10.4.1 Module Clocking Requirements

Two clocks are provided to the DCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

Note

ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the DCAN. Here, also the frequency shift of the modulated ICLK has to be considered:

$f_{0,ICLK}(OCP) \pm \Delta f_{FM,ICLK}(OCP) \geq f_{FCLK}$

For more information on how to configure the relevant clock source registers, see *PRCM* and the device data manual.

24.10.4.2 Interrupt Functionality

Interrupts can be generated on two interrupt lines: INT0 and INT1. These lines can be enabled by setting the DCAN_CTL[1] IE0 and [17] IE1 bits, respectively. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see Figure 24-170, *Error and Status Change Interrupts* and Figure 24-171, *Message Objects Interrupts*).

The source of an interrupt can be determined by the interrupt identifiers DCAN_INT[15:0] INT0ID/[23:16] INT1ID. When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register DCAN_INT[15:0] INT0ID/ [23:16] INT1ID again reach zero (this means the cause of the interrupt is reset), or until IE0/IE1 are reset.

The value 0x8000 in the INT0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register (DCAN_ES). This interrupt has the highest priority. The software can update (reset) the status bits [9] WAKEUPPND, [4] RXOK, [3] TXOK and [2:0] LEC by reading DCAN_ES, but a write access of the software will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, INT0ID resp. INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time (DCAN_IF1CMD/DCAN_IF2CMD[19] CLRINTPND bit). When IntPnd is cleared, DCAN_INT will point to the next message object with a pending interrupt.

24.10.4.2.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPnd, TxIE and RxIE that are described in Section 24.10.4.11.1, *Structure of Message Objects*.

Message object interrupts can be routed to either INT0 or INT1 line, controlled by the interrupt multiplexer registers (DCAN_INTMUX12 to DCAN_INTMUX78).

24.10.4.2.2 Status Change Interrupts

The events WAKEUPPND, RXOK, TXOK and LEC in the error and status register (DCAN_ES) belong to the status change interrupts. The status change interrupt group can be enabled by DCAN_CTL[2] SIE bit.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

Note

Reading DCAN_ES will clear the WAKEUPPND flag. If in global power-down mode, the WAKEUPPND flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WAKEUPPND flag, and a second interrupt may occur.

24.10.4.2.3 Error Interrupts

The events PER, BOFF and EWARN, monitored in the DCAN_ES register belong to the error interrupts. The error interrupt group can be enabled by setting bit DCAN_CTL[3] EIE = 1.

Error interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

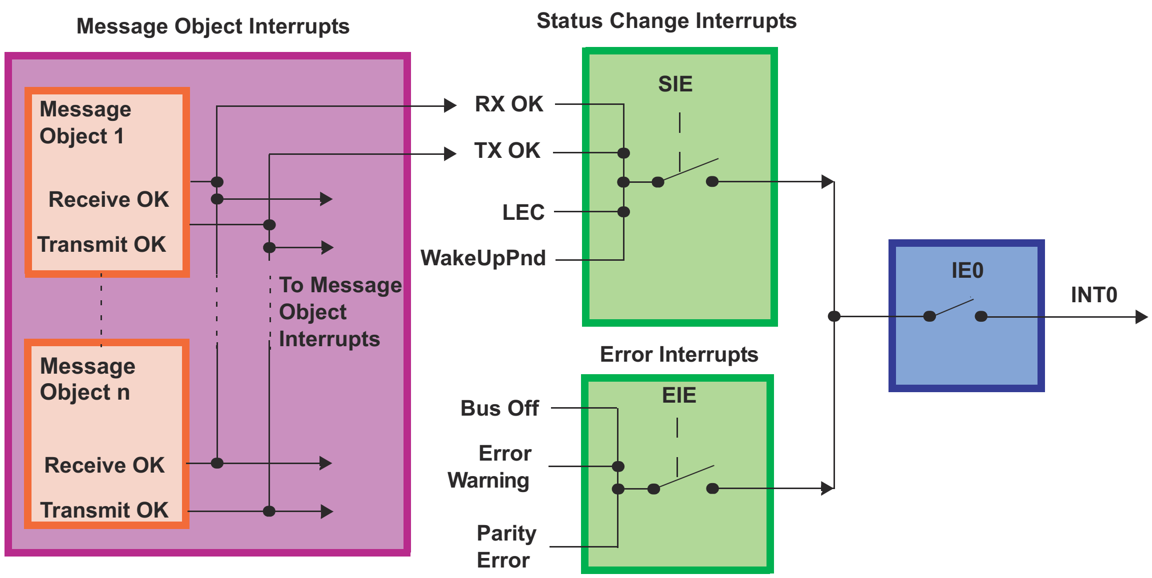

Figure 24-170. Error and Status Change Interrupts

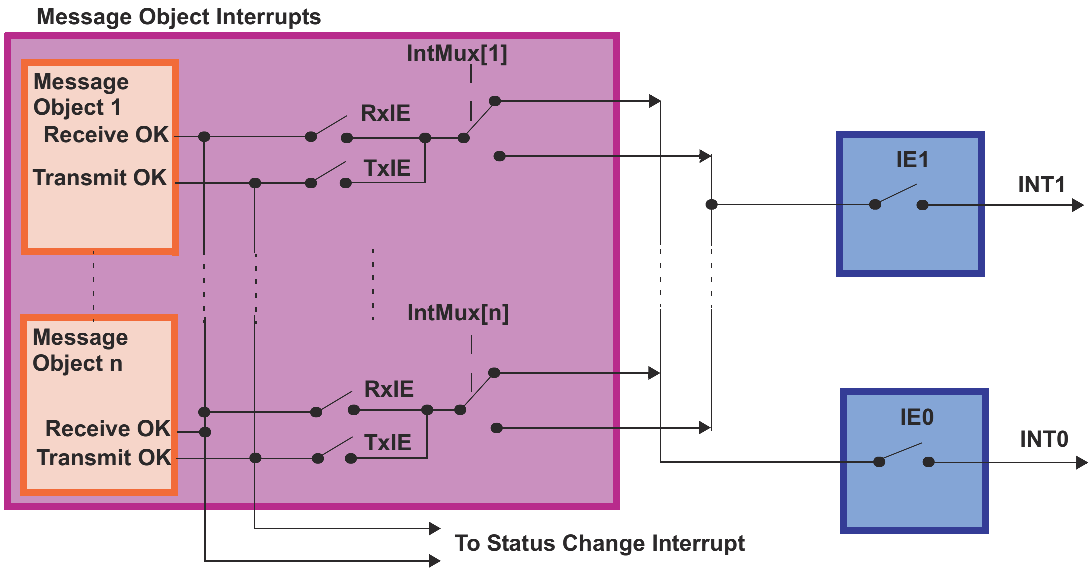

Figure 24-171. Message Objects Interrupts

24.10.4.3 DMA Functionality

The DCAN provides three DMA request lines, each indicating new data in one of the three interface register sets IF1, IF2 and IF3.

The update of IF1 and IF2 registers will be initiated by a write access to the IF1 respective IF2 Command Registers (DCAN_IF1CMD, DCAN_IF2CMD).

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update, see Section 24.10.4.10.2, *IF3 Register Set*.

When a DCAN internal IFx (x = 1 to 3) update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers. The DMA functionality has to be enabled by setting bit [18] DE0/[19] DE1/[20] DE3 in DCAN_CTL.

24.10.4.4 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the DCAN registers.

24.10.4.4.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the DCAN_CTL[24] PDR bit (=1).

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the DCAN_CTL[0] INIT bit to prevent any further CAN transfers, and it will also set the DCAN_ES[10] PDA bit. With setting the PDA bit, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see Section 24.10.4.4.2, *Wakeup From Local Power Down*) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

Note

In local low-power mode, the software must not clear the INIT bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the INIT bit, these messages may get sent.

24.10.4.4.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

- The application could wake up the DCAN module manually by clearing the DCAN_CTL[24] PDR bit and then clearing the DCAN_CTL[0] INIT.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity bit (DCAN_CTL[25] WUBA). If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the DCAN_CTL[24] PDR bit and also clear the DCAN_ES[10] PDA bit. The DCAN_ES[10] WAKEUPPND bit will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the DCAN_CTL[0] INIT bit will be cleared.

After the INIT bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

Note

The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 24-172 shows a flow diagram about entering and leaving local power-down mode.

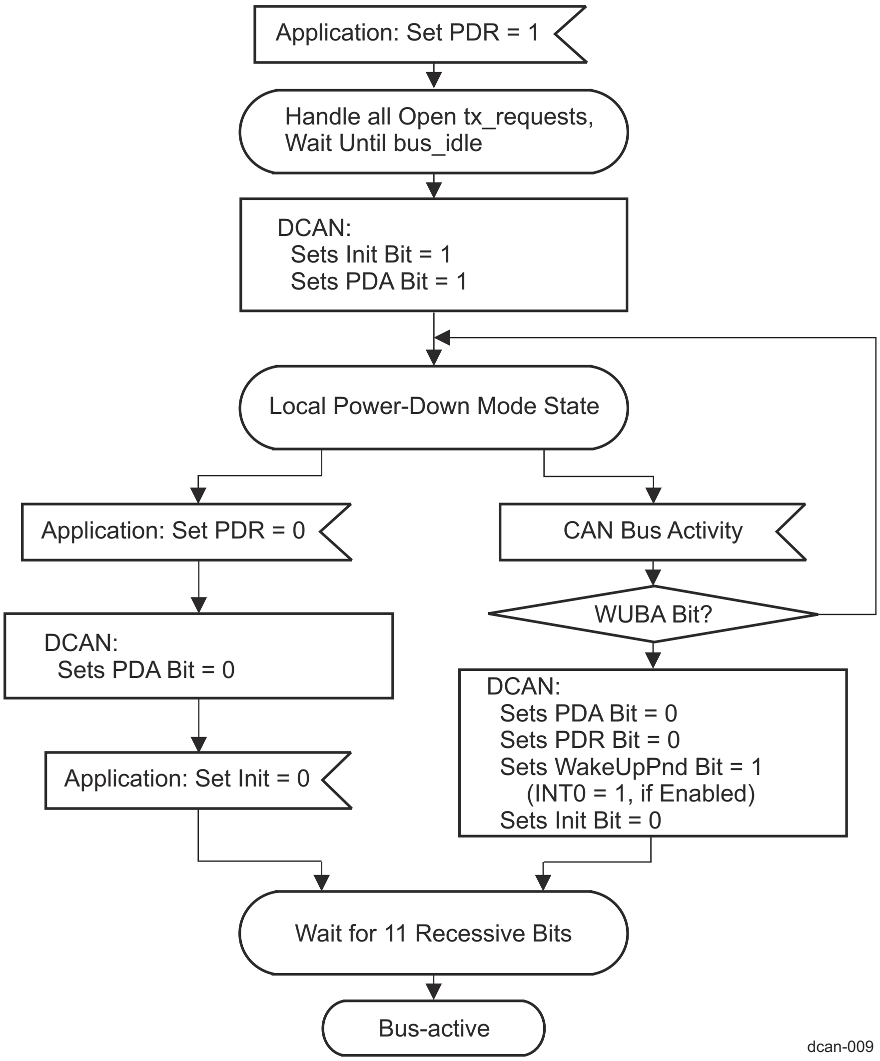

Figure 24-172. Local Power-Down Mode Flow Diagram

24.10.4.5 Parity Check Mechanism

The DCAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in message RAM, one parity bit will be calculated. The formation of the different words is according to the message RAM representation in RDA mode, see Section 24.10.4.11.4, *Message RAM Representation in Direct Access Mode*.

Parity information is stored in the message RAM on write accesses and will be checked against the stored parity bit from message RAM on read accesses.

The Parity check functionality can be enabled or disabled by DCAN_CTL[13:10] PMD bit field.

In case of disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the DCAN. The parity bits could be read in debug/suspend mode (see Section 24.10.4.11.3, *Message RAM Representation in Debug/Suspend Mode*) or in RDA mode (see Section 24.10.4.11.4, *Message RAM Representation in Direct Access Mode*). However, direct write access to the parity bits is only possible in this two modes with parity check disabled.

A parity bit will be set, if the modulo-2-sum of the data bits is 1. This definition is equivalent to: The parity bit will be set, if the number of 1 bits in the data is odd.

Note

DCAN is configured to even parity by the design.

24.10.4.5.1 Behavior on Parity Error

On any read access to message RAM (e.g., during start of a CAN frame transmission), the parity of the message object will be checked. If a parity error is detected, the DCAN_ES[8] PER bit will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset to 0.

The message object data can be read by the software, independently of parity errors. Thus, the software has to ensure that the read data is valid, for example, by immediately checking the parity error code register (DCAN_PERR) on parity error interrupt.

Note

During RAM initialization, no parity check is done, but if the PMD bit is set, the parity bits will be generated.

24.10.4.5.2 Parity Testing

Testing the parity mechanism can be done by enabling the bit RamDirectAccess (DCAN_TEST[9] RDA) and manually writing the parity bits directly to the dedicated RAM locations. With this, data and parity bits could be checked when reading directly from RAM.

Note

If parity check is disabled, the software has to ensure correct parity bit handling in order to prevent parity errors later on when parity check is enabled.

24.10.4.6 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via interconnect interface.

Before entering debug/suspend mode, the DCAN will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit DCAN_CTL[8] IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by DCAN_CTL [16] INITDBG flag.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return ‘0’. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see Section 24.10.4.11.3, *Message RAM Representation in Debug/Suspend Mode*.

Note

During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

Note

Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- DCAN_ES register (clear of status flags by read)
- DCAN_IF1CMD/DCAN_IF2CMD command registers (clear of [14] DMAACTIVE flag by read/write)

24.10.4.7 Configuration of Message Objects Description

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver must offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = ‘1’)

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.
