In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

24.10.4.7.1 Configuration of a Transmit Object for Data Frames

Table 24-741 shows how a transmit object can be initialized.

Table 24-741. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data length and data itself (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TXIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask=’1’) to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 24.10.4.8.8, *Reception of Remote Frames*.

Identifier masking must be disabled (UMask = ‘0’) if no remote frames are allowed to set the TxRqst bit (RmtEn = ‘0’).

24.10.4.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data rrame for which this receive object is configured.

24.10.4.7.3 Configuration of a Single Receive Object for Data Frames

Table 24-742 shows how a receive object for data frames can be initialized.

Table 24-742. Initialization of a single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to ‘0’.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = ’1’) to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to “don’t care,” the corresponding bits of the arbitration register (DCAN_IF1ARB, DCAN_IF2ARB, DCAN_IF3ARB) will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = ’1’) for acceptance filtering.

24.10.4.7.4 Configuration of a Single Receive Object for Remote Frames

Table 24-743 shows how a receive object for remote frames can be initialized.

Table 24-743. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 24.10.4.7.5, *Configuration of a FIFO Buffer*).

UMask must be set to ‘1.’ The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to “must-match” or to “don’t care,” to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 24.10.4.8.8, *Reception of Remote Frames*.

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to “don’t care,” the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to ‘0.’

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

24.10.4.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

24.10.4.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

24.10.4.8.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same or higher as the message the object found by last scanning
- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

24.10.4.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

24.10.4.8.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the MSGVAL bits in the Message Valid register (DCAN_MSGVAL12 to DCAN_MSGVAL78) and the TXRQST bits in the transmission request register (DCAN_TXRQ12 to DCAN_TXRQ78) are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object’s NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = ‘0’) since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DCAN_CTL[5] DAR bit, the behavior of bits TXRQST and NEWDAT in the DCAN_IF1CMD/DCAN_IF2CMD register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error), bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

24.10.4.8.4 Updating a Transmit Object

The software may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MSGVAL, nor TXRQST have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register (DCAN_IF1DATA/DCAN_IF2DATA) or IF1/IF2 Data B register (DCAN_IF1DATB/DCAN_IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the software has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the software writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1/IF2 Command register (DCAN_IF1CMD/DCAN_IF2CMD) and then the number of the message object is written to bits [7:0] MESSAGE_NUMBER of the command register, concurrently updating the data bytes and setting TXRQST with NEWDAT.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 24.10.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

24.10.4.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The software can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD) can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither Dir, nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD) should be set to 0x87.

Note

After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

24.10.4.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

24.10.4.8.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the software) has been received. The software should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the software) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the DCAN_INT to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

24.10.4.8.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = ‘1’ (direction = transmit), RmtEn = ‘1’, UMask = ‘1’ or ‘0’

  The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘0’

  The remote frame is ignored, this message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘1’

The remote frame is treated similar to a received data frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

24.10.4.8.9 Reading Received Messages

The software may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the software will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] MESSAGE_NUMBER of the command register (DCAN_IF1CMD/ DCAN_IF2CMD). That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register (DCAN_IF1MCTL/DCAN_IF2MCTL/DCAN_IF3MCTL) always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

24.10.4.8.10 Requesting New Data for a Receive Object

By means of a remote frame, the software may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD).

24.10.4.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). arbitration and mask registers of the FIFO buffer’s message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer’s message objects are ‘0’; in the last one the EoB bit is ‘1.’

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is ‘0’, the message object is locked for further write accesses by the message handler until the software has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to ‘0,’ all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = ‘1’) and therefore overwrite previous messages in this message object.

24.10.4.8.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

A FIFO buffer of length N will store N–1, plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 24-173.

Note

All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

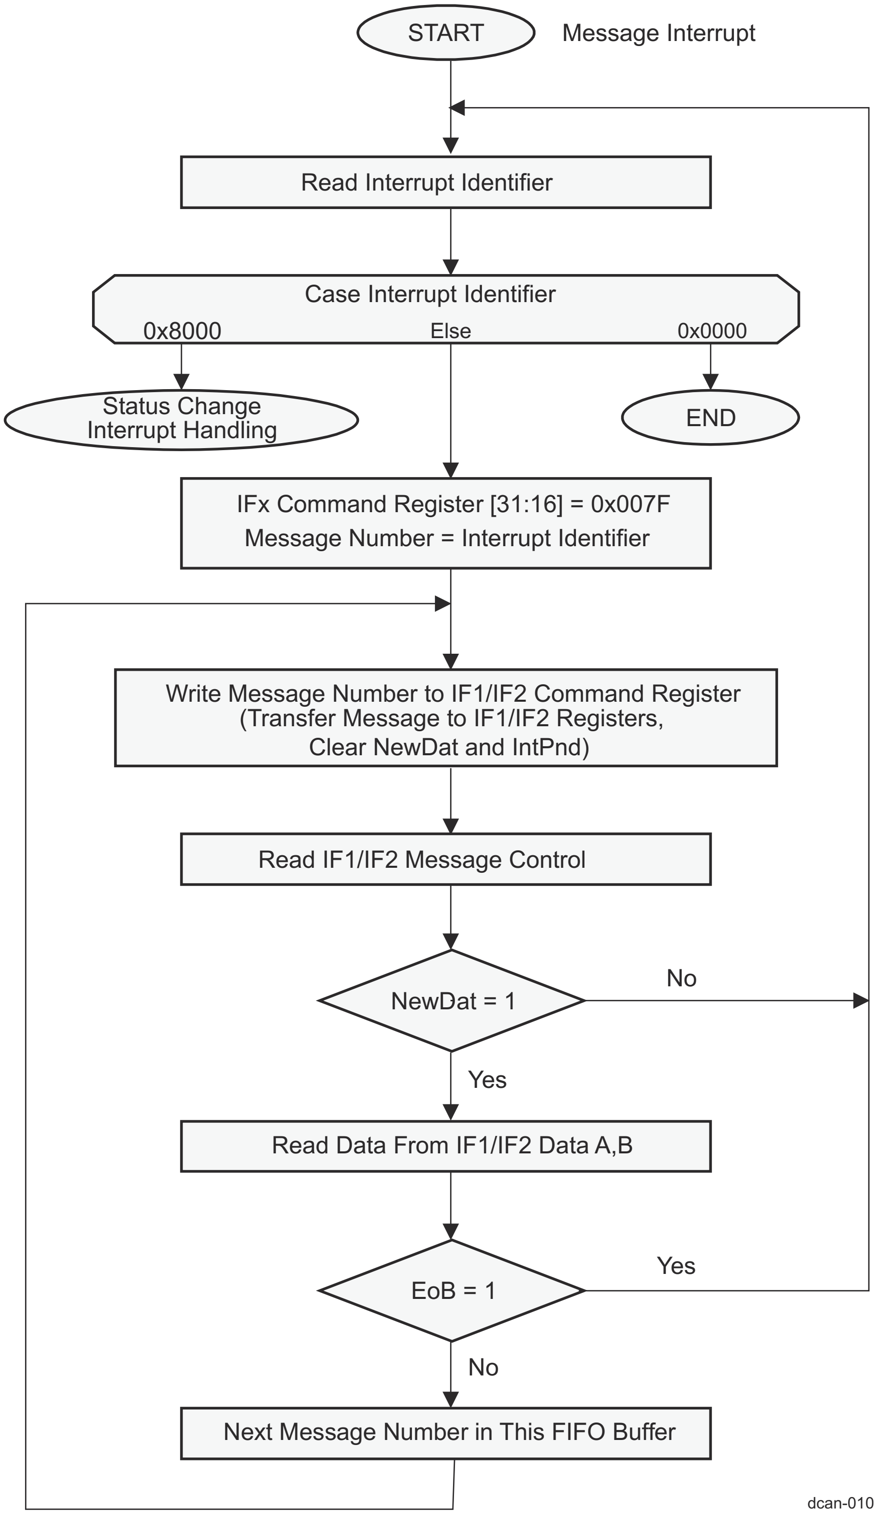

Figure 24-173. Software Handling of a FIFO Buffer (Interrupt Driven)

24.10.4.9 CAN Bit Timing

The DCAN supports bit rates between < 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

24.10.4.9.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 24-174):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

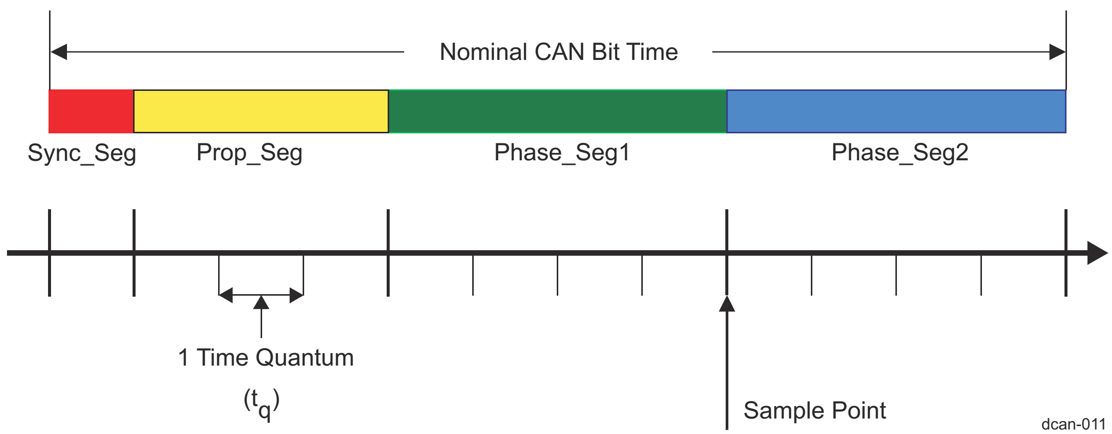

Figure 24-174. Bit Timing

Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the FCLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / FCLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 24-744 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Table 24-744. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to FCLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times

Table 24-744. Parameters of the CAN Bit Time (continued)

Parameter	Range	Remark
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

Note

For proper functionality of the CAN network, the physical delay times and the oscillator’s tolerance range have to be considered.

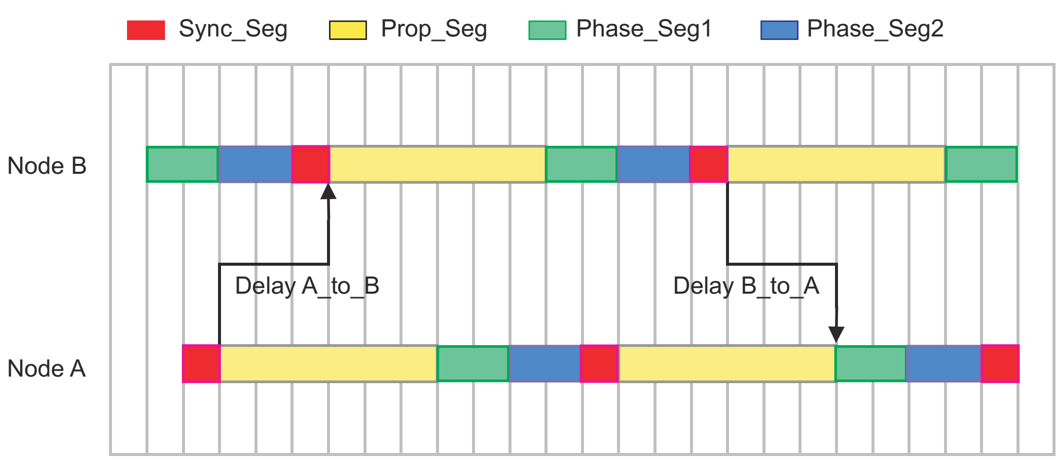
24.10.4.9.1.1 Synchronization Segment

The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

24.10.4.9.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol’s nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 24-175 shows the phase shift and propagation times between two CAN nodes.



Delay A_to_B ≥ node output delay(A) + bus line delay(AÆB) + node input delay(B)

Prop_Seg ≥ Delay A_to_B + Delay B_to_A

Prop_Seg ≥ 2 [max(node output delay + bus line delay + node input delay)]

dcan-012

Figure 24-175. The Propagation Time Segment

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B’s bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

24.10.4.9.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.
- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than

SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 24-176 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

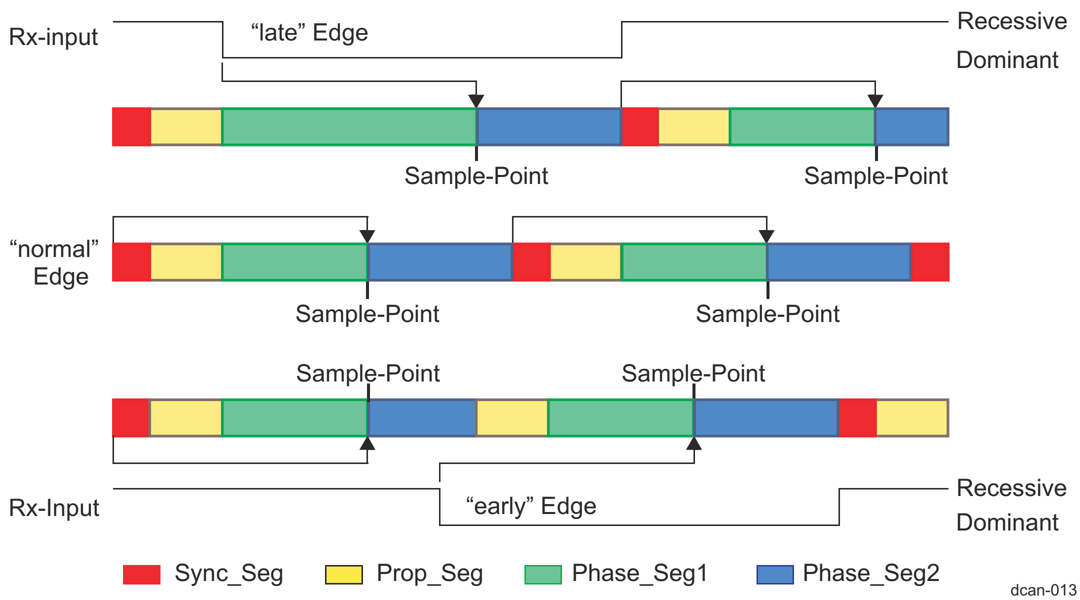


Figure 24-176. Synchronization on Late and Early Edges

In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

Figure 24-177 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

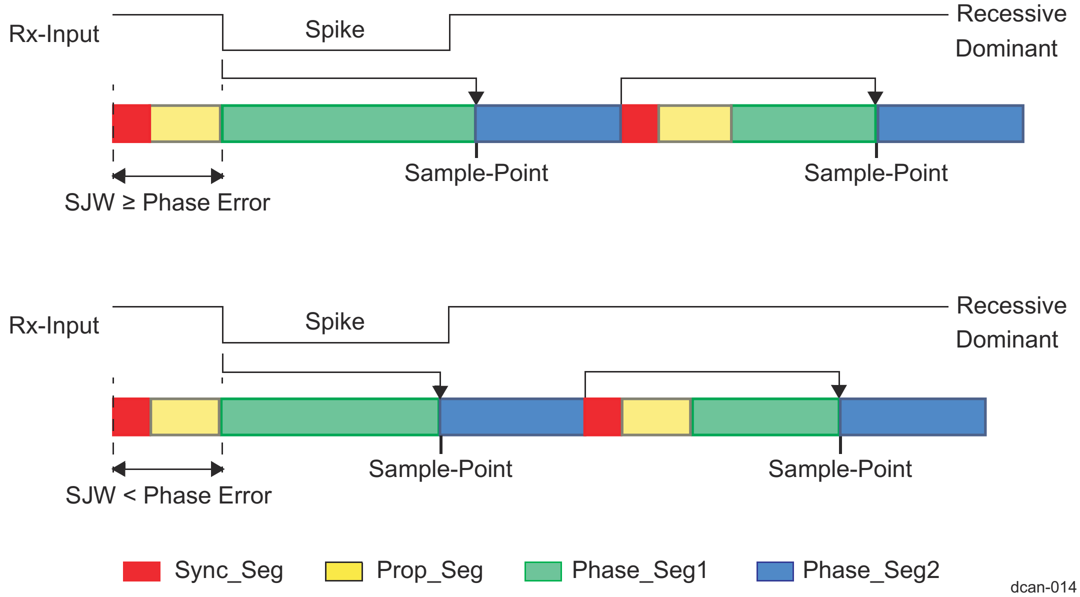

Figure 24-177. Filtering of Short Dominant Spikes

24.10.4.9.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) \bullet f_{nom} \le f_{osc} \le (1 + df) \bullet f_{nom}$$

dcan-e015

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \le \frac{\min(TSeg1, TSeg2)}{2x(13x(bit\_time - TSeg2))}$$

$$\text{II:} \quad df \le \frac{SJW}{20x bit\_time}$$

dcan-e016

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 µs) with a bus length of 40 m.

24.10.4.9.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in DCAN_BTR[14:0], additionally a baud rate prescaler extension of four bits (DCAN_BTR[19:16] BRPE) is provided.

- The sum of Prop_Seg and Phase_Seg1 is set in [11:8] TSEG1
- Phase_Seg2 in [14:12] TSEG2
- SynchronizationJumpWidth in [7:6] SJW
- and baud rate prescaler [5:0] BRP (plus [19:16] BRPE)

Figure 24-178 shows the CAN protocol controller.

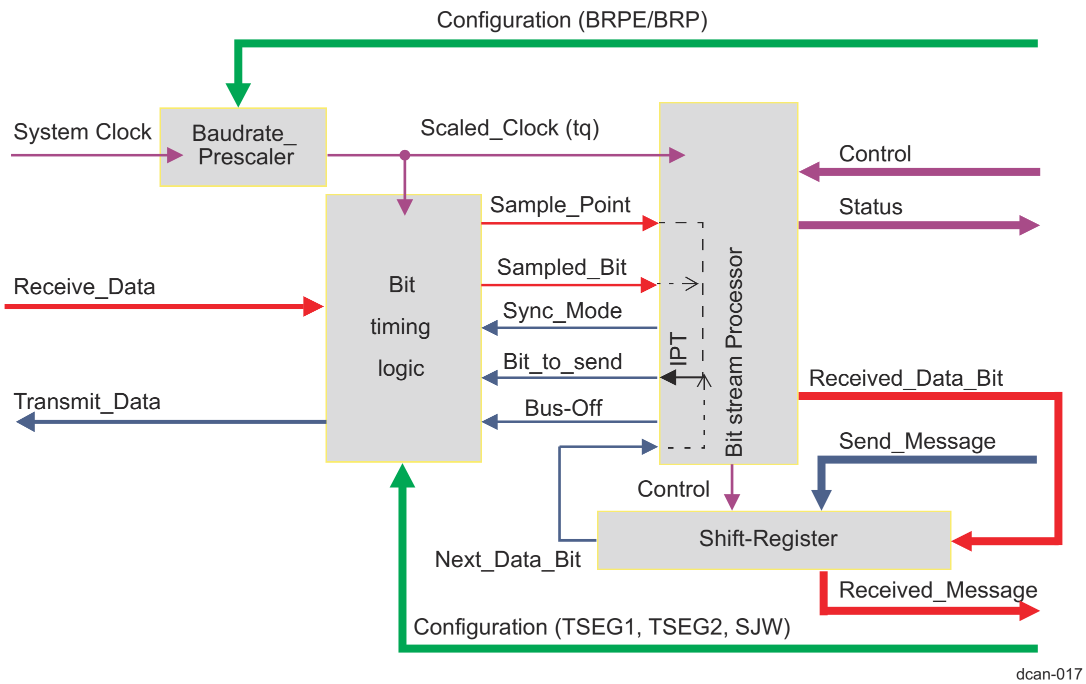

Figure 24-178. Structure of the CAN Core's CAN Protocol Controller

In DCAN_BTR register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1…n], values in the range of [0…n–1] are programmed. That way, e.g., SJW (functional range of [1…4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the bit timing register (DCAN_BTR) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (e.g., data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is 0 tq for the DCAN.

Generally, the IPT is CAN controller-specific, but may not be longer than 2 tq. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

24.10.4.9.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the baud rate prescaler with t_q = (Baud Rate Prescaler) / FCLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0…2] t_q.

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Table 24-745.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register (DCAN_BTR):

[14:12] TSEG2 = Phase_Seg2 - 1

[11:8] TSEG1 = Phase_Seg1+ Prop_Seg - 1

[7:6] SJW = SynchronizationJumpWidth - 1

[5:0] BRP = Prescaler - 1

24.10.4.9.2.2 Example for Bit Timing Calculation

In this example, the frequency of FCLK is 20 MHz, BRP is 2, the bit rate is 500 KBit/s.

Table 24-745. Example For Bit Timing

Parameter	Formula	Value	t_q
bit time (500 KBit/s)	1/bit rate, consists of $t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$	2000 ns	20
delay of bus driver		280 ns	-
delay of receiver circuit		29 ns	-
delay of bus line (16 m)	16 × 5.5 ns/m	88 ns	-
t_q	BRP/FCLK	100 ns	1
t_{Sync_Seg}	1 × t_q (fixed)	100 ns	1
t_{Prop_Seg}	INT (2×delays + 1) = 8 × t_q	800 ns	8
t_{Seg1}	$t_{Prop\_Seg} + t_{Phase\_Seg1}$	1400 ns	14
t_{Seg2}	bit time - ($_{Sync\_Seg}$ + t_{Seg1})	500 ns	5
t_{SJWmax}	MIN (4 × t_q, t_{Phase_Seg1})	400 ns	4

In this example, the bit timing register DCAN_BTR is programmed to:

- BRP = 2 - 1 = 1
- BRPE = 0
- TSEG1 = 14 - 1 = 13 (0xC)
- TSEG2 = 5 - 1 = 4
- SJW = 4 - 1 = 3

24.10.4.10 Message Interface Register Sets

The interface register sets control the software read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be left unchanged.

By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent software accesses to the message RAM and CAN message reception and transmission. A complete message object (see Section 24.10.4.11.1, *Structure of Message Objects*) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see Section 24.10.5, *DCAN Register Manual*) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

24.10.4.10.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. DCAN_IF1CMD/ DCAN_IF2CMD address the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] MESSAGE_NUMBER.

When the software initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the [15] BUSY bit in respective DCAN_IF1CMD/DCAN_IF2CMD to 1. After the transfer has completed, the BUSY bit is set back to 0 (see Figure 24-179).

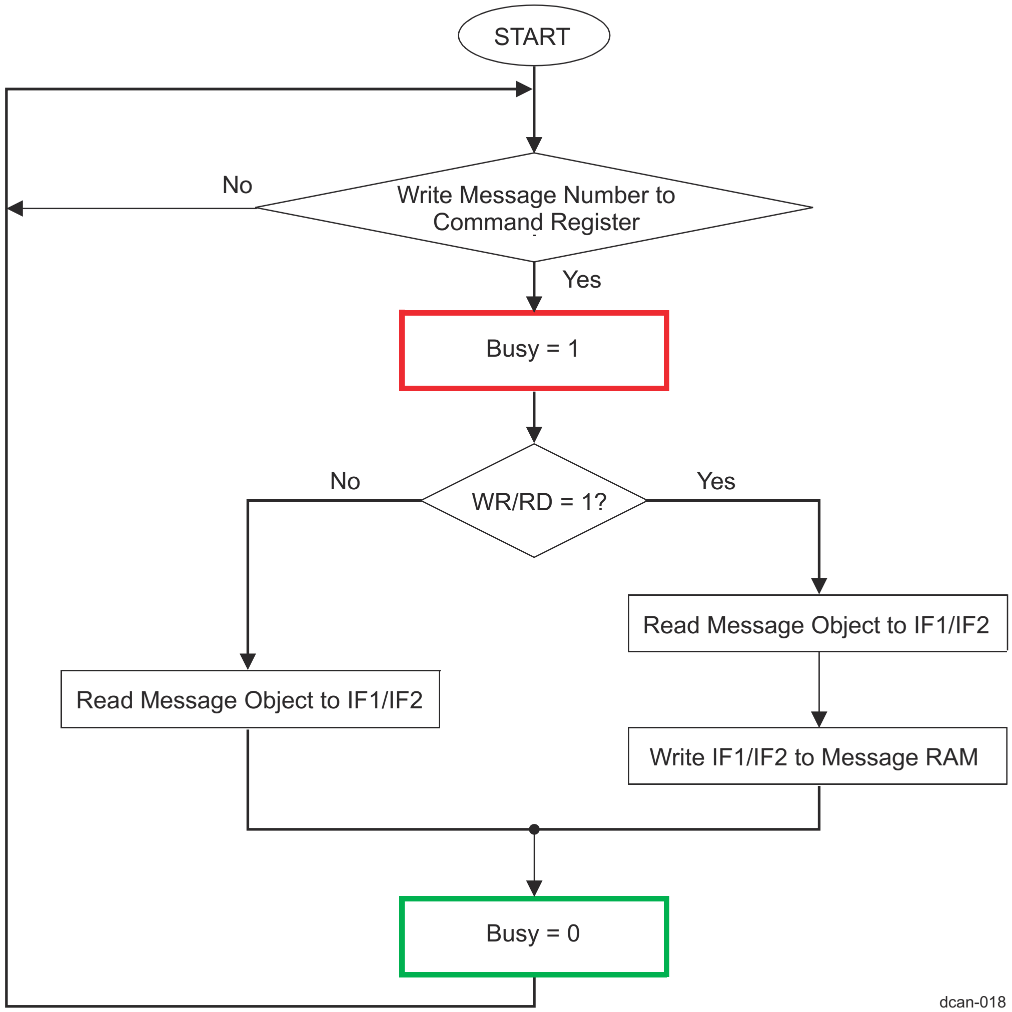

Figure 24-179. Data Transfer Between IF1/IF2 Registers and Message RAM

24.10.4.10.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object (DCAN_IF3UPD12 to DCAN_IF3UPD78).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register (DCAN_IF3OBS). If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DCAN_CTL[20] DE3 = 1.

Note

The IF3 register set cannot be used for transferring data into message objects.

24.10.4.11 Message RAM

The DCAN message RAM contains message objects and parity bits for the message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the software cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the software to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The software does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the software:

- Debug/Suspend mode (see Section 24.10.4.11.3, *Message RAM Representation in Debug/Suspend Mode*)
- RAM Direct Access (RDA) mode (see Section 24.10.4.11.4, *Message RAM Representation in Direct Access Mode*)

CAUTION

Writes to the DCAN RAM must not be done while it is in low-power mode. If such writes occur, the behavior is undefined and RAM content is corrupted. It has to be ensured in software that the low-power mode is removed from the DCAN RAM before writing to it.

24.10.4.11.1 Structure of Message Objects

Table 24-746 shows the structure of a message object.

The highlighted fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Table 24-746. Structure of a Message Object

UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 24-747. Message Object Field Descriptions

Field Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit may be kept at level ‘1’ even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required. The software must reset the MsgVal bit of all unused Messages Objects during the initialization before it resets the INIT bit in the DCAN_CTL register.

Table 24-747. Message Object Field Descriptions (continued)

Field Name	Value	Description
UMask		Use acceptance mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to one, the message object’s mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message identifier
	ID[28:0]	29-bit (“extended”) identifier bits
	ID[28:18]	11-bit (“standard”) identifier bits
Msk[28:0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don’t care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit (“standard”) Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the software.
	1	The message handler or the software has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the software.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register (DCAN_INT) will point to this message object if there is no other interrupt source with higher priority.

Table 24-747. Message Object Field Descriptions (continued)

Field Name	Value	Description
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0 - 8	Data frame has 0 - 8 data bytes.
	9 - 15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

24.10.4.11.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
Message RAM base address + (message object number) × 0x20

That is, message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

Note

Because 0 is not a valid message object number, at offset 0x0000 is not located message object 0, but the last implemented: 64.

The base address for DCAN1 RAM is 0x4AE3 D000 and DCAN2 RAM is 0x4848 1000.

Message object number 1 has the highest priority.

Table 24-748. Message RAM Addressing in Debug/Suspend and RDA Modes

Message Object Number	Offset	Word Number	Debug/Suspend Mode, see Section 24.10.4.11.3	RDA Mode, see Section 24.10.4.11.4
64 (last implemented)	0x0000	1	Parity	Data Bytes 4-7
	0x0004	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x0008	3	Xtd,Dir,ID	ID[27:0],DLC
	0x000C	4	Ctrl	Mask,Xtd,Dir,ID[28]

	0x07F4	6	Data Bytes 7-4	-

24.10.4.11.3 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

Note

During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

Table 24-749. Message RAM Representation in Debug/Suspend Mode

24.10.4.11.4 Message RAM Representation in Direct Access Mode

When the DCAN_TEST[9] RDA bit is set while the DCAN module is in test mode (DCAN_CTL[7] TEST = 1), the software has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The software has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RAM Direct Access during normal operation mode (TEST bit or RDA bit not set) will be ignored.

Writes to unused bits have no effect.

24.10.4.12 CAN Operation

After device reset, the DCAN_CTL[0] INIT is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 24-180 illustrates the basic initialization flow for the CAN module.

24.10.4.12.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the software has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

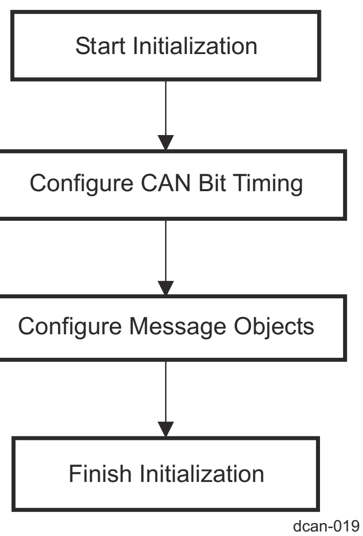

Figure 24-180. CAN Module General Initialization Flow

24.10.4.12.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see Figure 24-181, *CAN Bit-Timing Configuration*.

Step 1: Enter *initialization mode* (DCAN_CTL[0] INIT = 1).

While the INIT bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the INIT bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on device reset and during Bus-Off.

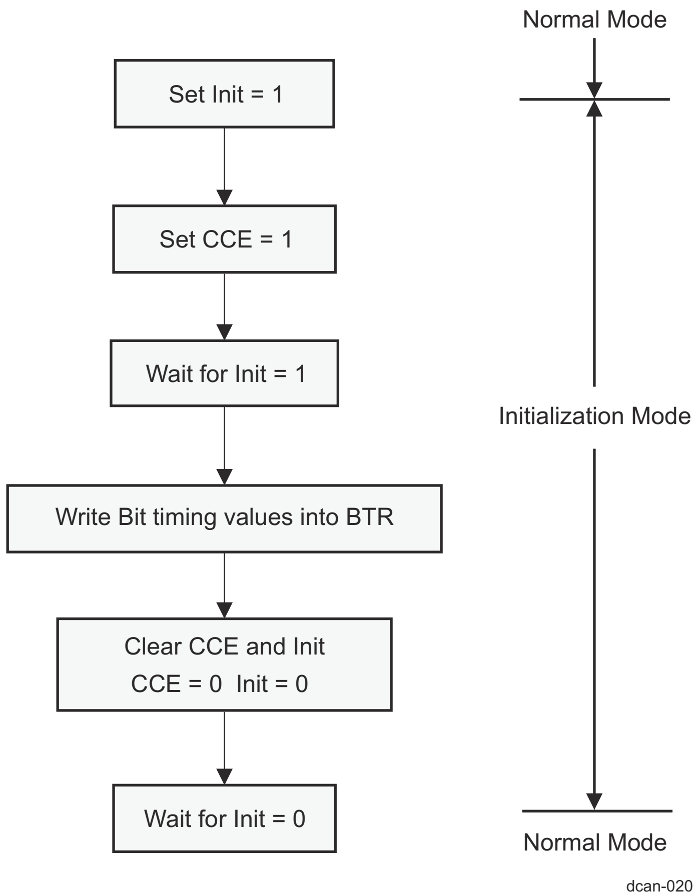

Figure 24-181. CAN Bit-Timing Configuration

Step 2: Set the Configure Change Enable bit (DCAN_CTL[6] CCE = 1).

The access to the Bit Timing register (DCAN_BTR) for the configuration of the bit timing is enabled when both INIT = 1 and CCE = 1.

Step 3: Wait for the INIT bit to get set (=1). This would make sure that the module has entered Initialization mode.

Step 4: Write the bit timing values into DCAN_BTR. See Section 24.10.4.9.2, *DCAN Bit Timing Registers* for the values calculation for a given bit timing.

Step 5: Clear the CCE and INIT bits (=0).

Step 6: Wait for the INIT bit to clear (=0). This would ensure that the module has come out of Initialization mode.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the DCAN_BTR is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

Note

The module will not come out of the Initialization mode if any incorrect DCAN_BTR values are written in step 4.

Note

The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in Section 24.10.4.12.1, *CAN Module Initialization*.

24.10.4.12.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the software does not have direct access to the message object (message RAM) . Familiarize yourself with the interface register set (IFx) usage (see Section 24.10.4.10, *Message Interface Register Sets*) and the message object structure (see Section 24.10.4.11, *Message RAM*) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see Section 24.10.4.7, *Configuration of Message Objects Description*. All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

Note

The message objects initialization is independent of the bit-timing configuration.

24.10.4.12.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control module. Setting RAMINIT_START to 1, causes RAM initialization with zeros and sets parity bits accordingly. Software must wait for the RAMINIT_DONE bit to be set to ensure successful RAM initialization.

For more details on CTRL_CORE_CONTROL_IO_2 register, see *Control Module Register Manual*.

24.10.4.12.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and DCAN_CTL[0] INIT bit is reset (=0), the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The software may enable the interrupt lines (DCAN_CTL[1] IE0 and [17] IE1 = 1) at the same time when it clears [0] INIT and [6] CCE = 0. The status interrupts [3] EIE and [2] SIE may be enabled (=1) simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The DCAN_INT register points to those message objects with IntPnd = 1. It is updated even if the interrupt lines to the host processor are disabled (DCAN_CTL[1] IE0 and [17] IE1 = 0).

The software may poll all MessageObject’s NewDat and TxRqst bits in parallel from the DCAN_NWDAT_X and the DCAN_TXRQ_X registers respectively. Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to “don’t care” may change in the message object when a received message is stored.

The software may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

24.10.4.12.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission (DCAN_CTL[5] DAR = 1). Further details to this mode are provided in Section 24.10.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

24.10.4.12.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the software can start a Bus-Off-Recovery sequence by resetting the DCAN_CTL[0] INIT bit to 0. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit DCAN_CTL[9] ABO. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of interface clock cycles which can be defined in the Auto-Bus-On Time register (DCAN_ABOTR).

Note

If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the INIT bit. Once the INIT bit has been reset by the software or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

24.10.4.12.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

For all test modes, the DCAN_CTL[7] TEST bit needs to be set to 1. This enables write access to the test register (DCAN_TEST).

Note

It must be ensured by software that all message transfers are completed before entering test mode.

24.10.4.12.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (e.g., acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Figure 24-182 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the DCAN_TEST[3] SILENT bit to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

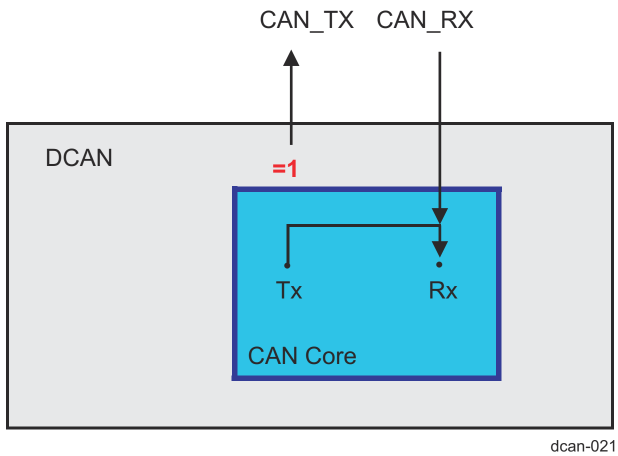

Figure 24-182. CAN Core in Silent Mode

24.10.4.12.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 24-183 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit DCAN_TEST[4] LBACK to 1.

Note

In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 24.10.4.12.3.3, *External Loopback Mode*.

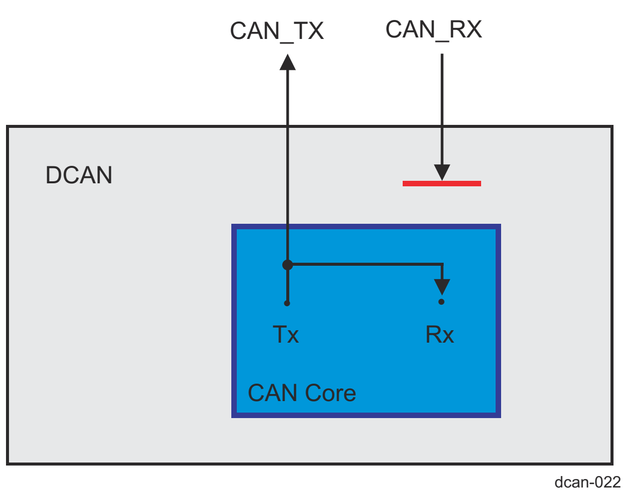

Figure 24-183. CAN Core in Loopback Mode

24.10.4.12.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit DCAN_TEST[8] EXL to 1.

Figure 24-184 shows the connection of signals CAN_TX and CAN_RX to the CAN core in external loopback mode.

Note

When loopback mode is active (LBACK bit set), the EXL bit will be ignored.

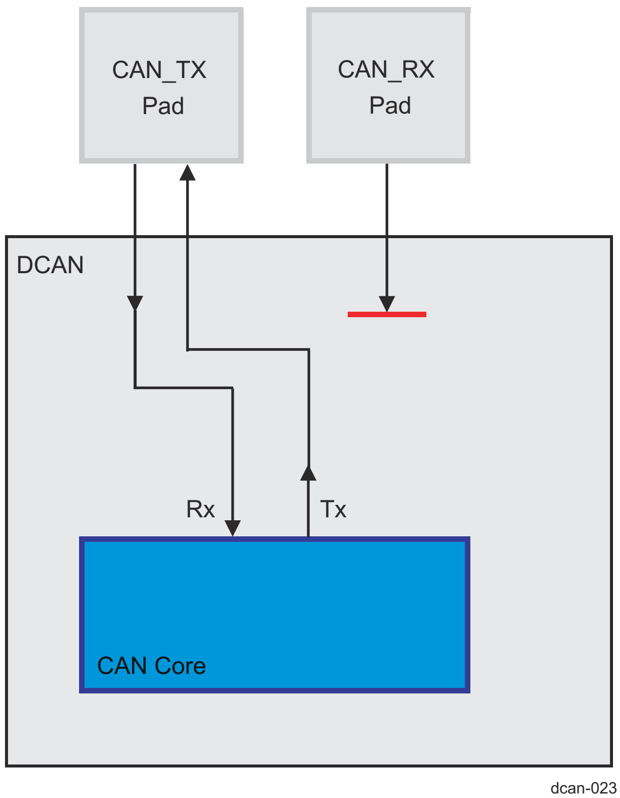

Figure 24-184. CAN Core in External Loopback Mode

24.10.4.12.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits DCAN_TEST[4] LBACK and [3] SILENT at the same time. This mode can be used for a "Hot Selftest", that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits will be sent on the CAN_TX pin.

Figure 24-185 shows the connection of the signals CAN_TX and CAN_RX to the CAN core in case of the combination of loopback mode with silent mode.

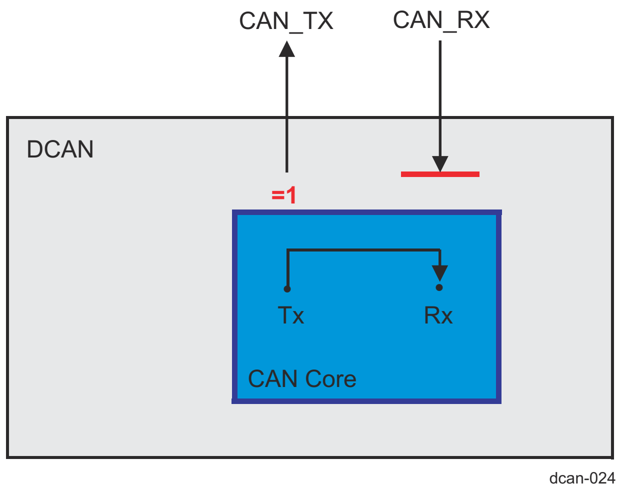

Figure 24-185. CAN Core in Loop Back Combined With Silent Mode

24.10.4.12.3.5 Software Control of CAN_TX Pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the DCAN_TEST[6:5] TX:
- 0x0: Normal operation, CAN_TX is controlled by the DCAN core
- 0x1: Sample point can be monitored at CAN_TX pin
- 0x2: CAN_TX pin drives a dominant value
- 0x3: CAN_TX pin drives a recessive value.

Note

The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

24.10.4.13 GPIO Support

The CAN_RX and CAN_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register (DCAN_TIOC) and the CAN RX IO control register (DCAN_RIOC).

24.10.5.1 DCAN Instance Summary

Table 24-751. DCAN Instance Summary

Module Name	Base Address	Size
DCAN1	0x4AE3 C000	8 KiB
DCAN2	0x4848 0000	8 KiB

24.10.5.2 DCAN Registers

Note

After device reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The INIT bit in the DCAN_CTL is set to enable the software initialization. The DCAN will not influence the CAN bus until the software resets INIT to 0.

24.10.5.2.2 DCAN Register Description

Table 24-753. DCAN_CTL

Address Offset	0x0000 0000		
Physical Address	0x4AE3 C000 0x4848 0000	**Instance**	DCAN1 DCAN2
Description	DCAN control register **NOTE**: The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting INIT bit. If the module goes Bus-Off, it will automatically set the INIT bit and stop all bus activities. When the INIT bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset. After the INIT bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to DCAN_ES, enabling the software to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.		

Table 24-753. DCAN_CTL (continued)

Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
25	WUBA	Automatic wake up on bus activity when in local power-down mode. Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost. 0: No detection of a dominant CAN bus level while in local power-down mode. 1: Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started (Additional information can be found in *Local Power-Down Mode*).	RW	0
24	PDR	Request for local low power-down mode 0: No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the INIT bit has to be cleared. 1: Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the DCAN_ES register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in *Local Power-Down Mode*).	RW	0
23:21	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0
20	DE3	Enable DMA request line for IF3. Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. 0: Disabled 1: Enabled	RW	0
19	DE2	Enable DMA request line for IF2. Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers. 0: Disabled 1: Enabled	RW	0
18	DE1	Enable DMA request line for IF1. Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. 0: Disabled 1: Enabled	RW	0
17	IE1	Interrupt line 1 enable 0: Disabled - Module interrupt INT1 is always low. 1: Enabled - interrupts will assert line INT1 to one; line remains active until pending interrupts are processed.	RW	0

Bits	Field Name	Description	Type	Reset
16	INITDBG	Internal init state while debug access 0: Not in debug mode, or debug mode requested but not entered. 1: Debug mode requested and internally entered; the DCAN is ready for debug accesses.	RW	0
15	SWR	Software reset enable. Note: To execute software reset, the following procedure is necessary: 1. Set INIT bit to shut down CAN communication. 2. Set SWR (this) bit additionally to INIT bit. 0: Normal Operation 1: Module is forced to reset state. This bit will automatically get cleared after execution of software reset after one OCP clock cycle.	RW	0
14	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
13:10	PMD	Parityon/off 0x5: function disabled Others: function enabled	RW	0x5
9	ABO	Auto-Bus-On enable 0: The Auto-Bus-On feature is disabled 1: The Auto-Bus-On feature is enabled	RW	0
8	IDS	Interruption debug support enable 0: When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode 1: When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/ Suspend mode immediately.	RW	0
7	TEST	Test mode enable 0: Normal Operation 1: Test Mode	RW	0
6	CCE	Configuration change enable 0: The software has no write access to the configuration registers. 1: The software has write access to the configuration registers (when INIT bit is set).	RW	0
5	DAR	Disable automatic retransmission 0: Automatic retransmission of not successful messages enabled. 1: Automatic retransmission disabled.	RW	0
4	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
3	EIE	Error interrupt enable 0: Disabled - PER, BOFF and EWARN bits can not generate an interrupt. 1: Enabled - PER, BOFF and EWARN bits can generate an interrupt at INT0 line and affect the interrupt register.	RW	0
2	SIE	Status change interrupt enable 0: Disabled - WAKEUPPND, RXOK, TXOK and LEC bits can not generate an interrupt. 1: Enabled - WAKEUPPND, RXOK, TXOK and LEC can generate an interrupt at INT0 line and affect the interrupt register.	RW	0

Bits	Field Name	Description	Type	Reset
1	IE0	Interrupt line 0 enable 0: Disabled - Module interrupt INT0 is always low. 1: Enabled - interrupts will assert line INT0 to one; line remains active until pending interrupts are processed.	RW	0
0	INIT	Initialization 0: Normal operation 1: Initialization mode is entered	RW	1

Table 24-755. DCAN_ES

Address Offset	0x0000 0004		
Physical Address	0x4AE3 C004 0x4848 0004	**Instance**	DCAN1 DCAN2
Description	Error and Status Register Interrupts are generated by bits PER, BOFF and EWARN (if EIE bit in DCAN_CTL is 1) and by bits WAKEUPPND, RXOK, TXOK, and LEC (if SIE bit in DCAN_CTL is 1). A change of bit EPASS will not generate an interrupt. Reading the DCAN_ES clears the WAKEUPPND, PER, RXOK and TXOK bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the DCAN_INT will be replaced by the next lower priority interrupt value. For debug support, the auto clear functionality of DCAN_ES (clear of status flags by read) is disabled when in debug/suspend mode.

</table>

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00 0000

Bits	Field Name	Description	Type	Reset
10	PDA	Local power-down mode acknowledge 0: DCAN is not in local power-down mode. 1: Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.	R	0
9	WAKEUPPND	Wake up pending. This bit can be used by the software to identify the DCAN as the source to wake up the system. This bit will be reset if DCAN_ES is read. 0: No Wake Up is requested by DCAN. 1: DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.	R	0
8	PER	Parity error detected. This bit will be reset if DCAN_ES register is read. Read 0: No parity error has been detected since last read access. Read 1: The parity check mechanism has detected a parity error in the Message RAM. Write 0: No effect Write 1: End of interrupt (EOI) for parity error on DCAN_PARITY interrupt line	RW	0
7	BOFF	Bus-Off state 0: The CAN module is not bus-off state. 1: The CAN module is in bus-off state.	R	0
6	EWARN	Warning state 0: Both error counters are below the error warning limit of 96. 1: At least one of the error counters has reached the error warning limit of 96.	R	0
5	EPASS	Error passive state 0: On CAN Bus error, the DCAN could send active error frames. 1: The CAN core is in the error passive state as defined in the CAN Specification.	R	0
4	RXOK	Received a message successfully. This bit will be reset if DCAN_ES register is read. 0: No message has been successfully received since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1: A message has been successfully received since the last time when this bit was reset by a read access of the software (independent of the result of acceptance filtering).	R	0
3	TXOK	Transmitted a message successfully. This bit will be reset if DCAN_ES register is read. 0: No message has been successfully transmitted since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1: A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the software.	R	0

Bits	Field Name	Description	Type	Reset
2:0	LEC	Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0x0: No error 0x1: Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed. 0x2: Form error: A fixed format part of a received frame has the wrong format. 0x3: Ack error: The message this CAN core transmitted was not acknowledged by another node. 0x4: Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 0x5: Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the software to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 0x6: CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). 0x7: No CAN bus event was detected since the last time the software read DCAN_ES. Any read access to DCAN_ES re-initializes the LEC to value '7.'	R	0x7

Address Offset	0x0000 00E4		
Physical Address	0x4AE3 C0E4 0x4848 00E4	**Instance**	DCAN1 DCAN2
Description	Interrupt Multiplexer Register The IntMux flag determine for each message object, which of the two interrupt lines (INT0 or INT1) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN control register. The IntPnd bit of a specific message object can be set or reset by the software via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the INT0ID resp INT1ID flags in the DCAN_INT register.

Physical Address	0x4AE3 C100 0x4848 0100	**Instance**	DCAN1 DCAN2

Table 24-819. DCAN_IF1CMD (continued)

Description	IF1 Command Register The IF1 Command Register (DCAN_IF1CMD) configure and initiate the transfer between the IF1 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. While BUSY bit is one, IF1/IF2 register sets are write protected. For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode. If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.

Table 24-823. DCAN_IF1ARB

Address Offset	0x0000 0108		
Physical Address	0x4AE3 C108 0x4848 0108	**Instance**	DCAN1 DCAN2
Description	IF1 arbitration register The Arbitration bits ID[28:0], XTD, and DIR are used to define the identifier and type of outgoing messages and (together with the mask bits MSK[28:0], MXTD, and MDIR) for acceptance filtering of incoming messages. A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame). Extended frames can be stored only in message objects with XTD = 1, standard frames in message objects with XTD = 0. If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number. The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in Section 24.10.4.11.1 *Structure of Message Objects* While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.		
Type	RW		

31	30	29	28:0
MSGVAL	XTD	DIR	ID

Bits	Field Name	Description	Type	Reset
31	MSGVAL	Message valid 0: The message object is ignored by the message handler. 1: The message object is to be used by the message handler. The software should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit INIT in the DCAN_CTL. This bit must also be reset if the messages object is no longer required.	RW	0
30	XTD	Extended identifier 0: The 11-bit (“standard”) Identifier is used for this message object. 1: The 29-bit (“extended”) Identifier is used for this message object.	RW	0
29	DIR	Message direction 0: Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, this message is stored in this message object. 1: Direction = transmit: On TxRqst, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).	RW	0
28:0	ID	Message identifier ID[28:0]: 29-bit identifier (extended frame) ID[28:18]: 11-bit identifier (standard frame)	RW	0x0000 0000

Table 24-835. DCAN_IF2ARB

Address Offset	0x0000 0128		
Physical Address	0x4AE3 C128 0x4848 0128	**Instance**	DCAN1 DCAN2
Description	IF2 arbitration register The Arbitration bits ID[28:0], XTD, and DIR are used to define the identifier and type of outgoing messages and (together with the mask bits MSK[28:0], MXTD, and MDIR) for acceptance filtering of incoming messages. A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame). Extended frames can be stored only in message objects with Xtd = 1, standard frames in message objects with Xtd = 0. If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number. The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in Section 24.10.4.11.1 *Structure of Message Objects* While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.

Table 24-843. DCAN_IF3OBS (continued)

Description	IF3 Observation Register The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software (Additional information can be found in Section 24.10.4.11.1 *Structure of Message Objects*). The observation flags (Bits [4:0]) are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data. Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read. NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses. A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).

Table 24-859. DCAN_IF3UPD56

Address Offset	0x0000 0168		
Physical Address	0x4AE3 C168 0x4848 0168	**Instance**	DCAN1 DCAN2
Description	Update Enable Register The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UPDEN flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set NOTE: IF3 Update enable should not be set for transmit objects.

RESERVED	PU	PD	OD	RESERVED	FUNC	DIR	OUT	IN

Bits	Field Name	Description	Type	Reset
31:19	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0000
18	PU	CAN_TX pull up/pull down select. This bit is only active when CAN_TX is configured to be an input. 0: CAN_TX pull down is selected, when pull logic is active (PD = 0). 1: CAN_TX pull up is selected, when pull logic is active(PD = 0).	RW	0
17	PD	CAN_TX pull disable. This bit is only active when CAN_TX is configured to be an input. 0: CAN_TX pull is active 1: CAN_TX pull is disabled	RW	0
16	OD	CAN_TX open drain enable. This bit is only active when CAN_TX is configured to be in GIO mode (FUNC=0). 0: The CAN_TX pin is configured in push/pull mode. 1: The CAN_TX pin is configured in open drain mode. Forced to '0' if INIT bit of DCAN_CTL is reset.	RW	0
15:4	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x000
3	FUNC	CAN_TX function. This bit changes the function of the CAN_TX pin 0: CAN_TX pin is in GIO mode. 1: CAN_TX pin is in functional mode (as an output to transmit CAN data). Forced to Tx output of the CAN core, if INIT bit of DCAN_CTL is reset.	RW	0
2	DIR	CAN_TX data direction. This bit controls the direction of the CAN_TX pin when it is configured to be in GIO mode only (FUNC=0) 0: The CAN_TX pin is an input. 1: The CAN_TX pin is an output Forced to '1' if INIT bit of DCAN_CTL is reset.	RW	0
1	OUT	CAN_TX data out write. This bit is only active when CAN_TX pin is configured to be in GIO mode (FUNC = 0) and configured to be an output pin (DIR = 1). The value of this bit indicates the value to be output to the CAN_TX pin. 0: The CAN_TX pin is driven to logic low 1: The CAN_TX pin is driven to logic high Forced to 1 if INIT bit of DCAN_CTL is reset.	RW	0
0	IN	CAN_TX data in 0: The CAN_TX pin is at logic low 1: The CAN_TX pin is at logic high Note: When CAN_TX pin is connected to a CAN transceiver, an external pullup resistor has to be used to ensure that the CAN bus will not be disturbed (e.g. while reset of the DCAN module).	RW	-

24.11 Gigabit Ethernet Switch (GMAC_SW)

This chapter describes the three-port gigabit switch ethernet subsystem in the device.

24.11.1 GMAC_SW Overview

The three-port gigabit ethernet switch subsystem (GMAC_SW) provides ethernet packet communication and can be configured as an ethernet switch. It provides the gigabit media independent interface (G/MII) in MII mode, reduced gigabit media independent interface (RGMII), reduced media independent interface (RMII), and the management data input output (MDIO) for physical layer device (PHY) management.

Figure 24-186 shows the GMAC_SW subsystem overview.

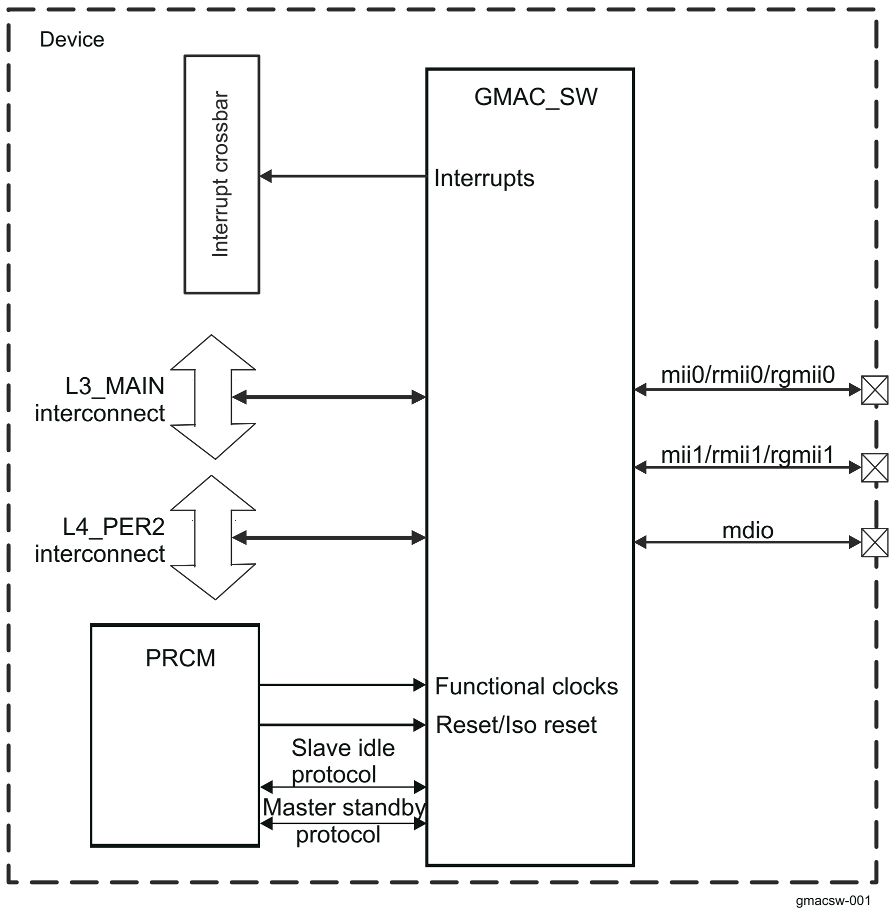

Figure 24-186. GMAC_SW Overview

24.11.1.1 Features

The GMAC_SW subsystem provides the following features:

- Two Ethernet ports (port 1 and port 2) with selectable RGMII, RMII, and G/MII (in MII mode only) interfaces plus internal Communications Port Programming Interface (CPPI 3.1) on port 0
- Synchronous 10/100/1000 Mbit operation
- Wire rate switching (802.1d)
- Non-blocking switch fabric
- Flexible logical FIFO-based packet buffer structure
- Four priority level Quality Of Service (QOS) support (802.1p)
- CPPI 3.1 compliant DMA controllers
- Support for Audio/Video Bridging (P802.1Qav/D6.0)

- Support for IEEE 1588 Clock Synchronization (2008 Annex D and Annex F)
  - Timing FIFO and time stamping logic embedded in the subsystem
- Device Level Ring (DLR) Support
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control Support (802.3x)
- Address Lookup Engine (ALE)
  - 1024 total address entries plus VLANs
  - Wire rate lookup
  - Host controlled time-based aging
  - Multiple spanning tree support (spanning tree per VLAN)
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive-based or destination-based multicast and broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
  - Remapping of priority level of VLAN or ports
- VLAN support
  - 802.1Q compliant
    - Auto add port VLAN for untagged frames on ingress
    - Auto VLAN removal on egress and auto pad to minimum frame size
- Ethernet Statistics:
  - EtherStats and 802.3Stats Remote network Monitoring (RMON) statistics gathering (shared)
  - Programmable statistics interrupt mask when a statistic is above one half its 32-bit value
- Flow Control Support (802.3x)
- Digital loopback and FIFO loopback modes supported
- Maximum frame size 2016 bytes (2020 with VLAN)
- 8k (2048 × 32) internal CPPI buffer descriptor memory
- Management Data Input/Output (MDIO) module for PHY Management
- Programmable interrupt control with selected interrupt pacing
- Emulation support
- Programmable Transmit Inter Packet Gap (IPG)
- Reset isolation (switch function remains active even in case of all device resets except for POR pin reset and ICEPICK cold reset)
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps.
- IEEE 802.3 gigabit Ethernet conformant

Note

G/MII interface is functional in MII mode only.

24.11.1.2

Terminology:

AVB	Audio Video Bridging
AVBTP	Audio Video Bridging Trasport Protocol
BMCA	Best Master Clock Algorithm
CFI	Canonical Format Indicator
CPPI	Communications Port Programming Interface
DLR	Device Level Ring
DSCP	Differentiated Services Code Point
EEE	Energy Efficient Ethernet
EMAC	Ethernet Media Access Control
EOP	End of Packet
EOQ	End of Queue
IPG	Inter-Packet Gap
LPI	Low Power Indicator
MDIO	Management Data Input/Output
MOF	Middle of Frame
PTP	Precision Time Protocol
RMON	Remote Monitoring
RTCP	RTP Control Protocol
RTP	Real-time Transport Protocol
SCR	Switched Central Resource
SRP	Stream Reservation Protocol
TOS	Type of Service
VLAN	Virtual Local Area Network

24.11.2 GMAC_SW Environment

24.11.2.1 G/MII Interface

G/MII Interface can operate only in MII Mode.

- In MII Mode (100/10 Mbps): GMAC_SW operates in full-duplex and half-duplex.

The pin connections of the G/MII Interface is shown in Figure 24-187. The detailed description of the signals are listed in the following tables.

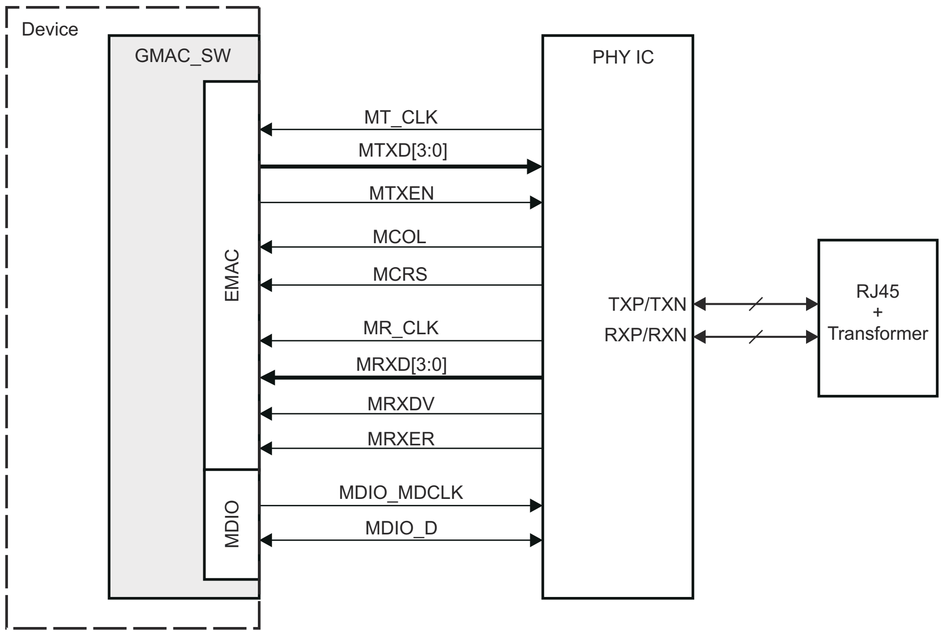

Figure 24-187. MII Interface Typical Application

Table 24-867. MII I/O Description

Signal	Device Pin(s)	I/O[1]	Description
MT_CLK	mii0_txclk mii1_txclk	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MTXD and MTXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MTXD[3:0]	mii0_txd[3:0] mii1_txd[3:0]	O	The transmit data pins are a collection of 4 data signals MTXD[3:0] comprising 4 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by MT_CLK and valid only when MTXEN is asserted.
MTXEN	mii0_txen mii1_txen	O	The transmit enable signal indicates that the MTXD pins are generating 4bit data for use by the PHY. It is driven synchronously by MT_CLK.
MTXER	mii0_txer mii1_txer	O	Transmit data error. Used only for EEE to request PHY for low power transition.
MCOL	mii0_col mii1_col	I	In half-duplex operation, the MCOL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used.
MCRS	mii0_crs mii1_crs	I	In half-duplex operation, the MCRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is de-asserted when both transmit and receive are idle. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCRS pin should be held low.

Table 24-867. MII I/O Description (continued)

Signal	Device Pin(s)	I/O[(1)]	Description
MR_CLK	mii0_rxclk mii1_rxclk	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MRXD	mii0_rxd[0:3] mii1_rxd[0:3]	I	The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRXD0 is the least-significant bit (LSB).The signals are synchronized by MR_CLK and valid only when MRXDV is asserted.
MRXDV	mii0_rxdv mii1_rxdv	I	The receive data valid signal indicates that the MRXD pins are generating nibble data for use by the GMAC_SW. It is driven synchronously to MR_CLK.
MRXER	mii0_rxer mii1_rxer	I	Receive Data Error input
MDIO_MDCLK	mdio_mclk	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

24.11.2.2 RMII Interface

Figure 24-188 shows a device with integrated GMAC_SW and MDIO interfaced via a RMII connection in a typical system. The individual CPSW and MDIO signals for the RMII interface are summarized in Table 24-868.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

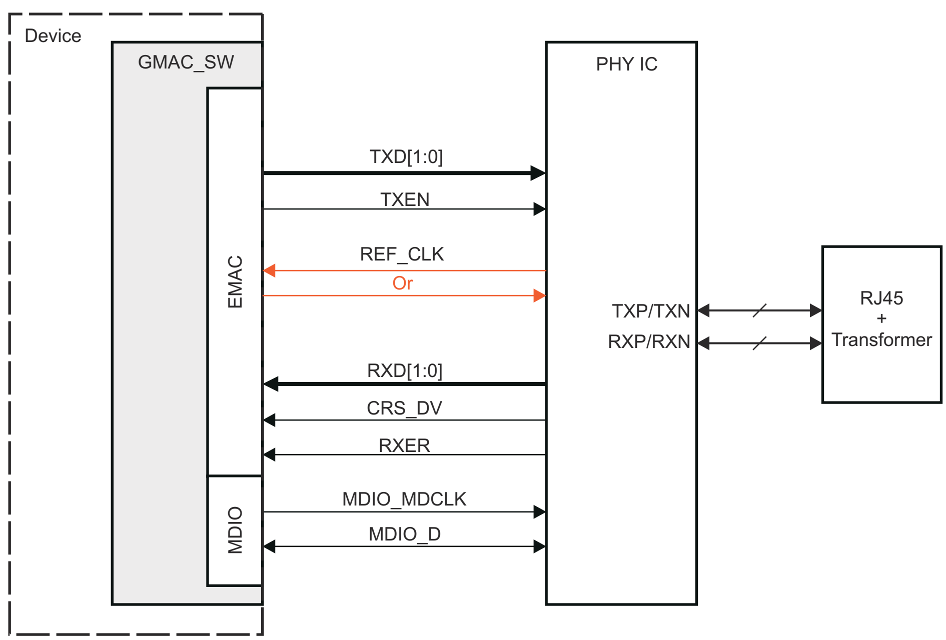

Figure 24-188. RMII Interface Typical Application

Table 24-868. RMII I/O Description

Signal	Device Pin(s)	I/O[(1)]	Description
TXD[1:0]	rmii0_txd[1:0] rmii1_txd[1:0]	O	Transmit data . The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when TXEN is asserted.

Table 24-868. RMII I/O Description (continued)

Signal	Device Pin(s)	I/O[(1)]	Description
TXEN	rmii0_txen rmii1_txen	O	Transmit enable. The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK
RMII0_MHZ_50_CLK RMII1_MHZ_50_CLK	RMII_MHZ_50_CLK	I/O	RMII reference clock. The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RXD[1:0]	rmii0_rxd[1:0] rmii1_rxd[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when CRS_DV is asserted and RXER is de-asserted.
CRS_DV	rmii0_crs rmii1_crs	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RXER	rmii0_rxer rmii1_rxer	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MDCLK	mdio_mclk	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

24.11.2.3 RGMII Interface

Figure 24-189 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW and MDIO signals for the RGMII interface are summarized in Table 24-869.

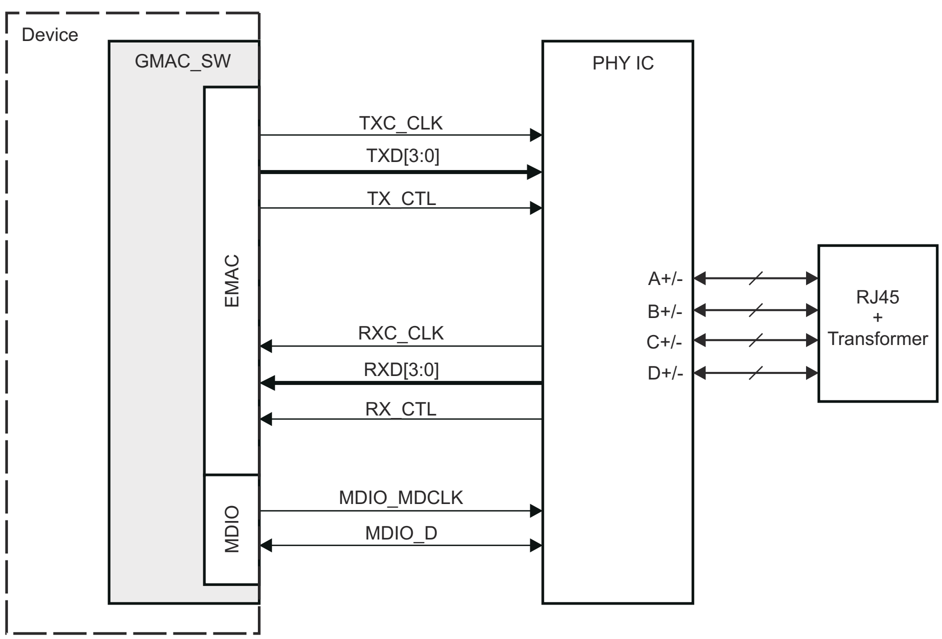

Figure 24-189. RGMII Interface Typical Application

Table 24-869. RGMII I/O Description

Signal	Device Pin(s)	I/O[(1)]	Description
TXD[3:0]	rgmii0_txd[3:0] rgmii1_txd[3:0]	O	The transmit data pins are a collection of 4 bits of data. TXD0 is the least-significant bit (LSB). The signals are valid only when TX_CTL is asserted.

Table 24-869. RGMII I/O Description (continued)

Signal	Device Pin(s)	I/O[1]	Description
TX_CTL	rgmii0_rxctl rgmii1_rxctl	O	Transmit Control/enable. The transmit enable signal indicates that the TXD pins are generating data for use by the PHY.
TXC_CLK	rgmii0_txc rgmii1_txc	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RXD[3:0]	rgmii0_rxd[3:0] rgmii1_rxd[3:0]	I	The receive data pins are a collection of 4 bits of data. RXD0 is the least-significant bit (LSB). The signals are valid only when RX_CTL is asserted
RX_CTL	rgmii0_rxctl rgmii1_rxctl	I	The receive data valid/control signal indicates that the RXD pins are nibble data for use by the GMAC_SW.
RXC_CLK	rgmii0_rxc rgmii1_rxc	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MDCLK	mdio_mclk	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers* in *Control Module*.

24.11.3 GMAC_SW Integration

Figure 24-190 shows the integration of the GMAC_SW module in the device.

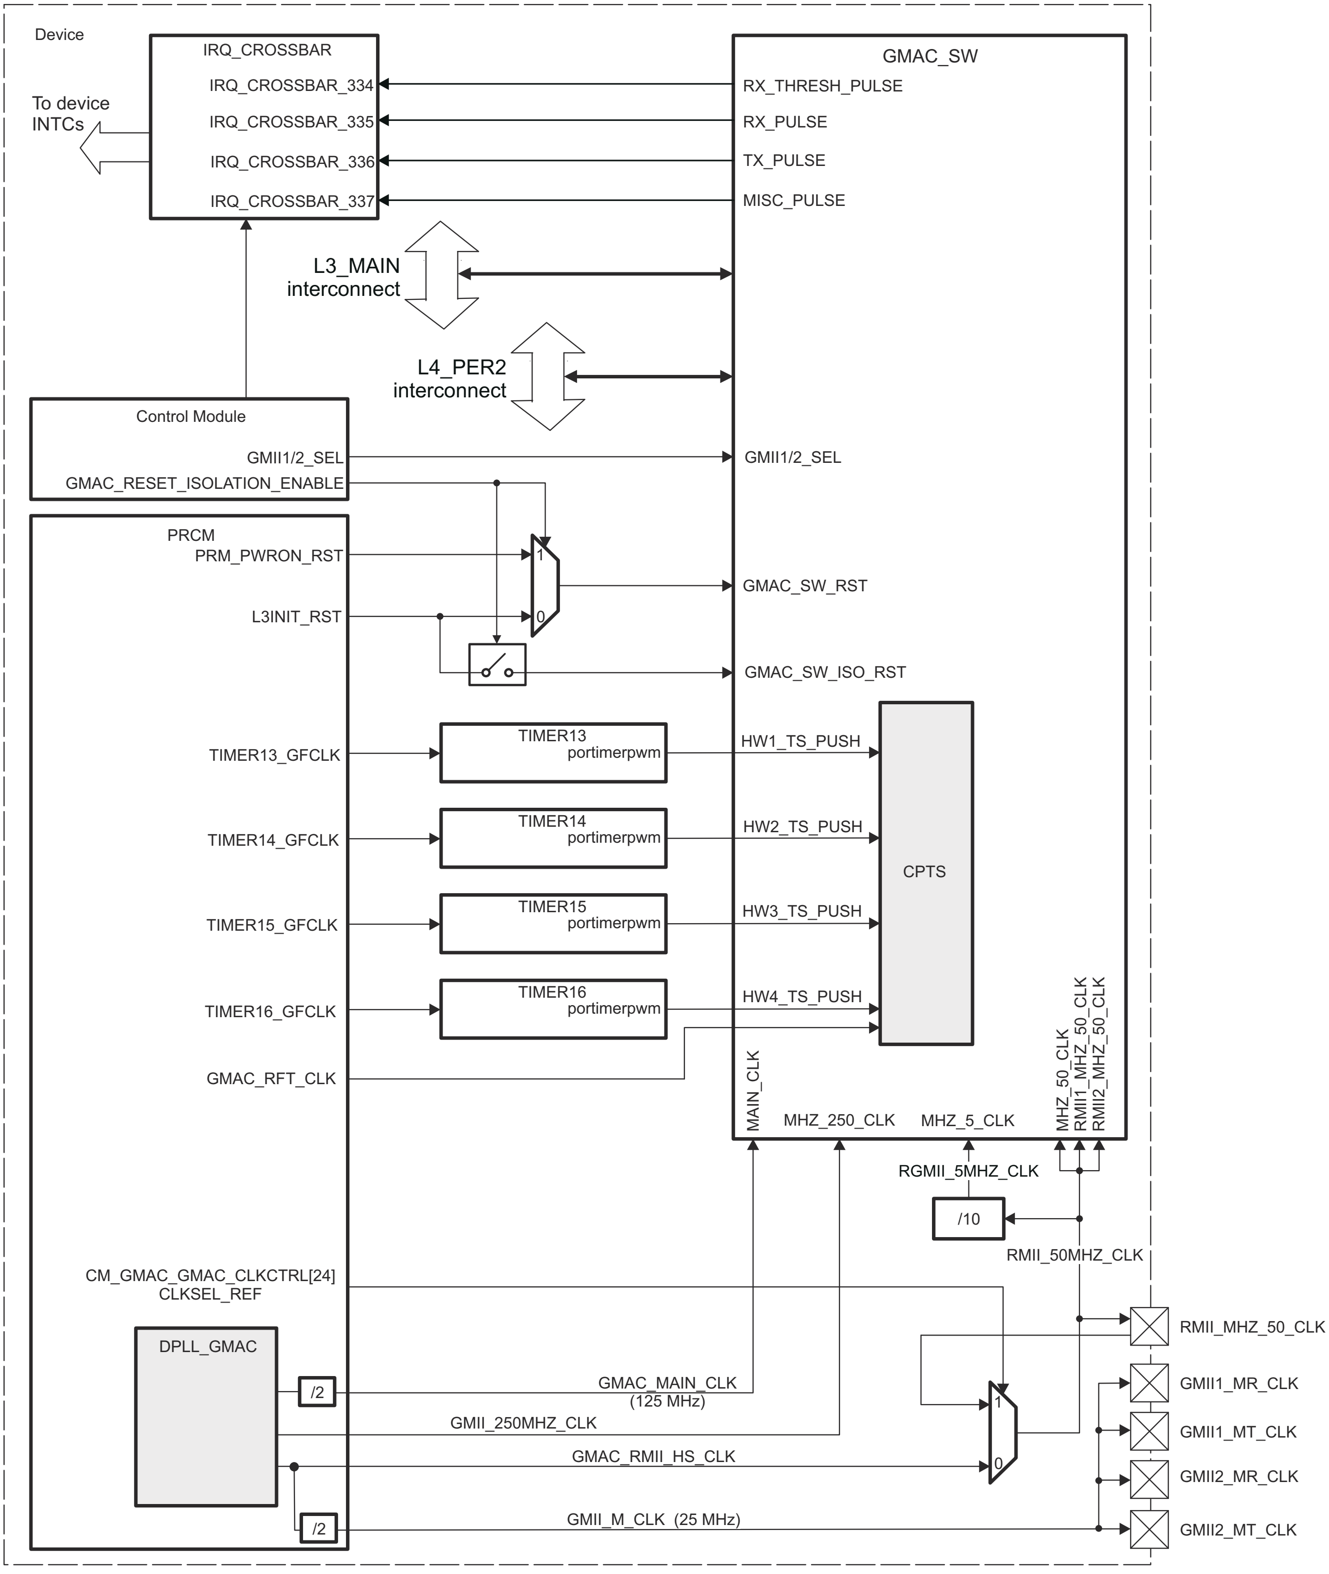

Figure 24-190. GMAC_SW Integration

Note

The device provides the option to receive or output the RMII reference clock (RMII_50MHZ_CLK) from/to external pin as shown in Figure 24-190. See the RMII_CLK_SETTING register bit in the *Control Module Register Manual*, and CLKSEL_REF in , *PRCM Register Manual* to configure the clocking option of RMII.

See *PRCM* for details about power, clock and reset options for GMAC_SW.

Table 24-870 through Table 24-872 summarize the integration of the GMAC_SW module in the device.

Table 24-870. GMAC_SW Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
GMAC_SW	PD_COREAON	Yes	L3_MAIN L4_PER2

Table 24-871. GMAC_SW Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GMAC_SW	GMAC_SW_RST	L3INIT_RST/ PRM_PWRON_RST	PRCM	GMAC_SW main reset
	GMAC_SW_ISO_RST	tied off/L3INIT_RST	PRCM	GMAC_SW isolate reset (must be enabled in Control module)

Table 24-872. GMAC_SW Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
GMAC_SW	RX_THRESH_PULSE	IRQ_CROSSBAR_334	-	Receive threshold interrupt
	RX_PULSE	IRQ_CROSSBAR_335	-	Receive packet completion interrupt
	TX_PULSE	IRQ_CROSSBAR_336	-	Transmit packet completion interrupt

Table 24-872. GMAC_SW Hardware Requests (continued)

MISC_PULSE	IRQ_CROSSBAR_337	-	Miscellaneous interrupt (SPF2_PEND, SPF1_PEND, EVNT_PEND,STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT)

Note

GMAC_SW has no default IRQ mappings through the IRQ_CROSSBAR. For GMAC_SW, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For the description of the interrupt source, see Section 24.11.4.5, *Interrupt Functionality*.

24.11.4 GMAC_SW Functional Description

The 3-port switch (GMAC_SW) Ethernet subsystem modules are compliant to the IEEE Std 802.3 Specification.GMAC_SW is shown in Figure 24-191.

24.11.4.1 Functional Block Diagram

The GMAC_SW subsystem consists of:

- CPSW_3G which contains two G/MII interfaces
- Two RGMII interface modules
- Two RMII interface modules
- One MDIO interface module
- One Interrupt Controller module
- One CPPI interface
- Local CPPI memory of size 8 KiB
- Two Static Packet Filters

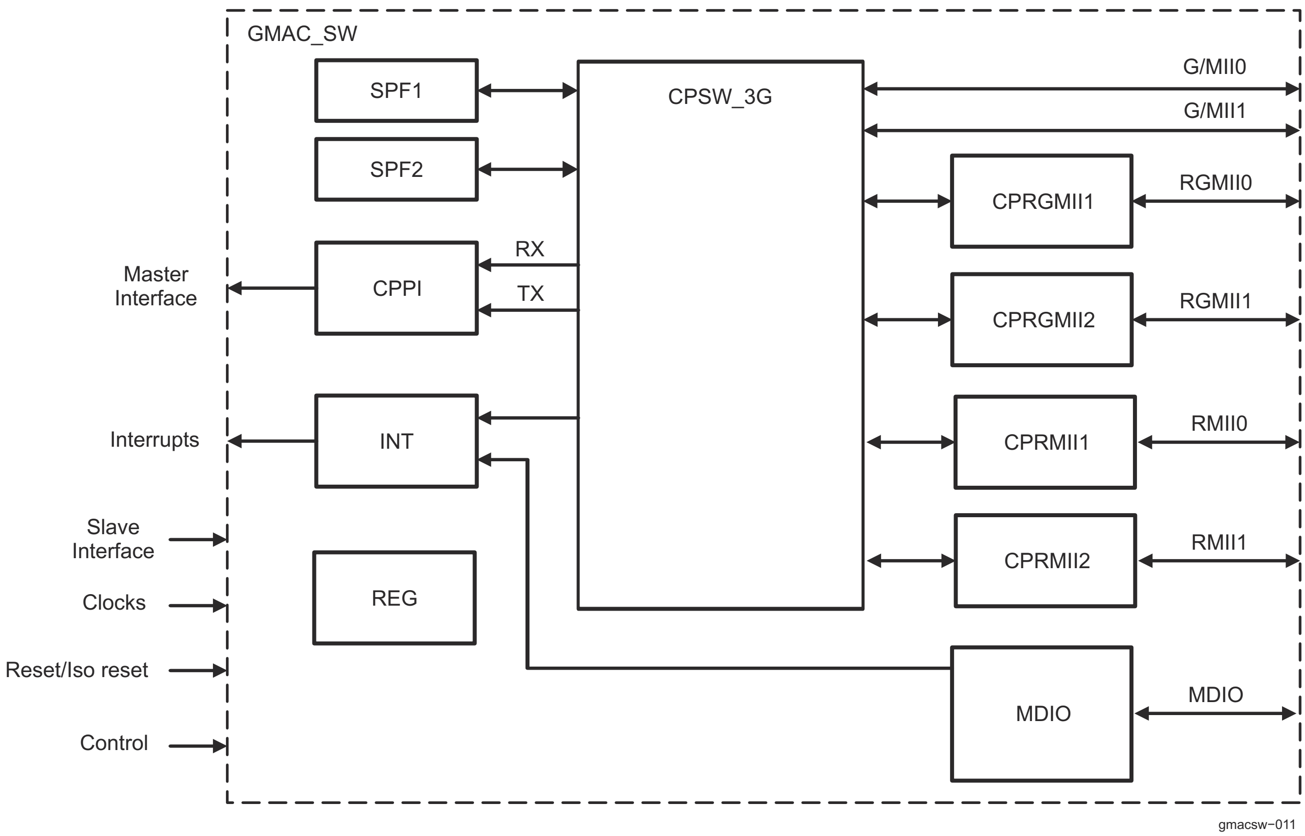

Figure 24-191. GMAC_SW Top Level Block Diagram

24.11.4.2 GMAC_SW Ports

Ethernet Subsystem has three Ports. Port 0 is the Host port (internal to the Subsystem). Ports 1 and 2 are the external ports connected to G/MII, RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the Host Port
- Port1 is referred to the interfaces GMII0/RGMII0/RMII0
- Port2 is referred to the interfaces GMII1/RGMII1/RMII1

24.11.4.2.1 Interface Mode Selection

The 3-port switch (GMAC_SW) Ethernet Subsystem has two 10/100/1000 Ethernet ports with selectable MII, RMII, and RGMII interfaces.

The interface mode is selected by configuring the MII mode selection register bitfields (GMII1_SEL and GMII2_SEL) in the control module. See *Control Module Register Manual* for details.

See device data manual for configuring the pin mux mode as per the interface selected.

24.11.4.3 Clocking

24.11.4.3.1 Subsystem Clocking

GMAC_SW clocking summary is shown in Section 24.11.3, *GMAC_SW Integration*.

24.11.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

24.11.4.3.2.1 G/MII Interface Clocking

GMII1_MR_CLK, GMII1_MT_CLK, GMII2_MR_CLK, GMII2_MT_CLK frequencies are fixed by the 802.3 specification.

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

24.11.4.3.2.2 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

24.11.4.3.2.3 RMII Interface Clocking

RMII interface clock RMII_50MHZ_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

See the RMII_CLK_SETTING bit in the device Control Module and CLKSEL_REF in PRCM to configure the clocking option of RMII (external pin or PRCM).

24.11.4.3.2.4 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (MAIN_CLK) clock, running at 125 MHz.The application software or driver must control the divide-down value.

See the MDIO_CONTROL register for configuring the Clock Divider (CLKDIV) value.

24.11.4.4 Software IDLE

The submodule software idle register bits enable CPSW_3G operation to be completely or partially suspended by software control. There are three CPSW_3G submodules that contain software idle register bits (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW_3G module enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW_3G is in the idle state when all three submodules are in the idle state. The CPSW_SOFT_IDLE[0] SOFT_IDLE bit may be set if desired after the submodules are in the idle state. The CPSW SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

24.11.4.5 Interrupt Functionality

GMAC_SW Ethernet Subsystem has four Interrupt outputs:

- RX_PULSE - Receive Interrupt
- TX_PULSE - Transmit Interrupt
- RX_THRESH_PULSE - Receive Threshold Interrupt
- MISC_PULSE - Miscellaneous Interrupt.

24.11.4.5.1 Receive Packet Completion Pulse Interrupt (RX_PULSE)

The RX_PULSE interrupt is a pulse interrupt selected from the GMAC_SW RX_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX_PEND[7:0]).

The following steps will enable the receive packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the CPDMA_RX_INTMASK_SET register.
2. The receive completion interrupt(s) to be routed to RX_PULSE is selected by setting one or more bits in the receive interrupt enable register (WR_C0_RX_EN) . The masked interrupt status can be read in the address location of RX_STAT bit in the WR_C0_RX_STAT register.

When the GMAC_SW completes a packet reception, the subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the software processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RX *n*_CP) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

1. Read the WR_C0_RX_STAT[7:0] RX_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process received packets for the interrupting channel(s).
3. Write the GMAC_SW completion pointer(s) (RX *n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the GMAC_SW has received more packets than the software has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the GMAC_SW is expecting is found by reading the receive channel *n* completion pointer register (RX *n*_CP).
4. Write the value 1h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the CPDMA_RX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the WR_C0_RX_EN register.

The software could still poll for the CPDMA_RX_INTSTAT_RAW and CPDMA_RX_INTSTAT_MASKED registers if the corresponding interrupts are enabled.

24.11.4.5.2 Transmit Packet Completion Pulse Interrupt (TX_PULSE)

The TX_PULSE interrupt is a pulse interrupt selected from the GMAC_SW TX_PEND[7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX_PEND[7:0]).

To enable the transmit packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the CPDMA_TX_INTMASK_SET register.
2. The transmit completion interrupt(s) to be routed to TX_PULSE is selected by setting one or more bits in the transmit interrupt enable register WR_C0_TX_EN .The masked interrupt status can be read in the address location of TX_STAT bit in the WR_C0_TX_STAT register.

When the GMAC_SW completes the transmission of a packet, the GMAC_SW subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon reception of an interrupt, software should perform the following:

1. Read the TX_STAT bit address location to determine which channel(s) caused the interrupt
2. Process received packets for the interrupting channel(s).
3. Write the GMAC_SW completion pointer(s) (TX *n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the GMAC_SW (address of last buffer descriptor used by the GMAC_SW). If the two values are not equal (which means that the GMAC_SW has transmitted more packets than the software has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the GMAC_SW is expecting is found by reading the transmit channel *n*completion pointer register (TX *n*_CP).
4. Write the 2h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the CPDMA_TX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the WR_C0_TX_EN register.

The software could still poll for the CPDMA_TX_INTSTAT_RAW and CPDMA_TX_INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

24.11.4.5.3 Receive Threshold Pulse Interrupt (RX_THRESH_PULSE)

The RX_THRESH_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW_3G RX_THRESH_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX_THRESH_PEND[7:0]).

To enable the receive threshold pulse Interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the CPDMA_RX_INTMASK_SET register.
2. The receive threshold interrupt(s) to be routed to RX_THRESH_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register WR_C0_RX_THRESH_EN. The masked interrupt status can be read in the address location of RX_THRESH_STAT bit in the WR_C0_RX_THRESH_STAT register.

The RX_THRESH_PULSE is asserted when enabled when the channel's associated free buffer count RX *n*_FREEBUFFER is less than or equal to the corresponding RX *n*_PENDTHRESH register.

Upon reception of an interrupt, software should perform the following:

1. Read the RX_THRESH_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process the received packets in order to add more buffers to any channel that is below the threshold value.
3. Write the CPSW_3G completion pointer(s).
4. Write the value 0h to the CPDMA_EOI_VECTOR register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

1. The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the CPDMA_RX_INTMASK_CLEAR register.
2. The receive threshold pulse interrupt could be disabled by clearing to 0 the corresponding bits in the WR_C0_RX_THRESH_EN register.

The software could still poll for the CPDMA_RX_INTSTAT_RAW and CPDMA_RX_INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

24.11.4.5.4 Miscellaneous Pulse Interrupt (MISC_PULSE)

The MISC_PULSE interrupt is an immediate pulse interrupt selected from the miscellaneous interrupts (SPF2_PEND, SPF1_PEND, EVNT_PEND,STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT).

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register (WR_C0_MISC_EN).

Upon reception of an interrupt, software should perform the following:

- Read the MISC_STAT bit address location to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the CPDMA_EOI_VECTOR register.

Note

The WR_C0_MISC_STAT register's MDIO_LINKINT and MDIO_USERINT bitfields represent the Port0/Phy0 status. MDIO_LINKINT[1] and MDIO_USERINT[1] are not provided in WR_C0_MISC_STAT register. As such, MDIO Link and User interrupts can only be generated for Port0. For Port1, software must poll the status, visible in the MDIO_LINKINTMASKED or MDIO_USERINTMASKED registers.

24.11.4.5.4.1 EVNT_PEND(CPTS_PEND) Interrupt

See Section 24.11.4.10, *Common Platform Time Sync (CPTS)* for more details on this interrupt.

24.11.4.5.4.2 Statistics Interrupt

The statistics level interrupt (STAT_PEND) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement all statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The raw and masked statistics interrupt status may be read by reading the CPDMA_TX_INTSTAT_RAW and CPDMA_TX_INTSTAT_MASKED registers, respectively.

The Statistics interrupt is enabled by setting to 1 the STAT_INT_MASK bit in the CPDMA_DMA_INTMASK_SET register

24.11.4.5.4.3 Host Error interrupt

The host error interrupt (HOST_PEND) will be asserted, if enabled when a host error is detected during transmit or receive CPDMA transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked host interrupt status can be read by reading the CPDMA_DMA_INTSTAT_RAW and CPDMA_DMA_INTSTAT_MASKED registers, respectively.

The transmit host error conditions are:

- SOP error
- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP cleared to 0
- buffer pointer cleared to 0

- buffer length cleared to 0
- packet length error

The receive host error conditions are:

- OWNERSHIP bit not set in input buffer
- Zero buffer pointer
- Zero buffer Length on non-SOP descriptor
- SOP buffer length not greater than offset

The HOST_PEND is enabled by setting to 1 the HOST_ERR_INTMASK in the CPDMA_DMA_INTMASK_SET register. The host error interrupt is disabled by setting to 1 the appropriate bit in the CPDMA_DMA_INTMASK_CLEAR register.

24.11.4.5.4.4 MDIO Interrupts

MDIO_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR_MON field of the MDIO_USERPHYSEL*n* register and the corresponding LINKINT_ENABLE bit is set. The MDIO_LINKINT event is also captured in the MDIO_LINKINTMASKED register. When the GO bit in the MDIO_USERACCESS*n* register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the MDIO_USERINTMASKSET register is set, the MDIO_USERINT signal is asserted. The MDIO_USERINT event is also captured in the MDIO_USERINTMASKED register.

24.11.4.5.5 Interrupt Pacing

RX_PULSE and TX_PULSE interrupts can be paced. The RX_THRESH_PULSE and MISC_PULSE interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (for example, 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the processor cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the processor instruction cache.

Each RX_PULSE and TX_PULSE interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1 ms interval of time. At the end of each 1 ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1 ms interval is derived from a 4 µs pulse that is created from a prescale counter whose value is set in the INT_PRESCALE field in the WR_INT_CONTROL register. The INT_PRESCALE value should be written with the number of ICLK periods in 4 µs. The pacing timer determines the interval during which interrupts are blocked and decrements every 4 µs. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1 ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
    pace_timer = 255;
  else if (intr_count > 1.5*intr_max)
    pace_timer = last_pace_timer*2 + 1;
  else if (intr_count > 1.0*intr_max)
    pace_timer = last_pace_timer + 1;
  else if (intr_count > 0.5*intr_max)
    pace_timer = last_pace_timer - 1;
  else if (intr_count != 0)
    pace_timer = last_pace_timer/2;
else
pace_timer = 0;
```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be "paced" at the rate specified in the interrupt maximum register. The WR_C0_RX_IMAX/ WR_C0_TX_IMAX register should be written with a value between 2 and 63 inclusive, indicating the target number of interrupts per millisecond.

24.11.4.6 Reset Isolation

Reset isolation for the GMAC_SW allows the switch function to remain active in during all device resets except for POR pin reset and ICEPICK COLD reset. Packet traffic to/from the GMAC_SW host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is undergoing a device reset. Pin mux configuration for ethernet related I/O and reference clocks needed by the GMAC_SW to be active is controlled by a protected control module bit.

24.11.4.6.1 Reset Isolation Functional Description

The device has two modes of operation concerning the reset of the GMAC_SW Ethernet switch. The mode is controlled by the GMAC_RESET_ISOLATION_ENABLE bit in the Control Module. This bit defaults to 0. Any modification of this bit first requires writing an unlock pattern to lock register in device control module. After modification, the bit should again be locked by writing appropriate value to the lock register. Writes to the GMAC_RESET_ISOLATION_ENABLE bit and to the lock register must all be supervisor mode writes.

GMAC_RESET_ISOLATION_ENABLE = 0 (disabled)

1. This is the default state of the bit after control module reset.
2. Upon any device level resets, the entire GMAC_SW, DPLL_GMAC, L3/L4 interconnect, control module (including all pin mux control and the GMAC_RESET_ISOLATION_ENABLE bit itself) are immediately reset.

GMAC_RESET_ISOLATION_ENABLE = 1 (enabled)

1. This mode is selected when the GMAC_RESET_ISOLATION_ENABLE bit is set to 1 by software.
2. Upon any device reset source other than porz pin or ICEPICK cold (that is, this includes software global cold, any watchdog reset, warm resetn pin, ICEPICK warm, software global warm or security violation), the following is true:
   a. The CPSW_3GSS_R is put into "isolate" mode and non-switch related portions of the subsystem are reset.
   b. The 50 MHz and 125 MHz reference clocks to the GMAC_SW Ethernet Subsystem remain active throughout the entire reset condition.
   c. The control for pin multiplexing for all of the signals maintain their current configuration throughout the entire reset condition.
   d. The reset-isolated logic inside GMAC_SW Ethernet Subsystem maintains the switch functionality
3. Upon any cold reset sources, the entire GMAC_SW Ethernet Subsystem, DPLL_GMAC, control module (including all pin mux control and the GMAC_RESET_ISOLATION_ENABLE bit itself) are reset.

For more details on the register configuration, see the Control Module CTRL_CORE_CONTROL_IO_2 register in *Control Module Register Manual*.

24.11.4.7 Software Reset

The CPSW_3G software reset register (CPSW_SOFT_RESET), CPSW_3GSS software reset register (WR_SOFT_RESET) and the three submodule software reset registers enable the CPSW_3GSS to be reset by software.

There are three CPSW_3G submodules that contain software reset registers (CPGMAC_SL1, CPGMAC_SL2 (SL_SOFT_RESET), and CPDMA (CPDMA_SOFT_RESET)). Each of the three submodules may be individually commanded to be reset by software.

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW_3G software reset register bit may be written to complete the CPSW_3G module software reset operation. The CPSW_3G software reset bit controls the reset of the FIFO's, the statistics submodule, and the address lookup engine (ALE). The CPSW_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

The CPSW_3GSS software reset bit controls the reset of the INT, REGS, and CPPI. The CPSW_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

24.11.4.8 CPSW_3G

The CPSW_3G G/MII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW_3G contains two CPGMAC_SL interfaces (ports 1 and 2), one CPPI interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA. A top-level block diagram of the CPSW_3G is shown in Figure 24-192.

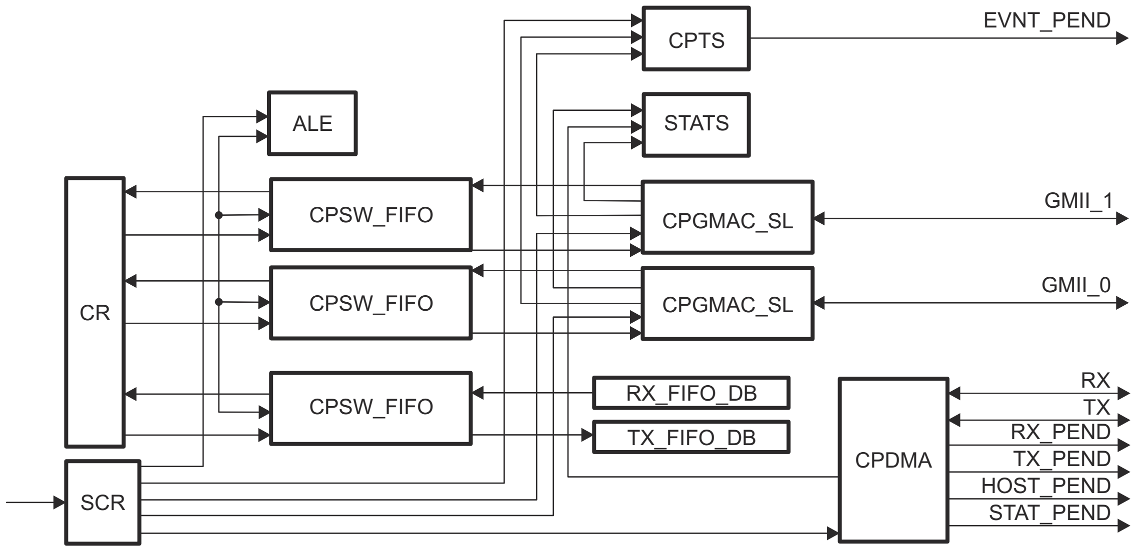

Figure 24-192. CPSW_3G Block Diagram

24.11.4.8.1 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI compliant packet DMA transfer controller. The CPPI interface is port 0.

24.11.4.8.1.1 Functional Operation

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI protocol. For a detailed description of buffer descriptors, see Section 24.11.4.11, *CPPI Buffer Descriptors*.

24.11.4.8.1.2 Receive DMA Interface

The receive DMA is an eight channel CPPI compliant interface. Each channel has a single queue for frame reception.

24.11.4.8.1.2.1 Receive DMA Host Configuration

To configure the RX DMA for operation the software must perform the following:

1. Initialize the receive addresses.
2. Initialize the RX_HDP registers to 0.

3. Enable the desired receive interrupts in the CPDMA_RX_INTMASK_SET register.
4. Write the CPDMA_RX_BUFFER_OFFSET register value.
5. Setup the receive channel(s) buffer descriptors in host memory as required by CPPI
6. Enable the RX DMA controller by setting the RX_EN bit in the CPDMA_RX_CONTROL register.

24.11.4.8.1.2.2 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the CPDMA_RX_TEARDOWN register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown_complete bit will be set in the next buffer descriptor in the chain (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- A receive interrupt for the channel will be issued to the host.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh Acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by a set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

24.11.4.8.1.3 Transmit DMA Interface

The tranmsit DMA is an eight channel CPPI compliant interface. Priority between the eight queues may be either fixed or round robin as selected by the TX_PTYPE bit in the CPDMA_DMACONTROL register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7.

24.11.4.8.1.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the software must do the following:

1. Initialize the TX_HDP registers to 0.
2. Enable the desired transmit interrupts in the CPDMA_TX_INTMASK_SET register.
3. Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI.
4. Configure and enable the transmit operation as desired in the CPDMA_TX_CONTROL register.
5. Write the appropriate TX_HDP registers with the appropriate values to start transmit operations.

24.11.4.8.1.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the CPDMA_TX_TEARDOWN register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- An interrupt will be issued to inform the host of the channel teardown.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

24.11.4.8.1.4 Transmit Rate Limiting

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the TX_RLIM bit associated with that channel is set in the CPDMA_DMACONTROL register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then TX_RLIM should be set to 11000000b with the MSB corresponding to channel 7. When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (TX_PRI(0..7)_RATE) when the channel is rate-limiting. Each priority has a send count (PRI(0..7)_SEND_CNT) and an idle count (PRI(0..7)_IDLE_CNT). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the equation:

Priority Transfer rate in Mbit/s = ((PRI_IDLE_CNT/(PRI_IDLE_CNT + PRI_SEND_CNT)) × frequency × 32

Where *frequency* is the CPDMA interface clock (MAIN_CLK) frequency.

24.11.4.8.1.5 Command IDLE

The CMD_IDLE bit in the CPDMA_DMACONTROL register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

24.11.4.8.2 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should the forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE_ALE bit in the ALE_CONTROL register is set. All packets are dropped when the ENABLE_ALE bit is cleared to 0.

In normal operation, the CPGMAC_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the SL_MACCONTROL configuration bit(s) RX_CEF_EN, RX_CSF_EN, or RX_CMF_EN are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

The ALE may be configured to operate in bypass mode by setting the ALE_BYPASS bit in the ALE_CONTROL register. When in bypass mode, all CPGMAC_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate RX DMA channels by configuring the P0_CPDMA_RX_CH_MAP register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the ENABLE_OUI_DENY bit in the ALE_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

24.11.4.8.2.1 Address Table Entry

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 24-873. Learned Address Control Bits

Bit(s)	Value
unicast_type	11
Block	0
Secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40.**

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40.**

24.11.4.8.2.1.2 Multicast Address Table Entry

Table 24-875. Multicast Address Table Entry Bit Values

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE(01)	Reserved	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

24.11.4.8.2.1.3 VLAN/Multicast Address Table Entry

Table 24-876. VLAN/Multicast Address Table Entry Bit Values

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE(11)	VLAN_ID	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASk has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

24.11.4.8.2.1.4 Unicast Address Table Entry

Table 24-877. Unicast Address Table Entry Bit Values

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE(01)	Reserved	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure

must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/ Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

24.11.4.8.2.1.5 OUI Unicast Address Table Entry

Table 24-878. OUI Unicast Address Table Entry Bit Values

71:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE(10)	ENTRY_TYPE(01)	Reserved	UNICAST_OUI	Reserved

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

24.11.4.8.2.1.6 VLAN/Unicast Address Table Entry

Table 24-879. Unicast Address Table Entry Bit Values

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE(11)	VLAN_ID	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/ Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

24.11.4.8.2.1.7 VLAN Table Entry

Table 24-880. VLAN Table Entry

71:62	61:60	59:48	47:27	26:24	23:19	18:16	15:11	10:8	7:3	2:0
Reserved	ENTRY_TYPE(10)	VLAN_ID	Reserved	FORCE_UNTAGGED_EGRESS	Reserved	REG_MCAST_FLOOD_MASK	Reserved	UNREG_MCAST_FLOOD_MASK	Reserved	VLAN_MEMBER_LIST

Table Entry Type (ENTRY_TYPE)

10: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

Registered Multicast Flood Mask (REG_MCAST_FLOOD_MASK)

Mask [port 2-1-0] used for multicast when the multicast address is found.

Unregistered Multicast Flood Mask (UNREG_MCAST_FLOOD_MASK)

Mask [port 2-1-0] used for multicast when the multicast address is not found.

VLAN Member List (VLAN_MEMBER_LIST)

This 3-bit field indicates which port(s) are members of the associated VLAN.

24.11.4.8.2.2 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN_Aware Lookup, VLAN_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The mcast_fwd_state indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/ unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the CPGMAC_SL to the ALE. Packets with errors may be passed to the host (not aborted) by a CPGMAC_SL port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set. Error packets that are passed to the host by the CPGMAC_SL are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the SL_MACCONTROL register:

- [22] RX_CEF_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX_CSF_EN - enables short frames to be forwarded
- [24] RX_CMF_EN - enables MAC control frames to be forwarded.

24.11.4.8.2.3 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

24.11.4.8.2.4 VLAN Aware Mode

The CPSW_3G is in VLAN aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL register. In VLAN aware mode, ports 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set rx_vlan_encap bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (pkt_type), packet priority (pkt_pri), and VLAN information.

24.11.4.8.2.5 VLAN Unaware Mode

The CPSW_3G is in VLAN unaware mode when the VLAN_AWARE bit is cleared to 0 in the CPSW_CONTROL register. Port 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 transmit packets are never VLAN encapsulated.

24.11.4.8.3 Packet Priority Handling

Packets are received on three ports, two are CPGMAC_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is the port priority for untagged packets, and the actual packet priority for priority tagged and VLAN tagged packets. The received packet priority is mapped through the receive ports associated packet priority to header packet priority mapping register to obtain the header packet priority (the CPDMA RX and TX nomenclature is reversed from the CPGMAC_SL nomenclature).

The header packet priority is mapped through the header priority to switch priority mapping register to obtain the hardware switch priority (0 to 3, with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

24.11.4.8.4 FIFO Memory Control

Each of the three CPSW_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX_MAX_BLKS field in the FIFOs associated Px_MAX_BLKS register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total). The RX_MAX_BLKS field in the FIFO's associated Px_MAX_BLKS register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX_MAX_BLKS value plus the RX_MAX_BLKS value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports are Port1 and Port2.

24.11.4.8.5 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC_SL nomenclature due to legacy reasons.

24.11.4.8.5.1 Normal Priority Mode

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used. For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting TX_IN_SEL = 00 for all ports (default value in P0/1/2_TX_IN_CTL)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to Section 24.11.4.8.3, *Packet Priority Handling*.

24.11.4.8.5.2 Dual MAC Mode

When operating in dual MAC mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each CPGMAC_SL appears as a single MAC with no bridging between MAC's. Each CPGMAC_SL has at least one unique (not the same) mac address.

Dual MAC mode is configured as described below:

- Set the ALE_VLAN_AWARE bit in the ALE_CONTROL register. This bit configures the ALE to process in VLAN aware mode. The CPSW_3G VLAN aware bit (VLAN_AWARE in CPSW_CONTROL) determines how packets VLAN's are processed on CPGMAC_SL egress and does not affect how the ALE processes packets or the packet destination. The CPSW_3G VLAN aware bit may be set or not as required (must be set, if VLAN's are to exit the switch).
- Configure the Port 1 to Port 0 VLAN
  – Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).
  – Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Configure the Port 2 to Port 0 VLAN
  – Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).
  – Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting TX_IN_SEL = 01 in P0_TX_IN_CTL. The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

24.11.4.8.5.3 Rate Limit Mode

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some CPGMAC_SL FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown below:

1. Set TX_IN_SEL = 10 in P1/2_TX_IN_CTL to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
2. Configure the number of rate-limited queues for port 1 and 2 transmit FIFO's by setting the TX_RATE_EN field in P1/2_TX_IN_CTL. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
3. Set P1_PRIN_SHAPE_EN and P2_PRIN_SHAPE_EN in the CPSW_PTYPE register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in TX_RATE_EN are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired. When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on a single queue then it must

be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).

4. P0_TX_IN_CTL[17:16] TX_IN_SEL should be set to 00, so Port 0 egress (CPDMA RX) is not rate-limited.
5. The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the TX_RLIM field in the CPDMA_DMACONTROL register. If there are two rate-limited channels, then TX_RLIM = 11000000 (the rate limited channels must be the highest priorities). Also, the TX_PTYPE bit in the CPDMA_DMACONTROL register must be set (fixed priority mode). Rate-limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

24.11.4.8.6 Audio Video Bridging

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks.* "a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks:* Forwarding and Queuing for Time-Sensitive Streams."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9:* Stream Reservation Protocol (SRP)."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

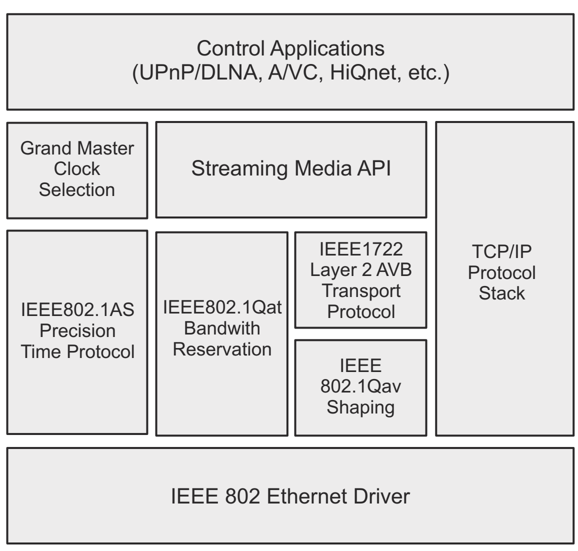

Figure 24-193. The Network Static with AVB

The following sections describe the media transport protocols that work within the AVB framework.

24.11.4.8.6.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))

The protocol defined by 802.1AS automatically selects a device to be the master clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

Note

The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

Based on IEEE 1588:2002,Â PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock master selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2--in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock master, the Best Master Clock Algorithm (BMCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandmaster. Once a Grandmaster has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Slave nodes compare the value of their RTC against the PTP Grandmaster and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1-µs accuracy over seven network hops.

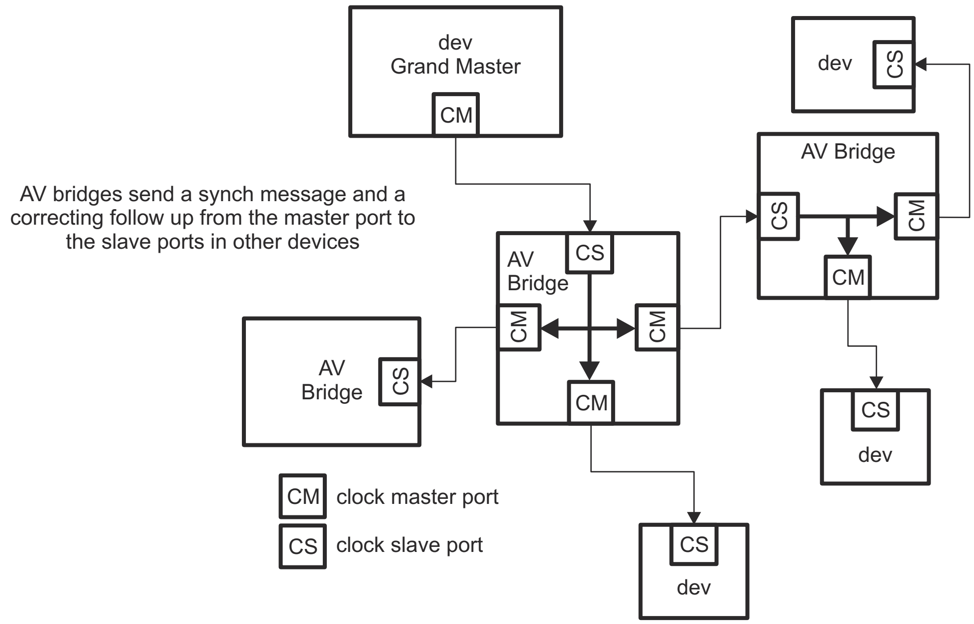

Figure 24-194. AVB Network & PTP Clock Entities

The media transport protocols that work within the AVB framework are:

24.11.4.8.6.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in Figure 24-195 and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

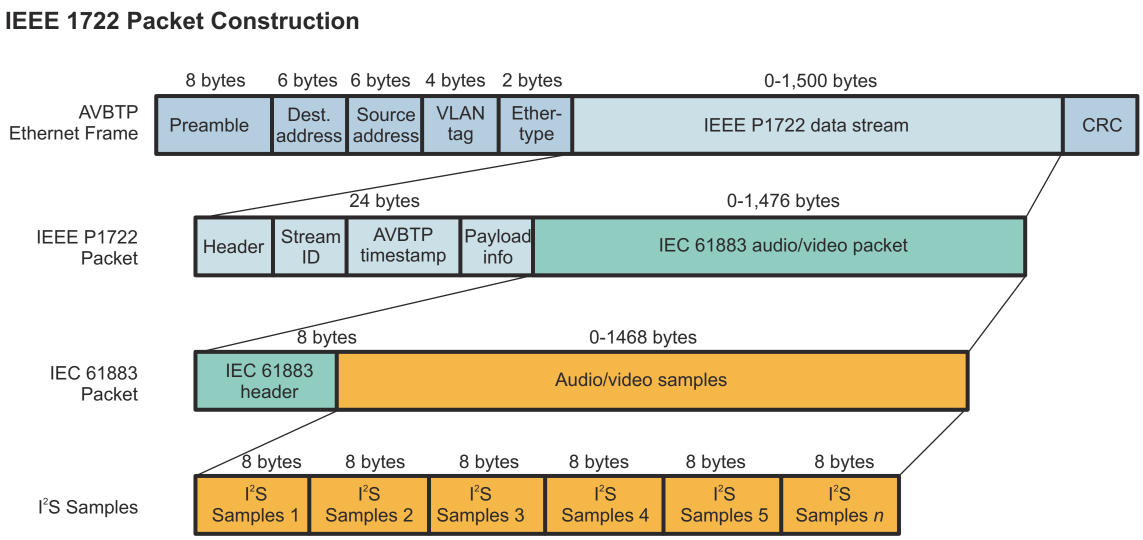

Figure 24-195. IEEE 1722 Packets

1722 or AVBTP Presentation Time and Synchronization:

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandmaster. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. Figure 24-196 illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

24.11.4.8.6.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/ Video Bridging (AVB) protocols.

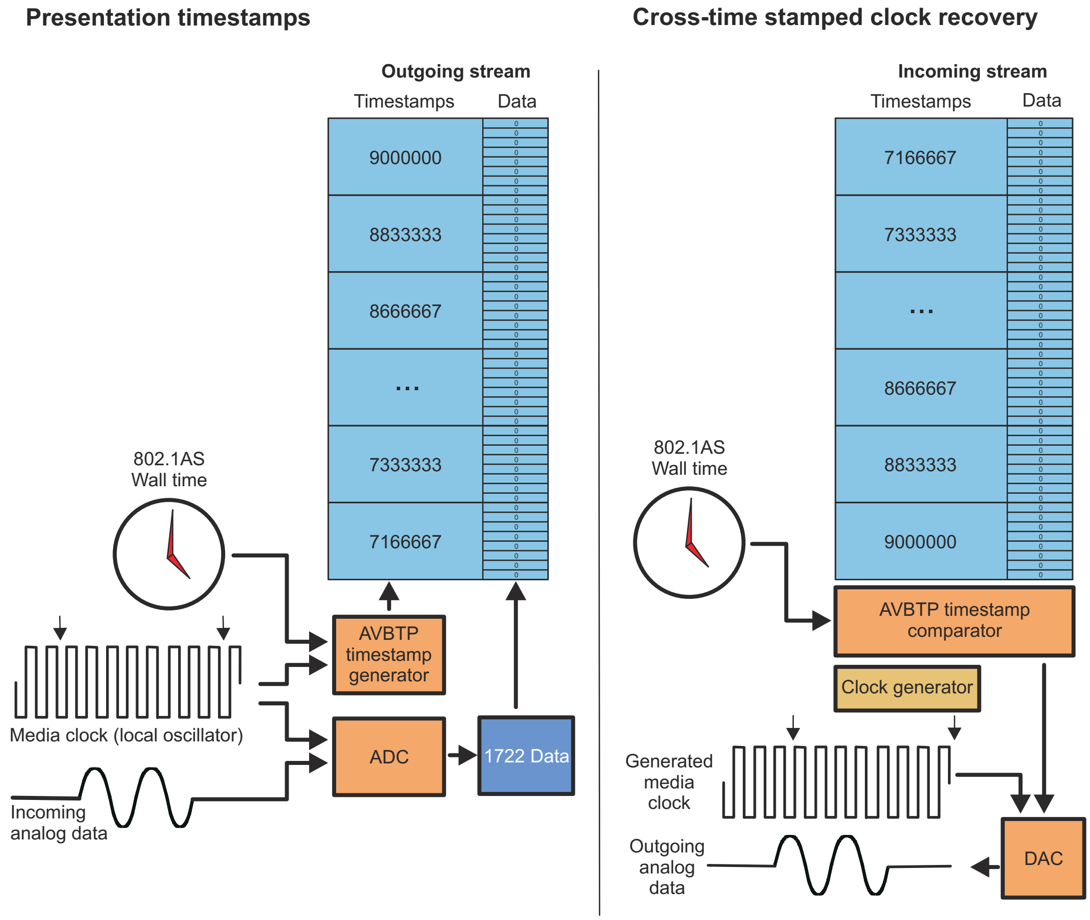

Figure 24-196. Cross Time Stamping and Presentation Timestamps

24.11.4.8.6.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
  - Receive policing and
  - Transmit rate control.

End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like Figure 24-197.

Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

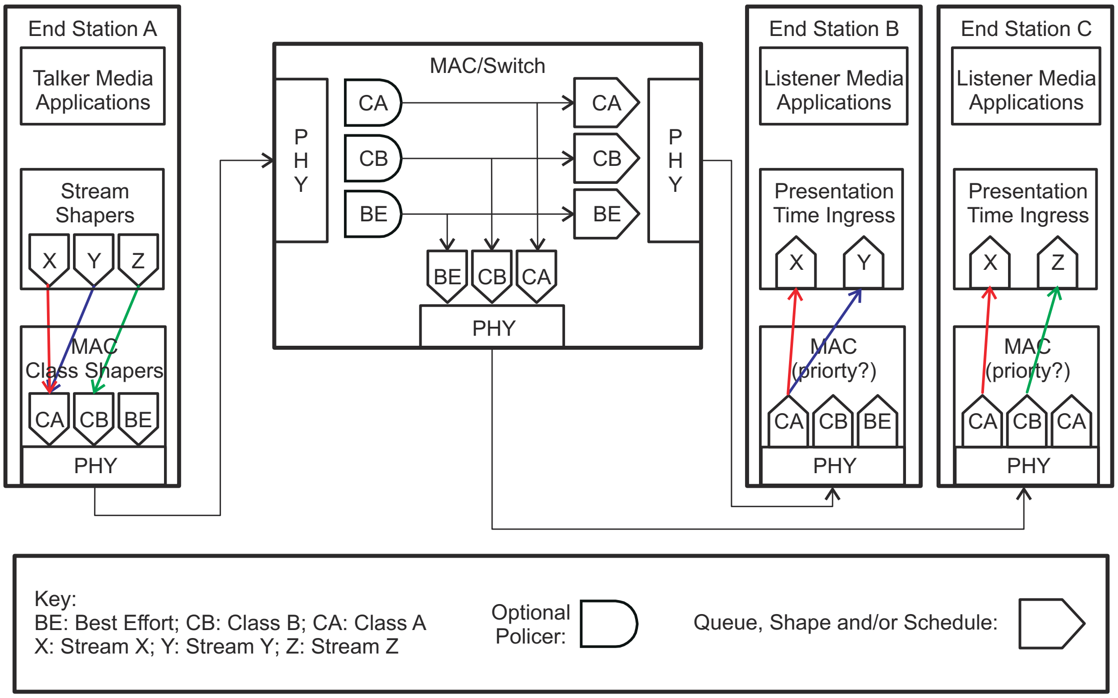

Figure 24-197. AV Stream Queuing/Policing

24.11.4.8.6.2.1 Configuring the Device for 802.1Qav Operation:

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW_3G that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
  – CPPI TX and RX descriptors
  – VLAN and Priority tags

Table 24-881. Example of TX Configuration

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

Table 24-882. Example of RX Configuration

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
  – ALE in VLAN-ware mode, Non-ALE in bypass mode.

Table 24-883. Example of Rate-limit Configurations

Register	Value	Description
CPSW_PTYPE	0x0006 0000	For Port1 -- 2 highest priority channels.

Table 24-883. Example of Rate-limit Configurations (continued)

Register	Value	Description
P1_TX_IN_CTL[23:20] TX_RATE_EN	0b1100	2 highest priority channels are rate limited
P1_TX_IN_CTL[17:16] TX_IN_SEL	0b10	Rate limit mode
P1_SEND_PERCENT	0x14 3E00	20% PRI7, 62% PRI5
CPDMA_DMACONTROL	0xC001	Chan7, Chan6 are Rate Limited. Round-robin selection of DMA channel.
CPDMA_TX_PRI7_RATE	0x1 0013	200 Mbps
CPDMA_TX_PRI6_RATE	0x1 0005	~600 Mbps

24.11.4.8.7 Ethernet MAC Sliver (CPGMAC_SL)

The CPGMAC_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation
- G/MII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control
- Programmable Inter Packet Gap (IPG).

24.11.4.8.7.1 G/MII Media Independent Interface

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

24.11.4.8.7.1.1 Data Reception

24.11.4.8.7.1.1.1 Receive Control

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

24.11.4.8.7.1.1.2 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

24.11.4.8.7.1.2 Data Transmission

The Gigabit Ethernet Mac Sliver (GMII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

24.11.4.8.7.1.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

24.11.4.8.7.1.2.2 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS_CRC bit is 0. For the CPMAC_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS_CRC bit is set.

24.11.4.8.7.1.2.3 MTXER

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

24.11.4.8.7.1.2.4 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX_PACE bit in the SL_MACCONTROL register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

24.11.4.8.7.1.2.5 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRS is de-asserted within approximately 48 bit times of MTXEN being de-asserted, then 96 bit times is measured from MTXEN. If the frame suffered a collision, or if MCRS is not de-asserted until more than approximately 48 bit times after MTXEN is de-asserted, then 96 bit times (approximately, but not less) is measured from MCRS.

The transmit IPG can be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the SL_MACCONTROL register enables the TX_SHORT_GAP input to determine whether the transmit IPG is shorted by eight bit times.

24.11.4.8.7.1.2.6 Back Off

The Gigabit Ethernet Mac Sliver (GMII) implements the 802.3 binary exponential back-off algorithm.

24.11.4.8.7.1.2.7 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the SL_TX_GAP register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

24.11.4.8.7.1.2.8 Speed, Duplex and Pause Frame Support Negotiation

The CPMAC_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

24.11.4.8.7.2 RMII Interface

The CPRMII peripheral is compliant to the RMII specification document.

24.11.4.8.7.2.1 Features

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

24.11.4.8.7.2.2 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMRXER on any di-bit in the received packet will cause an MRXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMCRSDV toggle will issue an MRXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMCRSDV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

24.11.4.8.7.2.3 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the GMAC_SW MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The GMAC_SW does not source the transmit error (MII TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMTXD[1:0] for each clock that RMTXEN is de-asserted.

24.11.4.8.7.3 RGMII Interface

The CPRGMII peripheral is compliant to the RGMII specification document.

24.11.4.8.7.3.1 RGMII Features

- Supports 1000/100/10 Mbps speed
- In SR1.1, Internal TXC delay on transmit is always enabled
- In SR2.x, Internal TXC delay on transmit can be enabled or disabled using bits [26] RGMII2_ID_MODE_N and [25] RGMII1_ID_MODE_N of the CTRL_CORE_SMA_SW_1 register.
- MII mode is not supported

24.11.4.8.7.3.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

24.11.4.8.7.3.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the EXT_EN bit of the SL_MACCONTROL register is set to 1. The link status, duplexity, and speed are determined from the RGMII input data stream

RXD[3:0] when RX_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in Table 24-884.

Table 24-884. In-Band Data

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0: half-duplex	00: 10-Mbps mode	2.5 MHz	0: Link is down
1: full-duplex	01: 100-Mbps mode	25 MHz	1: Link is up
	10: 1000-Mbps mode	125 MHz	
	11: reserved	reserved	

24.11.4.8.7.3.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the EXT_EN bit of the SL_MACCONTROL register is set to 0. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the SL_MACCONTROL[0] FULLDUPLEX and [7] GIG bits. If GIG = 1, then operation is gigabit mode. If the GIG is 0, the operation is 100 Mbps mode.

24.11.4.8.7.3.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRGMII module.

The TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII_LINK. Packet transmission will begin on the first TX_CTL rising edge after the 4096 transmit clock count has expired.

24.11.4.8.7.4 Frame Classification

Received frames are proper (good) frames if they are between 64 and RX_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the SL_RX_MAXLEN register. The SL_RX_MAXLEN register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain RX_MAXLEN number of bytes transferred to memory (if RX_CEF_EN = 1). An example with RX_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

24.11.4.8.8 Embedded Memories

Table 24-885. Embedded Memories

Memory Type Description	Number of Instances	
Single-port 2560 × 64 RAM	3	(Packet FIFO's)
Single-port 64-word × 1152-bit RAM	1	(ALE)
Single-port 2048-word × 32-bit RAM	1	(CPPI)

24.11.4.8.9 Flow Control

There are two types of switch flow control: CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

24.11.4.8.9.1 CPPI Port Flow Control

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the P0_FLOW_EN bit in the CPSW_FLOW_CONTROL register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

24.11.4.8.9.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX_PKT_CNT = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX_FLOW_EN bit in the associated CPGMAC_SL be set to 1. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for G/MII ports, then any packets that are dropped are dropped on transmit and not on receive.

24.11.4.8.9.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the RX_FLOW_EN bit in the SL_MACCONTROL register. Receive flow control is triggered (when enabled) when the RX_FLOW_TRIGGER input is asserted. The CPGMAC_SL is configured for collision or IEEE 802.3X flow control via the FULLDUPLEX bit in the SL_MACCONTROL register.

24.11.4.8.9.2.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in SL_MACCONTROL). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

24.11.4.8.9.2.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX is set in SL_MACCONTROL). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC_SL will transmit pause frames as:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL_SA[47:0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX_FLOW_EN is cleared to 0 while the pause time is nonzero, then the pause time will be cleared to 0 and a zero count pause frame will be sent.

24.11.4.8.9.2.2 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC_SL from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TX_FLOW_EN bits in the SL_MACCONTROL register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the RX_CMF_EN (copy MAC frames) bit in the SL_MACCONTROL register is set. The TX_FLOW_EN and FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- TX_FLOW_EN is set in SL_MACCONTROL register, and
- the frame's length is 64 to SL_RX_MAXLEN bytes inclusive, and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If TX_FLOW_EN in SL_MACCONTROL register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01
  - , or the CPGMAC_SL SL_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC_SL will recognize any pause frame between 64 bytes and RX_MAXLEN bytes in length.

24.11.4.8.10 Short Gap

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the SL_MACCONTROL register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The CPSW_GAP_THRESH register value determines the port 1 short gap threshold, and the CPSW_GAP_THRESH register value determines the port 2 short gap threshold.

24.11.4.8.11 Switch Latency

The CPSW_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

Table 24-886. Switch Latency

Mode	Latency
Gig (1000)	880 ns
100	1.3 µs
10	6.5 µs

24.11.4.8.12 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW_3G operation to be completely or partially suspended. There are three CPSW_3G submodules that contain emulation control registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW_3G emulation control. The CPSW_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

CPGMAC_SL Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the SL_EMCONTROL register) allow CPGMAC_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

CPDMA Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the CPDMA_EMCONTROL register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals

Table 24-887 shows the operations of the emulation control input and register bits.

Table 24-887. Emulation Control Input

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

24.11.4.8.13 FIFO Loopback

FIFO loopback mode is entered when the FIFO_LOOPBACK bit in the CPSW_CONTROL register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel 0 in FIFO loopback mode. The RXSOFOVERRUN statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in fullduplex mode only.

24.11.4.8.14 Device Level Ring (DLR) Support

Device Level Ring (DLR) support is enabled by setting the DLR_EN bit in the CPSW_CONTROL register. When enabled, incoming received DLR packets are detected and sent to queue 3 (highest priority) of the egress port(s). If the host port is the egress port for a DLR packet then the packet is sent on the CPDMA Rx channel selected by the P0_DLR_CPDMA_CH field in the P0_CONTROL register. The supervisor node MAC address feature is supported with the dlr_unicast bit in the unicast address table entry. When set, the dlr_unicast bit causes a packet with the matching destination address to be flooded to the vlan_member_list minus the receive port and minus the host port (the port_number field in the unicast address table entry is a don't care). Matching dlr_unicast packets are flooded regardless of whether the packet is a DLR packet or not. The EN_P0_UNI_FLOOD bit in the ALE_CONTROL register has no effect on DLR unicast packets. Packets are determined to be DLR packets as shown below:

1. DLR is enabled (DLR_EN is set in the CPSW_CONTROL).
2. One of the sequences below are true.
   a. The first packet ltype matches CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1 and Px_CONTROL[20] Px_VLAN_LTYPE1_EN is set and the second packet ltype matches CPSW_DLR_LTYPE[15:0] DLR_LTYPE.
   b. The first packet ltype matches CPSW_VLAN_LTYPE[31:16] VLAN_LTYPE2 and Px_CONTROL[21] Px_VLAN_LTYPE2_EN is set and the second packet ltype matches CPSW_DLR_LTYPE[15:0] DLR_LTYPE.
   c. The first packet ltype matches CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1 and Px_CONTROL[20] Px_VLAN_LTYPE1_EN is set and the second packet ltype matches CPSW_VLAN_LTYPE[31:16] VLAN_LTYPE2 and Px_CONTROL[21] Px_VLAN_LTYPE2_EN is set and the third packet ltype matches CPSW_DLR_LTYPE[15:0] DLR_LTYPE.

24.11.4.8.15 Energy Efficient Ethernet Support (802.3az)

Note

CM_GMAC_CLKSTCTRL[1:0]CLKTRCTRL bit field must not be programmed for SW_SLEEP or HW_AUTO.

Energy Efficient Ethernet (EEE) allows the PRCM to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. EEE operations are configured as shown below:

1. The 10-bit EEE clock pre-scale value is written to the CPSW_EEE_PRESCALE register. The pre-scaler is used to clock all EEE-related counters
2. The port Idle to LPI count values (Px_IDLE2LPI) are written with the desired values
3. The port LPI to Wake count values (Px_LPI2WAKE) are written with the desired values
4. The EEE_EN bit is set in the switch CPSW_CONTROL register
5. Set the WR_CONTROL[8] SS_EEE_EN bit to enable energy efficient operations at subsystem level.

EEE operation can begin after configuration. The host allows (through PRCM) the CPSW_3G to enter a low power state by asserting the CLKSTOP_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert CLKSTOP_REQ to the CPSW_3G.

Each ethernet port has a transmit and a receive LPI (low power indicate) state. The receive LPI state is entered when the port's corresponding PHY indicates the LPI state via the CPSW_3G GMII interface. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the Px_IDLE2LPI value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPDMA LPI state includes transmit and receive. The CPDMA LPI state is entered when the CPDMA transmit and receive have both been idle for the Idle to LPI time (P0_IDLE2LPI). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

Note

The procedure above is described for the GMII interfaces at the CPSW_3G boundary. External PHY signaling has the following conditions:

- GMII interface is used only in MII mode. Therefore, only MRXD[3:0] and MTXD[3:0] are pinned out
- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX_CTL at the rising and the falling TXC_CLK edges, respectively. RXDV and RXER are the sampled values of RX_CTL at the rising and the falling RXC_CLK edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the CLKSTOP_ACK signal is asserted, and the PRCM is allowed to stop the module clock. When CLKSTOP_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the CPSW_3G memory address space, and then turn off the clock again while CLKSTOP_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting CLKSTOP_REQ. The host may queue transmit packets at any time including without regard to the CPSW_3G LPI state (the clock must be restarted in order to write the CPSW_3G slave address space as described above). Host writes to transmit head descriptor pointers will cause the CLKSTOP_WAKEUP signal to be asserted if the CPSW_3G is in the low power state (if CLKSTOP_ACK is asserted).

The external Ethernet PHY's can also wakeup the PRCM by removing the Ethernet receive LPI indication. If the module is in the CPSW Idle state with CLKSTOP_ACK asserted and the receive LPI indication is removed, the CLKSTOP_WAKEUP signal will be asynchronously asserted. On wakeup, the PRCM restarts the clock and de-assert the CLKSTOP_REQ signal. The CLKSTOP_WAKEUP signal will be synchronously deasserted with CLKSTOP_ACK. Upon the deassertion of CLKSTOP_REQ, the Ethernet ports will count the Px_LPI2WAKE time for each port at which time the port is available for transmit. Upon the de-assertion of CLKSTOP_REQ, the CPDMA transmit will count the P0_LPI2WAKE count at which time the CPDMA will begin to send any packets that the host has queued (switch ingress). The wait time on CPDMA transmit is included to preclude the host from filling up the Ethernet port transmit FIFO's while the Ethernet ports are in the LPI to wake time. There is no LPI to wake time on CPDMA receive (switch egress).

24.11.4.8.16 CPSW_3G Network Statistics

The CPSW_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of GMAC_RST. When one or more port enable (Pn_STAT_EN) bits in the CPSW_STAT_PORT_EN register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, "the port" refers to any enabled port (with a corresponding set Pn_STAT_EN bit).

The statistics interrupt (STAT_PEND) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

See *STATS Registers* for description of every network statistic.

Rx Statistics Summary and *Tx Statistics Summary* summarize network statistics.

24.11.4.8.16.1

Table 24-888. Rx Statistics Summary

Rx Statistic	Frame/Oct	Rx/Rx+Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data[5]															
			Pause frame	Non-pause[4]	Multicast	Broadcast	Unicast	<64	64	65-127	128-255	256-511	512-1023	1024-rx_max len	>rx_max len	Flow Coll.[8]	CRC Error	Align/Code	Overrun	Addr. Disc.
Good Rx Frames	F	R	(y|[1]	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-[2]	n	n	-	n
Broadcast Rx Frames	F	R	(%|[6]	%|	n	y)	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Multicast Rx Frames	F	R	(%|	%|	y)	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Pause Rx Frames	F	R	y	n	n	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	-
Rx CRC Errors	F	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	-	y	-	n
Oversized Rx Frames	F	R	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	R	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	(y|	y)	-	n
Undersized Rx Frames	F	R	n	n	(y|	y|	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	R	n	n	(y|	y|	y)	y^[7]	n	n	n	n	n	n	n	-	(y|	y)	-	-
Rx Overruns[9]	F	R	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	y	n
64octet Frames	F	R+T[3]	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	y	n	n	n	n	-	-	-	-	n
256-511octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Net Octets	O	R+T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	-

(1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
(2) "-" indicates conditions which are ignored in the formations of the statistic.
(3) Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.
(4) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
(5) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
(6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
(7) "y^" Frame fragments are not counted if less than 8 bytes.
(8) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
(9) The rx_overruns stat is for RX_MOF_OVERRUNS and RX_SOF_OVERRUNS added together.

Table 24-889. Tx Statistics Summary

Tx Statistic[9]	Frame/Oct	Tx/Rx+Tx	Frame Type					Frame Size (bytes)							Event									
			MAC control[4]		Data			64	65-127	128-255	256-511	512-1023	1024-1535	>1535	CRC Error	Collision Type					No Carrier	Queued	Deferred	Underrun
			Pause-MAC	Any-CPU	Multicast	Broadcast	Unicast									Flow[8]	1	2-15	16	Late				
Good Tx Frames	F	T	(y|[1]	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-[2]	-	-	-	n	n	n	-	-	n
Broadcast Tx Frames	F	T	n	(%|[5]	n	y)	n	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Multicast Tx Frames	F	T	(y|	%|	y)	n	n	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Pause Tx Frames	F	T	y	n	n	n	n	y	n	n	n	n	n	n	-	-	-	-	-	-	-	-	-	-
Collisions	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	(+[6]	+	+	+	+)	n	-	-	-
Single Collision Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	y	n	n	n	n	-	-	-
Multiple Collision Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	y	n	n	n	-	-	-
Excessive Collisions	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	y	n	n	-	-	-
Late Collisions	F	T	n	(y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	-	-	-	-	-	y	-	-	-	-
Deferred Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	n	n	n	-	y	n
Carrier Sense Errors	F	T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	-	-	y	-	-	-
64octet Frames	F	R+T[3]	(y|	y|	y|	y|	y)	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
65-127octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
128-255octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-
256-511octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-
512-1023octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-
1024-UPoctet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-
Tx Octets	O	T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Net Octets	O	R+T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	$[7]	$	$	$	$	-	-	-

(1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
(2) “-“ indicates conditions which are ignored in the formations of the statistic.
(3) Statistics marked “R+T” are formed by summing the Rx and Tx statistics, each of which is formed independently.
(4) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
(5) “%” If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.

(6) “+” indicates collisions which are “summed” (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
(7) “$” Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
(8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the ‘-‘s in this column might in reality be ‘n’s. To prevent double-counting, Net Octets are unaffected by the jam sequence – the ‘received’ bytes, however, are counted. (See Table 24-888.)
(9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

24.11.4.9 Static Packet Filter (SPF)

24.11.4.9.1 SPF Overview

The Static Packet Filter (SPF) provides protection against some of the most common forms of Denial of Service (DoS) attacks that exploit the Layer 3 and Layer 4 functions of the network stack running on a system. The DoS attacks that are mitigated by the SPF module are:

- ARP Flood
- Fraggle
- Illegal Fragment Offset
- Illegal TCP Options
- Jolt2
- Jolt
- Land
- Micro Fragment
- Null Scan
- Ping Flood
- Short ICMP Packet
- Smurf
- SSPing
- SYN Fragment
- TCP SYN Flood
- Xmas Scan

24.11.4.9.2 SPF Functional Description

24.11.4.9.2.1 SPF Block Diagram

Figure 24-198 shows the block diagram of the Static Packet Filter module. There are three main components of the static packet filter – packet header extractor to decode packet formats, rule engine to check for malformed protocol header fields and a host interface to provide control and configuration access to a host processor and to keep a log of filtered packets in system memory.

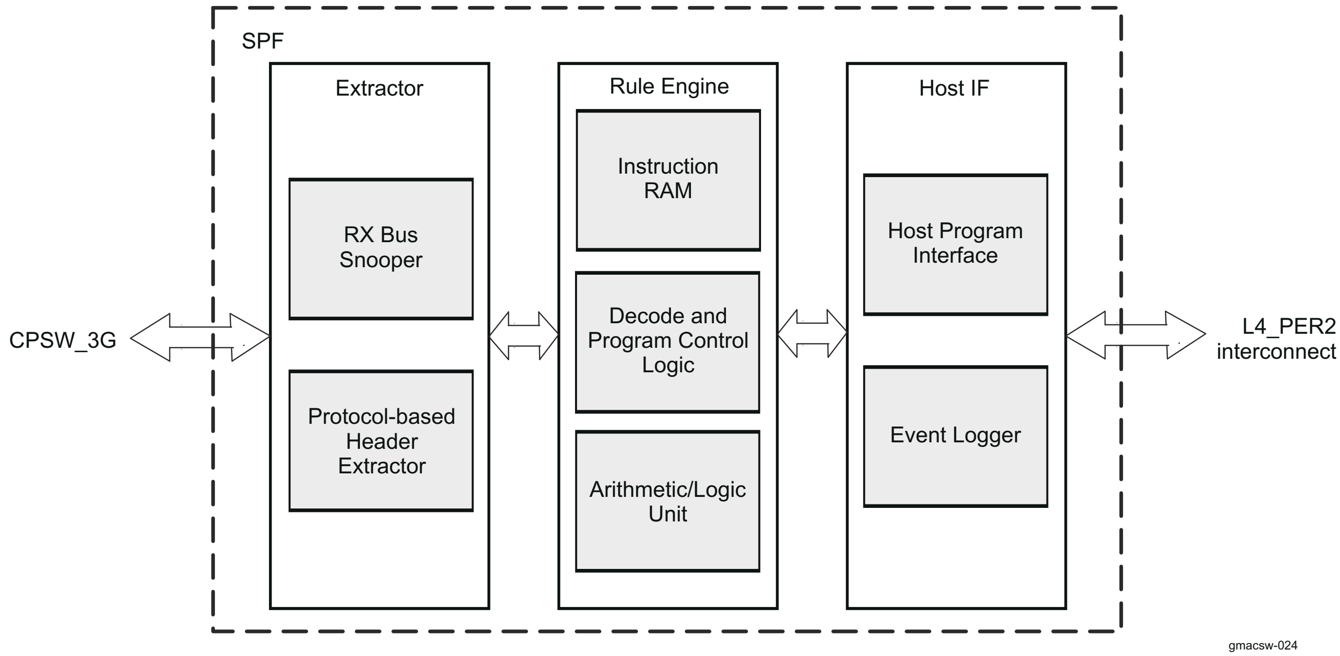

Figure 24-198. SPF Block Diagram

The packet parser interfaces to the three-port Ethernet switch (CPSW_3G). The CPSW_3G signals are snooped for receive traffic and the packet contents are provided to the packet header extractor. The parser can decode various network packet formats and determine the location of the header corresponding to each of the specified protocols and store the values in internal registers. The packet parser can decode VLAN, PPPoE, IP, TCP, UDP and ICMP frame formats and determine the location of each protocol header in a frame. The location of each of these headers is used by the rule engine for performing checks against preprogrammed conditions.

The rule engine monitors information in the header fields and upon detection of an abnormal combination of values in these packet header fields, issues an instruction to drop the packet to the external RFIFO interface. The rule engine can also monitor the receive rate of a particular class of packets and can limit the number of packets that actually pass through the system. The operation of rule engine is programmable and that gives flexibility to perform a range of different checks on the contents of packet to determine whether or not it should be accepted.

The event logger captures the activity in the packet filter. In addition, based upon the settings programmed by the host software, the event logger writes detailed information about any frames that have been dropped thus far. This information is written to a part of the system memory as configured by the host software.

24.11.4.9.2.2 Interrupts

The Static Packet Filter has one interrupt that is used to inform the host about excessive number of logged packet drops. The addresses of the instructions (or drop codes) in the instruction memory that cause packet to be dropped are associated with a threshold. When the threshold is met, the packet drop is logged. Each time a packet drop is logged, it is counted. When the number of logged records reaches the value specified by the SPF_INTCNT register, the host is interrupted. The threshold settings can be controlled by host software to limit the frequency of interrupts. Writing a zero to SPF_INTCNT disables the interrupt in this scenario. Whenever interrupt is enabled and is triggered, it can be cleared by writing one to either Raw register or Masked register.

Interrupts are controlled by the following registers:

1. Raw register SPF_INT_RAW: Holds the Raw state of interrupt, that is, without mask. The hardware interrupt is latched in this register and is only cleared when a one is written to either Raw register or Masked register. Writing a zero has no effect on this register.

2. Masked register SPF_INT_MASKED: This is the actual interrupt given to the system. It is the result of bitwise AND operation of Raw and Mask registers. Once the interrupt is sensed by the system, this register should be cleared by writing one to this register or to Raw register during ISR execution. Writing zero has no effect on this register
3. Mask set register SPF_MASK_SET: Writing one to this register enables the interrupt. By default, the interrupt is disabled and needs to be enabled by writing a one to this register. Writing a zero has no effect on this register. Writing to this register also set clear register.
4. Mask clear register SPF_MASK_CLR: Writing one to this register disables interrupt. Writing a zero has no effect on this register.

24.11.4.9.2.3 Protocol Header Extractor

The extractor module has a protocol aware state machine. It decodes the header field in the current protocol header to determine the encapsulating protocol type and extracts various parameters used for software logging. The extractor module also provides the offset to octets in the packet, where Layer 3 and Layer 4 protocol headers start, to the rule engine. These protocol headers correspond to the location of IP and TCP/UDP/ICMP headers from the beginning of the packet.

Ethernet packets with VLAN, PPPoE, IP, IP Options, and ICMP/TCP/UDP protocol are supported by the extractor. When unknown protocols are detected, the extractor skips any additional packet processing. Some examples of how packet parsing is done by the Extractor are given below.

- Ethernet – VLAN - PPPoE – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – IP options – Unknown – Payload
- Ethernet – VLAN – PPPoE – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – Unknown – Payload
- Ethernet – VLAN – PPPoE – Fragmented IP – Unknown – Payload
- Ethernet – VLAN – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – IP options – Unknown – Payload
- Ethernet – VLAN – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – Unknown – Payload
- Ethernet – VLAN – Fragmented IP – Unknown – Payload
- Ethernet – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – IP – IP options – Unknown – Payload
- Ethernet – IP – TCP/UDP/ICMP – Payload
- Ethernet – IP – Unknown – Payload
- Ethernet – Fragmented IP – Unknown – Payload
- Ethernet – Unknown

The flow of Extractor state machine flow is as follows.

1. Wait for start of packet and proceed to step 2 if start of packet detected.
2. Read Ethernet header Length/Type field (at offset 13). Go to step 3 if next header is VLAN, to step 4 if it is PPP header, to step 5 if it is IP header and to step 8 otherwise.
3. Allow VLAN header to pass and read the Length/Type field. Go to step 4 if next header is PPP, to step 5 if it is IP header and to step 8 otherwise.
4. Read the protocol type in PPP header. Go to step 5 if protocol is IP and to step 8 for unknown protocol
5. Extract source IP address and destination IP address from the IP header. Determine if the packet has IP options or if the packet is fragmented. Go to step 6 if the packet has IP options and to step 8 if the packet is fragmented. If there are no options and the next protocol header is TCP/UDP, go to step 7. Otherwise, skip processing and go to step 8 because the packet has unrecognized protocol header
6. Skip IP options and determines the next protocol header. Go to step 7 if next header is TCP/UDP/ICMP. In case the packet contains an IP fragment or if the protocol in the next header is unknown, skip processing and go to step 8.
7. The packet has TCP/UDP/ICMP header. Extract TCP/UDP source and destination port numbers for logging or ICMP type and code fields and go to step 8.
8. Wait for end of frame and go to step 1 at end of frame.

In case the packet is aborted (indicated by address 0x10 on VBUSP with request and write ready asserted), the extractor state machine flushes its current state, goes back to the idle state and waits for next packet.

The Extractor provides information to rule engine about location of Layer 3 and Layer 4 protocols. When this information is provided to rule engine, the Base Register 1 and Base register 2 are loaded with Layer 3 start offset and Layer 4 start offset respectively. Until the extractor completes decoding of these protocol headers and sends the offset values to rule engine, the rule engine does not execute any instruction that operates on fields in these protocol headers.

Extractor module extracts IP protocol, Source IP address, Destination IP address, TCP/UDP source port, TCP/UDP destination port and ICMP type/code from incoming packet and provides this information to the Host logger module for software reporting. In case IP header or TCP/UDP header does not contain the extractable fields then the corresponding field is logged as zero.

In case packet has unknown Layer 4 protocol or IP packet is fragmented such that the packet does not contain TCP/UDP/ICMP header then TCP/UDP source/destination ports or ICMP type/code fields are logged as zeros.

24.11.4.9.2.4 Programmable Rule Engine

The rule engine is a micro-coded machine that is programmed by the host software. The rule engine is programmed to evaluate various expressions involving the header fields of different protocols that the incoming packet belongs to. These expressions are coded into the instructions that are stored in an internal RAM and are used to check whether a packet is mal-formed or is potentially a DoS attack packet. The rule engine executes the instructions for each incoming packet and makes a decision about accepting or rejecting the packet.

Since each packet can have multiple distinct protocol headers, the location of the headers can be different from packet to packet. The rule engine gets information about the location of the protocol headers from the packet header extractor. The packet header extractor can decode several different protocol types. The octet number at which a particular protocol header is stored is loaded into SPF Base Registers. An application may require SPF to filter packets based on protocols that are not decoded by the extractor. In such cases, SPF allows bypassing the header extractor and then the rule engine can be programmed to analyze packets and figure out the location of each header.

The Rule Engine instructions are programmed before the SPF module is enabled. The instructions cannot be overwritten while the rule engine is processing packets. To modify the contents of code RAM during operation, SPF must be disabled temporarily and then new instructions can be loaded.

Once SPF is enabled, the rule engine starts to fetch instructions one at a time. For each instruction, the operands are obtained from either the packet octets that are being received, from internal registers or from the immediate values inside the instruction itself. If the octet that is needed for execution has not yet been received, then the execution stalls until the required octet is received. In case the operand specified in the instruction refers to a packet octet that has already gone by and is not available in the packet buffer, then the execution stalls until the end of packet. An instruction is executed only when all the required operands are available. Based on the instruction execution results, the packet may immediately be dropped or the results of the evaluated expressions may be stored for future use. In addition, the current instruction can also cause the rule engine to skip a specified number of instructions (immediately following the current instruction) and resume from another location in the instruction RAM.

The rule engine operates on multiple operands and performs multiple tasks in each clock cycle. In each cycle, it can perform one arithmetic and/or logical operation on two pairs of operands. The operands are masked with a 32-bit mask that is generated from the information provided in the instruction. The mask allows for operations that involve variable sized operands. Each operation generates a 32-bit number and a flag bit. The 32-bit number is typically either the sum or the output of bit-wise logical operation. The flag is a single bit result of a comparison operation. The result of each operation can be saved in the internal registers if a specified condition is satisfied. Similarly, depending on the result of the operation, the rule engine can jump to another location in the instruction memory. The program can instruct the rule engine to either perform two save operations, two conditional jumps or one jump and one save. The conditions must be mutually exclusive to prevent unspecified operation. In addition to providing an alternate path for execution, the instruction can cause the rule engine to accept or reject the current packet and exit from the program until the next packet is received.

When the execution of an instruction does not result in a decision to accept or reject the packet, the rule engine progresses to the next instruction. Instructions are executed until a final decision is made. If a packet is aborted in the middle at the network interface, the rule engine aborts execution and clears all base registers, program counter, octet counter and packet buffer. It is then ready to process next packet.

From a hardware perspective, the rule engine contains a buffer to store packet octets, several internal registers for temporary storage, instruction decoding logic and control circuitry. A description of each of the hardware resources in the rule engine follows.

24.11.4.9.2.4.1 Internal Registers

Several different types of registers are provided in the rule engine. The description of each of theese is provided below.

- Base Registers (B0-B4): There are four hardware base registers (B1-B4) that store the location of various protocol headers. The B0 register is not a hardware register and it always means a reference to the first octet in a packet. Each base register is eight bits wide and is used to reference octets in a packet. The base registers can point to any octet in the packet upto 255 octets. These registers are readable and writable by the rule engine. In addition, base registers B1 and B2 are loaded with data provided by the extractor when the rule engine is not running in extractor bypass mode (SPF_CONTROL[2] SPF_EXT_BYPASS). The rule engine can write to base registers irrespective of whether extractor bypass is enabled. When an operand needs to use contents of B1-B4 registers, the instruction only executes if the specified base register was loaded at least once after the beginning of current packet. If the specified base register was not loaded during the current packet, then the operand referenced by this base register cannot be extracted from the packet and will cause the rule engine to stall.
- Constant Registers (C0-C7): The rule engine can refer to any of eight 32-bit constant values. These are programmed by the host (SPF_CONSTj, j = 0 to 7) and the rule engine only has read access to these registers. Each of these registers can be changed at any time by the host software. However, changing the value of these registers is not recommended as unpredictable behavior may occur if contents are changed while the rule engine is executing instructions that use the C0-C7 values.
- General Purpose 32-bit registers (R0-R7): There are eight 32-bit registers that can be read/written by the rule engine. These are general purpose registers and can be used as temporary storage. In addition, when the rule engine is required to provide logging information, R4-R7 are used to store information that will be written to memory.
- Rate limit registers (L0-L3): Four 8-bit rate limit registers are used by rule engine to count specific types of packets that are to be rate limited. These registers are counters that are loaded with programmed threshold values (SPF_RATELIMi, i = 0 to 3) at the end of time interval determined by the clock pre-scaler (SPF_PRESCALE)
- General Purpose 1-bit registers (T0-T3): Four 1-bit registers are provided to store comparison results by the rule engine. These registers can be used to store 1-bit output from ALUs. In addition, the logical OR and logical AND of the flags can also be stored in T0-T3 registers. The 32-bit ALU results may also be stored in T0-T3 registers but only the LSB will be stored.

The rule engine instructions refer to these internal registers during execution. More details about instruction encoding are in subsequent sections.

24.11.4.9.2.4.2 Packet Buffer

When the rule engine is processing a packet, it stored a snapshot of latest 32 octets in an internal buffer. This buffer allows evaluation of expressions on packet octets even after the packet octets have gone by on the external receive VBUSP network interface.

At the start of packet, the first eight octets received are loaded into the first eight locations of the packet buffer. When the next eight octets arrive, these are loaded into the first eight locations and the existing octets are moved to the following eight locations. This process is continued until the packet buffer is full. When packet buffer is full and additional octets arrive, the oldest eight octets are shifted out and are no longer available to the rule engine. Thus, the packet buffer provides a snapshot of most recent octets received.

When the rule engine encounters instructions that reference packet octets which have not yet been received then the rule engine stalls until the required octets are available. Similarly, instructions which require octets that have already been shifted out of the packet buffer will cause rule engine to stall. And since these octets will never be available, the rule engine will not execute any further instructions for the current packet. It will return to the first instruction when the packet ends.

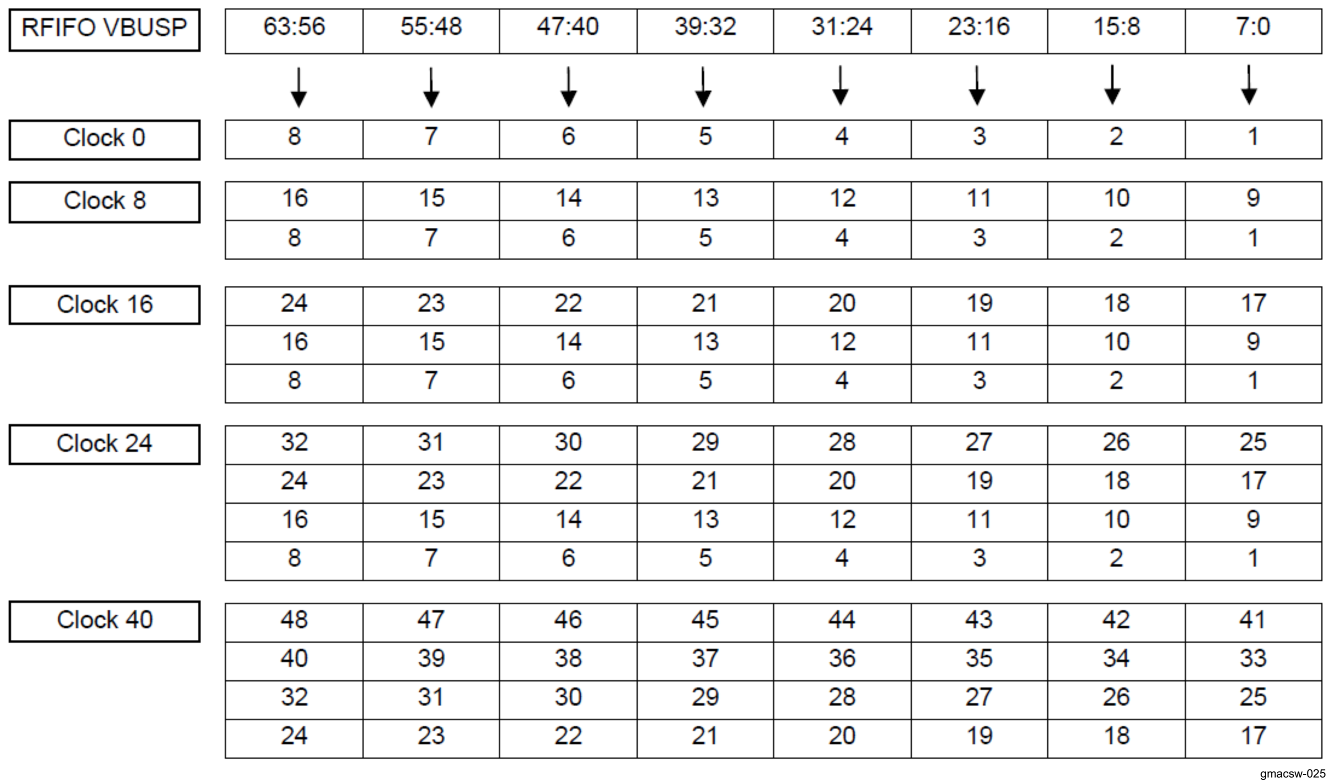

Figure 24-199. Packet Octets as Stored in the Packet Buffer

The contents of a packet, when used as one or more operands in an instruction, are always fetched from the packet buffer. The Base registers (B0-B4) in conjunction with an offset and bits are used to specify which octets are to be used as operands.

24.11.4.9.2.5 Intrusion Event Logger

The activity of the static packet filter is logged by the intrusion event logger. Based on the configuration, the event logger writes specific fields of the incoming packet that violate a particular rule to the system memory for software diagnostics.

The logging module allows controlling the frequency at which events are logged to the memory. A set of nine counters are provided and, of these, eight can be mapped to any address of the rule engine's instruction RAM using map registers. This mapping logically associates the log information with the instruction that caused the packet to be dropped. The 9th counter is not associated with any particular instruction and it can be used to count the packets that were dropped at instructions not mapped to any of the other eight counters.

For each of the nine counters, there is a register to store the minimum number of attacks that must be detected before any information is logged to memory. Only when this threshold is met and logging is enabled, the host interface module writes log data in system memory. The memory area used to log is specified by the host in the SPF_LOG_BEGIN address and SPF_LOG_END address registers.

The event logger continues to write data to memory until it runs out of space and the log overwrite is disabled. With each update of the log, the SPF_LOG_HWPTR is updated. This information can be used by the host to determine how much data has been logged. The software in turn keeps the SPF_LOG_SWPTR updated to inform the SPF about the next address from where information will be read by the host software. It is required that software program correct value of SPF_LOG_END address to enable hardware to determine roll-over location. The SPF considers all space before the SPF_LOG_SWPTR as available for logging. In case SPF_CONTROL[9] SPF_LOGOW_EN control bit is set, SPF ignores SPF_LOG_SWPTR and logs data irrespective of software read log status. Note that the memory space allocated for logging is a multiple of four 32-bit words and end address SPF_LOG_END should be loaded with byte address of the next byte following the last log entry. For example if 16 bytes space is allocated for SPF logging from address 0x1400_0000, then SPF_LOG_BEGIN should be 0x1400_0000 and SPF_LOG_END should be 0x1400_0010.

The host software must set SPF_CONTROL[8] SPF_LOG_EN bit to activate logging. The setting of SPF_LOG_EN bit has no effect on the threshold based counters and they are always active. In addition to the log counters, SPF has one master drop count register (SPF_DROPCNT) which tracks the total number of packets dropped thus far. This counter does not roll over and must be cleared for re-run by the host processor once it reaches the maximum value.

The format in which packet information is written in the memory by the event logger is shown in Table 24-890 and Table 24-891.

Table 24-890. Format for TCP/UDP Packets

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Source TCP/UDP Port		Destination TCP/UDP Port	

Table 24-891. Format for ICMP Packets

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Type	Code	Checksum	

Each entry logged to memory has a drop code associated with it. The drop code is the address in instruction memory that actually triggered the drop. Up to eight drop codes can be monitored in this manner. In addition to drop code, the protocol, IP addresses and source/destination ports associated with the dropped packet are recorded.

Log data can be supplied by either Extractor module or by Rule engine. The SPF_CONTROL[3] SPF_RULE_LOG bit must be set to use log data from Rule Engine and cleared to use data supplied by the Extractor.

When logging is done through the Rule Engine, contents of internal registers R4-R7 are written to memory. The format of packet information stored can be programmed in the rule engine except for the drop code field which is static and cannot be changed. The format in which rule engine information is written in the memory by the event logger is shown in Table 24-892.

Table 24-892. Rule Engine Format

Drop Code	Register 4[23:0]
Register 5[31:0]	
Register 6[31:0]	
Register 7[31:0]	

The rule engine programming must ensure that these registers contain all required information that is to be recorded before the packet drop instruction is executed. As soon as the drop instruction is executed, the logging module starts to send data from the registers R4, R5, R6 and R7 to the system memory and is not possible to modify the contents of these registers.

24.11.4.9.2.6 Rate Limiter

The static packet filter provides a way to limit the rate of specific types of incoming packets. The SPF module provides four rate limit registers (L0-L3) that are used in conjunction with a clock prescaler (SPF_PRESCALE) and rule engine instructions. The clock prescaler is a clock divider and every count down to zero and the subsequent roll-over indicates end of a time interval. At every such event, each of the four rate limit registers is loaded with a preset value (SPF_RATELIMi, i= 0 to 3) that is programmable by the host processor. When packets are received, the rule engine can identify packets of particular types and execute a limit operation. The limit operation specifies a condition (described in Table 24-910) and a limit register. If the condition evaluates to true, the packet is dropped if the rate limit register is zero. If it is non-zero, then the rate limit register is decremented by one.

Thus, by using the prescaler and the limit registers, it is possible to control the rate of specific type of packets. By controlling the value of prescale counter (common to all rate limit registers) and the rate limit thresholds, the granularity of the rate can be modified. A lower value of prescale counter will cause frequent reloads of the rate limit registers and will allow rate control over small time intervals. Keeping the prescale counter at extremely small values may cause the rate limiter to be ineffective because the limit registers will be reloaded too frequently to count down to zero. Conversely, a higher value of prescale counter will cause less frequent reloads of the rate limit registers and the rate control will be over longer time intervals. The reload value of each 8-bit rate limit register and the prescale register are programmed by the host processor before SPF is enabled. A reload value of 0xFF can be used to disable any of the rate limiters at run-time without changing the firmware. Both the prescale and limit registers can be modified during run-time.

24.11.4.9.2.7 Rule Engine Instruction Set Architecture

24.11.4.9.2.7.1 Instruction Format

The design supports 64 deep instruction memory. Each of the instructions is 78 bit wide and is stored in a RAM internal to the SPF module. Each instruction can have up to four operands, two arithmetic/logical operations and two conditional jump/save actions based on the outcome of the operations.

The operand field is 52 bits wide and it can have up to four operands. The arithmetic and logical operation codes are four bits each. The operation codes are nine bits each.

Table 24-893. Instruction Format

Bits	Field Name	Description
77:26	OPERAND	Up to four operands are specified in this field. The source of the operands can be the packet that is being received at the network interface, one of the internal register values or an 8/16/32 bit operand specified within the instruction.
25:22	FUNCTION0	This field specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of first two operands specified in the instruction.
21:18	FUNCTION1	This field also specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of the third and fourth operands specified in the instruction.

Table 24-893. Instruction Format (continued)

Bits	Field Name	Description
17:9	OPERATION0	A Save/Jump/Limit/Nop operation is specified in this function. Save operation code includes the source and destination information. The save source is the output of functions and the destination is one of the internal registers where data should be saved. Jump operation code has information about a condition and a destination. The jump occurs when the condition, which is based on the result of function0 and function1, is true. The Jump destination controls the flow of instruction execution. Jump to location 1 results in the packet being dropped. Rule engine goes back to initial instruction and waits for next packet. The event logger writes information to memory. Jump to location zero results in the packet being accepted. The rule engine goes back to initial instruction and waits for next packet. Limit operation code has information about a condition and a rate limit register. The Limit operation either causes the packet to be dropped or results in the specified rate limit register to be decremented by one.
8:0	OPERATION1	This field specifies a second save/jump operation. The format for this field is same as for Operation0.

24.11.4.9.2.7.2 Operand Field

The operand field specifies up to four operands. Each operand is obtained from the incoming packet data, from an internal register or as an immediate value specified in the instruction itself. In addition, there is a bit mask associated with each operand. The mask values are encoded in the instruction itself and the mask for each operand is applied before it is used by the Arithmetic and Logic Unit.

The operands are input to the two 32-bit Arithmetic and Logic units. For all calculations, a mask is used with each operand. The mask is a 32-bit number that is generated from a 5-bit code provided in the instruction or from an immediate value in the instruction. The 5-bit mask code specifies how many bits (from the LSB side) will be input to the ALU. An immediate mask must be used when the mask is not a continuous sequence of 1's. Whenever an immediate mask value is specified, the mask value specified by the 'Bits' fields is ignored.

Each operand is at least 13-bits long and the encoding for each operand types is shown in Table 24-894 to Table 24-901.

Table 24-894. Packet Data Operand

Description	This type of operand is derived from the packet itself. The encoding specifies a number of bits (up to 32) to be extracted from a location in the packet indicated by the selected base register and offset. The format of 13-bit operand code is shown below. Internally, a 32-bit number is obtained from the packet. Then, a mask is created from the bits[4:0] field and bitwise ANDed with the 32- bits extracted from the packet.

12	11	10	9	8	7	6	5	4	3	2	1	0
Base[2:0]			Offset[4:0]					Bits[4:0]				

Bits	Field Name	Description
12:10	Base[2:0]	The Base field selects one of the Base registers B0, B1, B2, B3 or B4. The operand comprises of (Bits+1) bits extracted from the packet. The offset from where the operand octets are extracted is determined by the sum of the value of specified base register (Base 0 to Base 4) and the specified offset. Base 0 is start of packet.
9:5	Offset[4:0]	The value of the selected base register plus the specified offset is the octet location in the packet from where the specified number of bits will be picked.
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, only one bit is used as operand. When Bits[4:0] is 31, then 32 bits are used as operand.

Table 24-895. Constant Operand

Description	One of the eight constants programmed by the host software can be used as operand. The bits field specifies the mask to be applied to the selected 32-bit constant.

12	11	10	9	8	7	6	5	4	3	2	1	0

1	0	1	0	0	C[2:0]	Bits[4:0]

Bits	Field Name	Description
7:5	C[2:0]	This field selects one of the constants (C0-C7).
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.

Table 24-896. 32-bit Register Operand

Description	One of eight 32-bit registers is used as operand and bits[4:0] field specifies the bitmask to be applied to that register.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	0	1	R[2:0]			Bits[4:0]				

Bits	Field Name	Description
7:5	R[2:0]	This field selects one of the 32-bits registers (R0-R7).
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.

Table 24-897. 1-bit Register Operand

Description	One of the four 1-bit registers is used as operand.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	0	T[1:0]		0	0	0	0	0

Bits	Field Name	Description
6:5	T[1:0]	This field selects one of the four 1-bits registers (T0-T3).

Table 24-898. Base Register Operand

Description	One of the base registers is used. The 2-bit codes are 00, 01, 10 and 11 for B1 to B4 respectively.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	B[1:0]		0	0	Bits[2:0]		

Bits	Field Name	Description
6:5	B[1:0]	This field selects one of the four base registers (B1-B4). Note that B0 is a virtual register which is always zero and specifies the start of packet.
2:0	Bits[2:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.

Table 24-899. End of Packet Operand

Description	The End-of-Packet (EOP) operand can be used to detect the end of current packet. Use of this operand will stall the CPU until the end of packet is reached. The end of packet operand will always be equal to one when the CPU detects end of packet. It will be zero until packet data is being received and will also stall the CPU. The recommended use of this operand is in the last instruction where a check may be made for size of current packet. Note that this operand only tracks the end of a complete successfully received packet by the RFIFO. The EOP operand does not detect abort of a packet.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	0	1	0	Bits[4:0]				

Bits	Field Name	Description
4:0	Bits[4:0]	The number of bits specifies the mask. However, these bits are inconsequential for EOP operand. Irrespective of the mask specified by bits[4:0], the EOP operand is always equal to 0x1 in the execution cycle of the instruction it is used.

Table 24-900. Octet Count Operand

Description	The Octet count operand is used to determine the number of bytes that have been received by rule engine.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	0	0	1	1	1	Bits[4:0]				

Bits	Field Name	Description
4:0	Bits[4:0]	The number of bits specifies the mask that is applied to octet counter value. The recommend value for this field is 0x1F.

Table 24-901. Immediate Data Operands

Description	The immediate data operands can be bigger than 13 bits as shown in the codes below. Each of such operands is directly sent to the ALU without applying any addition bit mask. The immediate data operands can be 8, 16 or 32 bits wide.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	0	Data[7:0]							

20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	Data[15:0]															

36	35	34	33	32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	Data[31:0]																															

Table 24-902. Immediate Operand Masks

Description	The operand fields can also be used to specify bit masks. These are used when only specific bits from an operand are to be extracted. There is provision for 8-bit and 16-bit masks that can be encoded into an instruction's operand field.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	Mask[7:0]							

20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	1	Mask[15:0]															

When the operand field is all-ones it does not specify any operand and is considered zero.

The tables below list the combinations in which operands may be programmed in an instruction. In this list, Pkt/Reg operand is an operand consisting of octets from the packet or the contents of one of the internal registers; mask specifies the value that is used as a mask instead of the mask generated from the Bits field in the instruction; immediate operand (immediate[7:0], immediate[15:0] and immediate[31:0]) is an 8/16/32 bit number that is used as an operand. The format of Pkt/Reg operand is as shown previously. The decoding of operands for each ALU is dependent upon the type of operation specified in the ALU and the format of the operand field. When there are four operands in the operand field, the first and second operands are used in ALU0 and the rest by ALU1. When ALU0 needs only one operand, then the remaining operands are fed to ALU1. The order of decoding operands is designed to first provide operands to ALU0 from the more significant side of operand field and then to ALU1. If the number of operands specified in instruction does not match with the number of operands required by the ALUs, unspecified behavior can occur. For an instruction to execute, both ALUs must have valid data. If any of the ALUs uses a packet data operand which is not yet available then the rule engine stalls until data is available. During the stall phase, the instruction is decoded every cycle and all required operands must be available simultaneously for the instruction to be executed In addition, if an instruction refers to packet octets that are no longer available, the rule engine stalls until the end of packet.

Table 24-906. Operand Field With One Operand

Pkt / Reg / Imm[7:0] Operand[12:0]	Reserved	Reserved	Reserved

Pkt/Reg Operand[12:0]	11000 Mask[7:0]	Reserved	Reserved

Pkt/Reg Operand[12:0]	11001 Mask[15:0] 11111	Reserved

11101 Immediate[15:0] 11111	Reserved	Reserved

11110 Immediate[31:0] 11	Reserved

The formats in which operands are specified in the operand field have certain restrictions:

- a mask cannot follow an immediate value
- a mask cannot follow a previous mask
- a reserved field should have all following fields reserved as well
- the first field cannot be a mask

24.11.4.9.2.7.3 Arithmetic/Logical Function Field

There can be two codes for arithmetic and logical functions in each instruction. Each of the operations can involve one or two operands.

The location of each function field in an instruction is listed in Table 24-907.

Table 24-907. Arithmetic/Logical Instruction Field

Bits	Description
23:20	Single or Dual operand Arithmetic/Logic Function (function 0)
19:16	Single or Dual operand Arithmetic/Logic Function (function 1)

The bit codes for each arithmetic/logic function that can be performed on the operands of an instruction are listed in Table 24-908.

Table 24-908. Arithmetic/Logical Operation Codes

Code	Description	Operands Required	32-bit result	1-bit flag result
0x0	Less Than	2	0	Set if true
0x1	Less Than Equal To	2	0	Set if true
0x2	Greater Than	2	0	Set if true
0x3	Greater Than Equal To	2	0	Set if true
0x4	Equal to Zero	1	0	Set if true
0x5	Not Equal to Zero	1	0	Set if true
0x6	Equal to One	1	0	Set if true
0x7	Not Equal to One	1	0	Set if true
0x8	Equal	2	0	Set if true
0x9	Not Equal	2	0	Set if true
0xA	Add	2	Sum	Set if overflow
0xB	Subtract	2	Difference	Set if output is negative
0xC	Bitwise AND	2	Bitwise AND	0

Table 24-908. Arithmetic/Logical Operation Codes (continued)

Code	Description	Operands Required	32-bit result	1-bit flag result
0xD	Bitwise OR	2	Bitwise OR	0
0xE	Result is same as Operand	1	Same as operand	0
0xF	No Function (NOF)	0	0	0

The ALU0 and ALU1 are assigned function0 and function1 respectively. In case only one function is to be performed in an instruction, function0 field should be used to do that. An instruction with no function for ALU0 and a valid function for ALU1 will result in unspecified behavior.

The output of each function is in the form of a 32-bit number and a single bit value. The single bit value is either the carry bit from an add/subtract operation or the Boolean result from a comparison function. The single bit output from each function is referred as the flag0 or flag1 result. The 32-bit number is the outcome of arithmetic or a bitwise logical operation and it is referred to as the word0 or word1 result.

24.11.4.9.2.7.4 Operation Field

The operation field specifies a limit, save or a jump operation. All of these operations involve two arguments that are specified within the instruction.

In case of limit operation, one of the arguments is a condition and the other argument is a limit register. In case of save operation, one of the arguments is source data and the other argument is a destination where the data will be saved. In jump operation, the first argument is a condition that must be true for the jump to occur and the second argument is a destination to which the program control will be moved to. The destination argument in a jump operation also specifies specific destinations that lead to the current packet being immediately rejected or accepted.

The location of operation field in an instruction is shown in Table 24-909.

Table 24-909. Operation Fields

Bits	Description
17:9	Limit/Save/Jump Operation (operation 0) For limit operation, [17:16] is the operation field, [15:13] is the condition field and [12:9] is a limit register. For save operation, [17:16] is the operation field, [15:13] is the source field, and [12:9] is the destination field. For jump operation, [17:16] is the operation field, [15:13] is the condition field, and [12:9] is the destination field
8:0	Limit/Save/Jump Operation (operation 1) For limit operation, [8:7] is the operation field, [6:4] is the condition field and [3:0] is a limit register. For save operation, [8:7] is the operation field, [6:4] is the source field, and [3:0] is the destination field. For jump operation, [8:7] is the operation field, [6:4] is the condition field, and [3:0] is the destination field.

Table 24-910. Limit Operation

Description	In a limit operation, the condition argument specifies a condition that must be true for the specified limit register to be decremented if non-zero or the packet to be dropped if the limit register is zero.

<table>
<tr><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td>0</td><td>0</td><td colspan="3">Condition Code</td><td colspan="4">Limit Register</td></tr>
</table>

Bits	Field Name	Description
6:4	Condition Code	It is a 3-bit code that specifies the condition that must be true for the operation to be executed. 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 | flag1) 0x3: Logical NOR of flags (!(flag0 | flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Decrement/Limit

Bits	Field Name	Description
3:0	Limit Register	It is a 4-bit code that specifies the limit register that is to be decremented or checked for zero value. 0x0: Rate limit register L0 0x1: Rate limit register L1 0x2: Rate limit register L2 0x3: Rate limit register L3 0x4-0xF: Reserved

Table 24-911. Save Operation

Description	The arguments for a save operation include a code for source data and a code for the destination. The source is either a single bit data or a 32-bit word. The single bit data is either a flag from the functions or a logical OR/AND of the flags. The 32-bit word is the result of the ALU arithmetic/logical functions.

8	7	6	5	4	3	2	1	0
0	1	Source Data Code			Destination Register Code			

Bits	Field Name	Description
6:4	Source Data Code	It is a 3-bit code that specifies the source data which is to be save in another register 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 | flag1) 0x3: Logical AND of flags (flag0 & flag1) 0x4: Output of function (word0) 0x5: Output of function (word1) 0x6-0x7: Reserved
3:0	Destination Register Code	It is a 4-bit code that specified the register in which source data is to be stored 0x0-0x3: Single Bit register (T0-T3) 0x4-0x7: Base Register (B1-B3) 0x8-0xF: 32-bit Register (R0-R7)

For some instructions, the rule engine extracts the operand from the current packet. To determine the packet bits to be used as operands, it refers to one or more base registers. Whenever an instruction causes a change in value of any of the base registers, it cause the rule engine to wait for one clock cycle before executing the next instruction. The rule engine is a pipelined processor and change in the value of a base register causes the prefetched operand values to become stale and these need to be fetched again. The clock cycle inserted allows rule-engine to fetch the data again before the instruction using this data is executed. Only the instructions that use packet data will be delayed by a clock cycle if the previous instruction caused a change in the base register that is referenced in the current instruction.

Table 24-912. Jump Operation

Description	For jump operation, one of the operands is a condition that must evaluate to true for the jump operation to occur. The other operand is the destination to which the program counter will move to if the jump operation is executed. The condition in a jump operation is either one of the flags from the output of the arithmetic/logic unit or a logical AND/OR of the flags.

8	7	6	5	4	3	2	1	0
1	0	Condition Code			Destination Code			

Bits	Field Name	Description
6:4	Condition Code	Condition Code 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 | flag1) 0x3: Logical NOR of flags (!(flag0 | flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Jump

Bits	Field Name	Description
3:0	Destination Code	Destination Code 0x0: Accept packet, return to instruction zero and wait for the next packet. 0x1: Reject packet and return to instruction zero. 0x2-0xF: Go to instruction at offset +2 ...+15

The jump operation results in a change of program execution flow. The jump destination determines the next instruction that will be executed by the rule engine. The destination is only specified as a positive offset to the current value of the program counter. The program counter can result in the rule engine skipping a given number of instructions instead of executing the next instruction. In addition, the destination field can instruct the rule engine to immediately reject or accept the current packet without any further checks. The rule engine then goes back to the first instruction and waits for a new packet to arrive before it executes any further instructions.

The rule engine is a pipelined processor. When it executes a jump operation, there is a delay of one clock cycle before the next instruction is executed.

The operations specified in the two operation fields are independent of each other. However, it is possible that conflicting operations are specified in the operation fields of an instruction. When conflicting operations are specified and conditions of both operations evaluate to true; then the execution flow is determined as described below:

1. If one of the ALUs has a limit/jump operation that will cause the packet to be dropped, then the packet will be dropped irrespective of what the other ALU indicates.
2. If case 1 above is false and one of the ALUs has a jump operation that will cause the packet to be accepted, then the packet will be accepted and the rule engine will return to idle state.
3. If case 1 and 2 above are false and one of the ALUs has a jump to offset with the respective condition true, the jump will be executed. If there is conflicting jump to offset information in the two ALUs, ALU0 is given priority.

Table 24-913. No Operation

Description	If there is no Save, Jump or Limit operation specified in the operation field, it is interpreted as a no operation. There is no change in execution flow, no change in any register values or rate limit registers when a no operation is encountered.

8	7	6	5	4	3	2	1	0
1	1	Reserved			Reserved			

It is expected that the rule engine will be programmed such that a decision to accept or discard the current packet is made before all instructions have executed. If the rule engine reaches the last instruction and it does not result in a decision to accept/reject the packet, then the execution flow does not stop and all instructions from the first instruction are executed again until the end of packet is reached.

24.11.4.9.3 Programming Guide

24.11.4.9.3.1 Initialization Routine

The packet filter must be initialized in order for it to operate as specified. A typical order in which the module can be initialized is shown below:

1. Initialize the firmware by programming the internal memory and verify it (SPF_INSTR_W2, SPF_INSTR_W1, SPF_INSTR_W0, SPF_INSTR_CTL)
2. Allocate memory for logs written by SPF and initialized the log space parameters (SPF_LOG_BEGIN, SPF_LOG_END, SPF_SW_PTR)
3. Program the log map registers to associate drop codes with the log thresholds. (SPF_LOG_MAP0, SPF_LOG_MAP1)
4. Program log thresholds (SPF_LOG_THRESHk, where k = 0 to 8)
5. Program constant registers if required by the firmware (SPF_CONSTj, where j = 0 to 7)
6. Program clock prescale counters and rate limit registers if required by the firmware (SPF_PRESCALE, SPF_RATELIMi , where i = 0 to 3)

7. Program the interrupt frequency control register and interrupt mask register to setup interrupts (SPF_INTCNT, SPF_MASK_SET)
8. Program the control registers to enable SPF filter and logger (SPF_CONTROL).

24.11.4.9.3.2 Interrupt Service Routine

The interrupt service routine in SPF should be designed to process the data logs generated by SPF. It should trigger a higher layer application software that can analyze the data logs and determine if any remedial measures are required based on the information in the logs. At the minimum, the interrupt service routine must reprogram the software pointer for the logging machine to be able to continue logging.

The typical tasks performed following an interrupt are listed in the pseudo code below.

```
SPF_ISR {
read log hardware pointer
read log software pointer
determine how many log entries are to be read
read each log entry starting with the software pointer
update software pointer to reflect the next unread entry
clear interrupt
}
```

24.11.4.9.3.3 Rule Engine Example Program

Here is an example of how the rule engine can be programmed to detect packets that resemble Denial of Service traffic. The pseudo code is shown below.

```
IDLE:
jump to ICMP if start_of_packet
ICMP:
if (protocol==ICMP)
limit_ICMP
if (fragmented packet)
drop and jump to IDLE
accept and jump to IDLE
else
jump to IP
IP:
if (source_ip==dest_ip)
drop and jump to IDLE
if (fragmented and (fragment_offset+ip_size)>2^16)
drop and jump to IDLE
accept the packet and jump to IDLE
```

24.11.4.10 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

24.11.4.10.1 CPTS Architecture

Figure 24-200 shows the architecture of the CPTS module inside the GMAC_SW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the GMAC_SW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value though the Event FIFO

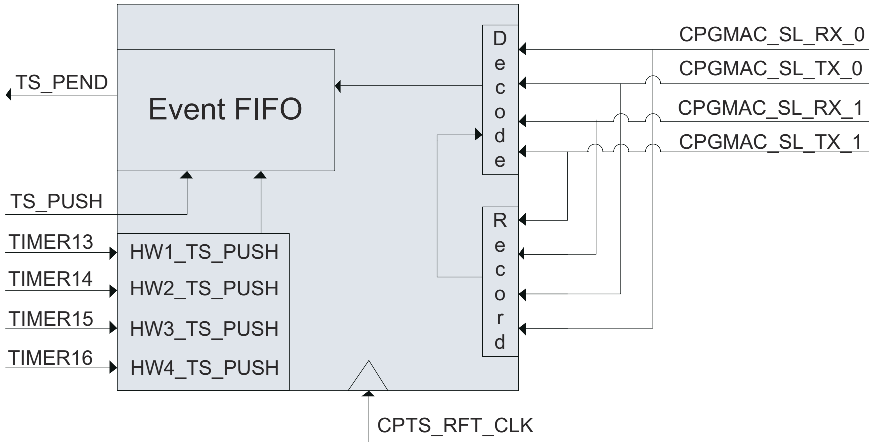

Figure 24-200. CPTS Block Diagram

The reference clock used for the time stamp (CPTS_RFT_CLK) can be derived from several sources. See *PRCM* for more details.

24.11.4.10.2 CPTS Initialization

The CPTS module should be configured as:

1. Reset the CPTS module.
2. Clear the CPTS_EN bit in the CPTS_CONTROL register.
3. Write the CLKSEL_RFT value in the CM_GMAC_GMAC_CLKCTRL register in the PRCM with the desired reference clock selection.
4. Set the CPTS_EN bit in the CPTS_CONTROL register.
5. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPTS_INT_ENABLE register.

24.11.4.10.3 Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS_RFT_CLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_VAL and CPTS_TS_LOAD_EN registers).

24.11.4.10.4 Event FIFO

All time sync events are push onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

24.11.4.10.5 Time Sync Events

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. Two 32-bit registers, CPTS_EVENT_HIGH and CPTS_EVENT_LOW hold the data of a time sync event. There are five types of sync events:

- Time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

24.11.4.10.5.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPTS_TS_PUSH register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

24.11.4.10.5.2 Time Stamp Counter Rollover Event

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from FFFF FFFFh to 0000 0000h, and the software maintained upper count value should be incremented.

24.11.4.10.5.3 Time Stamp Counter Half-rollover Event

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 7FFF FFFFh to 8000 0000h. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 24-201 shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0000 0000h through 7FFF FFFFh), then the event time stamp was taken after the rollover and no correction is required. If the value is high (8000 0000h through FFFF FFFFh), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

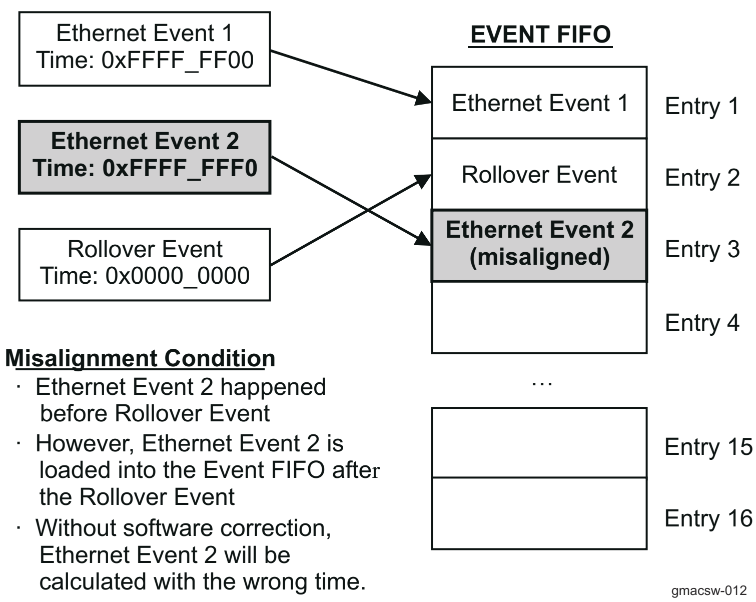

Figure 24-201. Event FIFO Misalignment Condition

24.11.4.10.5.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in Figure 24-202.

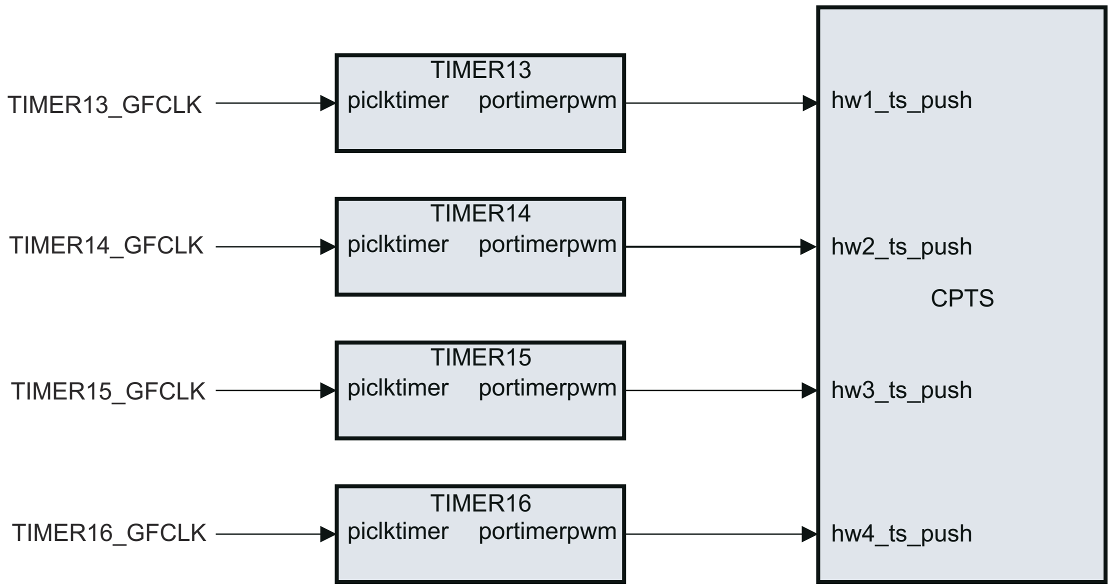

Figure 24-202. HW1/4_TSP_PUSH Connection

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPTS_EVENT_HIGH register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS_CONTROL register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

24.11.4.10.5.5 Ethernet Port Events

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in Figure 24-203. For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field or the TS_LTYPE2 field (depending on which enable bit was set) in the CPSW_TS_LTYPE register, which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in Figure 24-203. To indicate to the CPTS hardware that a virtual LAN is in use, the Pn_TS_VLAN_LTYPE1_EN (or Pn_TS_VLAN_LTYPE2_EN) enable bit must be set in the Pn_CONTROL register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the VLAN_LTYPE1 (or VLAN_LTYPE2 depending on which enable bit was set) field in the CPSW_VLAN_LTYPE register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 24-203. In this case, both VLAN_LTYPE1 and VLAN_LTYPE2 must be enabled. The outer tag must match the value of the VLAN_LTYPE1 field, and the inner tag must match the value of the VLAN_LTYPE2 field.

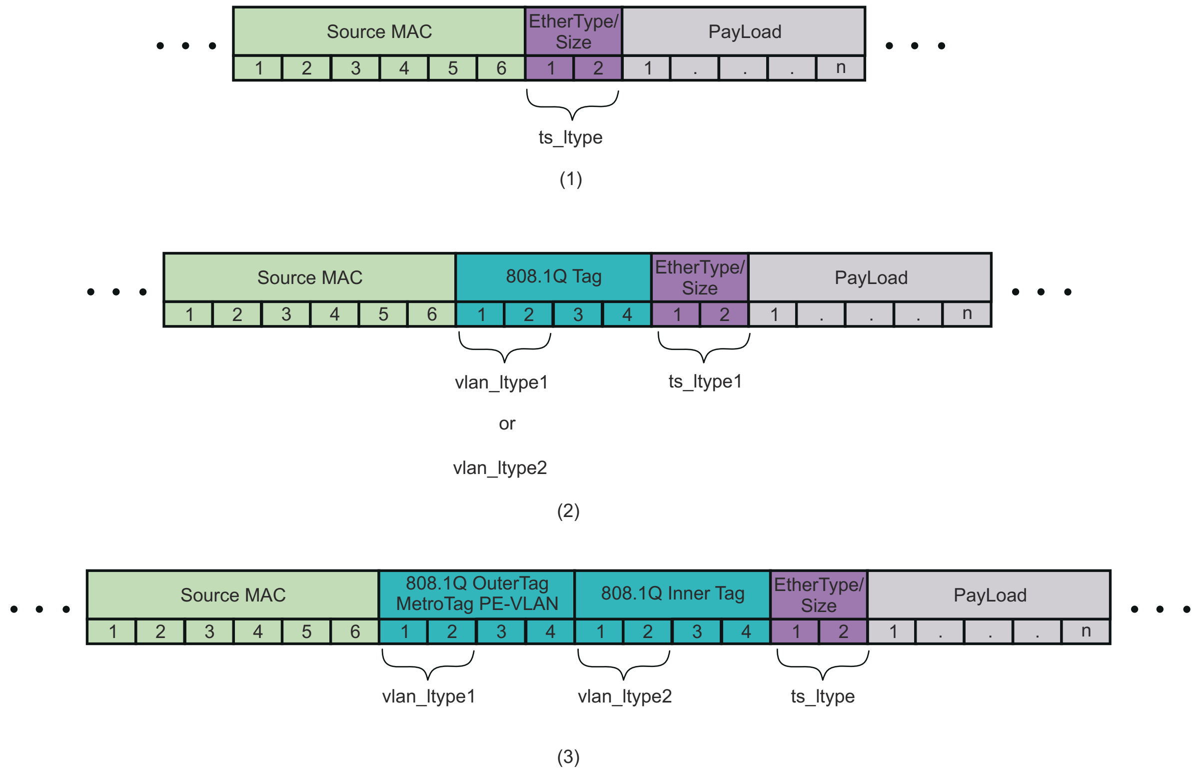

Figure 24-203. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)

To enable transmit/receive event packets on a given Ethernet port, perform the following steps, where n is the port number:

1. Set the [1] Pn_TS_TX_EN or the [0] Pn_TS_RX_EN bit in the Pn_CONTROL register to enable transmit/ receive event packets
2. Configure the register fields as follows:
   a. Set the Pn_CONTROL[2] Pn_TS_LTYPE1_EN or [3] Pn_TS_LTYPE2_EN bit to 1
   b. Set the CPSW_TS_LTYPE[15:0] TS_LTYPE1 or [31:16] TS_LTYPE2 (depending on which enable bit was set in 2(a)) field to 88F7h, which corresponds to the Precision Time Protocol (IEEE 1588) EtherType.
   c. Set the Pn_TS_SEQ_MTYPE[21:16] Pn_TS_SEQ_ID_OFFSET field to 1Eh, which is the sequence ID offset in the common message header given in the IEEE 1588 specification.
3. To enable support for VLAN tagging (IEEE 802.1Q):
   a. Set the [20] Pn_TS_VLAN_LTYPE1_EN or [21] Pn_TS_VLAN_LTYPE2_EN bit in the Pn_CONTROL register.
   b. Set the CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1 or [31:16] VLAN_LTYPE2 field (matching what was used in step 3a) to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType.
4. To enable support for up to two stacked VLANs (IEEE 802.1ad):
   a. Set the Pn_TS_VLAN_LTYPE1_EN and Pn_TS_VLAN_LTYPE2_EN bits in the Pn_CONTROL register.
   b. Set the VLAN_LTYPE1 field in the CPSW_VLAN_LTYPE register to match the EtherType of the outer tag.
   c. Set the VLAN_LTYPE2 field in the CPSW_VLAN_LTYPE register to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType of the inner tag.
5. Set the Pn_TS_SEQ_MTYPE[15:0] Pn_TS_MSG_TYPE_EN field to choose which types of time stamp messages will push events onto the Event FIFO. Table 9-20 lists the message types defined in the IEEE 1588-2008 specification. Table 24-914 lists the message types defined in the IEEE 1588-2008 specification.

Table 24-914. Values of Message Type Field

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4-7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E-F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO. The CPTS_EVENT_HIGH register contains the Message Type and Sequence ID values from the original time sync packet. The CPTS_EVENT_LOW register contains the time stamp value when the packet arrived at the corresponding port.

24.11.4.10.6 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP field (bit 0) of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP bit of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four CPTS_RFT_CLK periods plus four MAIN_CLK periods.
5. Read the TS_PEND_RAW bit in the CPTS_INTSTAT_RAW register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, go to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPTS_INTSTAT_RAW register to determine if a valid event is on the event FIFO.

24.11.4.11 CPPI Buffer Descriptors

The buffer descriptor is a central part of the GMAC_SW Ethernet Subsystem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

Host Software sends and receives network frames via the CPPI compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

Note

The 8K bytes of Ethernet Subsystem CPPI RAM begin at address 0x4848 6000 and end at 0x4848 7FFF from the GMAC_SW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use this address range.

24.11.4.11.1 TX Buffer Descriptors

A TX buffer descriptor () is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

24.11.4.11.1.1 CPPI TX Data Word 0

Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC. The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC

24.11.4.11.1.2 CPPI TX Data Word 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the buffer_pointer. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

24.11.4.11.1.3 CPPI TX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the Buffer_Offset value (which may be zero to the buffer length minus 1). Valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the Buffer_Length. The Buffer_Length must be greater than zero.

24.11.4.11.1.4 CPPI TX Data Word 3

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise,,the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer.

1 - Start of packet buffer.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

Ownership (OWNER) Flag

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

0 - The TX queue has more packets to transfer.

1 - The Descriptor buffer is the last buffer in the last packet in the queue.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

0 - The port has not completed the teardown process.

1 - The port has completed the commanded teardown process.

Pass CRC (PASSCRC) Flag

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC. When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

0 - The CRC is not included with the packet data and packet length.

1 - The CRC is included with the packet data and packet length.

TO_PORT

Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode.

1 - Send the packet to port 1 if TO_PORT_EN is asserted.

2 - Send the packet to port 2 if TO_PORT_EN is asserted.

TO_PORT_ENABLE

Indicates when set that the packet is a directed packet to be sent to the TO_PORT field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

0 - not a directed packet

1 - directed packet

24.11.4.11.2 RX Buffer Descriptors

A RX buffer descriptor () is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

24.11.4.11.2.1 CPPI RX Data Word 0

Next Descriptor Pointer

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the Next_Descriptor_Pointer.

24.11.4.11.2.2 CPPI RX Data Word 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the Buffer_Pointer.

24.11.4.11.2.3 CPPI RX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the Buffer_Offset with the value from the CPDMA_RX_BUFFER_OFFSET register value. The host initializes the Buffer_Offset to zero for free buffers. The Buffer_Length must be greater than the CPDMARX_BUFFER_OFFSET register value. The buffer offset is valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the Buffer_Length, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The Buffer_Length must be greater than zero.

24.11.4.11.2.4 CPPI RX Data Word 3

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

Long (Jabber) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX_CEF_EN bit was set in the SL_MACCONTROL register. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

Short (Fragment) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX_CSF_EN bit was set in the SL_MACCONTROL register.

Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX_CMF_EN bit was set in the SL_MACCONTROL register.

Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

Packet Error (PKT_ERR) Flag

Packet Contained Error on Ingress:

00 - no error

01 - CRC error on ingress

10 - Code error on ingress

11 - Align error on ingress

VLAN Encapsulated Packet (RX_VLAN_ENCAP)

Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the CPSW_CONTROL register RX_VLAN_ENCAP bit.

FROM_PORT

Indicates the port number that the packet was received on (ingress to the switch).

24.11.4.12 MDIO

The MII Management interface module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers (MDIO_USERACCESS0/MDIO_USERACCESS1) control and monitor up to two PHYs simultaneously.

24.11.4.12.1 MDIO Frame Formats

Table 24-915 shows the read format and Table 24-916 shows the write format of the 32-bit MII Management interface frames.

Table 24-915. MDIO Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 24-916. MDIO Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 01 pattern. The pattern assures transitions from the default logic 1 state to logic 0, and back to logic 1.

Operation Code

The operation code for a read is 10, while the operation code for a write is a 01.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

24.11.4.12.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the MDIO_CONTROL register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO_LINK register. The LINKSEL bit in the MDIO_USERPHYSEL0/1 register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO_LINKINTRAW register and the MDIO_LINKINTMASKED register, if enabled by the LINKINT_ENABLE bit in the MDIO_USERPHYSEL0/1 register.

The MDIO_ALIVE register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO_ALIVE register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a MDIO_USERACCESS0/1 register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW bit in the MDIO_USERINTRAW register corresponding to the MDIO_USERACCESS0/1 register being used. The corresponding bit in the MDIO_USERINTMASKED register may also be set depending on the mask setting in the MDIO_USERINTMASKSET and MDIO_USERINTMASKCLR registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different MDIO_USERACCESS0/1 registers. The host should check the status of the GO bit in the MDIO_USERACCESS0/1 register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO_USERACCESS0/1 register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the SL_MACCONTROL register in the corresponding MAC.

24.11.5 GMAC_SW Programming Guide

24.11.5.1 Transmit Operation

After reset, the host must write zeroes to all TX DMA State head descriptor pointers. The TX port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate TX DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the TX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Write the Buffer Length with the number of bytes in the buffer
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only)
5. Set the SOP, EOP, and Ownership bits as appropriate
6. Clear the End Of Queue bit

The port begins TX packet transmission on a given channel when the host writes the channel's TX queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each TX packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each TX packet must have the End of Packet (EOP) bit set to one by the host. The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's TX DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written. When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a TX interrupt to the host by writing to the queue's associated TX completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete. The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated TX Completion Pointer in the TX DMA State. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is de-asserted. The port write to the completion pointer actually stores the value in the state register (RAM). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

A mis-queued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The mis-queued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the mis-queued packet condition by initiating a new packet transfer for the mis-queued packet by writing the mis-queued packet's SOP buffer descriptor address to the appropriate DMA State TX Queue head Descriptor Pointer.

The host may add packets to the tail end of an active TX queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a TX queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate TX DMA State head descriptor pointer. The host software should always check for and reinitiate transmission for mis-queued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any TX packet that is not complete and ready for transmission.

The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

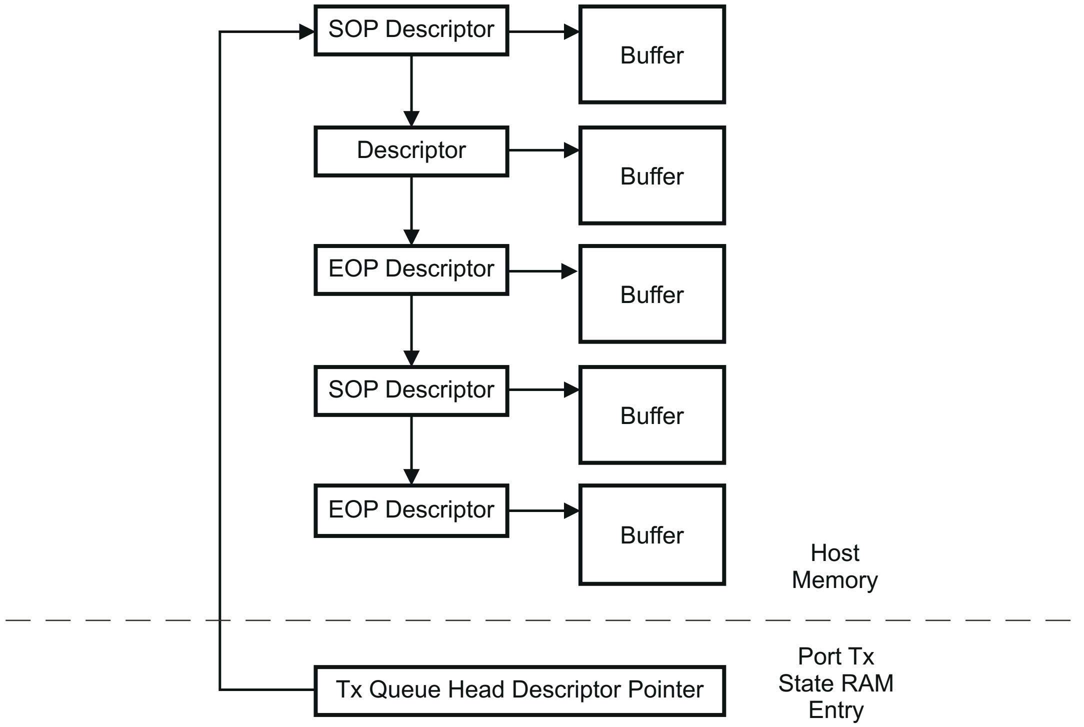

Figure 24-204. TX Queue Head Descriptor

24.11.5.2 Receive Operation

After reset, the host must write zeroes to all RX DMA State head descriptor pointers. The RX port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate RX DMA state head descriptor pointer. For each RX buffer descriptor added to the queue, the host must initialize the RX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Clear the Offset field
4. Write the Buffer Length with the number of bytes in the buffer
5. Clear the SOP, EOP, and EOQ bits
6. Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's RX DMA state. When packet reception begins on a given channel, the port fills each RX buffer with data in order starting with the first buffer and proceeding through the RX queue. If the Buffer Offset in the RX DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

1. Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value will be less than or equal to the host initialized value.
2. Set the EOP bit in the packet's EOP buffer descriptor.
3. Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
4. Overwrite the packet's SOP buffer descriptor Buffer Offset with the RX DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.

5. Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
6. Set the SOP bit in the packet's SOP buffer descriptor.
7. Write the SOP buffer descriptor Packet Length field.
8. Clear the Ownership bit in the packet's SOP buffer descriptor.
9. Issue an RX host interrupt by writing the address of the packet's last buffer descriptor to the queue's RX DMA State Completion Pointer. The interrupt is generated by the write to the RX DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the RX buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host. The host may continue RX queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the RX queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A mis-queued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The mis-queued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the mis-queued buffer case. If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start of packet overrun). If the mis-queued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the mis-queued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the mis-queued buffer condition by writing the added buffer descriptor address to the appropriate RX DMA State Head Descriptor Pointer.

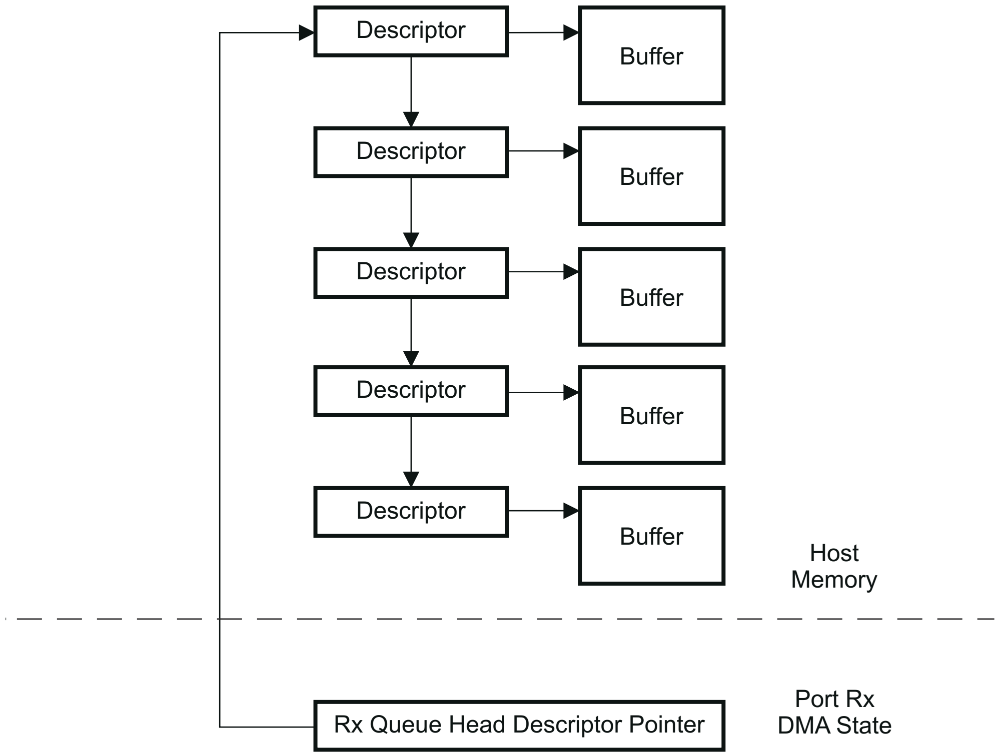

Figure 24-205. RX Queue Head Descriptor

24.11.5.3 MDIO Software Interface

24.11.5.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (MDIO_CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in MDIO_CONTROL.
3. The MDIO PHY alive status register (MDIO_ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO_LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (MDIO_USERPHYSEL0/1), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO_USERINTMASKSET) to use the MDIO user access register (MDIO_USERACCESS0/1). Since only one PHY is used in this device, the application software can use one MDIO_USERACCESS0/1 to trigger a completion interrupt; the other MDIO_USERACCESS0/1 is not setup.

24.11.5.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO_USERACCESS0/1) to directly access a specified PHY device.To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO_USERACCESS0/1) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO_USERACCESS0/1 corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO_USERACCESS0/1 for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIO_USERINTRAW) corresponding to MDIO_USERACCESS0/1 used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register

(MDIO_USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIO_USERINTMASKED) and an interrupt is triggered on the host processor.

24.11.5.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO_USERACCESS0/1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO_USERACCESS*n*) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in MDIO_USERACCESS0/1 corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in MDIO_USERACCESS0/1 after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in MDIO_USERACCESS0/1. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIO_USERINTRAW) corresponding to MDIO_USERACCESS0/1 used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIO_USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIO_USERINTMASKED) and an interrupt is triggered on the host processor.

24.11.5.4 Initialization and Configuration of CPSW

To configure the GMAC_SW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (G/MII, RGMII, RMII) Mode
2. Configure pads (PIN muxing), as per the interface selected.
3. Enable the GMAC_SW Ethernet Subsystem Clocks
4. Configure the PRCM registers CM_GMAC_CLKSTCTRL and CM_GMAC_GMAC_CLKCTRL to enable power and clocks to GMAC_SW Ethernet Subsystem.
5. Apply Soft Reset to GMAC_SW Subsystem, CPSW_3G, CPGMAC_SL1/2, and CPDMA
6. Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL
7. Configure the Interrupts
8. Configure the CPSW_CONTROL register
9. Configure the CPSW_STAT_PORT_EN register
10. Configure the ALE
11. Configure the MDIO
12. Configure the CPDMA receive DMA controller
13. Configure the CPDMA transmit DMA controller
14. Configure the CPPI TX and RX Descriptors
15. Configure CPGMAC_SL1 and CPGMAC_SL2, as per the desired mode of operations.
16. Start up RX and TX DMA (Write to HDP of RX and TX)
17. Wait for the completion of Transfer (HDP cleared to 0)

24.11.6 GMAC_SW Register Manual

24.11.6.1 GMAC_SW Instance Summary

Table 24-917. GMAC_SW Instance Summary

Module Name	Module Base Address	Size
SS	0x4848 4000	80 Bytes
PORT	0x4848 4100	1792 Bytes
CPDMA	0x4848 4800	256 Bytes
STATS	0x4848 4900	128 Bytes
STATERAM	0x4848 4A00	288 Bytes
CPTS	0x4848 4C00	240 Bytes
ALE	0x4848 4D00	88 Bytes

Table 24-988. P1_SEND_PERCENT

Address Offset	0x0000 0128		
Physical Address	0x4848 4228	**Instance**	PORT
Description	CPSW PORT 1 transmit queue send percentages		

Table 24-988. P1_SEND_PERCENT (continued)

Type	RW

31–23	22–16	15	14–8	7	6–0
RESERVED	PRI3_SEND_PERCENT	RESERVED	PRI2_SEND_PERCENT	RESERVED	PRI1_SEND_PERCENT

Bits	Field Name	Description	Type	Reset
31:23	RESERVED		R	0x0
22:16	PRI3_SEND_PERCENT	Priority 3 Transmit Percentage - This percentage value is sent from FIFO priority 3 (maximum) when CPSW_PTYPE[18] P1_PRI3_SHAPE_EN is set (queue shaping enabled). This is the percentage of the wire that packets from priority 3 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).	RW	0x0
15	RESERVED		R	0x0
14:8	PRI2_SEND_PERCENT	Priority 2 Transmit Percentage - This percentage value is sent from FIFO priority 2 (maximum) when CPSW_PTYPE[17] P1_PRI2_SHAPE_EN is set (queue shaping enabled). This is the percentage of the wire that packets from priority 2 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).	RW	0x0
7	RESERVED		R	0x0
6:0	PRI1_SEND_PERCENT	Priority 1 Transmit Percentage - This percentage value is sent from FIFO priority 1 (maximum) when the CPSW_PTYPE[16] P1_PRI1_SHAPE_EN is set (queue shaping enabled). This is the percentage of the wire that packets from priority 1 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).	RW	0x0

Table 24-1012. P2_MAX_BLKS

Address Offset	0x0000 0208		
Physical Address	0x4848 4308	**Instance**	PORT
Description	CPSW PORT 2 maximum FIFO blocks register		

Table 24-1012. P2_MAX_BLKS (continued)

Type	RW

31–9	8–4	3–0
RESERVED	P2_TX_MAX_BLKS	P2_RX_MAX_BLKS

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x0
8:4	P2_TX_MAX_BLKS	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of P2_TX_MAX_BLKS unless the port is in fullduplex flow control mode. In flow control mode, the P2_RX_MAX_BLKS will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in P2_RX_MAX_BLKS. 0xE is the minimum value P2_TX_MAX_BLKS.	RW	0x11
3:0	P2_RX_MAX_BLKS	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In fullduplex flow control mode to 0x5 or 0x6 depending on the required runout space. The P2_TX_MAX_BLKS value must be decreased by the amount of increase in P2_RX_MAX_BLKS. 0x3 is the minimum value P2_RX_MAX_BLKS and 0x6 is the maximum value.	RW	0x3

RESERVED	SOFT_RESET

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	SOFT_RESET	Software reset - Writing a one to this bit causes the CPDMA logic to be reset. Software reset occurs when the RX and TX DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.	RW	0x0

RESERVED	TX_RLIM	RESERVED	RX_CEF	CMD_IDLE	RX_OFFLEN_BLOCK	RX_OWNERSHIP	TX_PTYPE

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
15:8	TX_RLIM	Transmit Rate Limit Channel Bus 00000000 - no rate-limited channels 10000000 - channel 7 is rate-limited 11000000 - channels 7 downto 6 are rate-limited 11100000 - channels 7 downto 5 are rate-limited 11110000 - channels 7 downto 4 are rate-limited 11111000 - channels 7 downto 3 are rate-limited 11111100 - channels 7 downto 2 are rate-limited 11111110 - channels 7 downto 1 are rate-limited 11111111 - channels 7 downto 0 are rate-limited all others invalid - this bus must be set MSB towards LSB. TX_PTYPE must be set if any TX_RLIM bit is set for fixed priority.	RW	0x0
7:5	RESERVED		R	0x0
4	RX_CEF	RX Copy Error Frames Enable - Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when RX_CEF is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. 0 - Frames containing overrun errors are filtered. 1 - Frames containing overrun errors are transferred to memory.	RW	0x0
3	CMD_IDLE	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read IDLE in CPDMA_DMASTATUS)	RW	0x0
2	RX_OFFLEN_BLOCK	Receive Offset/Length word write block. 0 - Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0. 1 - Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor.	RW	0x0
1	RX_OWNERSHIP	Receive Ownership Write Bit Value. 0 - The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0. 1 - The CPDMA writes the receive ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.	RW	0x0
0	TX_PTYPE	Transmit Queue Priority Type 0 - The queue uses a round robin scheme to select the next channel for transmission. 1 - The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission	RW	0x0

IDLE	RESERVED							TX_HOST_ERR_CODE				RESERVED	TX_ERR_CH			RX_HOST_ERR_CODE				RESERVED	RX_ERR_CH			RESERVED							

Bits	Field Name	Description	Type	Reset
31	IDLE	Idle Status Bit - Indicates when set that the CPDMA is not transferring a packet on transmit or receive.	R	0x0
30:24	RESERVED		R	0x0
23:20	TX_HOST_ERR_CODE	TX Host Error Code - This field is set to indicate CPDMA detected TX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. A zero packet length is an error, but it is not detected. 0x0 - No error 0x1 - SOP error. 0x2 - Ownership bit not set in SOP buffer. 0x3 - Zero Next Buffer Descriptor Pointer Without EOP 0x4 - Zero Buffer Pointer. 0x5 - Zero Buffer Length 0x6 - Packet Length Error (sum of buffers is less than packet length) 0x7 - 1xF - reserved	R	0x0
19	RESERVED		R	0x0
18:16	TX_ERR_CH	TX Host Error Channel - This field indicates which TX channel (if applicable) the host error occurred on. This field is cleared to zero on a host read.	R	0x0
15:12	RX_HOST_ERR_CODE	RX Host Error Code - This field is set to indicate CPDMA detected RX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. 0x0 - No error 0x1 - reserved 0x2 - Ownership bit not set in input buffer. 0x3 - reserved 0x4 - Zero Buffer Pointer. 0x5 - Zero buffer length on non-SOP descriptor 0x6 - SOP buffer length not greater than offset 0x7 - 1xF - reserved	R	0x0
11	RESERVED		R	0x0
10:8	RX_ERR_CH	RX Host Error Channel - This field indicates which RX channel the host error occurred on. This field is cleared to zero on a host read.	R	0x0
7:0	RESERVED		R	0x0

Type	RW		

31–16	15–0
RESERVED	RX_BUFFER_OFFSET

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_BUFFER_OFFSET	Receive Buffer Offset Value - The RX_BUFFER_OFFSET will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the rx_buffer_offset value of bytes. A value of 0x0000 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.	RW	0x0

31:16	15:0
RESERVED	RX_FREEBUFFER

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_FREEBUFFER	Rx Free Buffer Count - This field contains the count of free buffers available. The CPDMA_RX0_PENDTHRESH[7:0] RX_PENDTHRESH value is compared with this field to determine if the receive threshold pending interrupt should be asseted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If receive threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the received frame) the associated channel register for each received frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.	W	0x0

15:0	RX_FREEBUFFER	Rx Free Buffer Count - This field contains the count of free buffers available. The CPDMA_RX5_PENDTHRESH[7:0] RX_PENDTHRESH value is compared with this field to determine if the receive threshold pending interrupt should be asseted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If receive threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the received frame) the associated channel register for each received frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.	W	0x0

24.11.6.5.2 STATS Register Description

Table 24-1150. GOOD_RX_FRAMES

Address Offset	0x0000 0000		
Physical Address	0x4848 4900	**Instance**	STATS
Description	The total number of good frames received on the port. A good frame is defined to be: - Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode - Had a length of 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had no CRC error, alignment error or code error. See the RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

Table 24-1154. MULTICAST_RX_FRAMES

Address Offset 0x0000 0008

Physical Address 0x4848 4908 **Instance** STATS

Description The total number of good multicast frames received on the port. A good multicast frame is defined to be:
- Any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFFFFFF
- Had a length of SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.
See the RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

Table 24-1156. PAUSE_RX_FRAMES

Address Offset 0x0000 000C

Physical Address 0x4848 490C **Instance** STATS

Description The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:
- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (SL_MACCONTROL[4] TX_FLOW_EN = 1). The port could have been in either half or full-duplex mode.
See the RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

Type RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 24-1160. RX_ALIGN_CODE_ERRORS

Address Offset	0x0000 0014		
Physical Address	0x4848 4914	**Instance**	STATS
Description	The total number of frames received on the port that experienced an alignment error or code error. Such a frame: - Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode - Was of length 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had either an alignment error or a code error Overruns have no effect upon this statistic. An alignment error is defined to be: - A frame containing an odd number of nibbles - Failing the Frame Check Sequence test if the final nibble is ignored A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception. Note: RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS.

Table 24-1178. PAUSE_TX_FRAMES

Address Offset	0x0000 0040		
Physical Address	0x4848 4940	**Instance**	STATS
Description	This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count. Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic. Transmitted pause frames are always 64 byte multicast frames so will appear in the MULTICAST_TX_FRAMES and RX_TX_64_OCTET_FRAMES statistics.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 24-1182. COLLISIONS

Address Offset	0x0000 0048		
Physical Address	0x4848 4948	**Instance**	STATS
Description	This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances. 1. When a transmit data or MAC control frame: - Was destined for any unicast, broadcast or multicast address - Was any size - Had no carrier loss and no underrun - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions) CRC errors have no effect upon this statistic. 2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

Table 24-1190. LATE_COLLISIONS

Address Offset	0x0000 0058		
Physical Address	0x4848 4958	**Instance**	STATS
Description	The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame: - Was any data or MAC control frame destined for any unicast, broadcast or multicast address - Was any size - Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The Late Collisions statistic dominates over the single, multiple and excessive Collisions statistics - if a late collision occurs the frame will not be counted in any of these other three statistics. CRC errors have no effect upon this statistic.

Table 24-1194. CARRIER_SENSE_ERRORS

Address Offset	0x0000 0060		
Physical Address	0x4848 4960	**Instance**	STATS
Description	The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be: - Was any data or MAC control frame destined for any unicast, broadcast or multicast address - Was any size - The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted. CRC errors have no effect upon this statistic.

Table 24-1210. NET_OCTETS (continued)

Description	The total number of bytes of frame data received and transmitted on the port. Each frame counted: - was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter) - Any length (including less than 64 bytes and greater than SL_RX_MAXLEN[13:0] RX_MAXLEN bytes) Also counted in this statistic is: - Every byte transmitted before a carrier- loss was experienced - Every byte transmitted before each collision was experienced, (i.e. multiple retries are counted each time) - Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting) Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic. The objective of this statistic is to give a reasonable indication of ethernet utilization

31:0	RX_CP	Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted. Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port). The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted. The value written is not actually stored in the location. The interrupt is deasserted if the two values are equal.	RW	0x0

RESERVED																															TS_PUSH

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	TS_PUSH	Time stamp event push - When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.	W	0x0

TS_LOAD_VAL																															

Bits	Field Name	Description	Type	Reset
31:0	TS_LOAD_VAL	Time Stamp Load Value - Writing the CPTS_TS_LOAD_EN[0] TS_LOAD_EN bit causes the value contained in this register to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register.	RW	0x0

</table>

Bits	Field Name	Description	Type	Reset
31	ENABLE_ALE	Enable ALE - 0 - Drop all packets 1 - Enable ALE packet processing	RW	0x0

Bits	Field Name	Description	Type	Reset
30	CLEAR_TABLE	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.	RW	0x0
29	AGE_OUT_NOW	Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case.	RW	0x0
28:9	RESERVED		R	0x0
8	EN_P0_UNI_FLOOD	Enable Port 0 (Host Port) unicast flood 0 - do not flood unknown unicast packets to host port (p0) 1 - flood unknown unicast packets to host port (p0)	RW	0x0
7	LEARN_NO_VID	Learn No VID - 0 - VID is learned with the source address 1 - VID is not learned with the source address (source address is not tied to VID).	RW	0x0
6	EN_VID0_MODE	Enable VLAN ID = 0 Mode 0 - Process the packet with VID = PORT_VLAN[11:0]. 1 - Process the packet with VID = 0.	RW	0x0
5	ENABLE_OUI_DENY	Enable OUI Deny Mode - When set this bit indicates that a packet with a non OUI table entry matching source address will be dropped to the host unless the destination address matches a multicast table entry with the super bit set.	RW	0x0
4	BYPASS	ALE Bypass - When set, all packets received on ports 0 and 1 are sent to the host (only to the host).	RW	0x0
3	RATE_LIMIT_TX	Rate Limit Transmit mode - 0 - Broadcast and multicast rate limit counters are received port based 1 - Broadcast and multicast rate limit counters are transmit port based.	RW	0x0
2	VLAN_AWARE	ALE VLAN Aware - Determines what is done if VLAN not found. 0 - Flood if VLAN not found 1 - Drop packet if VLAN not found	RW	0x0
1	ENABLE_AUTH_MODE	Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). 0 - The ALE is not in MAC authorization mode 1 - The ALE is in MAC authorization mode	RW	0x0
0	ENABLE_RATE_LIMIT	Enable Broadcast and Multicast Rate Limit 0 - Broadcast/Multicast rates not limited 1 - Broadcast/Multicast packet reception limited to the port control register rate limit fields.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
24	RX_CMF_EN	RX Copy MAC Control Frames Enable - Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the SL_MACCONTROL register, regardless of the value of RX_CMF_EN. Frames transferred to memory due to RX_CMF_EN will have the control bit set in their EOP buffer descriptor. 0 - MAC control frames are filtered (but acted upon if enabled). 1 - MAC control frames are transferred to memory.	RW	0x0
23	RX_CSF_EN	RX Copy Short Frames Enable - Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RX_CSF_EN will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. 0 - Short frames are filtered 1 - Short frames are transferred to memory.	RW	0x0
22	RX_CEF_EN	RX Copy Error Frames Enable - Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when RX_CEF _EN is not set. 0 - Frames containing errors are filtered. 1 - Frames containing errors are transferred to memory.	RW	0x0
21	TX_SHORT_GAP_LIM_EN	Transmit Short Gap Limit Enable When set this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed.	RW	0x0
20:19	RESERVED		R	0x0
18	EXT_EN	Control Enable - Enables the fullduplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the FULLDUPLEX and GIG bits in this register. The FULLDUPLEX_MODE bit reflects the actual fullduplex mode selected 0 - Use this setting for RMII/GMII mode . 1 - Use this setting for RGMII mode	RW	0x0
17	GIG_FORCE	Gigabit Mode Force - This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.	RW	0x0
16	IFCTL_B	Interface Control B (NOT FUNCTIONAL) 0 - 10Mbps operation 1 - 100Mbps operation	RW	0x0
15	IFCTL_A	Interface Control A 0 - 10Mbps operation 1 - 100Mbps operation	RW	0x0
14:12	RESERVED		R	0x0
11	CMD_IDLE	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read IDLE in SL_MACSTATUS)	RW	0x0

Bits	Field Name	Description	Type	Reset
10	TX_SHORT_GAP_EN	Transmit Short Gap Enable 0 - Transmit with a short IPG is disabled 1 - Transmit with a short IPG (when TX_SHORT_GAP input is asserted) is enabled.	RW	0x0
9:8	RESERVED		R	0x0
7	GIG	Gigabit Mode - 0 - 10/100 mode 1 - Gigabit mode (full duplex only) The GIG_OUT output is the value of this bit.	RW	0x0
6	TX_PACE	Transmit Pacing Enable 0 - Transmit Pacing Disabled 1 - Transmit Pacing Enabled	RW	0x0
5	GMII_EN	GMII Enable - 0 - GMII RX and TX held in reset. 1 - GMII RX and TX released from reset.	RW	0x0
4	TX_FLOW_EN	Transmit Flow Control Enable - Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_MBP_Enable bits determine whether or not received pause frames are transferred to memory. 0 - Transmit Flow Control Disabled. Full-duplex mode - Incoming pause frames are not acted upon. 1 - Transmit Flow Control Enabled . Full-duplex mode - Incoming pause frames are acted upon.	RW	0x0
3	RX_FLOW_EN	Receive Flow Control Enable - 0 - Receive Flow Control Disabled Half-duplex mode - No flow control generated collisions are sent. Full-duplex mode - No outgoing pause frames are sent. 1 - Receive Flow Control Enabled Half-duplex mode - Collisions are initiated when receive flow control is triggered. Full-duplex mode - Outgoing pause frames are sent when receive flow control is triggered.	RW	0x0
2	MTEST	Manufacturing Test mode - This bit must be set to allow writes to the SL_BOFFTEST and SL_RX_PAUSE/ SL_TX_PAUSE registers.	RW	0x0
1	LOOPBACK	Loop Back Mode - Loopback mode forces internal fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The LOOPBACK bit should be changed only when GMII_EN is deasserted. 0 - Not looped back 1 - Loop Back Mode enabled	RW	0x0
0	FULLDUPLEX	Full Duplex mode - Gigabit mode forces fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit 0 - half duplex mode 1 - full duplex mode	RW	0x0

Address Offset	0x0000 0014

Table 24-1332. SL_BOFFTEST (continued)

Physical Address	0x4848 4D94 0x4848 4DD4	**Instance**	SL1 SL2
Description	CPGMAC_SL backoff test register		
Type	RW		

31	30:26	25:16	15:12	11:10	9:0
RESERVED	PACEVAL	RNDNUM	COLL_COUNT	RESERVED	TX_BACKOFF

Bits	Field Name	Description	Type	Reset
31	RESERVED		R	0x0
30:26	PACEVAL	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to zero. When PACEVAL is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce 'capture' effects improving overall network bandwidth.	RW	0x0
25:16	RNDNUM	Backoff Random Number Generator - This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when mtest has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset.	RW	0x0
15:12	COLL_COUNT	Collision Count - The number of collisions the current frame has experienced.	R	0x0
11:10	RESERVED		R	0x0
9:0	TX_BACKOFF	Backoff Count - This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.	R	0x0

31	30	29	28:24	23:21	20	19	18	17	16	15:0
IDLE	ENABLE	RESERVED	HIGHEST_USER_CHANNEL	RESERVED	PREAMBLE	FAULT	FAULTENB	INTTESTENB	RESERVED	CLKDIV

Bits	Field Name	Description	Type	Reset
31	IDLE	MDIO state machine IDLE. Set to 1 when the state machine is in the idle state. 0: State machine is not in idle state. 1: State machine is in idle state.	R	0x0
30	ENABLE	Enable control. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the IDLE bit. If using byte access, the ENABLE bit has to be the last bit written in this register. 0: Disables the MDIO state machine. 1: Enable the MDIO state machine.	RW	0x0
29	RESERVED		R	0x0
28:24	HIGHEST_USER_CHANNEL	Highest user channel. This field specifies the highest user access channel that is available in the module and is currently set to 1. This implies that the MDIO_USERACCESS1 register is the highest available user access channel.	R	0x0
23:21	RESERVED		R	0x0
20	PREAMBLE	Preamble disable. 0: Standard MDIO preamble is used. 1: Disables this device from sending MDIO frame preambles.	RW	0x0
19	FAULT	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. 0: No failure. 1: Physical layer fault; the MDIO state machine is reset.	RW	0x0
18	FAULTENB	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. 0: Disables the physical layer fault detection. 1: Enables the physical layer fault detection.	RW	0x0

Bits	Field Name	Description	Type	Reset
17	INTTESTENB	Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes. 0: Interrupt bits are not set. 1: Enables the host to set the USERINT and LINKINT bits for test purposes.	RW	0x0
16	RESERVED		R	0x0
15:0	CLKDIV	Clock divider. This field specifies the division ratio between ICLK and the frequency of MDCLK. MDCLK is disabled when CLKDIV is set to 0. MDCLK frequency = ICLK frequency/(CLKDIV+1).	RW	0x0

ALIVE																															

Bits	Field Name	Description	Type	Reset
31:0	ALIVE	MDIO alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.	RW	0x0

LINK

Bits	Field Name	Description	Type	Reset
31:0	LINK	MDIO link state. This register is updated after a read of the Generic Status Register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. In addition, the status of the two PHYs specified in the MDIO_USERPHYSEL registers can be determined using the MLINK input pins (NOT PINNED OUT). This is determined by the LINKSEL bit in the MDIO_USERPHYSEL register.	R	0x0

Bits	Field Name	Description	Type	Reset
31	GO	Go. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so, this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is write able only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to the MDIO_USERACCESS0 register are blocked when the GO bit is 1. If byte access is being used, the GO bit should be written last.	RW	0x0

Bits	Field Name	Description	Type	Reset
30	WRITE	Write enable. Setting this bit to a 1 causes the MDIO transaction to be a register write, otherwise it is a register read.	RW	0x0
29	ACK	Acknowledge. This bit is set if the PHY acknowledged the read transaction.	RW	0x0
28:26	RESERVED		R	0x0
25:21	REGADR	Register address. Specifies the PHY register to be accessed for this transaction.	RW	0x0
20:16	PHYADR	PHY address. Specifies the PHY to be accesses for this transaction.	RW	0x0
15:0	DATA	User data. The data value read from or to be written to the specified PHY register.	RW	0x0

RESERVED																															SPF_BUSY

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	SPF_BUSY	SPF is Busy/Idle, Busy Packet processing or logging in progress.	RW	0x0

Table 24-1410. Register Call Summary for Register SPF_STATUS

Gigabit Ethernet Switch (GMAC_SW)

- SPF Register Summary: [0]

Table 24-1411. SPF_CONTROL

Address Offset	0x0000 0008		
Physical Address	0x4848 5C08 0x4848 5E08	**Instance**	SPF1 SPF2
Description	SPF control register		
Type	RW		

31:10	9	8	7:4	3	2	1	0
RESERVED	SPF_LOGOW_EN	SPF_LOG_EN	RESERVED	SPF_RULE_LOG	SPF_EXT_BYPASS	SPF_DROP	SPF_ENABLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED		R	0x0
9	SPF_LOGOW_EN	SPF Log Overwrite Enable. Setting this bit will cause SPF to overwrite previously logged data whether or not software has updated the software_working_pointer. Overwriting only occurs if there is new data but no space to write it in the space indicated by log_start_address and log_end_address.	RW	0x0
8	SPF_LOG_EN	SPF Log Enable. Setting this bit will allow SPF to log information about dropped packets to memory.	RW	0x0
7:4	RESERVED		R	0x0
3	SPF_RULE_LOG	SPF Rule Engine Log Enable. Setting this bit will allow SPF to log data from rule engine. The default is log data from extractor.	RW	0x0
2	SPF_EXT_BYPASS	SPF Extractor Bypass Enable. The extractor will not provide any offset information to rule engine if this bit is set. The rule engine must load each of the base registers it intends to use to determine if the packet should be discarded.	RW	0x0
1	SPF_DROP	SPF Drop Enable. This bit must be set to activate packet drops.	RW	0x0
0	SPF_ENABLE	SPF Enable. This bit must be set to enable any operation in SPF. The SPF instruction memory can only be accessed by host processor when the spf_enable is deasserted. Once spf_enable is set, writing a zero to this bit will only take effect when spf_busy signal is low. This ensures that spf stops only on packet boundaries.	RW	0x0

24.12 Media Local Bus (MLB)

24.12.1 MLB Overview

The Media Local Bus sub system (MLBSS) is based on a module designed by SMSC. This module provides a MediaLB/MediaLB+ controller and an interface to other MediaLB/MediaLB+ devices. The MediaLB/MediaLB+ interface allows also connection to a MOST (Media Oriented Systems Transport) network controller. MOST network is used to transport media and control data between various multimedia nodes in the car.

The MLBSS supports the following features:

- 3-pin MediaLB 3.3V LVCMOS I/Os compliant to MediaLB Physical Layer Specification v4.0
- 6-pin MediaLB+ low-voltage differential signaling (LVDS) I/Os (3 differential pairs) compliant to MediaLB Physical Layer Specification v4.0
- MediaLB core functionality compliant to MediaLB Physical and Link layer specification v4.0
- Supports 256/512/1024Fs in 3-pin mode, and 2048Fs in 6-pin mode
- Supports all types of transfer (synchronous stream data, asynchronous packet data, control message data, and isochronous data) over 64 logical channels
- Supports single 32-bit L4 slave interface for configuration
- Supports single 32-bit L3_MAIN master interface with burst capability for DMA transfers into system memory. The maximum burst size is 32 Bytes
- Has 16 KiB buffer for all types of transfers in the subsystem
- Support of pressure bits for controlling the MLBSS priority on the L3_MAIN interconnect

The MLBSS does not support:

- 400 MHz clock mode which enable half and full entitlement of MediaLB+ and MOST150
- 5-pin mode

Figure 24-206 shows the MLBSS overview.

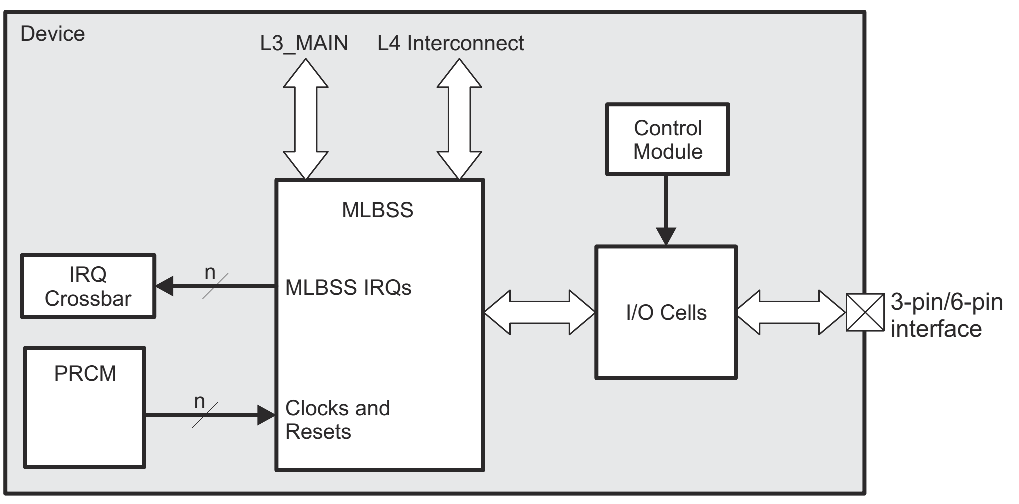

Figure 24-206. MLB Overview

24.12.2 MLB Environment

Figure 24-207 shows the MLBSS associated signals available on device pads.

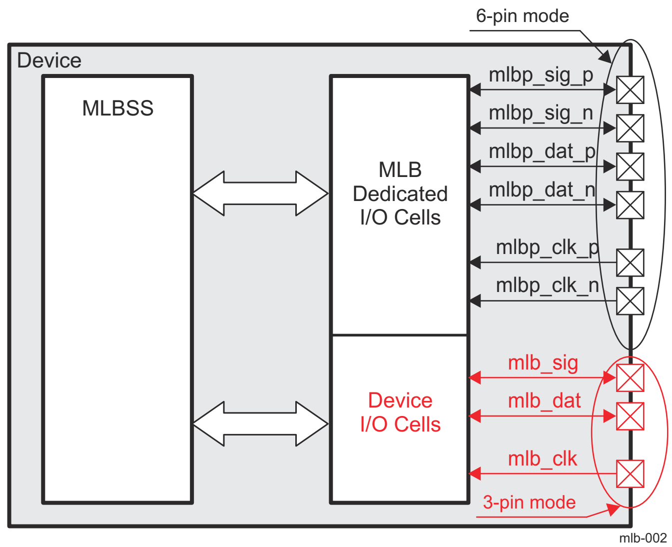

Figure 24-207. MLB Sub System Environment

Table 24-1455 describes the MLBSS I/O signals used in both 3-pin and 6-pin modes.

Table 24-1455. MLB Sub System I/O Description

Signal/Pad Name	I/O[(1)]	Description
		6-pin mode
mlbp_sig_p	IO	Differential pair signal line
mlbp_sig_n	IO	
mlbp_dat_p	IO	Differential pair data line
mlbp_dat_n	IO	
mlbp_clk_p	I	Differential pair clock line
mlbp_clk_n	I	
		3-pin mode
mlb_sig	IO	Single ended signal line
mlb_dat	IO	Single ended data line
mlb_clk	I	Single ended clock line

(1) I = Input; O = Output; I/O = Bidirectional

24.12.2.1 MLB IO Cell Controls

There are I/O cells specially intended for the MLB 6-pin interface. These are low-voltage differential signaling (LVDS) I/O cells with controls, which reside in several registers of the CTRL_MODULE_CORE. In addition, there is also a bandgap cell which provides a reference voltage to the LVDS IOs associated with the MLB interface. Without this reference voltage these differential receivers and transmitters cannot function properly. The LVDS IOs must be used only when 6-pin mode is selected. If this is done the six MLB signals are available on the following pads:

- mlbp_sig_p
- mlbp_sig_n
- mlbp_dat_p
- mlbp_dat_n
- mlbp_clk_p
- mlbp_clk_n

Figure 24-208 shows the LVDS IOs used when 6-pin MLB mode is selected, their controls from CTRL_MODULE_CORE, the MLB bandgap cell and details regarding the multiplexing scheme when 3-pin mode is used.

3-pin mode is used when the MLB_MLBC0[5] MLBPEN bit is set to 0x0. When this bit is set to 0x1 a 6-pin mode is used. In case of 3-pin mode an additional step must be performed to be the MLB signals (mlb_sig, mlb_dat and mlb_clk) available on the device pads. These signals are multiplexed along with other device signals on the following pads:

- mcasp5_aclkx
- mcasp5_axr[0]
- mcasp5_axr[1]

To provide the MLB 3-pin mode signals on these pads the MUXMODE bit field of the following registers should be set to 0x5:

- CTRL_CORE_PAD_MCASP5_ACLKX[3:0] MCASP5_ACLKX_MUXMODE
- CTRL_CORE_PAD_MCASP5_AXR0[3:0] MCASP5_AXR0_MUXMODE
- CTRL_CORE_PAD_MCASP5_AXR1[3:0] MCASP5_AXR1_MUXMODE

For more information about signal multiplexing see *Pad Configuration Registers* in *Control Module* and also table "Multiplexing Characteristics" of the device Data Manual.

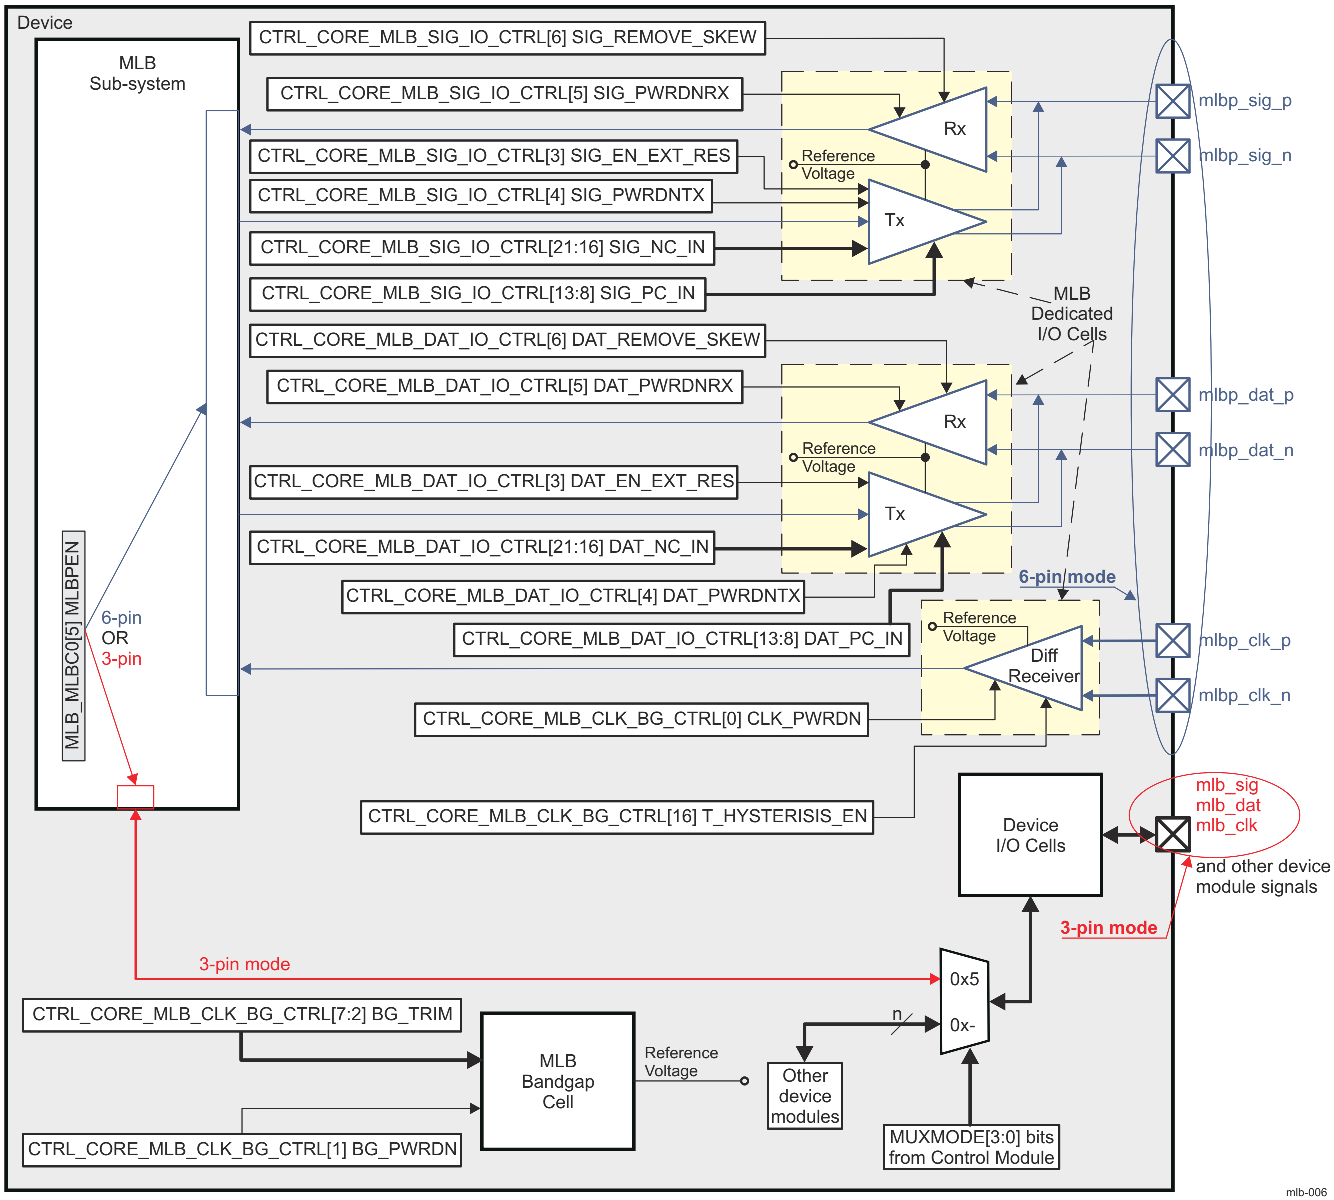

Figure 24-208. MLB I/O Cells And Their Controls

The MLB bandgap cell is intended to provide a stable reference voltage to the LVDS IOs across voltage and temperature variations. This cell is powered when the CTRL_CORE_MLB_CLK_BG_CTRL[1] BG_PWRDN bit is set to 0x0. When powerd the MLB bandgap cell provides its reference voltage to the LVDS IOs which is a prerequisite for their proper working. The CTRL_CORE_MLB_CLK_BG_CTRL[7:2] BG_TRIM bit field is used for trimming the reference voltage generated by the MLB bandgap cell. When reading the BG_TRIM bit field and if its value is 0x0 it is recommended to write 0x20 to this bit field. In all other cases (BG_TRIM != 0x0) software write to the BG_TRIM bit field is not recommended.

The MLB differential clock receiver is enabled when the CTRL_CORE_MLB_CLK_BG_CTRL[0] CLK_PWRDN bit is set to 0x0. The CTRL_CORE_MLB_CLK_BG_CTRL[16] T_HYSTERISIS_EN bit is used to enable/disable the hysteresis for the MLB differential clock receiver. A value of 0x1 enables the hysteresis and 0x0 disables it.

The power of the MLB differential receivers and transmitters can be switched ON and OFF using the PWRDNRX and PWRDNTX bits, respectively. A value of 0x0 powers up and a value of 0x1 powers down the receivers and transmitters. The bits are the following:

- CTRL_CORE_MLB_SIG_IO_CTRL[5] SIG_PWRDNRX for mlbp_sig_p/mlbp_sig_n receiver.
- CTRL_CORE_MLB_SIG_IO_CTRL[4] SIG_PWRDNTX for mlbp_sig_p/mlbp_sig_n transmitter.
- CTRL_CORE_MLB_DAT_IO_CTRL[5] DAT_PWRDNRX for mlbp_dat_p/mlbp_dat_n receiver.
- CTRL_CORE_MLB_DAT_IO_CTRL[4] DAT_PWRDNTX for mlbp_dat_p/mlbp_dat_n transmitter.

There are also CTRL_MODULE_CORE bits to remove the skew effect of the mlbp_sig_p/mlbp_sig_n and mlbp_dat_p/mlbp_dat_n signals caused by difference in the input impedance between "_p" and "_n" lines of the receivers. The bits for doing this are the following:

- CTRL_CORE_MLB_SIG_IO_CTRL[6] SIG_REMOVE_SKEW for mlbp_sig_p/mlbp_sig_n receiver.
- CTRL_CORE_MLB_DAT_IO_CTRL[6] DAT_REMOVE_SKEW for mlbp_dat_p/mlbp_dat_n receiver.

A value of 0x1 enables the skew compensation and 0x0 disables it.

The MLB differential transmitters have also controls for trimming their output impedance and for enabling/disabling their internal pull resistors. Setting to 0x1 the CTRL_CORE_MLB_SIG_IO_CTRL[3] SIG_EN_EXT_RES bit enables the internal pull resistors of the mlbp_sig_p/mlbp_sig_n transmitter. Setting to 0x1 the CTRL_CORE_MLB_DAT_IO_CTRL[3] DAT_EN_EXT_RES bit enables the internal pull resistors of the mlbp_dat_p/mlbp_dat_n transmitter. If the internal pull resistors are disabled external on-board pull resistors must be provided.

In addition, when 3-pin mode is used, there is no need to configure any of the previously described CTRL_MODULE_CORE registers associated with the MLB LVDS IOs. In this case a MUXMODE configuration is required.

24.12.3 MLB Integration

Figure 24-209 shows the integration of the MLB sub system in the device.

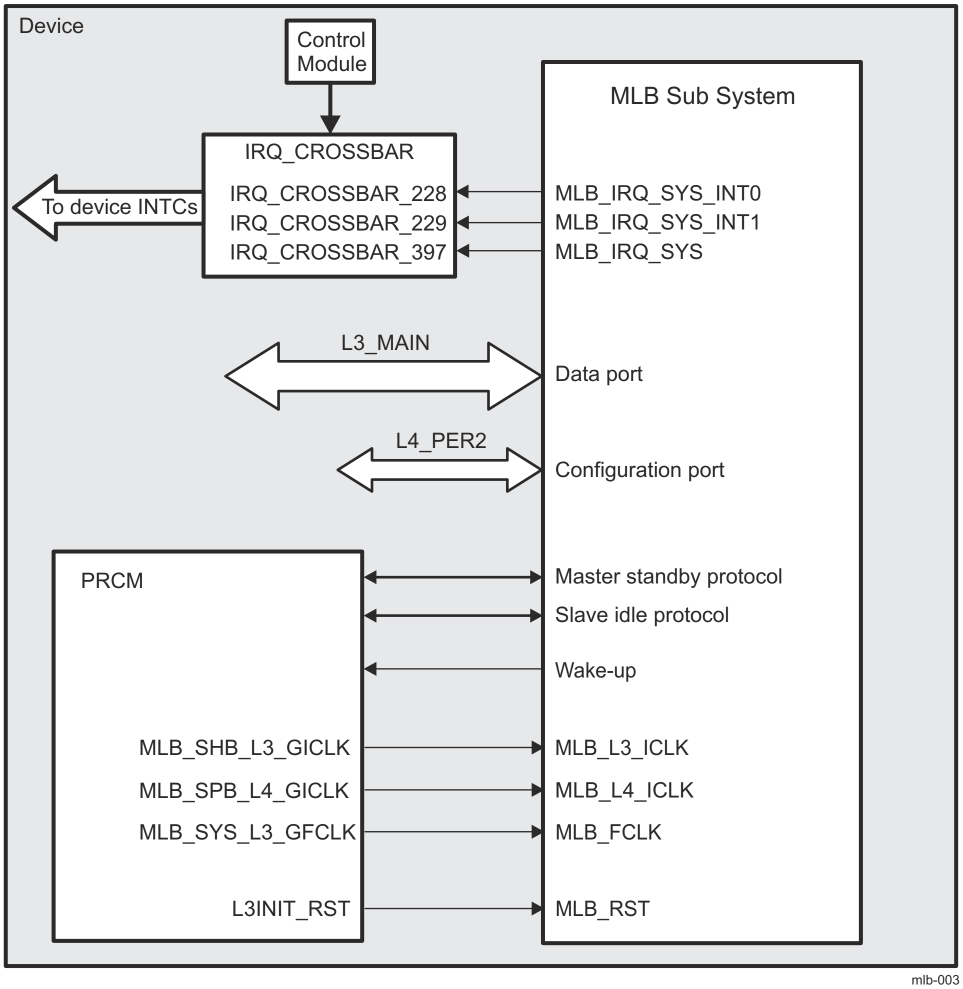

Figure 24-209. MLB Sub System Integration

Table 24-1456 through Table 24-1458 summarize the integration of the MLB sub system in the device.

Table 24-1456. MLB Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
MLB	MLB_IRQ_SYS_INT0	IRQ_CROSSBAR_228	-	MLBSS DMA interrupt request for logical channels 0 to 31 (1). This IRQ source signal is not mapped by default to any device INTC.
	MLB_IRQ_SYS_INT1	IRQ_CROSSBAR_229	-	MLBSS DMA interrupt request for logical channels 32 to 63(1). This IRQ source signal is not mapped by default to any device INTC.
	MLB_IRQ_SYS	IRQ_CROSSBAR_397	-	MLBSS interrupt for error notifications. This IRQ source signal is not mapped by default to any device INTC.

(1) If the MLB_DCTL[1] SMX bit is set to 0x1 the MLB_IRQ_SYS_INT0 line is used for all 64 logical channels.

Note

The "**Default Mapping**" column in Table 24-1458 *MLB Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

24.12.4 MLB Functional Description

24.12.4.1 Block Diagram

Figure 24-210 shows the MLBSS block diagram. It includes the following functional blocks:

- MediaLB core - Implements the physical and link layer requirements of either a 3-pin or the 6-pin interface. Serial-to-parallel/parallel-to-serial are also implemented along with MediaLB frame synchronization.
- Routing fabric block - Manages the flow of data between the MediaLB core and the DMA block, implementing bus arbiter and muxing logic to the channel table RAM and the data buffer RAM.
- Channel table RAM - Used for storing channel descriptors for managing accesses to dynamic buffers in the data buffer RAM.
- Data buffer RAM - Provides dynamic circular buffering between the transmit and receive devices.
- Memory interface - Implements a bridge between the configuration L4_PER2 slave interface and the channel table RAM or data buffer RAM interfaces.
- DMA - Implements a bus bridge between the DMA master and the routing fabric block.
- Registers - Used for configuration.
- Interrupt logic.

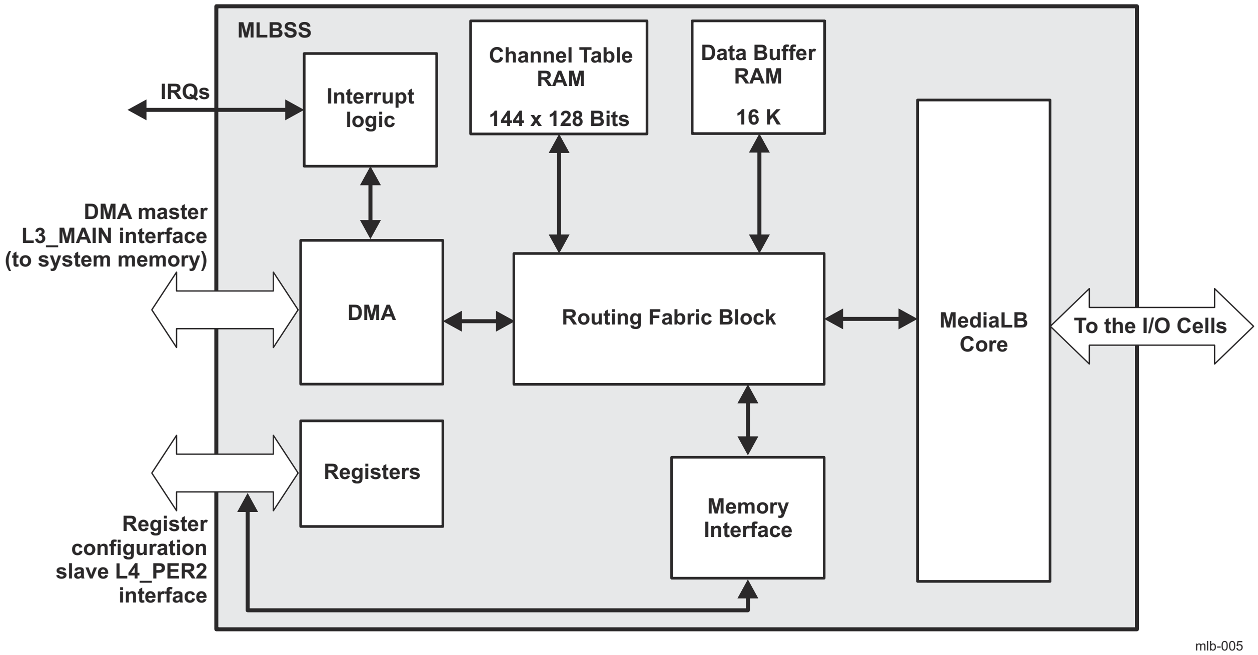

Figure 24-210. MLBSS Structural Overview

24.12.4.1.1 MediaLB Core Block

Although the MediaLB block supports both a MediaLB 3-pin and 6-pin interface, only one of these interfaces is active at any given time. The selection is done through the MLB_MLBC0[5] MLBPEN bit. Table 24-1455 describes the signals associated with 3-pin and 6-pin modes. Both MediaLB interfaces provide real-time access to all network data types including streaming, packet, control, and isochronous data.

The MediaLB 3-pin interface supports the MediaLB protocol for single-ended 3-pin mode with a maximum data rate of 1024Fs.

The MediaLB 6-pin interface supports the MediaLB protocol for high-speed differential 6-pin mode, with a maximum data rate of 2048Fs.

There is a set of physical channels implemented for exchanging data over the MediaLB 3-pin or 6-pin interface. These physical channels (called quadlets) are 4-byte wide and can also be grouped together to form logical channels. These logical channels are referenced using channel addresses, and define a uni-directional path between a specific MediaLB device transmitting data and another specific MediaLB device receiving data. In other words, the logical channel is a group of multiple quadlets, which selects an unique pair of MediaLB devices with a unique channel address. The logical channels, configured by the system software can be of any combination of channel types (synchronous, asynchronous, control, or isochronous) and direction (transmit/receive).

The MediaLB channel addresses are mapped to the logical channels as shown in Table 24-1459.

Table 24-1459. MediaLB Channel Address to Logical Channel Mapping

MediaLB Channel Address	Logical Channel Number
0x02	1
0x04	2
0x06	3
…	…
0x007C	62
0x007E	63

Table 24-1459. MediaLB Channel Address to Logical Channel Mapping (continued)

MediaLB Channel Address	Logical Channel Number
0x01FE	0 (1)

(1) The logical channel 0 is the system channel and is reserved.

Thus, 64 logical channels can be supported and one of them is the system channel which is reserved.

Note

The MediaLB channel address should always be an even number.

24.12.4.1.2 Routing Fabric Block

The routing fabric block manages the flow of data between the MediaLB core and the DMA block. Bus multiplexers and a bus arbiter are implemented in the routing fabric block for accessing the channel table RAM and data buffer RAM. Each DMA controller in the routing fabric uses channel descriptors to manage access to dynamic buffers in the data buffer RAM. These channel descriptors are stored in the channel table RAM.

24.12.4.1.3 Data Buffer RAM

The data buffer RAM is 8-bit × 16k entries deep and provides dynamic circular buffering between the transmit and receive devices. The size and location of each data buffer is defined by software in the channel descriptor table, which is located in the channel table RAM.

The DMA controllers in the routing fabric are responsible for ensuring that the circular buffers do not overflow or underflow. Each channel type (that is, synchronous, isochronous, asynchronous and control) has full and empty detection.

24.12.4.1.4 Channel Table RAM

The channel table RAM is 128-bit × 144-entry (max). It allows system software to dynamically configure channel routing and allocate data buffers in the data buffer RAM.

The channel table RAM is logically divided into three sub-tables:

- Channel descriptor table
- DMA descriptor table
- Channel allocation table

The details of the channel descriptor table and channel allocation table are described in Table 24-1460.

The details of the DMA descriptor table are described in Table 24-1470.

Table 24-1460. Channel Table RAM Address Mapping

Label	Address	Bits 127:96	Bits 95:64	Bits 63:32	Bits 31:0

	…	…			
	0x3D	CDT61[127:0], CL = 61			
	0x3E	CDT62[127:0], CL = 62			
	0x3F	CDT63[127:0], CL = 63			
DMA Descriptor Table (DDT):					

Table 24-1460. Channel Table RAM Address Mapping (continued)

Label	Address	Bits 127:96		Bits 95:64		Bits 63:32		Bits 31:0	
DMA descriptor table	0x40	DDT0[127:0], CAT64							
	0x41	DDT1[127:0], CAT65							
	0x42	DDT2[127:0], CAT66							
	…	…							
	0x7D	DDT61[127:0], CAT125							
	0x7E	DDT62[127:0], CAT126							
	0x7F	DDT63[127:0], CAT127							
Channel Allocation Table (CAT):									
Channel allocation table for MediaLB	0x80	CAT7	CAT6	CAT5	CAT4	CAT3	CAT2	CAT1	CAT0
	...	...	...	...	...	...	...	...	...
	0x87	CAT63	CAT62	CAT61	CAT60	CAT59	CAT58	CAT57	CAT56
Channel allocation table for DMA	0x88	CAT71	CAT70	CAT69	CAT68	CAT67	CAT66	CAT65	CAT64
	...	...	...	...	...	...	...	...	...
	0x8F	CAT127	CAT126	CAT125	CAT124	CAT123	CAT122	CAT121	CAT120

Note

A fixed relationship between DMA descriptor table entries and DMA channel allocation table entries exists. When using DMA channel 0 (CAT64) software should program DDT0. When using DMA channel 1 (CAT65) software should program DDT1, in case of CAT66 DDT2 should be programmed and so on. In case of CAT127 software should program DDT63.

The following base addresses are valid:

- Channel descriptor table has base address 0x00
- DMA descriptor table has base address 0x40
- Channel allocation table for MediaLB has base address 0x80
- Channel allocation table for DMA has base address 0x88

24.12.4.1.4.1 Channel Allocation Table

The channel allocation table comprises 16 entries of the channel table RAM. Each entry is 16-bit. The first entry starts at address 0x80 and the sixteenth entry at address 0x8F. Each 16-bit channel allocation table entry represents a logical connection to or from a transmit/receive device (that is, MediaLB or DMA channel). All entries are indexed according to a fixed physical address assigned to every Rx/Tx channel. This is shown in Table 24-1461. The value stored in a channel allocation table entry includes a 6-bit connection label (CL[5:0]), which provides a pointer to the channel descriptor table. To complete a logical channel and form a routing connection, system software must assign the same connection label to both the Rx and Tx channels.

Table 24-1461. Channel Allocation Table Entry Map

Peripheral	Number of Tx Channels Allowed	Number of Rx Channels Allowed	Channel Allocation Table Start Index	Channel Allocation Table End Index	Entries
MediaLB	0 to 64	64 - (Number of Tx channels)	0	63	64
DMA	0 to 64	64 - (Number of Tx channels)	64	127	64

The format of a full channel allocation table entry is shown in Table 24-1462. All reserved bits should be written to zero.

Table 24-1462. Format Of Channel Allocation Table Entry

Channel Type	15	14	13	12	11	10 8	7 6	5 0
Isochronous	Reserved	FCE	Reserved	RNW	CE	CT[2:0] = 3	Reserved	CL[5:0]
Asynchronous	Reserved		MT	RNW	CE	CT[2:0] = 2	Reserved	CL[5:0]
Control	Reserved		MT	RNW	CE	CT[2:0] = 1	Reserved	CL[5:0]
Synchronous	Reserved	MFE	MT	RNW	CE	CT[2:0] = 0	Reserved	CL[5:0]

The field descriptions of a channel allocation table entry are shown in Table 24-1463.

Table 24-1463. Field Descriptions Of Channel Allocation Table Entry

Field	Description
CL[5:0]	Connection Label (offset into channel descriptor table)
CT[2:0]	Channel type
	111 = Reserved
	110 = Reserved
	101 = Reserved
	100 = Reserved
	011 = Isochronous
	010 = Asynchronous
	001 = Control
	000 = Synchronous
CE	Channel enable
	0 = Disabled
	1= Enabled
RNW	Read, not Write [(1)]
	1 = Read
	0 = Write
MT	Mute Bit [(2)]
	1= Enabled
	0 = Disabled
FCE	Flow control enable [(3)]
	1 = Enabled
	0 = Disabled
MFE	Multi-frame per sub-buffer enable [(4)]
	1 = Enabled
	0 = Disabled
Reserved	Reserved. Software writes zeros to all reserved bits when the entry is initialized. The reserved bits are read-only after initialization.

(1) For a Tx channel (from the host to the MediaLB interface):

- DMA channel allocation table entry: RNW = 0 (write)
- MediaLB channel allocation table entry: RNW = 1 (read)

For a Rx channel (data from MediaLB to host):

- DMA channel allocation table entry: RNW = 1 (read)
- MediaLB channel allocation table entry: RNW = 0 (write)

(2) When set for synchronous channels, the MT bit forces Rx channels to write zeros into the channel data buffer, and Tx channels to output zeros on the physical interface. When set for asynchronous and control channels, the MT bit causes DMA to halt at a packet boundary. Not valid for isochronous channels.

(3) The FCE bit is used by MediaLB isochronous Rx channels only.

(4) The MFE bit is used by MediaLB synchronous channels only.

24.12.4.1.4.2 Channel Descriptor Table

The channel descriptor table comprises 64 channel table RAM entries. Each entry is 128-bit. The first entry starts at address 0x00 and the 64th entry at address 0x3F. Each 128-bit entry of the channel descriptor table is referenced by a connection label and contains information about data buffer in the data buffer RAM (that is, buffer size, or address pointers). The format of each channel descriptor table entry depends on the channel type (synchronous, isochronous, asynchronous, or control).

Software must write all reserved channel descriptor bits to ’0’ when the entry is initialized.

Synchronous Channel Descriptor Table

The MLBSS provides two modes of operation (standard and multi-frame per sub-buffer) to provide flexibility for implementing synchronous channels.

Channels set up for standard mode require less buffer space. For channels configured for standard mode, the host controller must transfer one full frame of streaming data in/out of the data buffer of each streaming channel.

Channels set up for multiple-frames per sub-buffer mode require more buffer space. For channels configured for multiple-frames per sub-buffer mode, the host controller must transfer N full frames of streaming data in/out of the data buffer of each streaming channel.

To set up a channel in multi-frame per sub-buffer mode:

- Program the MLB_MLBC0[17:15] FCNT bit field to select the number of frames per sub-buffer
- Program the channel allocation table to enable multi-frame sub-buffering (MFE = 1) for each particular channel
- Set the buffer depth (BD[11:0]) in the channel descriptor table
- Repeat for additional synchronous channels

The format of a synchronous channel descriptor table entry is shown in Table 24-1464. All reserved bits should be written to zero.

Table 24-1464. Format Of Synchronous Channel Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	WSBC[1:0]		Reserved													
16	RSBC[1:0]		Reserved													
32	Reserved															
48	Reserved															
64	WSTS[3:0]				WPTR[11:0]											
80	RSTS[3:0]				RPTR[11:0]											
96	Reserved				BD[11:0]											
112	Reserved		BA[13:0]													

The field descriptions of a synchronous channel descriptor table entry are shown in Table 24-1465.

Table 24-1465. Field Descriptions Of Synchronous Channel Descriptor Table Entry

Field	Description	Details	Accessibility [(1)]
BA	Buffer base address	BA can start at any byte in the 16k data buffer RAM	r, w
BD	Buffer depth	1. BD = size of buffer in bytes - 1 2. Buffer end address = BA + BD 3. BD = 4 × m × bpf - 1, where: m = frames per sub-buffer (for MFE = 0, m = 1) bpf = bytes per frame	r,w
RPTR	Read pointer	1. Software initializes to zero, hardware updates 2. Counts the read address offset within a buffer 3. DMA read address = BA + RPTR	r,w,u

Table 24-1465. Field Descriptions Of Synchronous Channel Descriptor Table Entry (continued)

Field	Description	Details	Accessibility [1]
WPTR	Write pointer	1. Software initializes to zero, hardware updates 2. Counts the write address offset within a buffer 3. DMA write address = BA + WPTR	r,w,u
RSBC	Read sub-buffer counter	1. Software initializes to zero, hardware updates 2. Counts the read sub-buffer offset 3. DMA uses for pointer management	r,w,u
WSBC	Write sub-buffer counter	1. Software initializes to zero, hardware updates 2. Counts the write sub-buffer offset 3. DMA uses for pointer management	r,w,u
RSTS	Read status	1. Software initializes to zero, hardware updates 2. RSTS states: (Only for DMA associated with MLB) xxx0 = normal operation (no mute) xxx1 = normal operation (mute) xx0x = idle	r,w,u
WSTS	Write status	1. Software initializes to zero, hardware updates 2. WSTS states: (Only for DMA associated with MLB) xxx0 = normal operation (no mute) xxx1 = normal operation (mute) xx0x = idle 1xxx = command protocol error	r,w,u
Reserved	Reserved	Software writes a zero to all Reserved bits when the entry is initialized. The Reserved bits are Read-only after initialization.	r,w,u

(1)
- r - software readable
- w - software writable
- u - updated periodically by hardware

Isochronous Channel Descriptor Table

The format of an isochronous channel descriptor table entry is shown in Table 24-1466. All reserved bits should be written to zero.

Table 24-1466. Format Of Isochronous Channel Descriptor Table Entry

<table>
<tr><th>Bit Offset</th><th>15</th><th>14</th><th>13</th><th>12</th><th>11</th><th>10</th><th>9</th><th>8</th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>

The field descriptions of an isochronous channel descriptor table entry are shown in Table 24-1467.

Table 24-1467. Field Descriptions Of Isochronous Channel Descriptor Table Entry

Field	Description	Details	Accessibility [1]
BA	Buffer Base Address	BA can start at any byte in the 16k data buffer RAM	r, w

Table 24-1467. Field Descriptions Of Isochronous Channel Descriptor Table Entry (continued)

Field	Description	Details	Accessibility [(1)]
BD	Buffer Depth	1. BD = size of buffer in bytes - 1 2. Buffer end address = BA + BD 3. Isochronous buffers must be large enough to hold at least 3 blocks (packets) of data 4. Buffer depth must be a integer multiple of blocks	r,w
BF	Buffer Full	1. Software initializes to zero, hardware updates 2. DMA write hardware sets BF when the buffer is full 3. DMA read hardware clears BF when the buffer is empty 4. BF is valid only when the buffer is full or empty, otherwise ignore	r,w,u
BS	Block Size	1. BS defines when to begin the DMA to the data buffer 2. BS = buffer block size in bytes - 1 3. For Rx channels, the DMA writes start when the number of empty bytes (SPACE) in the data buffer >= the block size 4. For Tx channels, the DMA reads start when the number of valid bytes (VALID) in the data buffer >= the block size	r,w,u
RPTR	Read Pointer	1. Software initializes to zero, hardware updates 2. Counts the read address offset within a buffer 3. DMA read address = BA + RPTR	r,w,u
WPTR	Write Pointer	1. Software initializes to zero, hardware updates 2. Counts the write address offset within a buffer 3. DMA write address = BA + WPTR	r,w,u
RSTS	Read status	1. Software initializes to zero, hardware updates 2. RSTS Status states (Only for DMA associated with MLB) xx1 = active xx0 = idle	r,w,u
WSTS	Write status	1. Software initializes to zero, hardware updates 2. WSTS states: (Only for DMA associated with MLB) xx1 = active xx= idle x1x = command protocol error 1xx = buffer overflow (FCE = 0 only)	r,w,u
Reserved	Reserved	Software writes a zero to all reserved bits when the entry is initialized. The reserved bits are read-only after initialization.	r,w,u

(1)
- r - software readable
- w - software writable
- u - updated periodically by hardware

Asynchronous and Control Channel Description Table

The format of an asynchronous and control channel descriptor table entry is shown in Table 24-1468. All reserved bits should be written to zero.

Table 24-1468. Format Of Asynchronous and Control Channel Descriptor Table Entry

- r - software readable
- w - software writable
- u - updated periodically by hardware

24.12.4.1.5 DMA Block

The DMA block manages data exchange between the local channel data buffers which reside in the MLBSS and a memory buffer residing in the system memory. To support system memory buffering, a ping-pong memory structure is implemented on a per channel basis using 128-bit descriptors for DMA descriptor table entries. 64 DMA descriptor table entries are directly mapped to the 64 DMA physical channels.

Each logical channel is assigned a separate 128-bit descriptor, defining data buffers in the system memory which are used by the DMA interface for this logical channel. The descriptors are stored at fixed addresses in the channel table RAM.

The description of the DMA descriptor table fields is shown in Table 24-1470.

Table 24-1470. Field Descriptions Of DMA Descriptor Table

Field	Numbers of bits	Description	Accessibilty (1)
CE	1	Channel enable: 0 = Disabled 1 = Enabled	r,w,u
LE	1	Endianess Enable: 0 = Big endian 1 = Little Endian	r, w
PG	1	Page pointer. Software initializes to zero, hardware writes thereafter. 0 = Ping buffer 1 = Pong buffer	r,w,u
RDY1	1	Buffer ready bit for ping buffer page: 0 = Not ready 1 = Ready	r, w
RDY2	1	Buffer ready bit for pong buffer page: 0 = Not ready 1 = Ready	r, w
DNE1	1	Buffer done bit for ping buffer page: 0 = Not done 1 = Done	r,u,c0
DNE2	1	Buffer done bit for pong buffer page: 0 = Not done 1 = Done	r,u,c0
ERR1	1	DMA error response detected for ping buffer page: 0 = No error 1 = Error	r,u,c0

Table 24-1470. Field Descriptions Of DMA Descriptor Table (continued)

Field	Numbers of bits	Description	Accessibilty [1]
ERR2	1	DMA error response detected for pong buffer page: 0 = No error 1 = Error	r,u,c0
PS1	1	Packet start bit for ping buffer page: 0 = No packet start 1 = Packet start Reserved for synchronous and isochronous channels.	r,w,u (both Tx and Rx)
PS2	1	Packet start bit for pong buffer page: 0 = No packet start 1 = Packet start Reserved for synchronous and isochronous channels.	r,w,u (both Tx and Rx)
MEP1	1	Most ethernet packet (MEP) indicator for ping buffer page: 0 = No MEP 1 = MEP MEP1 only valid for the first page of a segmented buffer. Reserved for control, synchronous and isochronous channels	r,w,u (both Tx and Rx)
MEP2	1	Most ethernet packet (MEP) indicator for pong buffer page: 0 = No MEP 1 = MEP MEP2 only valid for the first page of a segmented buffer. Reserved for control, synchronous and isochronous channels	r,w,u (both Tx and Rx)
BD1[2]	11 to 13	Buffer depth for ping buffer page: 11 or 12-bits for asynchronous and control channels. 13-bits for synchronous and isochronous channels.	r,w
BD2[2]	11 to 13	Buffer depth for pong buffer page: 11 or 12-bits for asynchronous and control channels. 13-bits for synchronous and isochronous channels.	r,w
BA1	32	Buffer base address for ping buffer page	r,w
BA2	32	Buffer base address for pong buffer page	r,w
Reserved	varies	Software writes a zero to all Reserved bits when the entry is initialized. The Reserved bits are Read-only after initialization.	r,w, u

(1)
- r - software readable
- w - software writable
- u - updated periodically by hardware
- c0 - software writes '0' to clear

(2) The buffer depth (BD1 and BD2) for synchronous channels must consider if multi-frame per sub-buffer mode (the MFE bit in the Channel Allocation Table) is enabled.

Data exchange across the DMA interface can be configured as little endian (LE = 0x1) or big endian (LE = 0x0). Figure 24-211 provides an overview of the endian options, chosen by the LE bit.

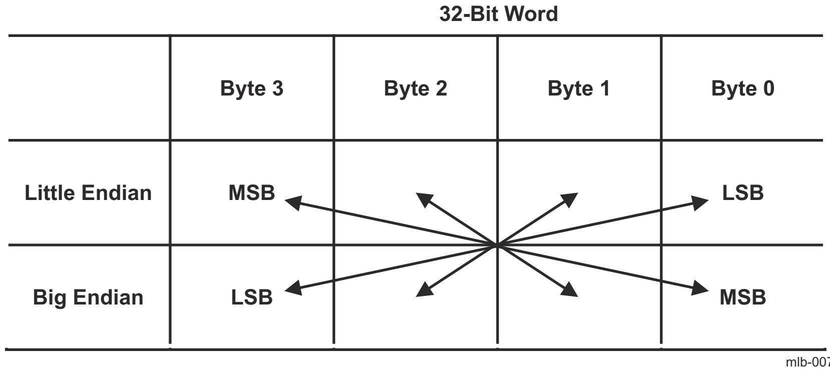

Figure 24-211. DMA Descriptor Table Endian Options

Figure 24-212 shows an example of ping-pong system memory structure. This system memory structure is similar for all channel types and shows the relationship between the BA1, BA2, BD1, BD2 and PG descriptor fields.

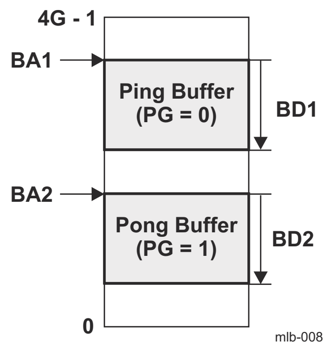

Figure 24-212. Ping-Pong System Memory Structure

Each DMA descriptor table entry (also referred to as a channel descriptor) holds a 32-bit BAn (n = 1 and 2) field which defines the start of each ping or pong buffer within system memory. The BDi (i = 1 and 2) field is used to indicate the size for the respective ping or pong page. The maximum size is 2k-entries for asynchronous and control channels, and 8k-entries for isochronous and synchronous channels.

24.12.4.1.5.1 Synchronous Channel Descriptor

The synchronous buffering scheme allows each ping or pong buffer to contain a single frame or a multiple number of frames. For this reason, the synchronous buffer depth (BDi) must be defined in terms of an integer number (n), frames per sub-buffer (m) and bytes per frame (bpf) of data (that is, BDi = n × m × bpf - 1).

Table 24-1471 shows the format for a synchronous DMA descriptor table entry. For more details about the field descriptions see Table 24-1470. Each synchronous channel buffer can be up to 8k-bytes deep.

Note

In synchronous transmit mode software should take care that the pong DDT is configured before ping DMA completion and ping DDT is configured before pong DMA completion. For more information about ping and pong DMA configuration see Table 24-1483 and Table 24-1484, respectively.

Table 24-1471. Format Of Synchronous DMA Descriptor Table Entry

96	BA2[15:0]															
112	BA2[31:16]															

24.12.4.1.5.2 Isochronous Channel Descriptors

The isochronous buffering scheme allows each ping or pong buffer to contain a single block or a multiple number of blocks. For this reason, the isochronous buffer depth (BDi) must be defined in terms of an integer number (n) and block size (BS) (that is, BDi = n × (BS + 1) - 1).

Table 24-1472 shows the format for an isochronous DMA descriptor table entry. For more details about the field descriptions see Table 24-1470. Each isochronous channel buffer can be up to 8k-bytes deep.

Table 24-1472. Format Of Isochronous DMA Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

96	BA2[15:0]															
112	BA2[31:16]															

24.12.4.1.5.3 Asynchronous and Control Channel Descriptors

Every asynchronous and control designates the first two bytes of each packet as the packet length (PML). Each packet must be no more than 2048 bytes (PML ≤ 2048).

Software must set the buffer ready bit (RDYn) for each buffer as it programs the DMA. As hardware processes each buffer, it sets the done bit (DNEn) and generates an interrupt. When hardware finishes the buffer processing, it can begin processing another buffer if RDYn is set. The application is responsible for setting up and configuring the channel buffer descriptor prior to every DMA access on the channel.

Two-packet modes are supported by hardware for programming the DMA. These are single-packet mode and multiple-packet mode.

24.12.4.1.5.3.1 Single-Packet Mode

The single-packet mode asynchronous and control buffering scheme supports a maximum of one packet per buffer (that is, ping or pong). Both non-segmented and segmented data packets are allowed while using single-packet mode. Non-segmented packets are exchanged when only one buffer (that is ping or pong) is needed for packet transfer. Segmented packets are exchanged when a single packet is too long for one buffer and the packet must span multiple buffers. Figure 24-213 shows the memory space usage for both non-segmented and segmented asynchronous or control packets along with the packet start bit (PSn).

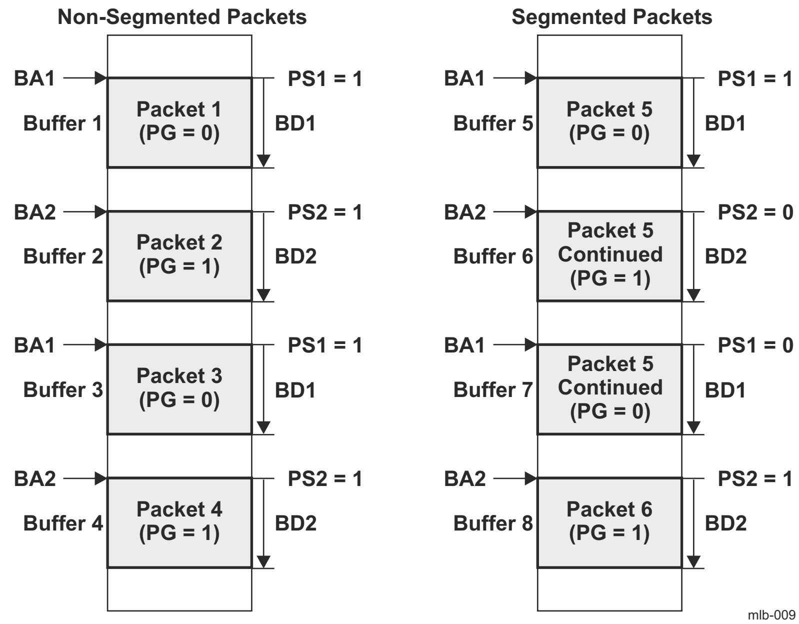

Figure 24-213. Single-Packet Mode Memory Space

While using single-packet mode, buffer done (DNEn) is set in hardware when a packet is done or the buffer is full.

Table 24-1473 shows the format for single-packet mode asynchronous and control DMA descriptor table entries. For more details about the field descriptions see Table 24-1470.

Table 24-1473. Format Of Single-Packet Asynchronous and Control DMA Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1	MEP1	BD1[10:0]										
48	RDY2	DNE2	ERR2	PS2	MEP2	BD2[10:0]										
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

24.12.4.1.5.3.2 Multiple-Packet Mode

The multiple-packet mode asynchronous and control buffering scheme supports more than one packet per system memory buffer, as shown in Figure 24-214. The multiple-packet mode reduces the interrupt rate for packet channels at the cost of increasing buffering and latency.

For Tx packet channels in multiple-packet mode, software sets the packet start bit (PSn) for every buffer. Setting PSn informs hardware that the first two bytes of the buffer contains the port message length (PML) of the first packet. After the first packet, hardware keeps track of where packets start and end within the current buffer. Software should not write to PSn while the buffer is active (RDYn = 1 and DNEn = 0). For Tx packet channels, the buffer is done (DNEn = 1) when the last byte of the last packet in the buffer is read from system memory. Software should set the buffer depth to contain the exact number of complete packets for that buffer. Segmented buffers are not supported for Tx packet channels in multiple-packet mode.

For Rx packet channels in multiple-packet mode, PSn has no meaning and should be ignored. Software is responsible for keeping track of where each packet starts and ends within the multiple-packet buffer via the packet PML. The buffer done bit (DNEn) is set in hardware for Rx channels when a buffer is full (see Buffer 1 in Figure 24-214) or if a packet ends exactly 1-byte before the end of the buffer (see Buffer 2 in Figure 24-214). Multiple-packet mode also supports segmented Rx packets spanning two or more buffers (see Buffers 3 – 6 in Figure 24-214).

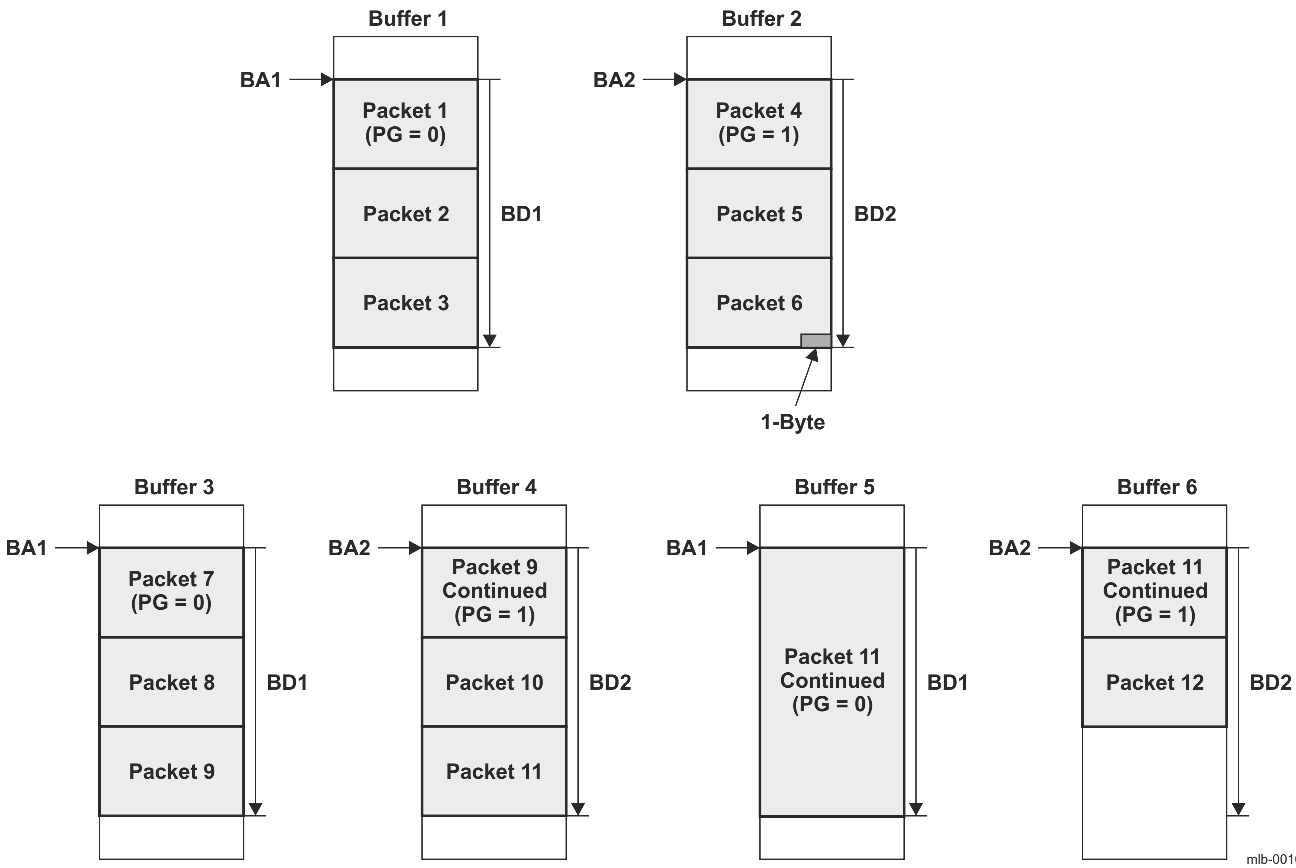

Figure 24-214. Multi-Packet Mode System Memory

Table 24-1474. Format Of Multiple-Packet Asynchronous And Control DMA Descriptor Table Entry

Bit Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CE	LE	PG	Reserved												
16	Reserved															
32	RDY1	DNE1	ERR1	PS1 (1)	BD1[11:0]											
48	RDY2	DNE2	ERR2	PS2 (1)	BD2[11:0]											
64	BA1[15:0]															
80	BA1[31:16]															
96	BA2[15:0]															
112	BA2[31:16]															

(1) PS1 and PS2 have no meaning and should be ignored in Rx mode.

24.12.4.2 Software and Data Flow for MLBSS

Figure 24-215 shows an overview of the MLBSS software and data flow.

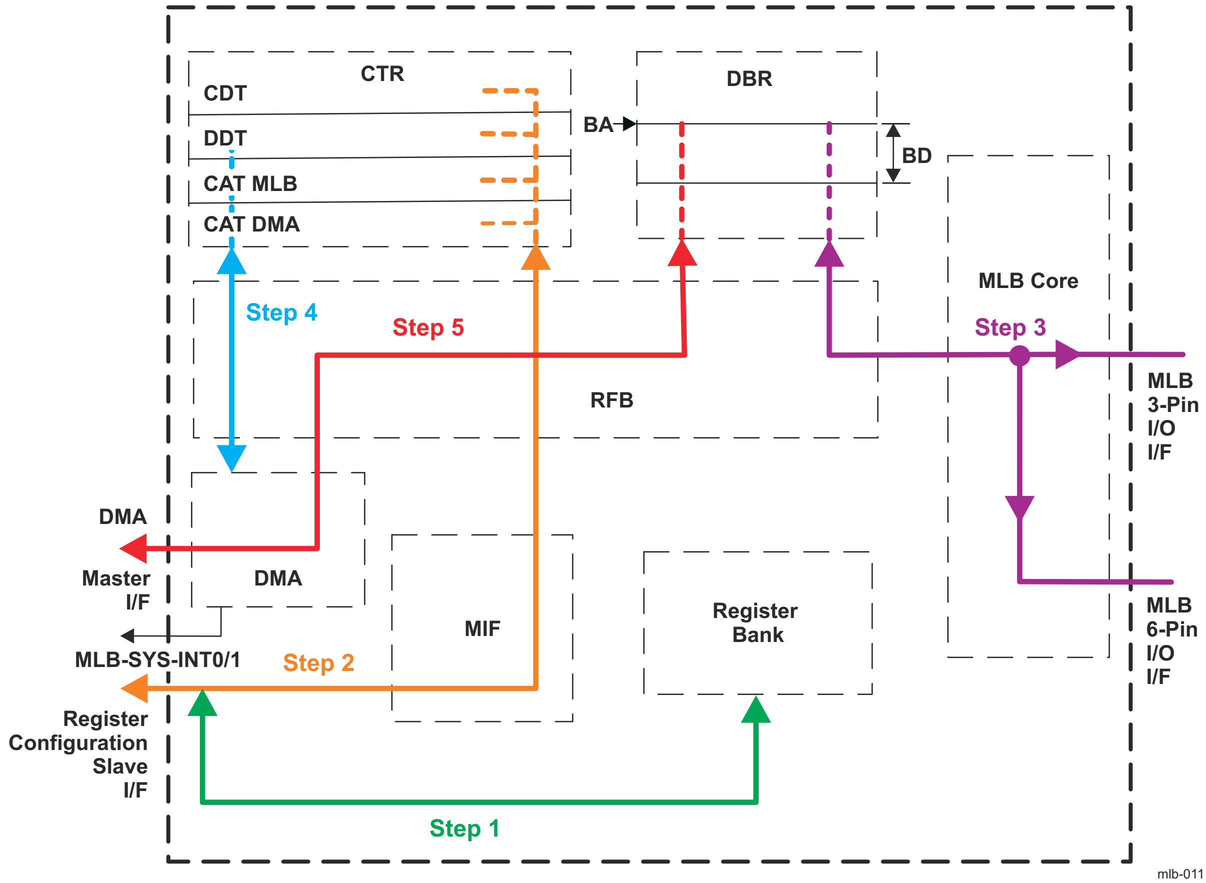

Figure 24-215. MLBSS Software and Data Flow Overview

The MLBSS data flow is defined in the following way:

1. Hardware is configured (see Table 24-1477)
2. Channel table RAM is cleared and configured (see Table 24-1478)
3. Data transaction begins through MediaLB 3-pin or 6-pin interface after MLBSS is synchronized.
4. DMA reads from channel table RAM.
5. Data transaction is done through the DMA master interface.

Steps 1 and 2 are done by software. For more information see Section 24.12.5.1.2.1, *Channel Initialization*

Steps 3-5 are handled by MLBSS internal hardware.

The top-level software tasks that the application must perform can be placed in two categories:

- Channel initialization
- Channel servicing

For more information about channel initialization, see Section 24.12.5.1.2.1, *Channel Initialization*.

For more information about channel servicing, see Section 24.12.5.2.1, *Channel Servicing*.

24.12.4.2.1 Data Flow For Receive Channels

The data flow for receive channels is as follows:

1. After MLBSS is configured (see Section 24.12.5.1.2.1) and MediaLB has synchronized to the incoming MediaLB framesync (MLB_MLBC0[7] MLBLK = 0x1), serial data is received either through the mlbp_dat_p and mlbp_dat_n pads or through the mlb_dat pad, depending on the pin mode (6-pin or 3-pin) selected.
2. The MLBSS logic writes incoming data to the appropriate buffer in the data buffer RAM. The data buffer RAM address to which data is written is the BA field of the channel descriptor table entry. The channel

descriptor table entry is specified by the CL field of the MediaLB channel allocation table entry for the channel. The MediaLB channel allocation table entry equals (1/2)*ChannelAddr.

3. The DMA access for a particular DMA channel (DMA channel allocation table entry) is started when there is sufficient data for the DMA channel in the data buffer RAM to write into system memory and the system memory buffer (ping or pong depending on the PG bit in DMA descriptor table entry) is marked as ready. Note that presence of a frame for synchronous/isochronous traffic (multiple frames in multi frame mode) or a packet for control/asynchronous traffic (multiple packets in multi packet mode) is deemed sufficient data to mark a DMA channel as ready.
4. The DMA hardware reads from the data buffer RAM memory address specified by the BA field of the channel descriptor table entry and writes to the system memory address specified in the DMA descriptor table. The CL field in the DMA channel allocation table entry is used to determine the appropriate channel descriptor table entry. Note that CL field of DMA channel allocation table and MLB channel allocation table entries must be the same, thus providing the common data buffer RAM address for MLB core to write into DMA and the DMA to read from the MLB core. Further, each DMA channel allocation table entry corresponds to a DMA descriptor table entry as per the following mapping:
   - Address of DMA descriptor table entry = 0x40 + Index of DMA channel allocation table entry.

24.12.4.2.2 Data Flow for Transmit Channels

The data flow for transmit channels is as follows:

1. The DMA access for a particular DMA channel (DMA channel allocation table entry) is started when data buffer RAM has sufficient buffer space and the system memory buffer (ping or pong depending on the PG bit in DMA descriptor table entry) is marked as ready for a particular DMA channel allocation table entry. Each DMA channel allocation table entry corresponds to a DMA descriptor table entry as per the following mapping:
   - Address of DMA descriptor table entry = 0x40 + Index of DMA channel allocation table entry.
2. The DMA reads from the system memory address specified in the DMA descriptor table and writes to the data buffer RAM memory address specified by the BA field of the channel descriptor table entry. The CL field in the DMA channel allocation table entry is used to determine the appropriate channel descriptor table entry. Note that CL field of DMA channel allocation table and MLB channel allocation table entries must be the same, thus providing the common data buffer RAM address for DMA to write into MLB core and the MLB core to read from the DMA.
3. Once the MLBSS is synchronized to the incoming MediaLB framesync (MLB_MLBC0[7] MLBLK = 0x1) and a MediaLB channel address is received, the MediaLB core refers to the specific MediaLB channel allocation table entry and reads data from the data buffer RAM buffer. The data buffer RAM address from which data is read is the BA field of the channel descriptor table entry. The channel descriptor table entry is specified by the CL field of the MLB channel allocation table entry for the channel. The MediaLB channel allocation table entry equals (1/2)*ChannelAddr.
4. This data is serialized and transmitted through the MediaLB 3-pin or 6-pin interface.

24.12.4.3 MLB Priority On The L3_MAIN Interconnect

There is a register used for controlling the priority of the MLB sub-system on the L3_MAIN. This is done through the CTRL_CORE_IP_PRESSURE register which reside in the CTRL_MODULE_CORE. The MLB has a default priority (pressure setting) on the L3_MAIN. To override the default setting the CTRL_CORE_IP_PRESSURE[2] MLB_L3_PRESSURE_ENABLE bit must be set to 0x1. When this is done the values configured through the CTRL_CORE_IP_PRESSURE[1:0] MLB_L3_PRESSURE bit field apply. Setting this bit field to 0x3 means that the MLB traffic has highest priority over the other initiator traffics. A value of 0x0 is for lowest priority.

24.12.5 MLB Programming Guide

This section describes the programming sequences for the configuration and use of the MLBSS.

24.12.5.1 Global Initialization

24.12.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MLB sub-system. For more information, see Section 24.12.3, *MLB Integration*, and Section 24.12.2, *MLB Environment*.Table 24-1475 shows the global initialization of MLBSS surrounding modules.

Table 24-1475. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The interface and functional clocks of the MLBSS must be enabled. See *Power, Reset, and Clock Management*.
Control module	The pad muxing must be configured in the control module. The MLBSS I/Os must be configured also in the control module. See *Pad Configuration Registers* in *Control Module* . See also table "Multiplexing characteristics" in the device Data Manual.
IRQ_CROSSBAR	Mapping of the MLBSS IRQs to a desired line of certain of the device interrupt controllers must be configured. See *IRQ_CROSSBAR Module Functional Description* in *Control Module* .
Interrupt Controllers	An INTC configuration must be done to enable the interrupts from the MLBSS. See *Interrupt Controllers*.

24.12.5.1.2 MLBSS Global Initialization

24.12.5.1.2.1 Channel Initialization

A channel initialization must be performed in order to ensure proper operation. Table 24-1476 shows the sequence.

Table 24-1476. Channel Initialization Steps

Step	Crossreference
Configuring the hardware	Table 24-1477
Programming the routing fabric block	Table 24-1478
Programming the DMA block	Table 24-1482
Synchronizing and unmuting the synchronous channel	Table 24-1485

Configuring The Hardware

To configure the MediaLB interface, the steps shown in Table 24-1477 should be followed.

Table 24-1477. Configuring The Hardware

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Clear channel table RAM, to ensure that no stray interrupts are generated	-	0x0
Clear the interrupt status bits for logical channels 0 to 63	MLB_DCSR0 and MLB_DCSR1	0xFFFF FFFF
Mask all DMA channels (from 0 to 63)	MLB_DCMR0 and MLB_DCMR1	0x0000 0000
Select 3-pin or 6-pin MediaLB operation	MLB_MLBC0[5] MLBPEN	0x0 for 3-pin 0x1 for 6-pin
Select MediaLB clock speed	MLB_MLBC0[4:2] MLBCLK	0x-
Enable the MediaLB	MLB_MLBC0[0] MLBEN	0x1
Activate all channels	MLB_DICER0 and MLB_DICER1	0xFFFF FFFF
Enable the DMA	MLB_DIENR[15] EN	0x1
Set the DMA channel mask bits according to all active DMA channels	MLB_DCMR0 and MLB_DCMR1	0x-
Select DMA Mode 1 to be used	MLB_DCTL[2] DMA_MODE	0x1
Select software to clear the interrupts	MLB_DCTL[0] SCE	0x1

Table 24-1477. Configuring The Hardware (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Enable MLB interrupts, if required	MLB_MIEN	0x-

Programming The Routing Fabric Block

The channel allocation table and channel descriptor table reside in the channel table RAM and are programmed indirectly through the memory interface block. The steps to be followed are shown in Table 24-1478.

Table 24-1478. Programming The Routing Fabric Block

Step	Register/ Bit Field/ Programming Model/ Comments	Value
1. Initialize all bits of the channel allocation table	-	0x0
2. Select a connection label	CL	N = 0x0 to 0x3F
3. Program the channel descriptor table for channel N	Use the memory interface registers to do a write to the channel descriptor table. See Table 24-1479.	Mask to be used : 0xFFFF FFFF
4. Program the channel allocation table for inbound data buffer RAM access	Write to the data buffer RAM. See Table 24-1480.	-
5. Program the channel allocation table for outbound data buffer RAM access	Read from the data buffer RAM. See Table 24-1481.	-
6. Repeat steps 2-5 to initialize all logical channels	-	-

Table 24-1479. Subsequence - Program The Channel Descriptor Table

Step	Register/ Bit Field/ Programming Model/ Comments	Value
1. Set the 14-bit base address	BA	0x-
2. Set the 12-bit or 13-bit buffer depth	BD (set this according to the BA so that it doesn't overflow the buffer)	BD = buffer depth in bytes - 1
IF: Synchronous channels		
Set the 12-bit or 13-bit buffer depth	BD	(BD + 1) = 4 × frames per sub-buffer (m) × bytes-per-frame (bpf)
ENDIF		
IF: Isochronous channels		
Set the 12-bit or 13-bit buffer depth	BD	(BD + 1) mod (BS + 1) = 0
ENDIF		
IF: Asynchronous channels		
Set the 12-bit or 13-bit buffer depth	BD	(BD + 1) >= max packet length (1024 for a MOST Data Packet (MDP))
ENDIF		
IF: Control channels		
Set the 12-bit or 13-bit buffer depth	BD	(BD + 1) >= max packet length (64)
ENDIF		
3. For isochronous channels, configure the block size	BS	BS = block size in bytes - 1
4. Write to all other bits of the channel descriptor table		0x0

Table 24-1480. Subsequence - Write To The Data Buffer RAM

Step	Register/ Bit Field/ Programming Model/ Comments	Value
For Tx channels the DMA block does the inbound data buffer RAM access	A Tx channel is from MLBSS to external host	-

Table 24-1480. Subsequence - Write To The Data Buffer RAM (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
For Rx channels MediaLB does the inbound data buffer RAM access	An Rx channel is from external host to MLBSS	-
Set the channel direction	RNW	0x0
Set the channel type	CT[2:0]	0x0: synchronous 0x1: control 0x2: asynchronous 0x3: isochronous
Set the connection label	CL[5:0]	CL[5:0] = N
IF: CT[2:0] = 0x0 (synchronous)		
Set the mute bit.	MT (the mute bit is set to avoid any flow of the garbage data that will be there in the data buffer prior to any transfer)	0x1
ENDIF		
Set the channel enable bit	CE	0x1
Clear all other bits of the channel allocation table	-	0x0

Table 24-1481. Subsequence - Read From The Data Buffer RAM

Step	Register/ Bit Field/ Programming Model/ Comments	Value
For Tx channels MediaLB does the outbound data buffer RAM access	A Tx channel is from MLBSS to external host	-
For Rx channels the DMA block does the outbound data buffer RAM access	An Rx channel is from external host to MLBSS	-
Set the channel direction	RNW	0x1
Set the channel type	CT[2:0]	0x0: synchronous 0x1: control 0x2: asynchronous 0x3: isochronous
Set the connection label	CL[5:0]	CL[5:0] = N
IF: CT[2:0] = 000 (synchronous),		
Set the mute bit.	MT	0x1
ENDIF		
Set the channel enable bit	CE	0x1
Clear all other bits of the channel allocation table	-	0x0

Programming The DMA Block

The DMA descriptor table resides in the channel table RAM and is programmed through L4_PER2 slave interface using the registers of the memory interface block. The steps to be followed are shown in Table 24-1482.

Table 24-1482. Programming The DMA Block

Step [(1)]	Register/ Bit Field/ Programming Model/ Comments	Value
1. Initialize all bits of the DMA descriptor table	-	0x0
2. Select a connection label	CL (Note that the CL number chosen in this step should be equal to the CL number chosen in step 2 of Table 24-1478)	N = 0x0 to 0x3F

Table 24-1482. Programming The DMA Block (continued)

Step [(1)]	Register/ Bit Field/ Programming Model/ Comments	Value
3. Program the DMA block ping page for channel N [(2)]	See Table 24-1483	-
4. Program the DMA block pong page for channel N	See Table 24-1484	-
5. Select big or little endian	LE	0x-
6. Select the active page	PG (Program this bit only once in the beginning of the configuration. It shouldn't be touched by the software after that. The hardware updates this bit as the transactions happen)	0x-
7. Set the channel enable bit for all active logical channels	CE	0x1
8. Repeat steps 2-7 for all active logical channels	-	-

(1) **Tip:** In order to program the MLB and DMA channel allocation table entries with respect to corresponding MLB and DMA channel address, the following steps are recommended:
- Given the MLB channel address is X (1-63), the MLB channel allocation table entry to be programmed should be X/2.
- Given the DMA channel address is X (0-63), the DMA channel allocation table entry to be programmed is X.

(2) For programming the 128-bit DMA descriptor table entry,
- IF: The DMA descriptor table is initialized with zeros and the PG bit is intended to be set to 0x0, the following mask should only be used: MLB_MDWE0 = 0x000C 0000
- ELSE: The following steps should be performed:
  – The mask to be used: = 0x000E 0000.
  – Program the DMA descriptor table and the PG bit.
  – Change the MLB_MDWE0 mask value to 0x000C 0000 after the first configuration has been done to prevent any further writes by host to the PG bit during ongoing MLB transactions.
  – Write the 0xFFFF FFFF mask to the MLB_MDWE1, MLB_MDWE2 and MLB_MDWE3 registers

Table 24-1483. Subsequence - Program The DMA Block Ping Page

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Set the 32-bit base address	BA1	0x-
Set the 11-bit buffer depth	BD1	BD1 = buffer depth in bytes - 1
IF: Synchronous channels		
Set the 11-bit buffer depth	BD1	(BD1+ 1) = n × frames per sub-buffer (m) × bytes-per-frame (bpf)
ENDIF		
IF: Isochronous channels		
Set the 11-bit buffer depth	BD1	(BD1 + 1) mod (BS + 1) = 0
ENDIF		
IF: Asynchronous and control Rx channels		
Set the 11-bit buffer depth	BD1	5 <= (BD1 + 1) <= 4096 [(1)]
ENDIF		
IF: Asynchronous and control Tx channels		
Set the 11-bit buffer depth	BD1	5 <= (BD1 + 1) <= 4096 [(1)]
Set the packet start bit if the page contains the start of the packet	PS1	0x1
ENDIF		
Clear the page done bit	DNE1	0x0
Clear the error bit	ERR1	0x0

Table 24-1483. Subsequence - Program The DMA Block Ping Page (continued)

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Set the page ready bit	RDY1	0x1

(1) 4096 is the max packet length.

Table 24-1484. Subsequence - Program The DMA Block Pong Page

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Set the 32-bit base address	BA2	0x-
Set the 11-bit buffer depth	BD2	BD2 = buffer depth in bytes - 1
IF: Synchronous channels		
Set the 11-bit buffer depth	BD2	(BD2+ 1) = n × frames per sub-buffer (m) × bytes-per-frame (bpf)
ENDIF		
IF: Isochronous channels		
Set the 11-bit buffer depth	BD2	(BD2 + 1) mod (BS + 1) = 0
ENDIF		
IF: Asynchronous and control Rx channels		
Set the 11-bit buffer depth	BD2	5 <= (BD2 + 1) <= 4096 (1)
ENDIF		
IF: Asynchronous and control Tx channels		
Set the 11-bit buffer depth	BD2	5 <= (BD2 + 1) <= 4096 (1)
Set the packet start bit if the page contains the start of the packet	PS2	0x1
ENDIF		
Clear the page done bit	DNE2	0x0
Clear the error bit	ERR2	0x0
Set the page ready	RDY2	0x1

(1) 4096 is the max packet length.

Synchronizing And Unmuting The Synchronous Channel

The steps to be followed are shown in Table 24-1485

Table 24-1485. Synchronizing And Unmuting The Synchronous Channel

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Check that MediaLB clock is running	MLB_MLBC1[7] CLKMERR	0x0
IF: The MediaLB clock is not toggling at the pads	MLB_MLBC1[7] CLKMERR	0x1
Clear the register bit	MLB_MLBC1[7] CLKMERR	
Wait one MLB_L4_ICLK or MLB I/O clock cycle		
Check that MediaLB clock is running	MLB_MLBC1[7] CLKMERR	0x0
ENDIF		
Poll for MediaLB lock	MLB_MLBC0[7] MLBLK	0x1
Wait four frames	-	-
Unmute the synchronous channel/ channels	MT	0x0

24.12.5.2 MLBSS Operational Modes Configuration

24.12.5.2.1 Channel Servicing

After initialization, each channel requires periodic servicing. Table 24-1486 shows the steps which can be performed concurrently and in any order.

Table 24-1486. Channel Servicing Steps

Step	Crossreference
Servicing the DMA Interrupts	Table 24-1487
Servicing MLB Interrupts	Table 24-1489
Polling for MediaLB System Commands	Table 24-1490

Servicing the DMA Interrupts

The steps to be followed are shown in Table 24-1487

Table 24-1487. Servicing the DMA Interrupts

Step	Register/ Bit Field/ Programming Model/ Comments	Value
1. Enable (unmask) the interrupts from all active DMA channels	MLB_DCMR0 and MLB_DCMR1	0x1 for each bit associated with an active DMA channel
2. Select the status clear method	MLB_DCTL[0] SCE	0x-
3. Select one (MLB_IRQ_SYS_INT0 only) or two (MLB_IRQ_SYS_INT0 and MLB_IRQ_SYS_INT1) interrupt signals	MLB_DCTL[1] SMX	0x-
4. Wait for an interrupt from MLB_IRQ_SYS_INT0 and/or MLB_IRQ_SYS_INT1 line	-	-
5. Determine which channel or channels are causing an interrupt	Read the MLB_DCSR0 and MLB_DCSR1 registers	0x-
6. IF: MLB_DCTL[0] SCE = 0x1 (software clears the interrupts)		
Write the results of step 5 back to the MLB_DCSR0 and MLB_DCSR1 registers to clear the interrupt	MLB_DCSR0 and MLB_DCSR1	MLB_DCSR0 and MLB_DCSR1
ENDIF		
7. Select a logical channel (N = 0-63) with an interrupt to service	-	-
8. Read the DMA descriptor table entry for channel N	See Table 24-1488	-
9. Reprogram the expired or broken DMA page/pages via steps 3 and 4 of Table 24-1482	-	-
10. Repeat steps 6-9 for all channels with pending interrupts	-	-
11. Repeat steps 4-10 while there are active channels	-	-

Note

The MLB_DCSR0, MLB_DCSR1, MLB_DCMR0 and MLB_DCMR1 register bits correspond to the DMA channel address for a particular logical channel. This should not be confused with the MLB channel address.

Channels that receive a DMA error response are disabled (CE = 0) by hardware.

Table 24-1488. Subsequence - Reading The DMA Descriptor Table Entry

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Determine the active page (ping or pong)	Use the PG bit	0x-
Determine which page/pages are done	Use the DNE1 and DNE2 bits	0x1
Determine which channels encountered a DMA error	Use the ERR1 and ERR2 bits	0x1
Determine which asynchronous and control Rx channel pages contain a packet start	Use the PS1 and PS2 bits	0x1

Servicing MLB Interrupts

To service the MLB interrupts, the steps desctibed in Table 24-1489 should be followed.

Table 24-1489. Servicing MLB Interrupts

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Clear the appropriate MediaLB channel status bits	MLB_MS0 and MLB_MS1 registers	0x0
Enable protocol error interrupts for all active MediaLB channels	MLB_MIEN[28] CTX_PE MLB_MIEN[25] CRX_PE MLB_MIEN[21] ATX_PE MLB_MIEN[18] ARX_PE MLB_MIEN[16] SYNC_PE MLB_MIEN[0] ISOC_PE	0x1 0x1 0x1 0x1 0x1 0x1
Wait for an interrupt on the MLB_IRQ_SYS line		
Determine which channel/channels are causing the interrupt	Read the MLB_MS0 and MLB_MS1 registers	0x1
Determine the interrupt type	Read the RSTS and WSTS bits of the appropriate channel descriptor tables	0x-
IF: Synchronous channels		
Clear WSTS errors to resume channel operation	WSTS[3]	0x0
ENDIF		
IF: Isochronous channels		
Clear WSTS errors to resume channel operation	WSTS[2:1]	0x0
ENDIF		
IF: Asynchronous and control channels		
Clear RSTS and WSTS errors to resume channel operation	RSTS[4], WSTS[4], RSTS[2] and WSTS[2]	0x0
ENDIF		

Polling For MediaLB System Commands

The MediaLB core supports the MediaLB system commands (MlbScan, MlbReset, MOST_Unlock). The MLB_MSS register is used to detect a system command received from the MediaLB controller. The MLB automatically sends the appropriate system response to the MediaLB Controller. Software should follow the procedure shown in Table 24-1490.

Table 24-1490. Polling For MediaLB System Commands

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Poll periodically for a system command received from the MediaLB controller	MLB_MSS	0x-
Clear the appropriate bits in MLB_MSS register after the application finishes the servicing	MLB_MSS	0x0
IF: Software system command is detected	MLB_MSS[4] SWSYSCMD	0x1
Read the MLB_MSD register to receive the system data sent from MediaLB Controller	MLB_MSD	0x-
ENDIF		

24.12.5.2.2 Channel Table RAM Access

The memory interface block allows a direct software access to the channel table RAM. Any write to the MLB_MADR register triggers a single read or write cycle. Reading from the MLB_MADR register does not initiate a read or write access.

Table 24-1491 shows a direct write to the channel table RAM.

Table 24-1491. Direct Channel Table RAM Writes

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Load the 128-bit data entry	MLB_MDAT0, MLB_MDAT1, MLB_MDAT2 and MLB_MDAT3 registers	0x-
Enable writing data	MLB_MDWE0, MLB_MDWE1, MLB_MDWE2 and MLB_MDWE3 registers	0x1
Write the 8-bit channel table RAM target address	MLB_MADR[7:0] ADDR	0x-
Initiate a write cycle	MLB_MADR[31] WNR	0x1
Determine when the transfer is complete	Poll the MLB_MCTL[0] XCMP	0x1

Table 24-1492 shows a direct read from the channel table RAM.

Table 24-1492. Direct Channel Table RAM Reads

Step	Register/ Bit Field/ Programming Model/ Comments	Value
Write the 8-bit channel table RAM target address	MLB_MADR[7:0] ADDR	0x-
Initiate a read cycle	MLB_MADR[31] WNR	0x0
Determine when the transfer is complete	Poll the MLB_MCTL[0] XCMP	0x1
Read the 128-bit data entry	MLB_MDAT0, MLB_MDAT1, MLB_MDAT2 and MLB_MDAT3 registers	0x-

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
16	WRNP	The WRNP bit controls whether the writes issued by the DMA OCP interface are posted (no write reponse required to complete transaction) or non posted (write response required to complete transaction). 0x0: Only posted writes are issued. This means that the performance of DMA OCP writes would be better, but the writes will complete before the data gets written to the destination. Posted writes do not require a write response from the destination to complete a write transaction. 0x1: Only non-posted writes are issued. This means that the performance of DMA OCP writes would be lesser, but would guarantee that when a write has completed, the data gets written into the final destination. Non posted writes require a write response from the destination to complete a write transaction. It is recommended to use only posted writes for better performance. This is a static configuration out of reset based on performance requirements and changing it while a transfer in progress could cause indeterminate behavior.	RW	0x0
15	RESERVED		R	0x0
14:12	ASYNC_PRI	ASYNC_PRI controls the priority carried in MREQINFO attribute of OCP DMA interface, when a asynchronous transaction is requested at the DMA interface. It is recommended that the ASYNC_PRI be set at lower priority compared to other masters in the system, as these transactions are not time-critical. 0x0: highest priority 0x7: lowest priority	RW	0x4
11	RESERVED		R	0x0
10:8	SYNC_PRI	SYNC_PRI controls the priority carried in MREQINFO attribute of OCP interface, when a synchronous transaction is requested at the DMA interface. It is recommended that the SYNC_PRI be set at a reasonably higher priority compared to other masters in the system, as these transactions could be time-critical. 0x0: highest priority 0x7: lowest priority	RW	0x0
7:6	RESERVED		R	0x0
5:4	ASYNC_FLAG	ASYNC_FLAG controls the value carried in MFLAG attribute of OCP DMA interface. This attribute is used in determining the priority of these transactions through the L3 system infrastructure. It is recommended that he ASYNC_FLAG be set at lower priority compared to other masters in the system, as these transactions are not time critical 0x0: Lowest priority through on chip network 0x1: Medium priority through on chip network 0x2: Reserved 0x3: Highest priority through on-chip network	RW	0x1

RESERVED																										SERVREQ	SWSYSCMD	CSSYSCMD	ULKSYSCMD	LKSYSCMD	RSTSYSCMD

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x0
5	SERVREQ	Service request enabled. When cleared, the MediaLB block responds with a "device present" system response. When set, the MediaLB block responds with a "device present, request service" system response if a matching channel scan system command is detected. 0x0: Service request disabled (not detected) 0x1: Service request enabled (detected)	RW	0x0
4	SWSYSCMD	Software system command detected (in the system quadlet). Set by hardware, cleared by software. Data is stored in the MLB_MSD register for this command. 0x0: Software system command not detected 0x1: Software system command detected	RW W0toClr	0x0
3	CSSYSCMD	Channel scan system command detected (in the system quadlet). Set by hardware, cleared by software. If the node address specified in Data quadlet matches the value in MLBC1.NDA, the device responds either "device present" or "device present, request service" system response in the next system quadlet. 0x0: Channel scan system command not detected 0x1: Channel scan system command detected	RW W0toClr	0x0

Bits	Field Name	Description	Type	Reset
2	ULKSYSCMD	Network unlock system command detected (in the system quadlet). Set by hardware, cleared by software 0x0: Unlock system command not detected 0x1: Unlock system command detected	RW W0toClr	0x0
1	LKSYSCMD	Network lock system command detected (in the system quadlet). Set by hardware, cleared by software. 0x0: Lock system not detected 0x1: Lock system detected	RW W0toClr	0x0
0	RSTSYSCMD	Reset system command detected (in the system quadlet). Set by hardware, cleared by software 0x0: Reset system command not detected 0x1: Reset system command detected	RW W0toClr	0x0

Chapter 25

eMMC/SD/SDIO

TEXAS INSTRUMENTS

This chapter describes the features and functions of the eMMC/SD/SDIO interface of the device.

25.1 eMMC/SD/SDIO Overview 6381
25.2 eMMC/SD/SDIO Environment 6385
25.3 eMMC/SD/SDIO Integration 6392
25.4 eMMC/SD/SDIO Functional Description 6398
25.5 eMMC/SD/SDIO Programming Guide 6430
25.6 eMMC/SD/SDIO Register Manual 6455

25.1 eMMC/SD/SDIO Overview

The eMMC/SD/SDIO host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either eMMC, SD® memory cards, or SDIO cards and handles eMMC/SD/SDIO transactions with minimal LH intervention.

Optionally, the controller is connected to the L3_MAIN interconnect to have a direct access to system memory. It also supports two direct memory access (DMA) slave channels or a DMA master access (in this case, slave DMA channels are deactivated) depending on its integration.

The eMMC/SD/SDIO host controller deals with eMMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit, and checking for syntactical correctness.

The application interface can send every eMMC/SD/SDIO command and poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The eMMC/SD/SDIO host controller also supports two DMA channels.

There are four eMMC/SD/SDIO host controllers inside the device. Figure 25-1 gives an overview of the eMMC/SD/SDIOi (i = 1 to 4) controllers.

Each controller has the following data width:

- eMMC/SD/SDIO1 - 4-bit wide data bus
- eMMC/SD/SDIO2 - 8-bit wide data bus
- eMMC/SD/SDIO3 - 8-bit wide data bus
- eMMC/SD/SDIO4 - 4-bit wide data bus

The eMMC/SD/SDIOi controller is also referred to as MMCi.

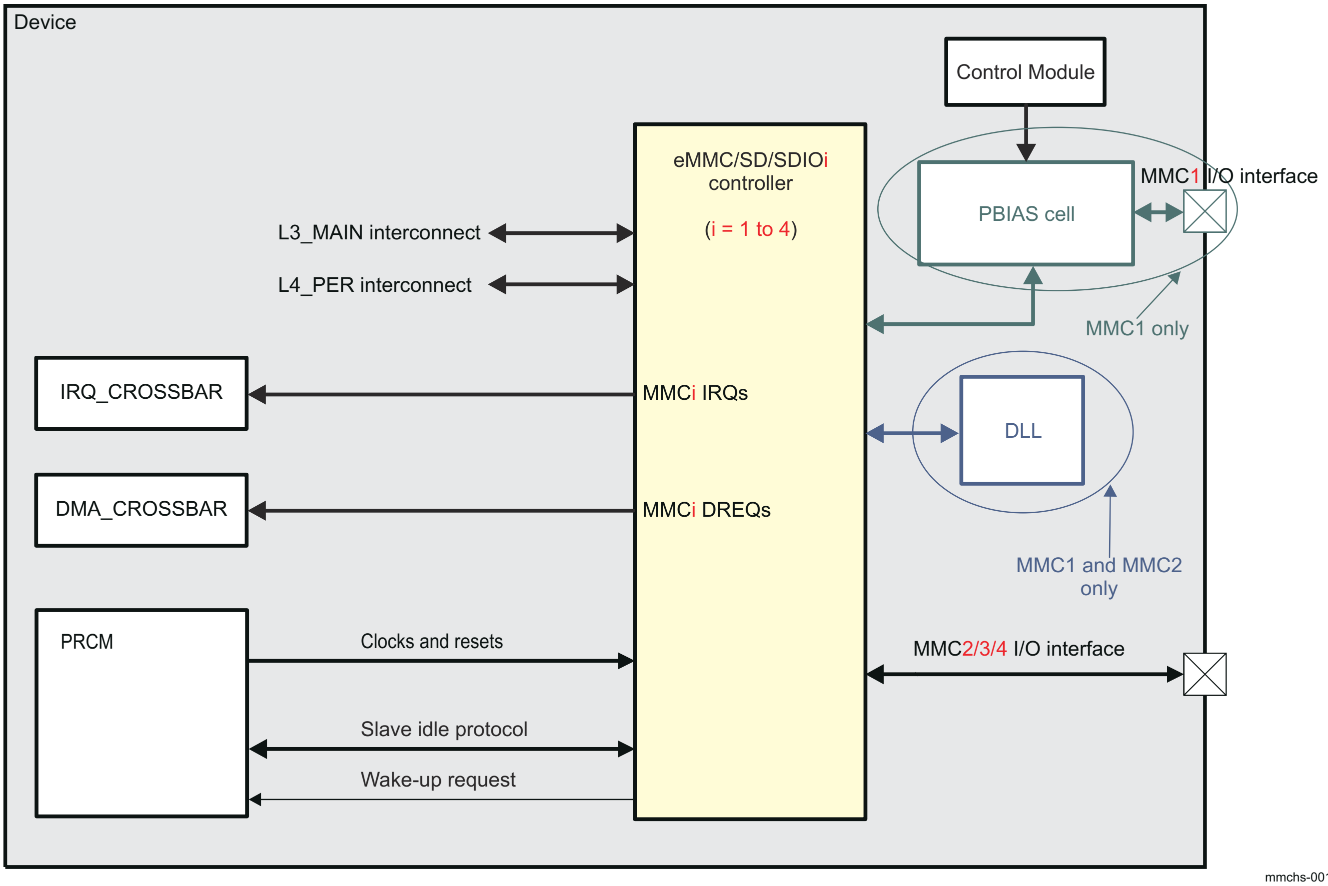

Figure 25-1. eMMC/SD/SDIOi Overview (i = 1 to 4)

25.1.1 eMMC/SD/SDIO Features

This section describes the features supplied by the eMMC/SD/SDIO controllers.

Compliance with standards:

- Full compliance with MMC/eMMC command/response sets as defined in the JC64 MMC/eMMC standard specification, v4.5.
- Full compliance with SD command/response sets as defined in the SD Physical Layer specification v3.01
- Full compliance with SDIO command/response sets and interrupt/read-wait suspend-resume operations as defined in the SD part E1 specification v3.00
- Full compliance with SD Host Controller Standard Specification sets as defined in the SD card specification Part A2 v3.00

Main features of the eMMC/SD/SDIO host controllers:

- Flexible architecture allowing support for new command structure
- 32-bit wide access bus to maximize bus throughput
- Designed for low power
- Programmable clock generation
- Dedicated DLL to support SDR104 mode (MMC1 only)
- Dedicated DLL to support HS200 mode (MMC2 only)
- Card insertion/removal detection and write protect detection
- L4 slave interface supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 9-bit address bus width

  - Streaming burst supported only with burst length up to 7
  - WNP supported
- L3 initiator interface Supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 32-bit address bus width
  - Burst supported
- Built-in 1024-byte buffer for read or write
- Two DMA channels, one interrupt line
- Support JC 64 v4.4.1 boot mode operations
- Support SDA 3.00 Part A2 programming model
- Support SDA 3.00 Part A2 DMA feature (ADMA2)
- Supported data transfer rates:
  - MMCi supports the following SD v3.0 data transfer rates:
    - DS mode (3.3V IOs): up to 12 MBps (24 MHz clock)
    - HS mode (3.3V IOs): up to 24 MBps (48 MHz clock)
    - SDR12 (1.8V IOs): up to 12 MBps (24 MHz clock)
    - SDR25 (1.8V IOs): up to 24 MBps (48 MHz clock)
    - SDR50 (1.8V IOs): up to 48 MBps (96 MHz clock) - MMC1 and MMC3 only
    - DDR50 (1.8V IOs): up to 48 MBps (48 MHz clock) - MMC1 only
    - SDR104 (1.8V IOs) cards can be supported up to 192 MHz clock (96 MBps max) - MMC1 only
  - MMCi supports the Default SD mode 1-bit data transfer up to 24Mbps (3MBps)
  - Only MMC2 supports also the following JC64 v4.5 data transfer rates:
    - Up to 192 MBps in eMMC mode, 8-bit SDR mode (192 MHz clock frequency)
    - Up to 96 MBps in eMMC mode, 8-bit DDR mode (48 MHz clock frequency)
- All eMMC/SD/SDIO controllers are connected to 1,8V/3.3V compatible I/Os to support 1,8V/3.3V signaling

Note

eMMC functionality is supported fully by MMC2 only. The other MMC modules are capable of eMMC functionality, but are not timing-optimized for eMMC. For more information about timing limitations, see the data manual of the device.

The differences between the eMMC/SD/SDIO host controllers and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v3.00 are:

- The clock divider in the eMMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v3.0. The eMMC/SD/SDIO host controller supports odd and even clock ratio.
- The eMMC/SD/SDIO host controller supports configurable busy time-out.
- ADMA2 64-bit mode is not supported.
- There is no external LED control.

Note

Only even ratios are supported in DDR mode.

Table 25-1 lists the features supported in the 4.5 standard.

Table 25-1. Standard 4.5 Supported Features

Feature	Support	Limitation	Comment
Bus width	1-bit mode		x 1, 4, 8 bits
	4-bit mode		
	8-bit mode		

Table 25-1. Standard 4.5 Supported Features (continued)

Feature	Support	Limitation	Comment
Support density	No hardware limitation for density support	Limitation can come from file system (32 GiB).	
Simple boot (CMD, alternate boot)	Yes		Device ROM code supports the following boot modes: 1. Alternate Boot 2. Raw (UDA) Boot 3. File System For more information about boot modes, see *Memory Booting*. in *Initialization.*
Sleep mode	Yes		
Reliable write	Yes		
Secure write protection	Yes		
Hardware reset	No		Use the reset command if hardware reset is needed.
Secure memory block (RPMB)	Yes		
Partition feature	Yes		
Secure erase	Yes		
DDR interface (bandwidth)	Up to 96 MBps in DDR mode – 8-bit		
High-priority interrupt (read while write)	Yes		
Background operation	Yes		
Enhanced reliable write	Yes		
HS200 mode	Yes		

Table 25-2 shows the supported by each MMCi host controller transfer rates and functionalities (SD, eMMC and SDIO).

Table 25-2. MMCi Supported Transfer Rates and Functionalities

	SD[1]	eMMC	SDIO
MMC1	Yes (Up to SDR104 mode)	Yes (Up to High Speed DDR mode; timings optimized for SD)	Yes (timings optimized for SD)
MMC2	Yes (Up to SDR25 mode; timings optimized for eMMC)	Yes (Up to HS200 mode)	Yes (timings optimized for eMMC)
MMC3	Yes (Up to SDR50 mode)	Yes (Up to High Speed SDR mode; timings optimized for SD/ SDIO)	Yes (Up to SDR50 mode)
MMC4	Yes (Up to SDR25 mode)	Yes (Up to High Speed SDR mode; timings optimized for SD/ SDIO)	Yes (Up to SDR25 mode)

(1) 3.3V IO required for initial SD Card communication.

25.2 eMMC/SD/SDIO Environment

One eMMC/SD/SDIO host controller can support one eMMC memory card, one SD memory card, or one SDIO card.

Other combinations (for example, two SD cards, one eMMC, and one SD card) are not supported through a single controller. The following is supported:

- The MMC1 instance supports 1- and 4-bit data transfers. (mainly used for connection with SD cards)
- The MMC2 instance supports 1-, 4-, and 8-bit data transfers. (mainly used for connection with eMMC cards)
- The MMC3 instance supports 1-, 4-, and 8-bit data transfers. (mainly used for connection with SDIO cards)
- The MMC4 instance supports 1- and 4-bit data transfers. (mainly used for connection with SDIO cards)

25.2.1 eMMC/SD/SDIO Functional Modes

25.2.1.1 eMMC/SD/SDIO Connected to an eMMC, SD, or SDIO Card

Figure 25-2 shows the eMMC/SD/SDIOi host controller (where i = 1 to 4) connected to an eMMC, SD, or SDIO card and its related external connections.

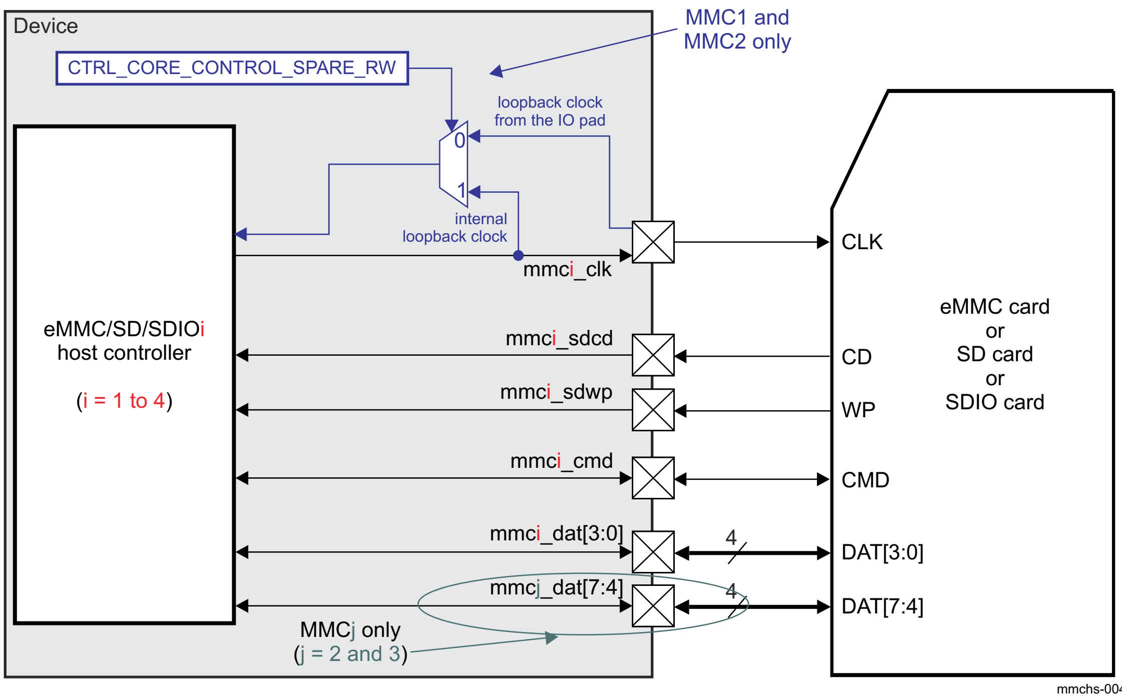

Figure 25-2. eMMC/SD/SDIOi Controller Connected to an eMMC, SD, or SDIO Card (where i = 1 to 4)

Table 25-3 describes the eMMC/SD/SDIOi host controller I/O's (where i = 1 to 4).

Table 25-3. Description of eMMC/SD/SDIOi host controller I/O's (where i = 1 to 4)

Instance	Signal name	I/O[1]	Description	Reset Value[2]
MMC1	mmc1_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc1_cmd	I/O	Command line	Hi-Z[3]
	mmc1_dat[3:0]	I/O	Data signals	Hi-Z[3]
	mmc1_sdcd	I	Card insertion/removal detection signal	Hi-Z
	mmc1_sdwp	I	Write protect detection signal	Hi-Z

Table 25-3. Description of eMMC/SD/SDIOi host controller I/O's (where i = 1 to 4) (continued)

Instance	Signal name	I/O[(1)]	Description	Reset Value[(2)]
MMC2	mmc2_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc2_cmd	I/O	Command line	Hi-Z[(3)]
	mmc2_dat[7:0]	I/O	Data signals	Hi-Z[(3)]
	mmc2_cd	I	Card insertion/removal detection signal	Hi-Z
	mmc2_wp	I	Write protect detection signal	Hi-Z
MMC3	mmc3_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc3_cmd	I/O	Command line	Hi-Z[(3)]
	mmc3_dat[7:0]	I/O	Data signals	Hi-Z[(3)]
	mmc3_cd	I	Card insertion/removal detection signal	Hi-Z
	mmc3_wp	I	Write protect detection signal	Hi-Z
MMC4	mmc4_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc4_cmd	I/O	Command line	Hi-Z[(3)]
	mmc4_dat[3:0]	I/O	Data signals	Hi-Z[(3)]
	mmc4_cd	I	Card insertion/removal detection signal	Hi-Z
	mmc4_wp	I	Write protect detection signal	Hi-Z

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High Impedance
(3) Initialized as input upon reset

Note

For mmc2_clk, mmc3_clk and mmc4_clk signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers must be set to 0x1 by software. This is because the eMMC/SD/SDIO controller uses the input from the pad as loopback clock, which the controller can use for read capture depending on the mode it is in.

Note

On SR2.0 devices the internal PU/PD resistors on pads mmc2_dat[7:0] can be permanently disabled. For more information, see *Permanent PU/PD disabling (SR 2.0 only)* in *Control Module*.

25.2.2 Protocol and Data Format

The bus protocol between the eMMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

- Command: A command starts an operation. The command is transferred serially from the eMMC/SD/SDIO host controller to the card on the CMD line.
- Response: A response is an answer to a command. The response is sent from the card to the eMMC/SD/SDIO host controller. It is transferred serially on the CMD line.
- Data: Data are transferred from the eMMC/SD/SDIO host controller to the card or from a card to the eMMC/SD/SDIO host controller using the data lines.
- Busy: The DAT[0] signal is maintained low by the card as far as it is programming the data received.

- CRC status: The CRC result is sent by the card through the DAT[0] line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on DAT[0]. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on DAT[0] and starts the data programming procedure.

25.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO cards, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

Figure 25-3 and Figure 25-4 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmci_cmd line.

Note

Stream commands are supported only by MMC cards.

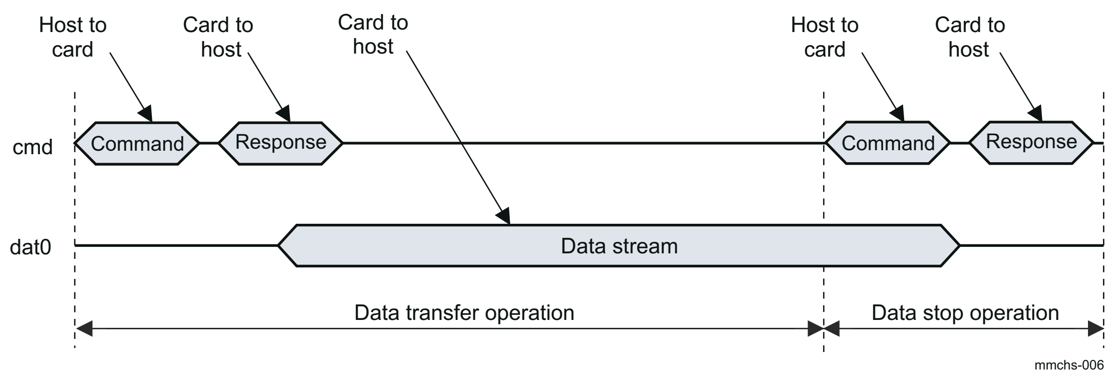

Figure 25-3. Sequential Read Operation (MMC Cards Only)

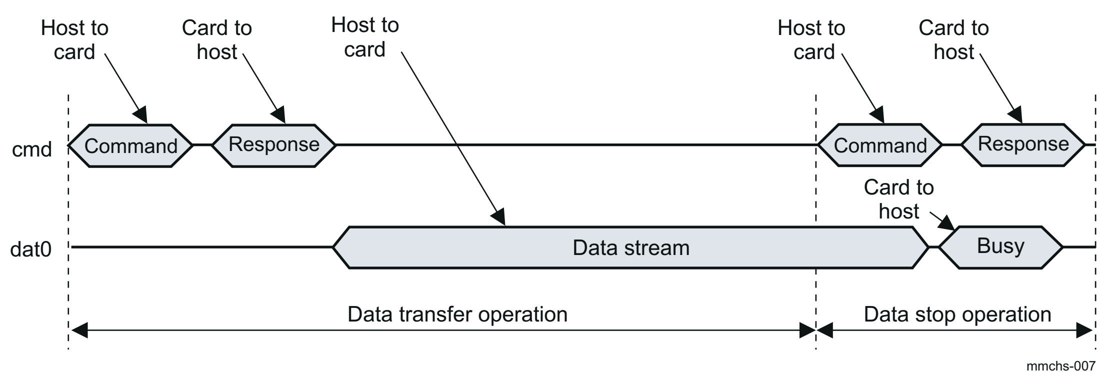

Figure 25-4. Sequential Write Operation (MMC Cards Only)

Figure 25-5 and Figure 25-6 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmci_cmd line. These operations are available for all kinds of cards.

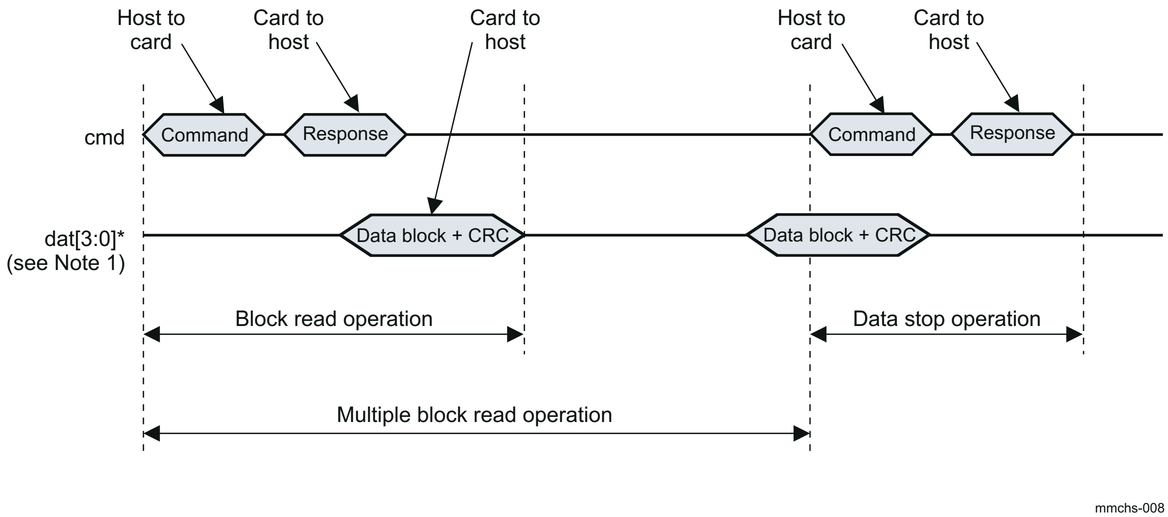

Figure 25-5. Multiple Block Read Operation

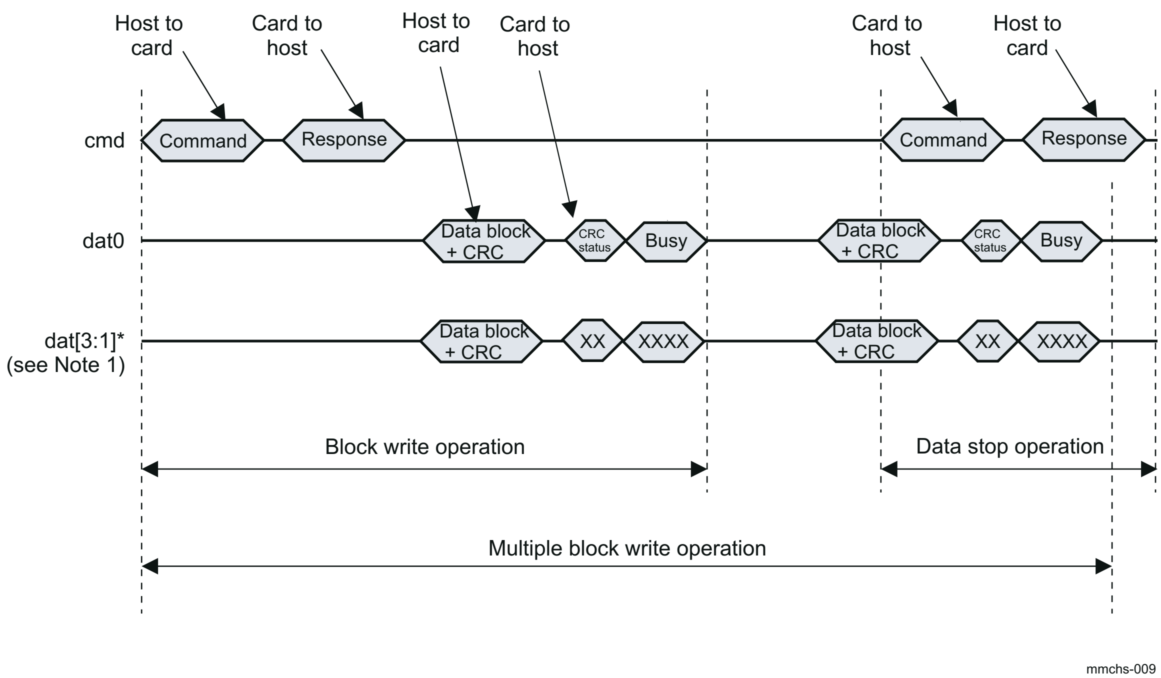

Figure 25-6. Multiple Block Write Operation With Card Busy Signal

Note

- The card busy signal is not always generated by the card; refer to Figure 25-5 and Figure 25-6, that show a particular case.
- Software must perform a software reset (set the MMCi.MMCHS_SYSCTL[26] SRD bit to 0x1) after a data time-out to ensure that CLK is stopped.
- For multiblock transfer, and especially for MMC cards, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

25.2.2.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 25-7).

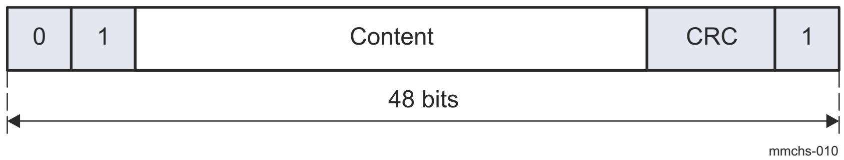

Figure 25-7. Command Token Format

Coding Scheme for Response Token

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SD]) and the content is protected by 7-bit CRC checksum (see Figure 25-8 and Figure 25-9). Depending on the type of commands sent to the card, the MMCHS_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see Table 25-4). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification*.

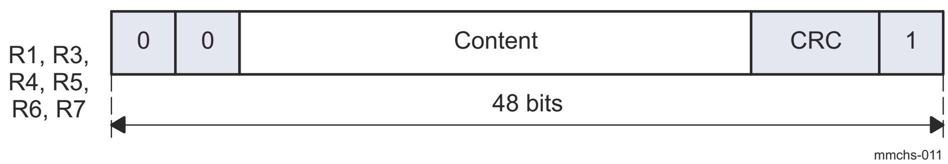

Figure 25-8. Response Token Format (R1, R3, R4, R5, R6, R7)

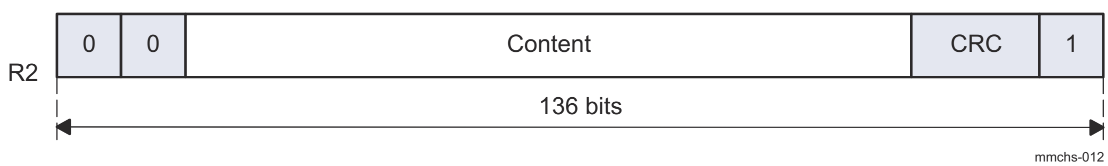

Figure 25-9. Response Token Format (R2)

Table 25-4. Relationship Between Configuration and Name of Response Type

Response Type MMCi.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCi.MMCHS_CMD[20] CICE	CRC Check Enable MMCi.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5, (R7 for SD cards)
11	1	1	R1b, R5b

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 25-10 through Figure 25-12).

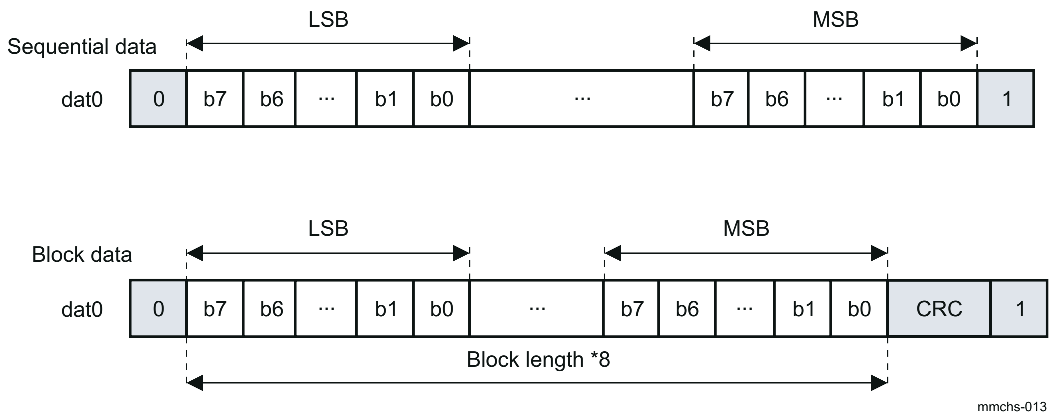

Figure 25-10. Data Token Format for 1-Bit Transfers

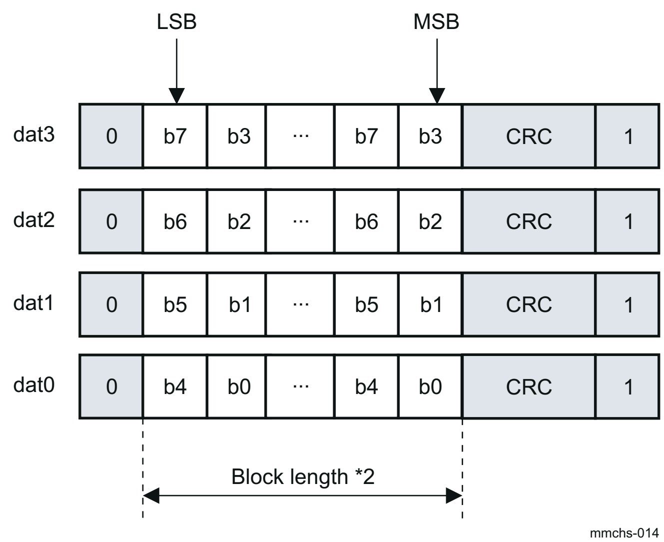

Figure 25-11. Data Token Format for 4-Bit Transfers

25.3 eMMC/SD/SDIO Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 25-13 shows the integration of the MMC1 and MMC2 controllers which are connected to both L3_MAIN and L4_PER1 interconnects and are able to act as master or slave. In master mode the L3_MAIN interconnect is used. In slave mode the L4_PER1 interconnect is used.

Figure 25-14 shows the integration of the MMC3 and MMC4 controllers which are connected to the L4_PER1 interconnect and act as a slave only.

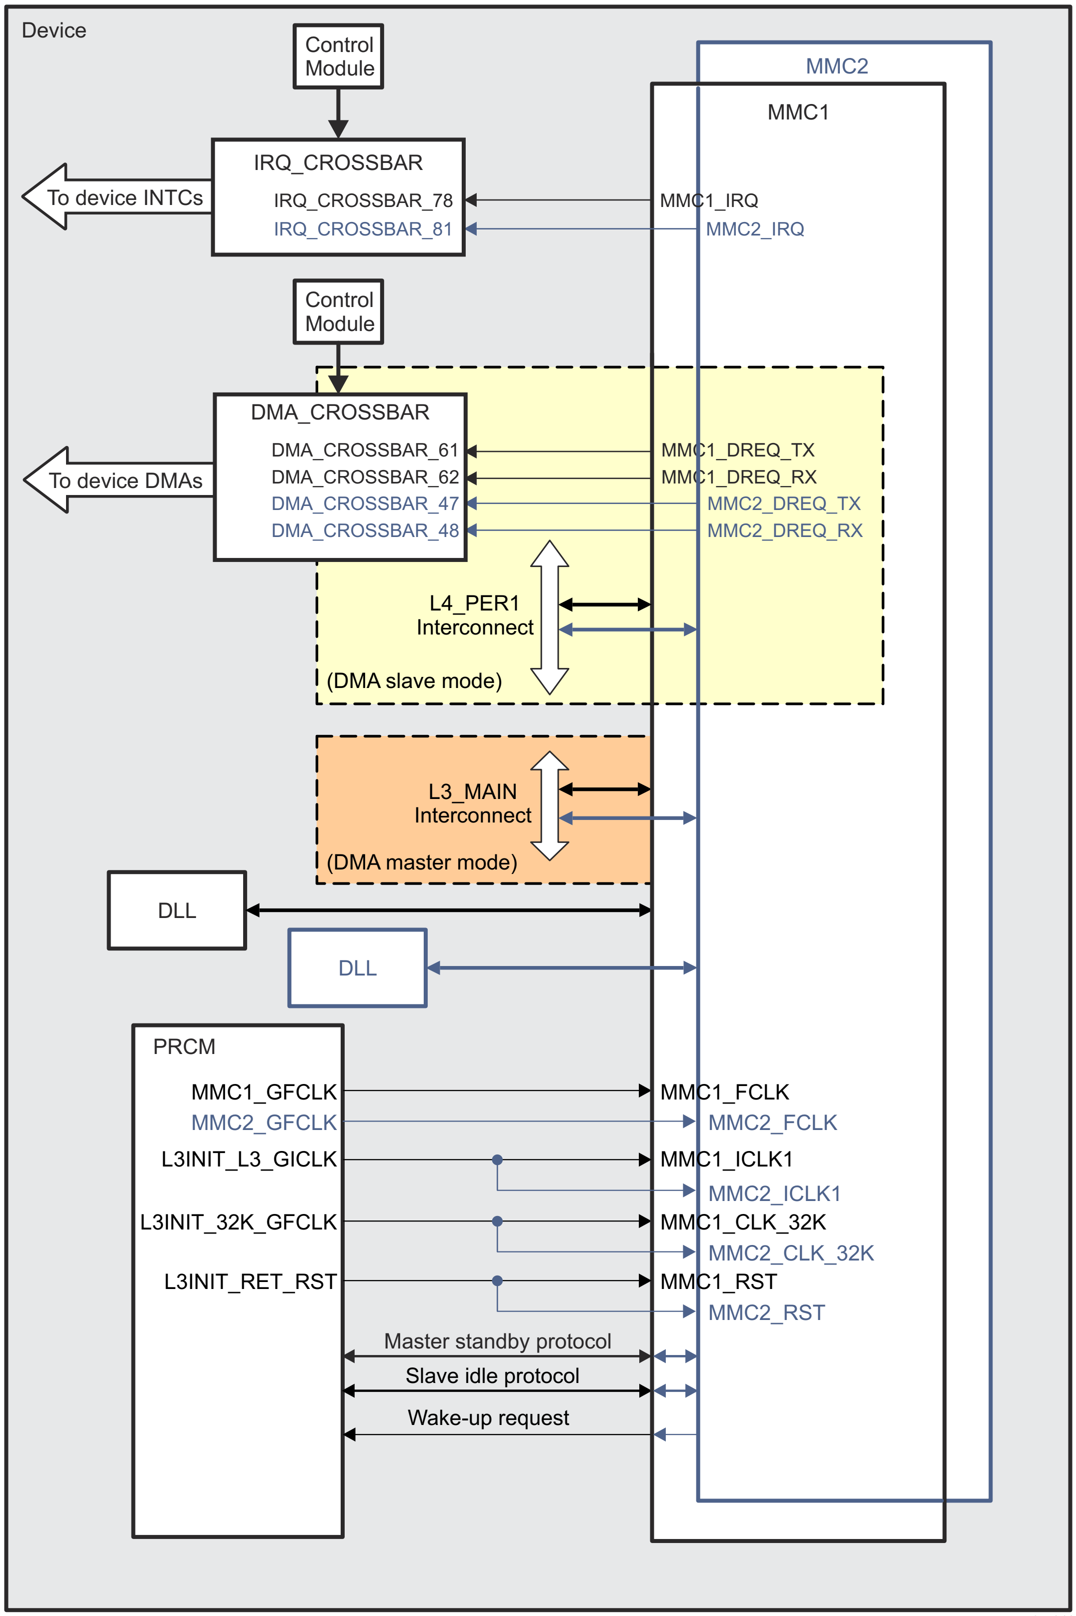

Figure 25-13. Integration of MMC1 and MMC2 Controllers – Master and Slave Capable

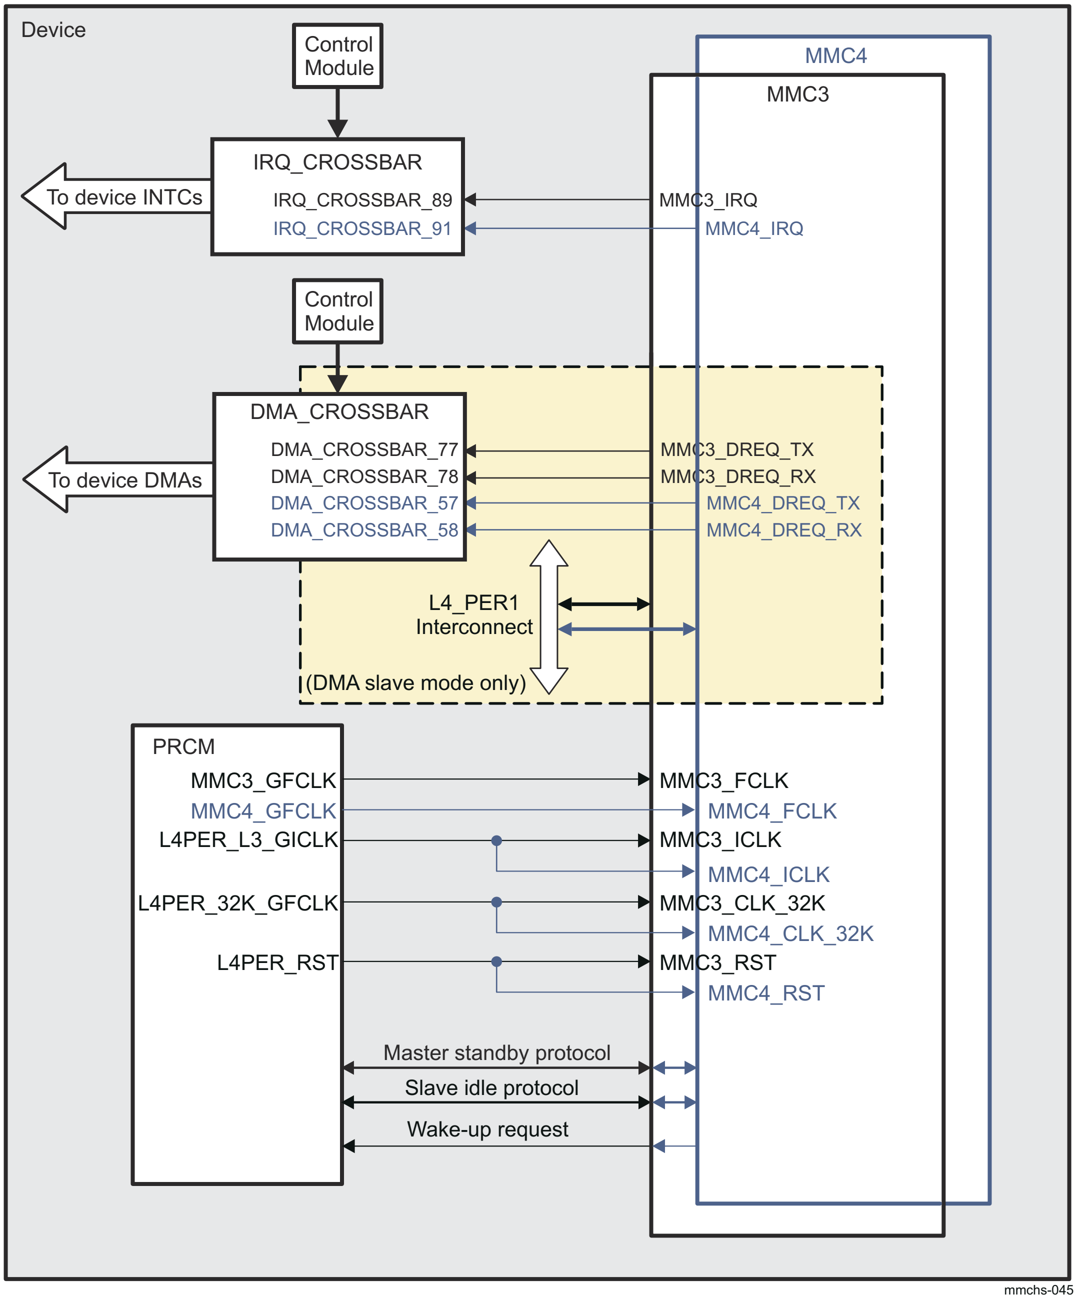

Figure 25-14. Integration of MMC3 and MMC4 Controllers – Slave Capable Only

Note

For more information about the slave idle protocol and the wake-up request, see *Device Power-Management Architecture Building Blocks*, in *Power, Reset, and Clock Management*.

Table 25-5 through Table 25-7 summarize the integration of the module in the device.

Table 25-5. MMC Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
MMC1	PD_COREAON	L3_MAIN L4_PER1

	MMC2_DREQ_RX	DMA_CROSSBAR_48	DMA_SYSTEM_DREQ_47	MMC2 DMA RX
			DMA_EDMA_DREQ_47	
MMC3	MMC3_DREQ_TX	DMA_CROSSBAR_77	DMA_SYSTEM_DREQ_76	MMC3 DMA TX
	MMC3_DREQ_RX	DMA_CROSSBAR_78	DMA_SYSTEM_DREQ_77	MMC3 DMA RX
MMC4	MMC4_DREQ_TX	DMA_CROSSBAR_57	DMA_SYSTEM_DREQ_56	MMC4 DMA TX
			DMA_EDMA_DREQ_56	
	MMC4_DREQ_RX	DMA_CROSSBAR_58	DMA_SYSTEM_DREQ_57	MMC4 DMA RX
			DMA_EDMA_DREQ_57	

Note

The “**Default Mapping**” column in Table 25-7 *MMC Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.
For more information about the device DMA_SYSTEM module, see *System DMA*.
For more information about the device EDMA module, see *Enhanced DMA*.

Note

- For a description of the interrupt source, see *Interrupt Requests*.
- For a description of the DMA source, see *DMA Modes*.

25.4 eMMC/SD/SDIO Functional Description

25.4.1 Block Diagram

Figure 25-15 is a block diagram of the eMMC/SD/SDIOi host controller.

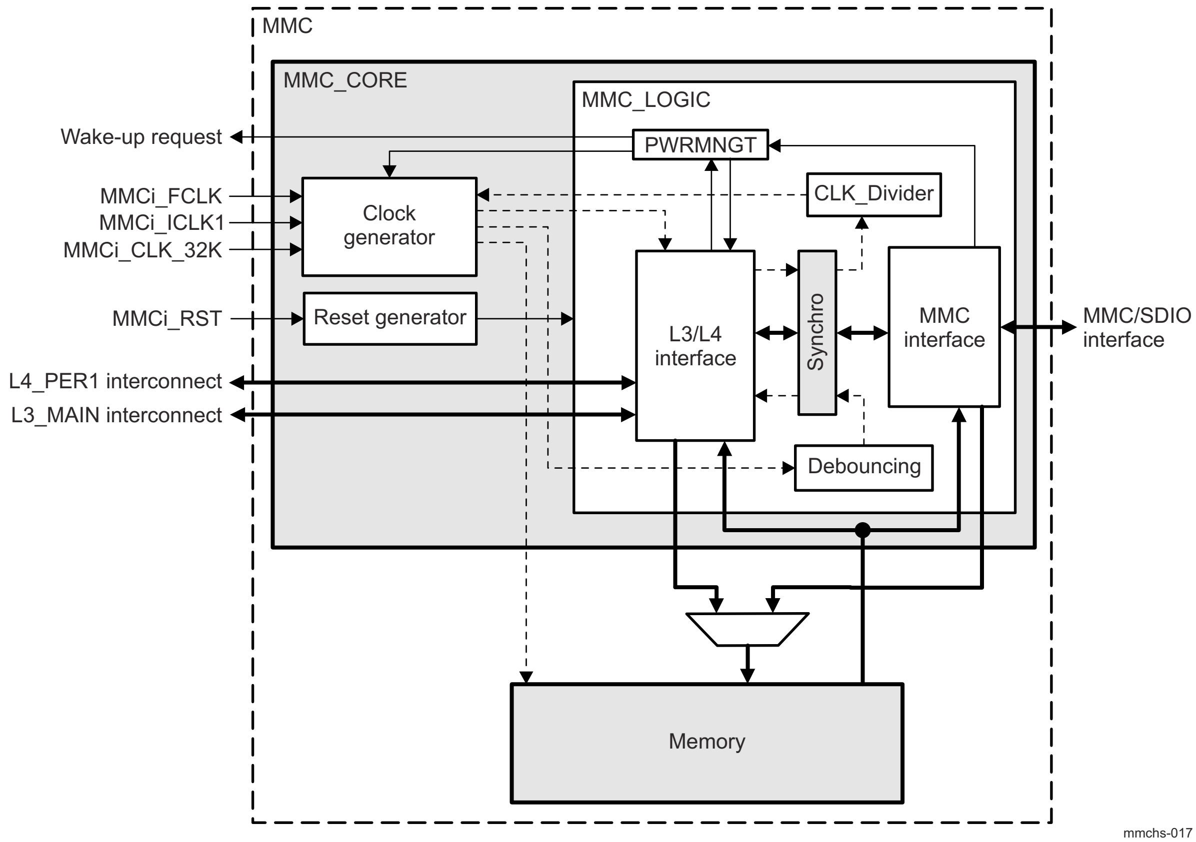

Figure 25-15. eMMC/SD/SDIO Diagram

25.4.2 Resets

25.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see Table 25-6 for more information about reset signals).

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a hardware reset.

Note

The functional clock (MMCi_FCLK) and interface clock (MMCi_ICLK) must be provided to the module to allow the RESETDONE status bit to be set.

The debounce clock (MMCi_32K) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

25.4.2.2 Software Reset

The module is reinitialized by software through the MMCi.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same effect on the module logic as the hardware signal (MMCi_RST), with the following exceptions:

- Debounce logic

- MMCi.MMCHS_PSTATE, MMCi.MMCHS_CAPA, and MMCi.MMCHS_CUR_CAPA registers (see the corresponding register description)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by hardware. The MMCi.MMCHS_SYSCTL[24] SRA bit has the same action on the design as the SOFTRESET bit.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS_SYSCTL[26] SRD
- MMCi.MMCHS_SYSCTL[25] SRC

These 2 reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When these bits are set to 1, a reset process is automatically released when the reset completes:

- The MMCi.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines (FSMs) and status management that handle data transfers on the interface and functional sides.
- The MMCi.MMCHS_SYSCTL[25] SRC bit resets all FSMs and status management that handle command transfers on the interface and functional sides.

25.4.3 Power Management

The eMMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The eMMC/SD/SDIO host controller is compliant with the handshake protocol of the power, reset, and clock management (PRCM) module.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (card insertion, card removal, an interrupt from a SDIO card).
- A transaction on the MMC/SD/SDIO interface starts.

When a card removal event is detected the eMMC/SD/SDIO host controller automatically clears MMCHS_HCTL[8] SDBP and MMCHS_SYSCTL[2] CEN bits. Then it enters into low power state with auto gated interface clock even if MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 0. The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCi_ICLK and MMCi_FCLK clocks provided to the eMMC/SD/SDIO host controller are switched off upon a PRCM module request. They are switched back upon module request.

The eMMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- IDLE request from the system power manager
- Idle acknowledgment from the eMMC/SD/SDIO host controller
- Wake-up request from the eMMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The eMMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.

- 0x1: No-idle mode. The eMMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The eMMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.
- 0x3: Smart-idle wake-up-capable mode. The eMMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when it is in IDLE state (related to IRQ or DMA requests)

During the smart-idle mode period, the eMMC/SD/SDIO host controller acknowledges that the MMCi_ICLK and MMCi_FCLK clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

The debounce clock is used to debounce the signals related to the card insertion and the card removal that are also sources of wake-up in idle mode. The debounce clock must never be switched off by the system power manager in order to detect card removal in functional mode, and detect wake-up in idle mode.

Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2 or 0x3.

The eMMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an IDLE request, according to its internal activity.

The eMMC/SD/SDIO host controller acknowledges the IDLE request from the PRCM after ensuring the following:

- The current multi- or single-block transfer is complete.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the DATA[1] signal.

As long as the eMMC/SD/SDIOi controller does not acknowledge the IDLE request, if an event occurs, the eMMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the IDLE request from the PRCM module.

As soon as the eMMC/SD/SDIOi controller acknowledges the IDLE request from the PRCM module:

- If smart-idle mode: The module does not assert any new interrupt or DMA request.
- If smart-idle wake-up-capable mode: The module may generate wake-up events related to an interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when both the MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit and one of the three bits MMCi.MMCHS_HCTL[26] REM, MMCi.MMCHS_HCTL[25] INS, MMCi.MMCHS_HCTL[24] IWE are set to 0x1.

The corresponding interrupt status enable bits must also be set before going in idle mode. Setting one of the following bits:

- MMCi.MMCHS_IE[8] CIRQ_ENABLE
- MMCi.MMCHS_IE[7] CREM_ENABLE
- MMCi.MMCHS_IE[6] CINS_ENABLE

to 0x1 enables the wakeup event detection. The source of wakeup can be identified after idle mode exiting by reading one of the corresponding MMCHS_STAT bits.

The wakeup is generated only in smart-idle mode, when the module is in idle mode.

Table 25-8 lists the supported cases in smart-idle mode.

Table 25-8. Smart-Idle Mode and Wake-Up Capabilities

Mode	MMCi_ICLK Clock	MMCi_FCLK Clock	Wake-Up Event
Card interrupt	May be switched off[(1)]	May be switched off[(1)]	The module sends an asynchronous wake-up request when a card interrupt on the DATA[1] signal is detected.
Card insertion	May be switched off[(1)]	May be switched off[(1)]	The module sends an asynchronous wake-up request when card insertion is detected.
Card removal	May be switched off[(1)]	May be switched off[(1)]	The module sends an asynchronous wake-up request when card removal is detected.

(1) The eMMC/SD/SDIOi host controller assumes that both clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

Transition From Smart-Idle Mode to Normal Mode

The eMMC/SD/SDIO host controller detects the end of the idle period when the PRCM module deasserts the IDLE request.

For the wake-up event, there is a corresponding interrupt status in the MMCi.MMCHS_STAT register. The eMMC/SD/SDIOi host controller operates the conversion between the wake-up and interrupt (or DMA request) upon exit from smart-idle mode, if the associated enable bit is set in the MMCi.MMCHS_ISE register.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MMCi.MMCHS_HCTL and MMCi.MMCHS_ISE registers. The overall consistency must be ensured by software.

One of the bits MMCHS_STAT[8] CIRQ, MMCHS_STAT[7] CREM, MMCHS_STAT[6] CINS in the interrupt status register is updated with the event that caused the wake-up when one of the bits MMCHS_IE[8] CIRQ_ENABLE, MMCHS_IE[7] CREM_ENABLE, MMCHS_IE[6] CINS_ENABLE is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCi.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the IDLE request from the PRCM module is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode in which the eMMC/SD/SDIOi host controller responds unconditionally to the IDLE request from the PRCM module. Moreover, in this mode, the eMMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines if they are asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCi.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCi_ICLK and MMCi_FCLK can be switched off.

> **CAUTION**
>
> In force-idle mode, an IDLE request from the PRCM module during a command or a data transfer can lead to an unexpected and unpredictable result.
> When the module is idle, any access to the module generates an error as long as the MMCi_ICLK clock is alive.

The module exits force-idle mode when the PRCM module deasserts the IDLE request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

Standby Mode

The eMMC/SD/SDIO host controller also provides standby information to the system power manager if the generic parameter MMCHS_HL_HWINFO[0] MADMA_EN is set to 1.

The eMMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- Standby request from the eMMC/SD/SDIO host controller
- Wait acknowledgement from the PRCM module

The standby request varies according to the MMCi.MMCHS_SYSCONFIG[13:12] STANDBYMODE bit field:

- 0x0: Force-standby. The eMMC/SD/SDIO host controller sends the standby request to the system power manager unconditionally.
- 0x1: No-standby. The eMMC/SD/SDIO host controller does not generate any standby request to the system power manager and behaves normally
- 0x2: Smart-standby. The eMMC/SD/SDIO host controller sends the standby request to the system power manager according to the master L3 interface state.

Power Pad Control

The eMMC/SD/SDIO host controller has the ability to reduce the pad power leakage when no transfer is sent through the pad. According to the MMCHS_CON[15] PADEN there are two different pad power management modes: automatic and manual.

If MMCHS_CON[15] PADEN is set to 1, pads CLK, CMD, DAT[0] and DATA[i] (where i = 2 through 7) are always powerd on.

If MMCHS_CON[15] PADEN is set to 0, the power for pads CLK, CMD, DAT[0] and DATA[i] (where i = 2 through 7) is "ON" only when there is a transfer on going. This is automatically managed by an internal state machine of the eMMC/SD/SDIO host controller.

The DATA[1] pad active state is controlled through MMCHS_CON[11] CTPL in order to detect SDIO asynchronous interrupt when there is no transaction.

The delay between pad power "ON" and the command transmission is controlled through the MMCHS_PWCNT register which act as a programmable counter. It is also used to delay the pad power "OFF" after the end of transmission. By default this counter is reset which means that no additional delay is added. But there is approximately 6-7 clock cycles margin between pad power "ON" and real start of the command due to an internal state machine of the eMMC/SD/SDIO host controller.

Note

The MMCHS_PWCNT register is considered as static. No dynamic configuration during the transfer is supported. This results in an unpredictable behavior.

Local Power Management

Table 25-9 describes the power-management features available for the eMMC/SD/SDIOi modules.

Note

For information about source clock gating and a description of the sleep/wake-up transitions, see *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.

Table 25-9. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	MMCHS_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module by gating the MMCi_ICLK clock upon the interface activity, or gating the MMCi_FCLK clock upon the internal activity.

Table 25-9. Local Power-Management Features (continued)

Feature	Registers	Description
Slave-idle modes	MMCHS_SYSCONFIG[3:4] SIDLEMODE	Force-idle, No-idle, Smart-idle and Smart-idle wake-up-capable modes are available.
Clock activity	MMCHS_SYSCONFIG[8:9] CLOCKACTIVITY	For configuration details, see Table 25-10.
Master standby modes	MMCHS_SYSCONFIG[12:13] STANDBYMODE	Force-standby, No-standby and Smart-standby modes are available.
Global wake-up enable	MMCHS_SYSCONFIG[2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	MMCHS_HCTL register	This register holds one active-high enable bit per event source that is able to generate a wake-up signal.

Table 25-10. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State	Wake-Up Events
	MMCi_ICLK	MMCi_ FCLK		
00	OFF	OFF	None	Card interrupt, Card insertion, Card removal
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMCi clock PRCM control bits. For a description of the Clock activity feature, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

25.4.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS_IE register enable or disable the automatic update of the MMCi.MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS_ISE register enable or disable the transmission of an interrupt request on the interrupt line MMCi_IRQ on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the eMMC/SD/SDIOi host controller updates the status bit) in the MMCi.MMCHS_STAT register. If a mask is later applied on the interrupt in the MMCi.MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS_STAT register and the corresponding mask is removed from the MMCi.MMCHS_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS_STAT register and the eMMC/SD/SDIOi host controller does not transmit an interrupt request.

Note

If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the eMMC/SD/SDIOi host controller waits for the service of the interrupt without updating the status MMCi.MMCHS_STAT register or transmitting an interrupt request.

Table 25-11 lists the event flags, and their mask, that can cause module interrupts.

Table 25-11. Events

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[29] BADA	MMCHS_IE[29] BADA_ENABLE	MMCi_IRQ	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE = 0). This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_PSTATE[10] BWE = 0).
MMCHS_STAT[28] CERR	MMCHS_IE[28] CERR_ENABLE	MMCi_IRQ	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the auto CMD12 command.
MMCHS_STAT[26] TE	MMCHS_IE[26] TE_ENABLE	MMCi_IRQ	Tuning Error. This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure. The Tuning Error is with higher priority than the other error interrupts generated during data transfer.
MMCHS_STAT[25] ADMAE	MMCHS_IE[25] ADMAE_ENABLE	MMCi_IRQ	ADMA error. This bit is set when the host controller detects errors during an ADMA-based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA error status register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.
MMCHS_STAT[24] ACE	MMCHS_IE[24] ACE_ENABLE	MMCi_IRQ	Auto CMD12 error and Auto CMD23 error. This bit is set automatically when one of the bits MMCHS_AC12[4:0] changes from 0 to 1.
MMCHS_STAT[22] DEB	MMCHS_IE[22] DEB_ENABLE	MMCi_IRQ	Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode.
MMCHS_STAT[21] DCRC	MMCHS_IE[21] DCRC_ENABLE	MMCi_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position 010 token during a block write command.
MMCHS_STAT[20] DTO	MMCHS_IE[20] DTO_ENABLE	MMCi_IRQ	Data time-out error. This bit is set automatically according to the following conditions: • Busy time-out for R1b, R5b response type • Busy time-out after write CRC status • Write CRC status time-out • Read data time-out

Table 25-11. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[19] CIE	MMCHS_IE[19] CIE_ENABLE	MMCi_IRQ	Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD[20] CICE bit.
MMCHS_STAT[18] CEB	MMCHS_IE[18] CEB_ENABLE	MMCi_IRQ	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
MMCHS_STAT[17] CCRC	MMCHS_IE[17] CCRC_ENABLE	MMCi_IRQ	Command CRC error. This bit is set automatically when a CRC7 error occurs in the command response. CRC check is enabled through the MMCHS_CMD[19] CCCE bit.
MMCHS_STAT[16] CTO	MMCHS_IE[16] CTO_ENABLE	MMCi_IRQ	Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles.
MMCHS_STAT[15] ERRI	MMCHS_IE[15] ERRI_ENABLE	MMCi_IRQ	Error interrupt. If any of the bits in the error interrupt status register (MMCHS_STAT[31:16]) are set, this bit is set to 1.
MMCHS_STAT[10] BSR	MMCHS_IE[10] BSR_ENABLE	MMCi_IRQ	Boot status received interrupt. This bit is set automatically when the MMCHS_CON[18] BOOT_CF0 bit is set to 0x1 or 0x2 and a boot status is received on the dat0 line. This interrupt is useful only for the MMC card.
MMCHS_STAT[8] CIRQ	MMCHS_IE[8] CIRQ_ENABLE	MMCi_IRQ	Card interrupt. This bit is used only for SD, SDIO, and CE-ATA cards. In 1-bit mode, the interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, the interrupt source is sampled during the interrupt cycle. In CE-ATA mode, the interrupt source is detected when the card drives the CMD line to 0 during one cycle after data transmission end.
MMCHS_STAT[7] CREM	MMCHS_IE[7] CREM_ENABLE	MMCi_IRQ	Card removal. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 1 to 0.
MMCHS_STAT[6] CINS	MMCHS_IE[6] CINS_ENABLE	MMCi_IRQ	Card insertion. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 0 to 1.
MMCHS_STAT[5] BRR	MMCHS_IE[5] BRR_ENABLE	MMCi_IRQ	Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH must empty the buffer by reading it.
MMCHS_STAT[4] BWR	MMCHS_IE[4] BWR_ENABLE	MMCi_IRQ	Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the MMCHS_BLK[10:0] BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer.
MMCHS_STAT[3] DMA	MMCHS_IE[3] DMA_ENABLE	MMCi_IRQ	DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completes.
MMCHS_STAT[2] BGE	MMCHS_IE[2] BGE_ENABLE	MMCi_IRQ	Block gap event. When a stop at the block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.

Table 25-11. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[1] TC	MMCHS_IE[1] TC_ENABLE	MMCi_IRQ	Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request (MMCHS_HCTL[16] SBGR). • In read mode: This bit is automatically set when a read transfer completes (MMCHS_PSTATE[9] RTA). • In write mode: This bit is automatically set when the DAT line use completes (MMCHS_PSTATE[2] DLA).
MMCHS_STAT[0] CC	MMCHS_IE[0] CC_ENABLE	MMCi_IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt.

Note

To send an interrupt request to the MMCi_IRQ line, the mask/unmask bit must be set in the MMCi.MMCHS_IE and MMCi.MMCHS_ISE registers.

The eMMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

25.4.4.1 Interrupt-Driven Operation

An interrupt-enable bit must be set in the MMCi.MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the MMCi.MMCHS_STAT register to identify which event occurred.
2. Write 1 into the corresponding bit of the MMCi.MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

Note

In the MMCi.MMCHS_STAT register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The MMCi.MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS_IE[8] CIRQ_ENABLE bit (set to 0x0), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The MMCi.MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in the MMCi.MMCHS_STATregister (bits 31 through 16) are cleared.

25.4.4.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

Note

See the previous note concerning clearing of the CIRQ and ERRI bits.

25.4.4.3 Asynchronous Interrupt

Asynchronous interrupt is defined in *SDIO Card Specification version 3.00, part E*. This interrupt is effective in 4-bit mode and is generated without SD clock. Asynchronous interrupt period is defined in the synchronous interrupt period after the last data block and until a next command is received.

Asynchronous interrupt period in a multiple block write operation.

If MMCHS_CAPA[29] AIS is set to 0, writing to MMCHS_AC12[30] AI_ENABLE is ignored. This bit is set to 0. A synchronous interrupt period starts two clocks after the last data block. If MMCHS_AC12[30] AI_ENABLE is set to 1, the asynchronous interrupt period starts four clocks after the start of the synchronous interrupt period. Four clocks after the start bit of the next command, the asynchronous interrupt period ends and goes back to the synchronous interrupt period.

25.4.5 DMA Modes

Two DMA management modes can be used to load data from memory to the internal buffer of the controller (or vice versa). These modes are exclusive and depend on the module integration.

- DMA master mode:

  DMA master mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 1. In this case, the controller has direct access to data using a specific algorithm called ADMA2 (prevents the system from being interrupted). Data are exchanged using the L3_MAIN master interface, which supports burst accesses to maximize throughput.

  Note

  This mode is supported only by modules connected to the L3_MAIN interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.1, *eMMC/SD/SDIO Overview*.

  This mode is available for modules MMC1 and MMC2.

- DMA slave mode:

  DMA slave mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMCi_DMA_TX and MMCi_DMA_RX).

  Note

  This mode is the only mode supported by modules that are not connected to the L3_MAIN interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.1, *eMMC/SD/SDIO Overview*.

  This mode is available for all MMC modules.

25.4.5.1 Master DMA Operations

The eMMC/SD/SDIOi host controller has direct access to the internal data. This feature is called advanced DMA (ADMA). It follows a specific algorithm (ADMA2) defined by an instruction in memory that starts at an address previously loaded in the MMCHS_ADMASAL register before any data command issued to the MMC card. Only 32-bit address spacing is supported by the controller for data storage.

Note

This mode is supported only by modules connected to the L3_MAIN interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.1, *eMMC/SD/SDIO Overview*.

These instructions must be loaded by software in a 32-bit-addressed descriptor table in system memory, as shown in Figure 25-16. In this case the MMCHS_ADMASAL register is used as the program address pointer

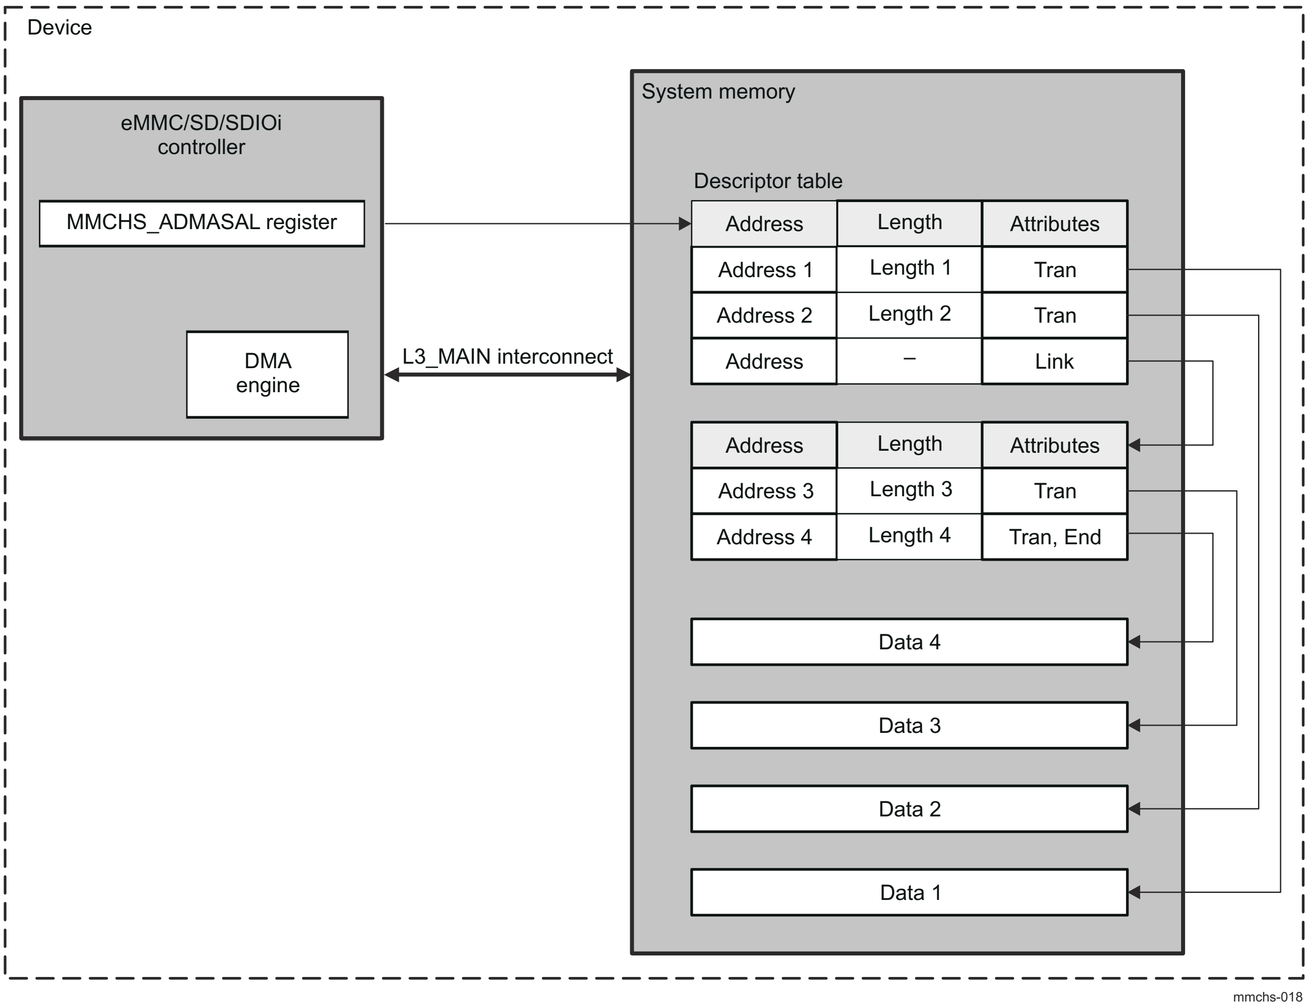

Figure 25-16. ADMA Block Diagram Overview

25.4.5.1.1 Descriptor Table Description

Each descriptor line contains an address, a length, and attributes fields. The attributes define which operation will be processed. Every descriptor line is a 64-bit-wide register that is fetched in the controller using the L3_MAIN master interface, and requires two 32-bit accesses to memory.

Table 25-12 shows the structure of a descriptor line.

Table 25-12. Descriptor Line Overview

Address Field		Length		Reserved		Attributes					
63	32	31	16	15	6	5	4	3	2	1	0
32-bit address		16-bit length		0x0		Act2	Act1	0	Int	Ent	Valid

The attribute of the descriptor line is divided into two parts:

- Attributes[5:4]: The action to be processed by the ADMA engine
- Attributes[3:0]: Additional parameters characterizing the behavior of the ADMA engine

Table 25-13 describes the available actions of a descriptor line.

Table 25-13. Available Actions of a Descriptor Line

Act2	Act1	Symbol	Comment	Operation
0	0	Nop	No operation	Do not execute the current line and go to the next line.
0	1	Rsv	Reserved	Reserved action. Behaves the same as the Nop command.
1	0	Tran	Transfer data	Transfer data of one descriptor line.
1	1	Link	Link descriptor	Link to another descriptor.

Table 25-14 describes the additional parameters of a descriptor line.

Table 25-14. Additional Parameters of a Descriptor Line

Bit	Description
Valid	Valid = 1 indicates that this descriptor line is effective. If Valid = 0, an ADMA error interrupt is generated and the ADMA is stopped. This prevents runaways.
End	End = 1 indicates the end of a descriptor. The transfer-complete interrupt is generated when the operation of the descriptor line is complete.
Int	Int = 1 generates a DMA interrupt when the operation of the descriptor line is complete.

25.4.5.1.2 Requirements for Descriptors

The following sections discuss restrictions and tips on how to correctly configure the descriptors to be used by the ADMA engine.

25.4.5.1.2.1 Data Length

There are three requirements to program descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64 KiB.
- Total length = $Length_1$ + $Length_2$+ $Length_3$ + ... + $Length_n$ must be a multiple of the block size.

If the total length of a descriptor is not a multiple of the block size, data transfer with the ADMA engine may not have been terminated. In this case, the controller returns a data time-out event and the transfer is aborted.

The block count register (the MMCHS_BLK[31:16] NBLK bit field) is defined as 16 bits and limits data transfers to a maximum of 65,535 blocks. If the ADMA data transfer size is less than or equal to the 65,535-block transfer, the block count register can be used. In this case, the total length of the descriptor table must be equivalent to "block size" by "block count." If the ADMA data transfer is greater than 65,535 blocks, the block count register must be disabled by setting the block count enable bit (MMCHS_CMD[1] BCE) to 0. In this case, the length of the data transfer is not designated by the block count but by the descriptor table.

Note

The timing for detecting the last block on the SD bus may differ, which affects control of the read transfer active (MMCHS_PSTATE[9] RTA), write transfer active (MMCHS_PSTATE[8] WTA), and DAT line active (MMCHS_PSTATE[2] DLA) bits. In case of a read operation, more blocks than required may be read from the card. The host driver must ignore an out-of-range error if the read operation is for the last block of the memory area.

25.4.5.1.2.2 Supported Features

The ADMA engine does not support the suspend/resume function. However, the stop and continue functions are available.

When the stop-at-block-gap request (the MMCHS_HCTL[16] SBGR bit) is set during the ADMA operation, the block gap event interrupt is generated when the ADMA is stopped at block gap (the MMCHS_STAT[2] BGE bit). The host controller must stop the ADMA read operation by using read wait or by stopping the SD clock. While stopping ADMA, SD commands cannot be issued.

25.4.5.1.2.3 Error Generation

When an error occurs during an ADMA transfer, the ADMA operation is stopped and the ADMA error interrupt is generated. The ADMA error state field (the MMCHS_ADMAES[1:0] AES bit field) holds the state of the ADMA when it is stopped. Software can identify the erroneous descriptor line by using the following method:

- If the ADMA stopped at ST_FDS state, the ADMA system address register (MMCHS_ADMASAL) points to the erroneous descriptor line.
- If the ADMA stopped at ST_TFR or ST_STOP state, the ADMA system address register points to the descriptor line following the erroneous one.

25.4.5.1.3 Advanced DMA Description

The ADMA is a DMA controller embedded in each eMMC controller. It can be seen as a small sequencer that fetches a descriptor line and executes the corresponding action. The base address of the descriptor table is stored in the MMCHS_ADMASAL register.

Note

Software must write the base address of the descriptor table in the MMCHS_ADMASAL register before the first use of the ADMA engine.

The ADMA program is executed according to descriptor attributes (see Section 25.4.5.1.1, *Descriptor Table Description*) and an FSM, as shown in Figure 25-17.

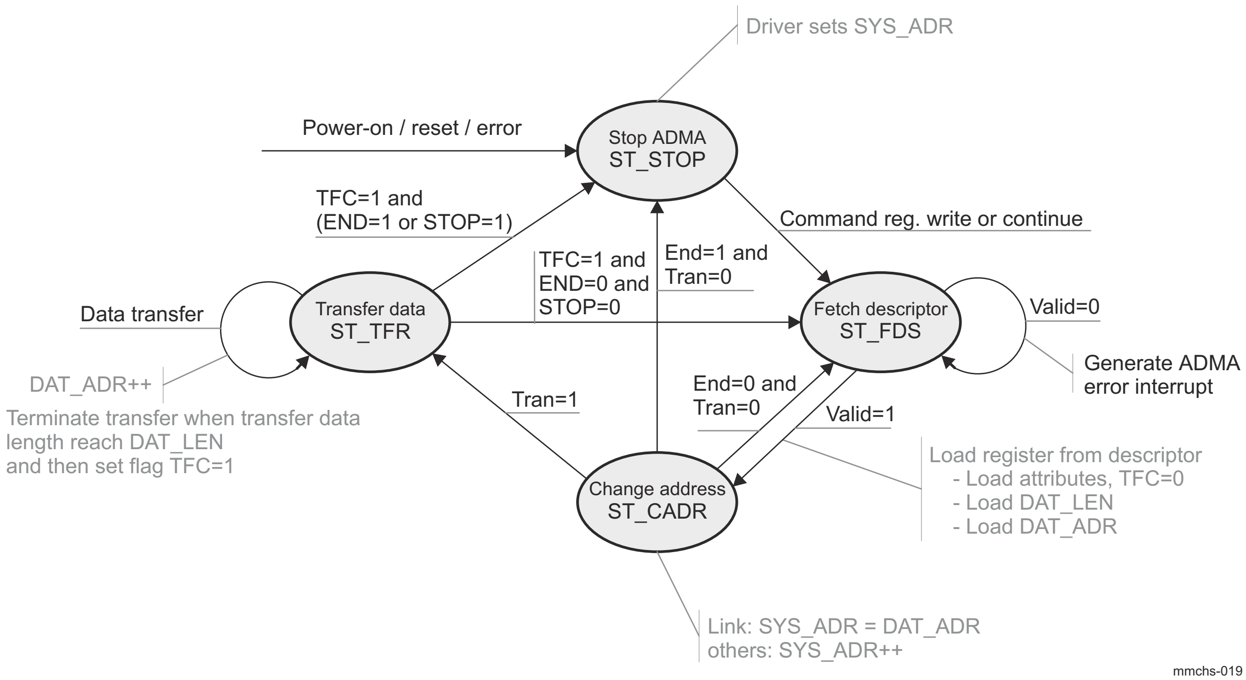

Figure 25-17. ADMA Finite State-Machine

Table 25-15 describes each state of the ADMA FSM.

Table 25-15. ADMA2 States Description

State Name	Operation
ST_FDS (fetch descriptor)	ADMA2 fetches a descriptor line and sets parameters in internal registers. It then goes to ST_CADR state.
ST_CADR (change address)	Link operation loads another descriptor address to the ADMA system address register (MMCHS_ADMASAL). In other operations, the ADMA system address register is incremented to point to the next descriptor line. If End = 0, go to ST_FDS state. **NOTE**: ADMA2 does not stop at this state if some errors occur.
ST_TFR (transfer data)	Data transfer of one descriptor line is executed between system memory and the SD card: • If data transfer continues (End = 0), go to ST_FDS state. • If data transfer completes, go to ST_STOP state.
ST_STOP (stop DMA)	ADMA2 stays in this state in the following cases: • After power-on reset (POR) or software reset • All descriptor data transfers are complete. If a new ADMA operation is stated by writing the command register, go to ST_FDS state.

Table 25-16 gives the description of each symbol used in the ADMA FSM (see Figure 25-17).

Table 25-16. ADMA FSM Symbol Definition

Symbol	Definition
SYS_ADR	ADMA system address register
SYS_ADR++	Point to next descriptor line
DAT_ADR	Data address register (internal)
DAT_LEN	Data length register (internal)
TFC	Transfer complete flag (internal)
STOP	Stop-at-block-gap request

25.4.5.2 Slave DMA Operations

The eMMC/SD/SDIOi host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (more than 1024 bytes) for SD cards, as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

Note

This mode is implied by modules that are not connected to the L3_MAIN interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.4.5.1, *Master DMA Operations*.

The DMA request is issued if the following conditions are met:

- The MMCi.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the CMD line.
- There is enough space in the buffer of the eMMC/SD/SDIOi host controller to write an entire block (BLEN writes).

25.4.5.2.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCi_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN bit field.

MMCi_DMA_RX is deasserted to its inactive level when the a certain device DMA module reads one word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

New DMA requests are internally masked if the DMA has not read exactly BLEN bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of DMA reads is Integer(BLEN / 4) + 1.

The receive buffer never overflows. In multiple block transfers for block sizes larger than 512 bytes, when the buffer becomes full, the mmci_clk clock signal (provided to the card) is momentarily stopped until a certain device DMA or the MPU performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 25-18 shows DMA receive mode.

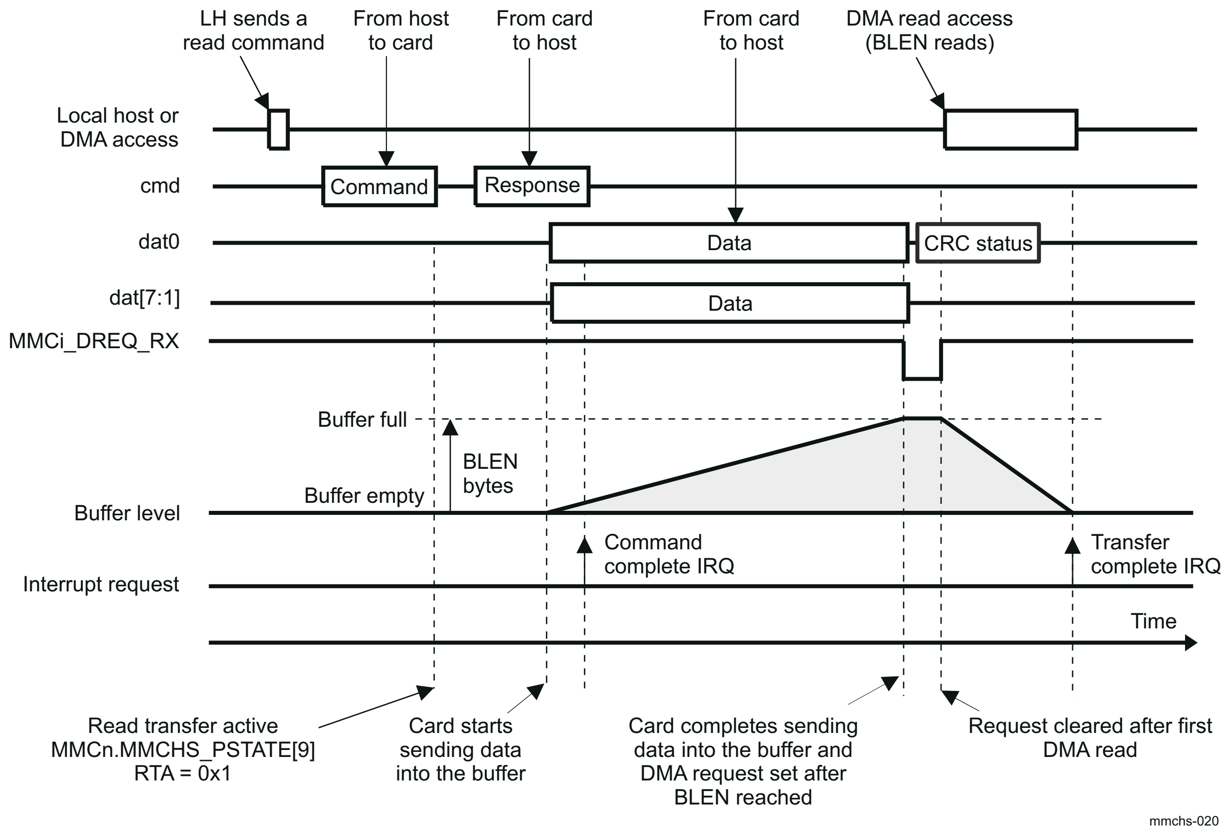

Figure 25-18. DMA Receive Mode

25.4.5.2.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMCi_DMA_TX is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN bit field.

MMCi_DMA_TX is deasserted to its inactive level when a certain device DMA writes one word to the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

New DMA requests are internally masked if the DMA has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of DMA reads is Integer(BLEN / 4) + 1) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 25-19 shows DMA transmit mode.

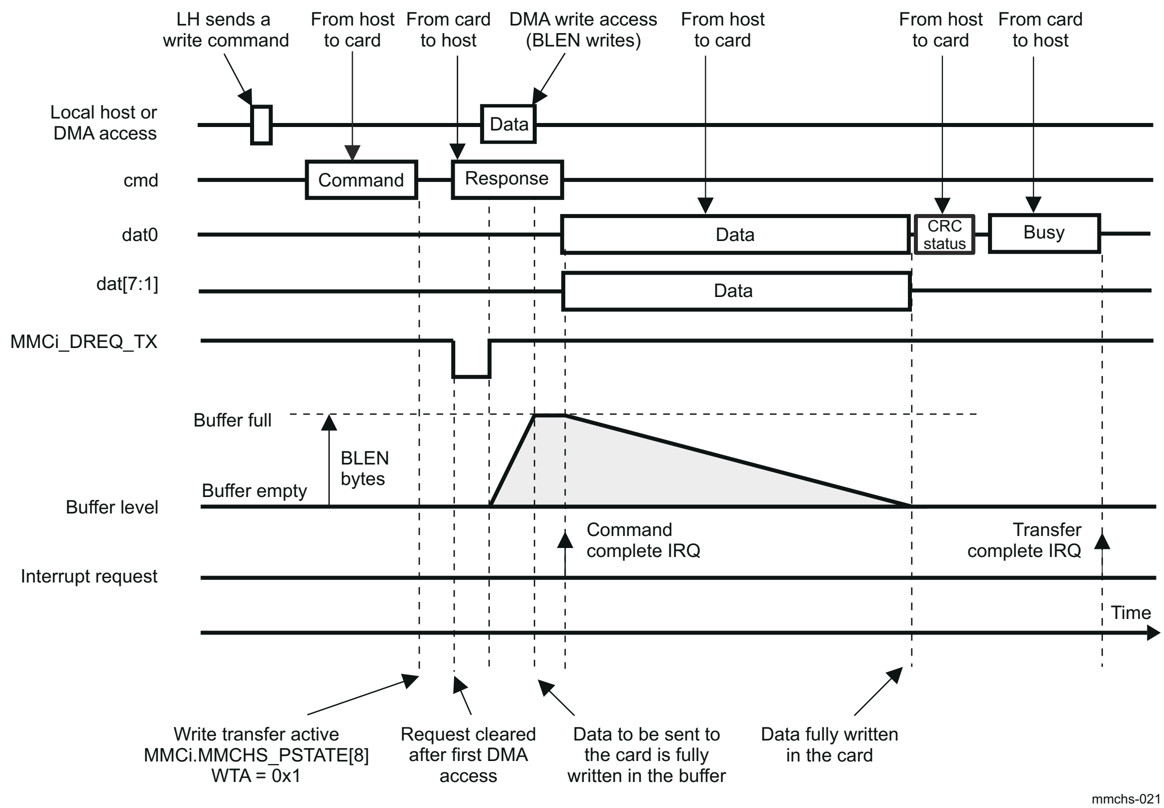

Figure 25-19. DMA Transmit Mode

25.4.6 Mode Selection

The eMMC/SD/SDIO host controller can be used in two modes: MMC and SD/SDIO. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification, Part E1*.

The purpose of the module is to transfer commands and data to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

25.4.7 Buffer Management

25.4.7.1 Data Buffer

The eMMC/SD/SDIOi host controller uses a data buffer. This buffer transfers data from one data bus (interconnect) to another data bus (SD/SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the prefetch buffer and the post-write buffer is the 32-bit MMCi.MMCHS_DATA register. A write access to the MMCi.MMCHS_DATA register followed by a read access from the MMCi.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCi.MMCHS_DATA register and the data of the read access to the MMCi.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCi.MMCHS_DATA register that are needed to read (or write) a data block with a size of the MMCi.MMCHS_BLK[11:0] BLEN bit field is equal to the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is hard-coded in the MMCi.MMCHS_CAPA[17:16] MBL bit field and cannot be changed.

A read access to the MMCi.MMCHS_DATA register is allowed only when the buffer read-enable status is set to 1 (the MMCi.MMCHS_PSTATE[11] BRE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled.

A write access to the MMCi.MMCHS_DATA register is allowed only when the buffer write-enable status is set to 1 (the MMCi.MMCHS_PSTATE[10] BWE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled and the data are not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus, and vice versa. The eMMC/SD/SDIOi host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time. In this way, data can be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) are being stored into the other portion, and vice versa. When BLEN is less than or equal to 0x200 (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits × BLEN divided by 4). No more than this total size of 2 × 32 bits × BLEN divided by 4 can be used.

CAUTION

The MMCi.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 25-20 and Figure 25-21 show the buffer management for a write and a read, respectively.

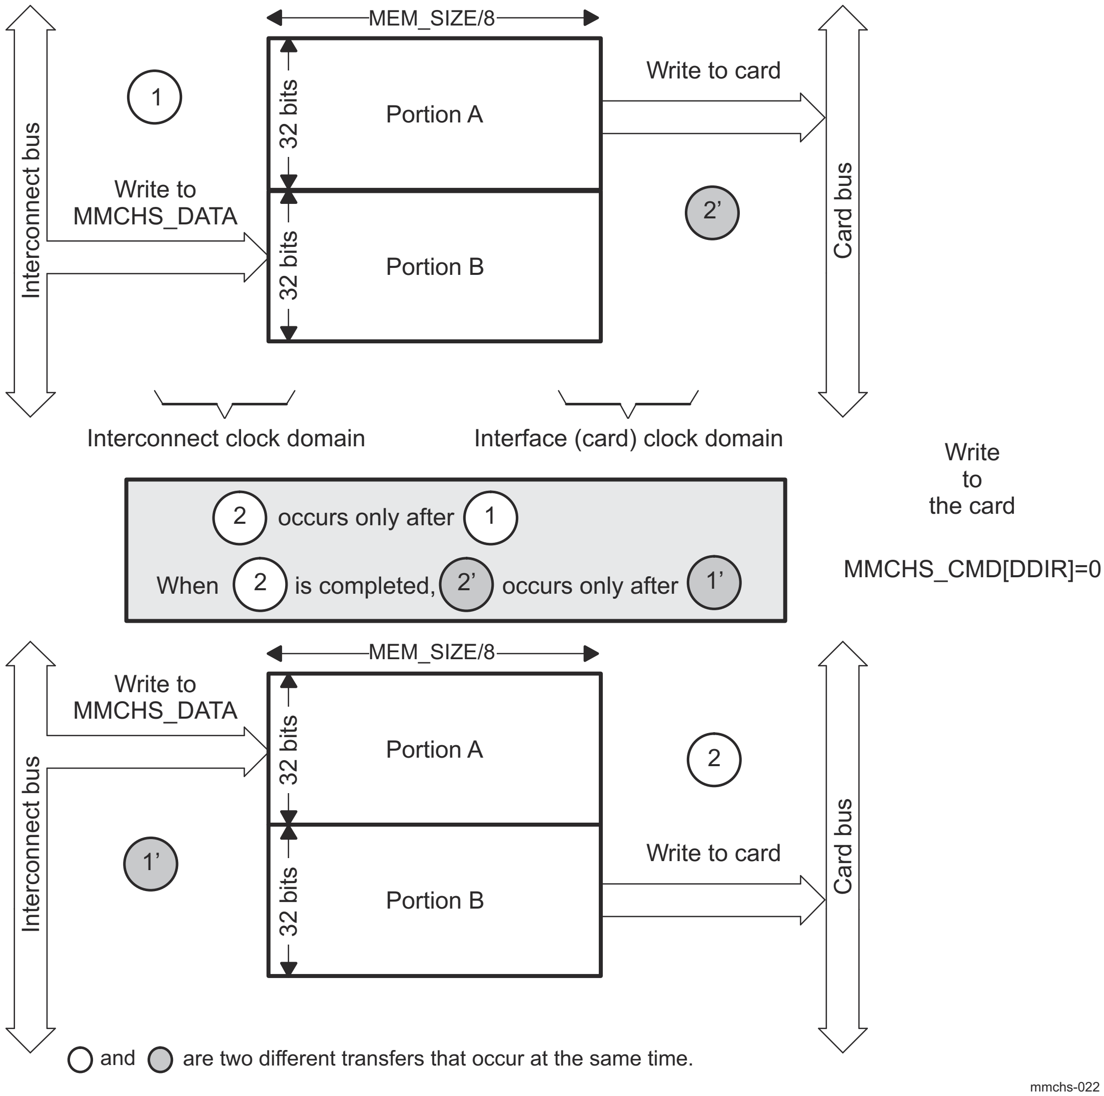

Figure 25-20. Buffer Management for a Write

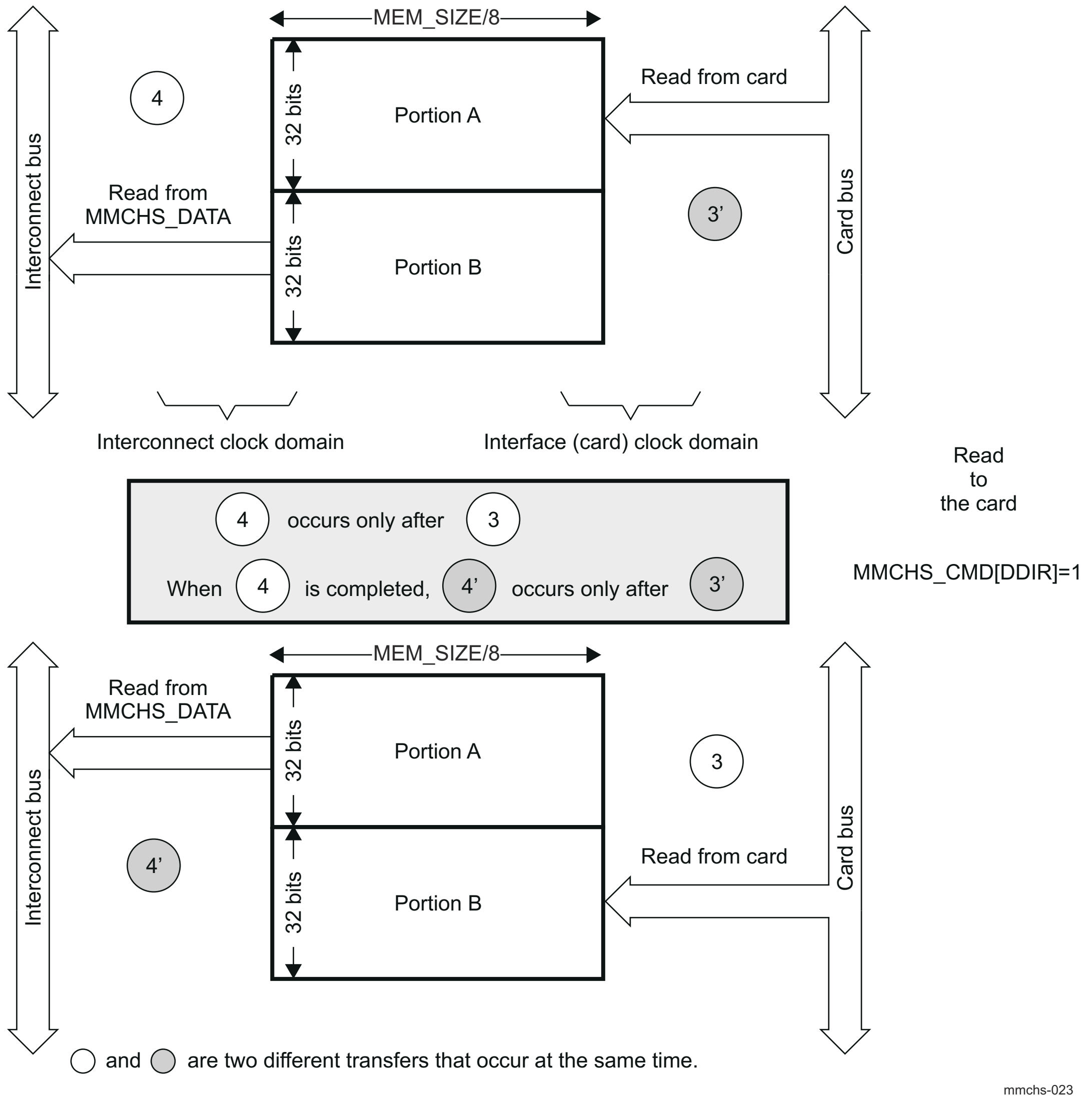

Figure 25-21. Buffer Management for a Read

- When the size of the data block to transfer is larger than MEM_SIZE / 2, only one data transfer at a time can occur from one data bus to the other data bus. The eMMC/SD/SDIOi host controller uses the entire data buffer as a single portion.

  In this mode, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

25.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see Table 25-17).

Note

Double-buffering is always the buffer management for large memory depth.

Table 25-17. Memory Size, BLEN, and Buffer Relationship

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024
Maximum block length supported	512	1024

Table 25-17. Memory Size, BLEN, and Buffer Relationship (continued)

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024
Double-buffering for maximum block length	N/A	BLEN <= 512
Single-buffering for block length	BLEN <= 512	512 < BLEN <= 1024

Note

For single-buffering management, throughput on the MMC bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the MMC bus. The clock is maintained on write MMC transfers (the MMCHS_CMD[4] DDIR bit is 0) and halted on read MMC transfers (the MMCHS_CMD[4] DDIR bit is 1).

25.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
  - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
  - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
  - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers:
  - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
  - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

25.4.8 Transfer Process

The process of a transfer depends on the type of command. It can be with or without a response, and with or without data.

25.4.8.1 Different Types of Commands

Different types of commands are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*; or *the SD Card Specification, Part A2, SD Host Controller Standard Specification*.

25.4.8.2 Different Types of Responses

Different types of responses are specific to the eMMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*; *SD Memory Card Specifications*; *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*.

Table 25-18 describes how the eMMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 25-18. MMC, SD, SDIO Responses in the MMCHS_RSPxx Registers

Type of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8][1]	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response), R1(Auto CMD23 response)	RESP[39:8][1]	MMCHS_RSP76[31:0]
R2	RESP[127:0][1]	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

(1) RESP refers to the command response format described in the specifications mentioned.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the host controller may execute multiple block data transfers on the DATA line concurrently with a command. This allows the host controller to avoid overwriting the response of Auto CMD12 with the command response stored in the MMCHS_RSP10 register, and vice versa.

While executing Auto CMD23 the response of CMD23 is saved in the MMCHS_RSP76[31:0] register and the response of multiple-block read and write command is saved in the MMCHS_RSP10 register. The response error of CMD23 is indicated in the MMCHS_AC12 register, bits [7:0].

25.4.9 Transfer or Command Status and Errors Reporting

Flags in the eMMC/SD/SDIOi host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see Table 25-19 and the register description.

Table 25-19. CC and TC Values Upon Error Detected

Error Hold in MMCi.MMCHS_STAT		CC	TC	Comments
29	BADA			No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion does not depend on the ongoing transfer.
28	CERR	1		CC is set upon CERR.
22	DEB		1	TC is set upon DEB.
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC. See CTO comment.
16	CTO			CTO and CC are mutually exclusive. CIE, CEB, and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears.

A MMCHS_STAT[20] DTO event can be asserted in the following conditions:

- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out
- Boot acknowledge time-out

25.4.9.1 Busy Time-Out for R1b, R5b Response Type

Figure 25-22 shows the DTO event condition asserted when there is a busy time-out for Rb1, R5b response.

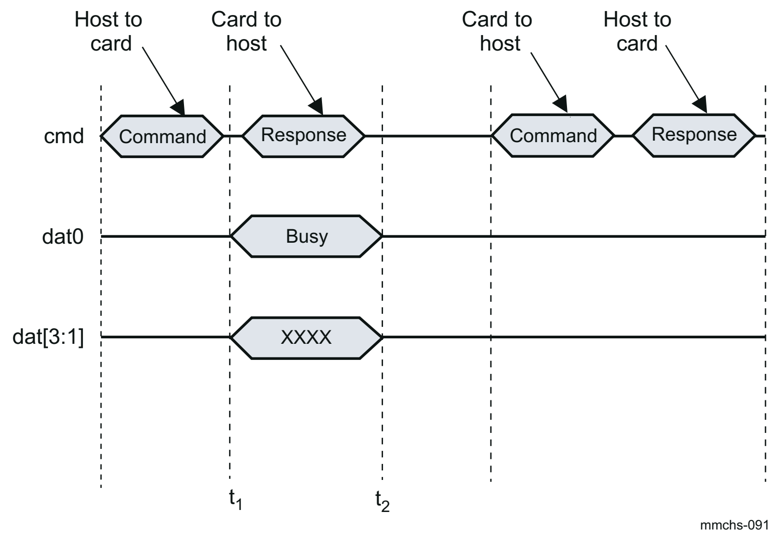

Figure 25-22. Busy Time-Out for R1b, R5b Response Type

t_1 – Data time-out counter is loaded and starts after R1b, R5b response type.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.2 Busy Time-Out After Write CRC Status

Figure 25-23 shows the DTO event condition asserted when there is a busy time-out after write CRC status.

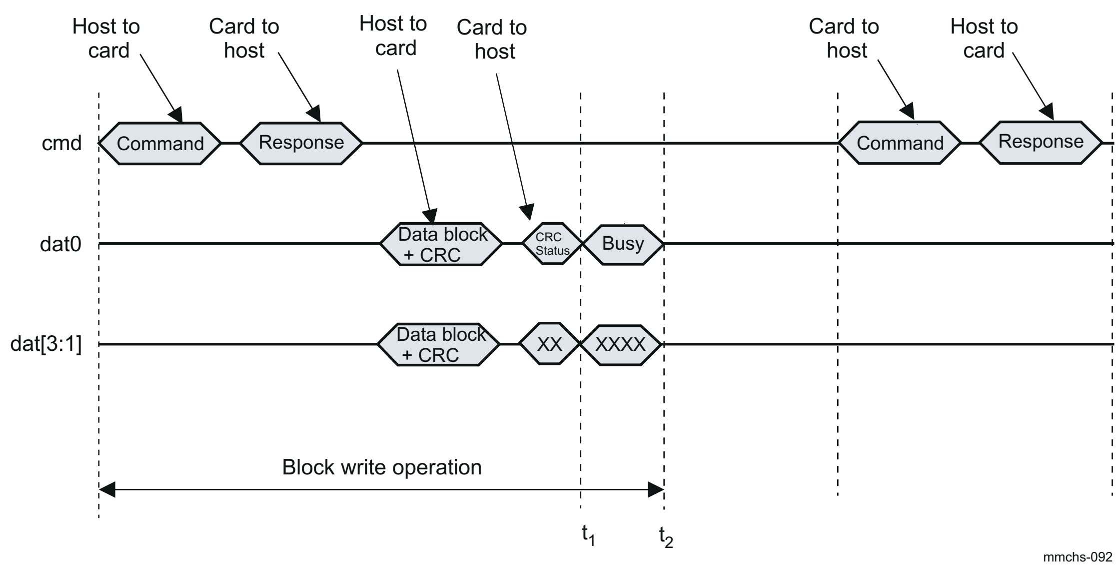

Figure 25-23. Busy Time-Out After Write CRC Status

t_1 – Data time-out counter is loaded and starts after CRC status.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.3 Write CRC Status Time-Out

Figure 25-24 shows the DTO event condition asserted when there is a write CRC status time-out.

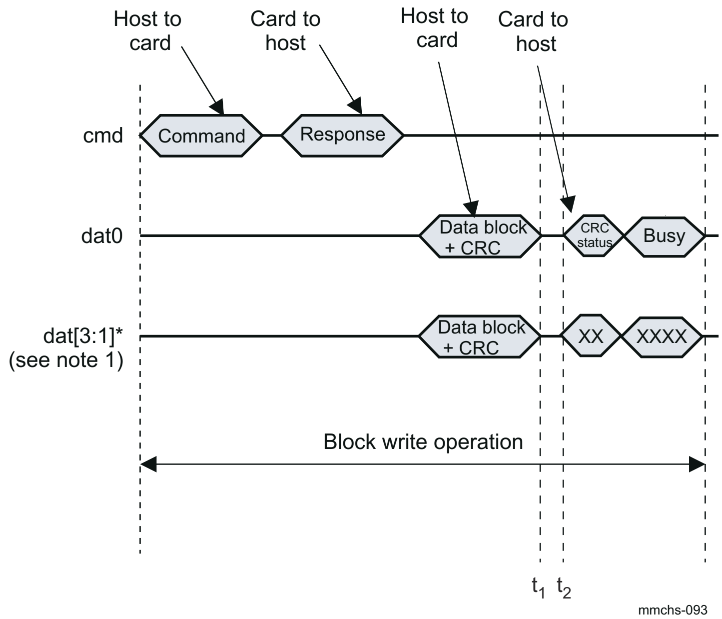

Figure 25-24. Write CRC Status Time-Out

t_1 – Data time-out counter is loaded and starts after data block + CRC.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.4 Read Data Time-Out

Figure 25-25 shows the DTO event condition asserted when there is a read data time-out.

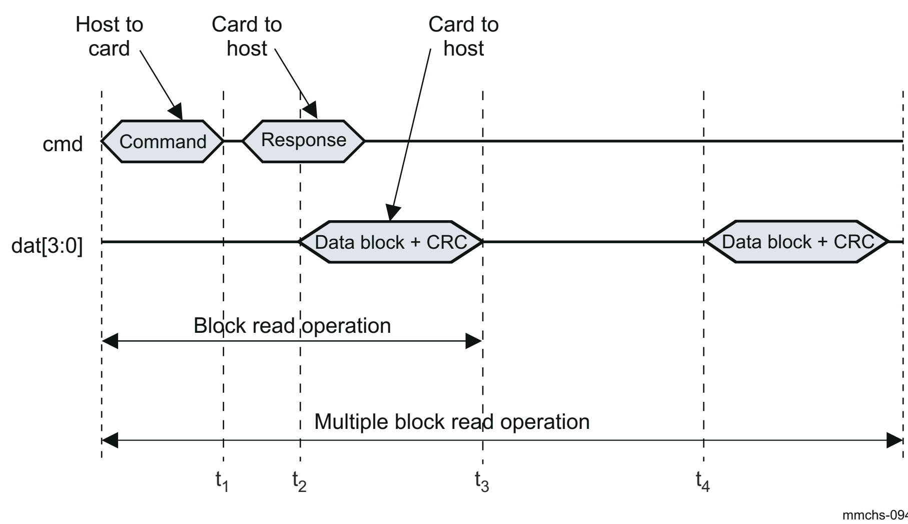

Figure 25-25. Read Data Time-Out

t_1 – Data time-out counter is loaded and starts after command transmission.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts after data block + CRC transmission.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.5 Boot Acknowledge Time-Out

Figure 25-26 shows the DTO event condition asserted when there is a boot acknowledge time-out and CMD0 is used.

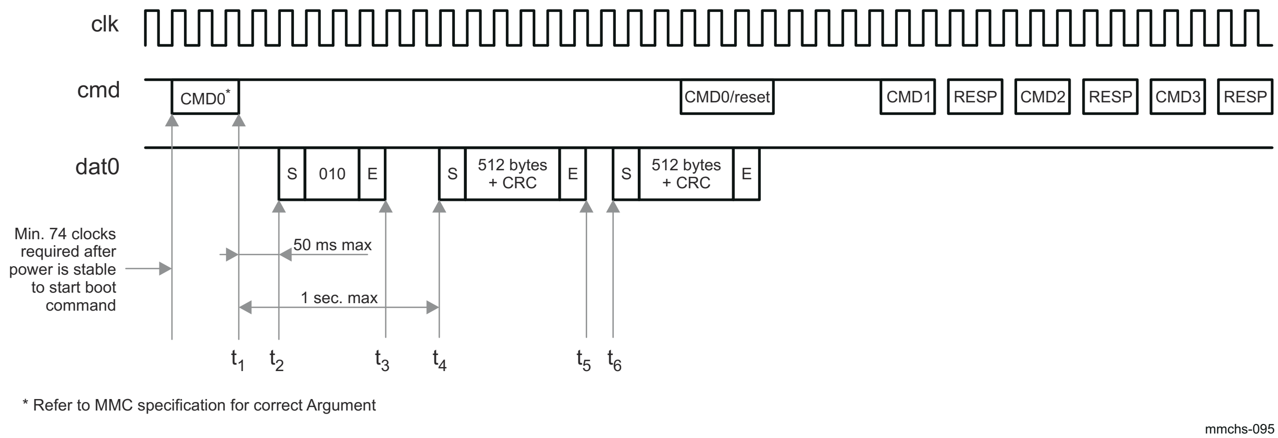

Figure 25-26. Boot Acknowledge Time-Out When Using CMD0

t_1 – Data time-out counter is loaded and starts after CMD0.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_5 – Data time-out counter is loaded and starts after data + CRC transmission.

t_6 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

Figure 25-27 shows the DTO event condition asserted when there is a boot acknowledge time-out when the CMD line is tied to 0.

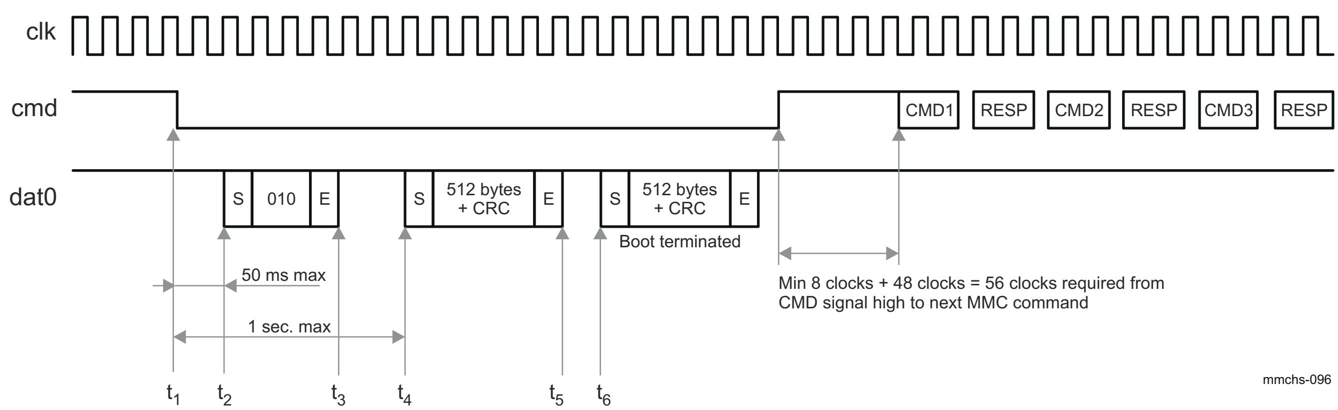

Figure 25-27. Boot Acknowledge Time-Out When CMD Line Tied to 0

t_1 – Data time-out counter is loaded and starts after the CMD line is tied to 0.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_5 – Data time-out counter is loaded and starts after data + CRC transmission.

t_6 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.10 Auto Command 12 Timings

With the UHS definition of SD cards with higher frequency for MMC clock up to 208, the SD standard imposes a specific timing for the arrival of the auto command 12 (Auto CMD12) end bit.

25.4.10.1 Auto CMD12 Timings During Write Transfer

A margin named Ncrc in the range of two to eight cycles has been defined for SDR50 and SDR104 card components for write data transfers, because the Auto CMD12 end bit must arrive after the CRC status end bit.

Figure 25-28 shows the Auto CMD12 timings during write transfer.

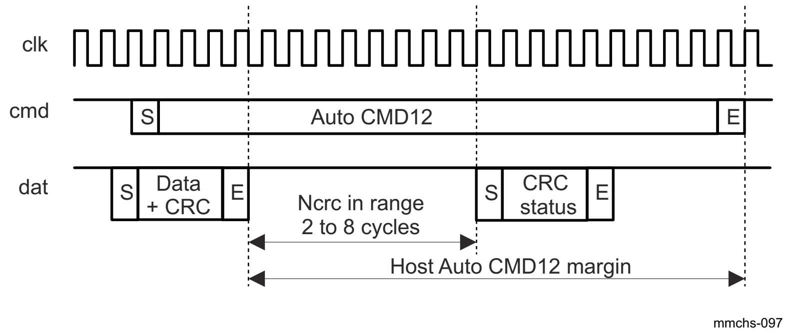

Figure 25-28. Auto CMD12 Timings During Write Transfer

The host controller has a margin of 18 clock cycles to enure that the Auto CMD12 end bit arrives after the CRC status. This margin does not depend on the MMC/SD bus configuration, DDR, or standard transfer, 1-, 4-, or 8-bit bus width.

25.4.10.2 Auto CMD12 Timings During Read Transfer

With UHS cards, the gap timing between two successive cards is extended from two cycles to four cycles. It provides more flexibility for the host Auto CMD12 arrival to receive the last complete and reliable block. The MMCHS controller follows only the left border case defined by the SD UHS specification.

Figure 25-29 shows Auto CMD12 timings during read transfer.

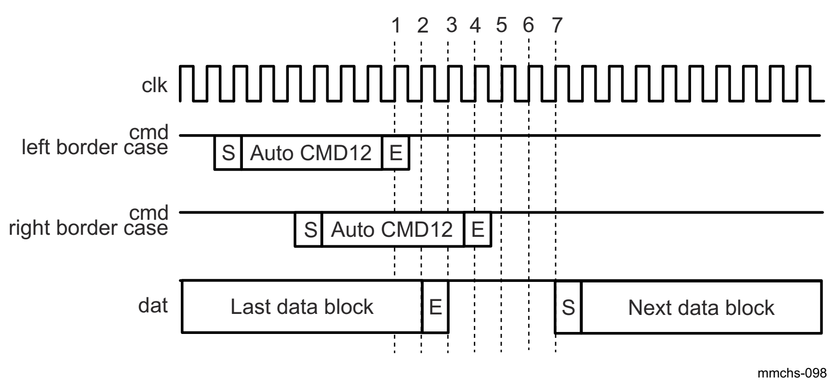

Figure 25-29. Auto CMD12 Timings During Read Transfer

The Auto CMD12 arrival sent by the host controller is not sensitive to the MMC/SD bus configuration, whether it is a DDR or standard transfer and whether it is a 1-, 4-, or 8-bit bus width transfer.

25.4.11 Transfer Stop

Whenever a transfer is initiated, the transmission can be stopped before it finishes. Several cases are possible, depending on the transfer type:

- Multiple-block-oriented transfers (transfer length is known)
- Continuous stream transfers (transfer has an infinite length)

Note

Because the eMMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

The eMMC/SD/SDIOi controller includes three features that make a transfer stop more convenient and easier to manage:

- Auto CMD12/Auto CMD23 (for eMMC and SD only):

  Auto CMD12/Auto CMD23 feature is enabled by setting the MMCi.MMCHS_CMD[3:2] ACEN bit field to 0x1 or to 0x2 respectively (this setting is relevant for an MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12/Auto CMD23 feature is enabled, the eMMC/SD/SDIOi controller automatically issues a CMD12/CMD23 command when the expected number of blocks is exchanged.
- Stop at block gap:

  This feature is enabled by setting the MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.
- ADMA mode:

  For ADMA-capable modules (MMC1 and MMC2) (for more information, see Section 25.4.5, *DMA Modes*), the last instruction can stop the transfer (the END bit is enabled in the descriptor line).

Note

For eMMC and SD cards, the stop-at-block-gap feature is not supported in read mode.

For SDIO cards, this setting can be supported in read mode if the card has read-wait capability.

Note

In SDR104 mode Auto CMD23 is used to stop multiple block read/write operation instead of Auto CMD12. In the other bus speed modes, if the card supports CMD23, Auto CMD23 is used instead of Auto CMD12.

Table 25-20 shows the common way to stop a transfer, indicating the command to send and the features to enable.

Table 25-20. eMMC/SD/SDIOi Controller Transfer Stop Command Summary

	Write Transfer		Read Transfer	
	SD/MMC	SDIO	SD/MMC	SDIO
Single block	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.

Table 25-20. eMMC/SD/SDIOi Controller Transfer Stop Command Summary (continued)

		Write Transfer		Read Transfer	
Multiblocks (finite or infinite)	Before the programmed block boundary	Send CMD12/ CMD23. Wait TC.	Send CMD52. Wait TC.	Send CMD12/ CMD23. Wait TC.	Send CMD52. Wait TC.
	Stop at the end of the transfer (finite transfer only)	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.	Set MMCi.MMCHS_HCTL [16] SBGR bit to 0x1. Send CMD52. Wait TC.	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.	**If READ_WAIT supported** Stop at block gap. Wait TC. **If READ_WAIT not supported** Send CMD52. Wait TC.

Note

The eMMC/SD/SDIOi controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

25.4.12 Output Signals Generation

The eMMC/SD/SDIO output signals can be driven on the falling edge or rising edge, depending on the MMCHS_HCTL[2] HSPE bit.

25.4.12.1 Generation on Falling Edge of MMC Clock

The controller defaults to this mode to maximize hold timings. In this case, the MMCHS_HCTL[2] HSPE bit is set to 0.

Figure 25-30 shows the output signals of the module when generating from the falling edge of the MMC clock.

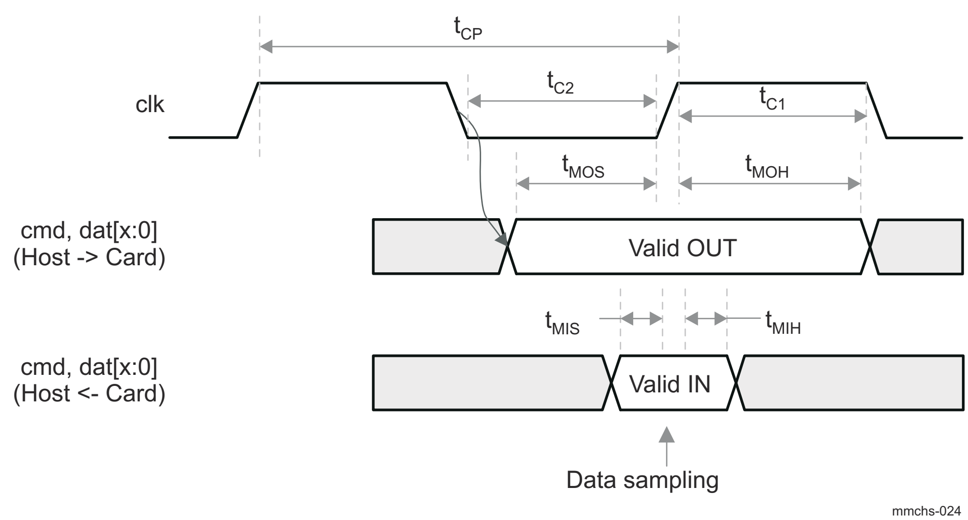

Figure 25-30. Output Driven on Falling Edge

25.4.12.2 Generation on Rising Edge of MMC Clock

This mode is intended to increase setup timings. This feature is activated by setting the MMCHS_HCTL[2] HSPE bit to 1.

Note

Do not use this feature in DDR mode (when the MMCHS_CON[19] DDR bit is set to 1).

Figure 25-31 shows the output signals of the module when generating from the rising edge of the MMC clock.

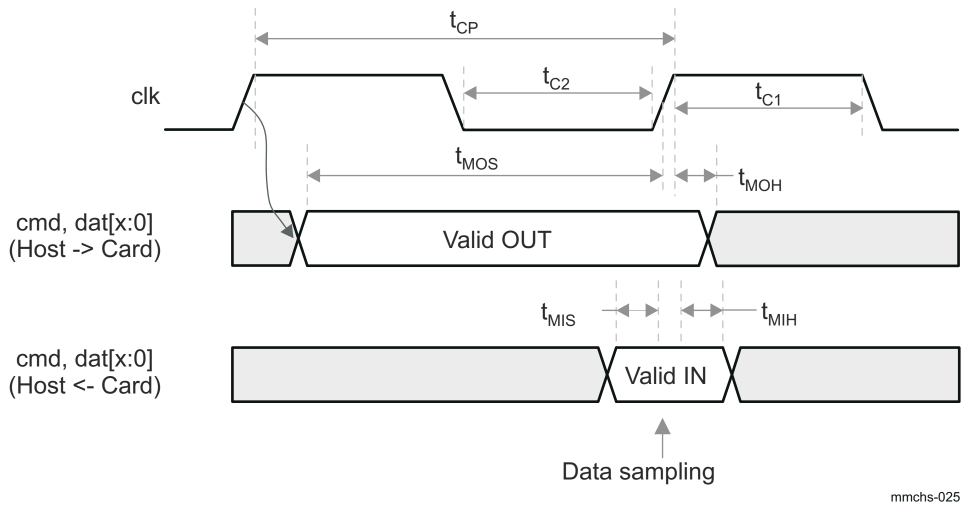

Figure 25-31. Output Driven on Rising Edge

25.4.13 Sampling Clock Tuning

In UHS-I mode the SD bus operates in high clock frequency mode and the data window from the card on CMD and DAT lines get smaller. The position of the data window varies depending on the card and the host system. To adjust the sampling clock when SDR104/HS200 operation mode is used the eMMC/SD/SDIOi host controller supports a tuning circuit. This tuning circuit is a dedicated DLL which delays the clock signal used for data sampling. The DLL is not part of the eMMC/SD/SDIOi host controller. It is instantiated at top level between the IOs and the host controller. There are two DLLs. One for MMC1 when SDR104 mode is used and one for MMC2 when HS200 mode is used.

In the default, lower frequency operation, a fixed sampling clock is used to receive signals on CMD and DAT lines. Before using the SDR104/HS200 or SDR50 (if MMCHS_CAPA2[13] TSDR50 = 0x1) modes software must execute the tuning procedure at the initialization sequence regardless of MMCHS_CAPA2[15:14] RTM value.

The software starts the tuning sequence by setting MMCHS_DLL[20] SWT to 1. Then it issues CMD19 for a SD card or CMD21 for an eMMC device repeatedly while cycling through 32 DLL ratios and recording pass/fail results for each. Thereafter the MMCHS_AC12[23] SCLK_SEL bit is checked and if it is set to 0 this indicates that the tuning procedure has failed. When MMCHS_AC12[23] SCLK_SEL is set to 1, this indicates that the tuning procedure has completed successfully. For more information about the DLL tuning procedure, see Section 25.5.1.2.4 , *SDR104/HS200 DLL Tuning Procedure*.

Note

The eMMC/SD/SDIO controller supports a Conflict Error (CFT Error) on the CMD line. This error detection logic must be disabled for SDR104/HS200 mode by setting the MMCHS_DLL[20] SWT bit to 0x1 during the DLL tuning procedure. This value (0x1) must be kept while SDR104/HS200 mode is used.

The eMMC/SD/SDIO controller generates a CFT error when it detects that the value sent on the CMD line is not the same as the value returned, indicating an external source is overriding the value.

25.4.14 Card Boot Mode Management

Boot operation mode lets the eMMC/SD/SDIOi host controller read boot data from the connected slave (MMC device) by keeping the CMD line low after power on (or sending CMD0 with a specific argument) before issuing CMD1. The data can be read from the boot area or user area, depending on the register setting.

Power-on boot defines a way for the boot code to be accessed by the eMMC/SD/SDIOi host controller without an upper-level software driver, thus speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

25.4.14.1 Boot Mode Using CMD0

Figure 25-32 shows the timing diagram of a boot sequence using CMD0.

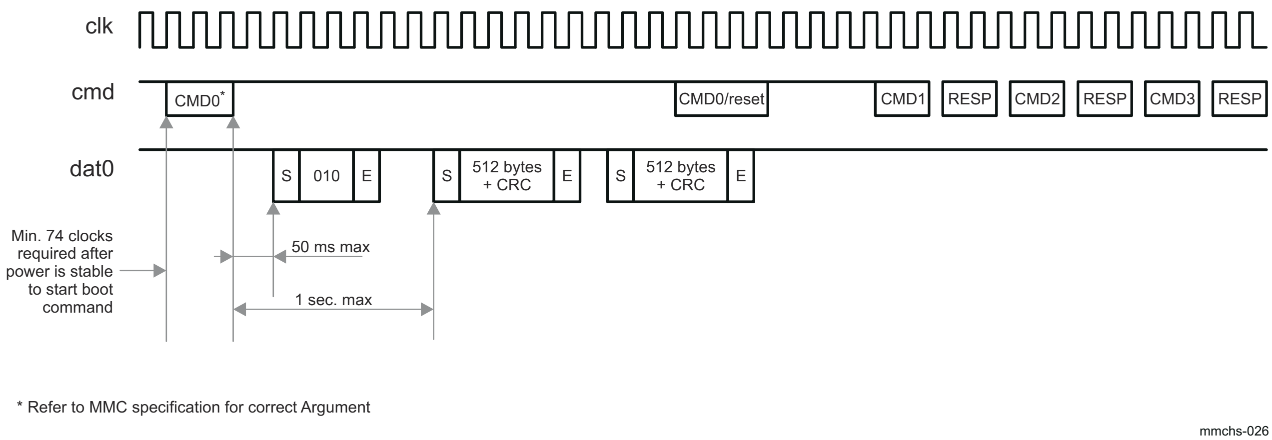

Figure 25-32. Boot Mode Using the CMD0 Timing Diagram

Note

Refer to MMC specification for correct Argument.

For more information about how to configure the eMMC/SD/SDIO host controller, see Section 25.5.1.2.3.1, *Boot Using the CMD0*.

25.4.14.2 Boot Mode With CMD Line Tied to 0

Figure 25-33 shows the timing diagram of a boot sequence with CMD line tied to 0.

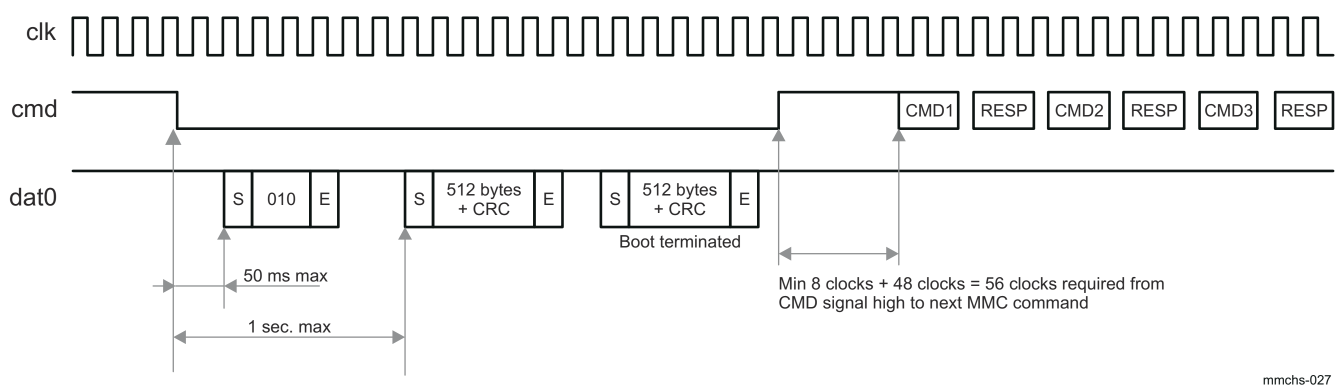

Figure 25-33. Boot Mode With CMD Line Tied to 0 Timing Diagram

For more information about how to configure the eMMC/SD/SDIO host controller, see Section 25.5.1.2.3.2, *Boot With CMD Line Tied to 0*.

25.4.15 MMC CE-ATA Command Completion Disable Management

The eMMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of the command completion token. When a command that requires a CCS (the MMCHS_CON[12] CEATA bit is set to 1 and the

MMCHS_CMD[3:2] ACEN bit field is set to 0x1) is launched, the host system is no longer allowed to emit a new command in parallel to the data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token are:

- Set the MMCHS_CON[12] CEATA bit to 1.
- Set the MMCHS_CON[2] HR bit to 1.
- Clear the MMCHS_ARG register.
- Write into the MMCHS_CMD register with the value 0x00000000.

When a command completion disable token was emitted (that is, the MMCHS_STAT[0] CC bit is received), the host system is again allowed to emit another type of command (for example, a CMD12 to abort transfer).

A critical case can be encountered when CCSD is emitted during the last data block transfer, and the sequence on the command line is sent close to the CCS token sent by the card.

Three possible cases are:

- CCS is received immediately before CCSD is emitted:

  An interrupt CIRQ is generated when CCS is detected, CCSD is transmitted to the card, and then an interrupt CC is generated when CCSD ends. In this case, the card considers the CCSD sequence.
- CCS is not generated or is generated during the CCSD transfer:

  The CCS bit cannot be detected (conflict is not possible because they drive the same level on the command line, and no CIRQ interrupt is generated; a CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

  Only the interrupt CIRQ is generated when CCS is detected.

25.4.16 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register (MMCHS_FE) is used to control the error status and error interrupt status for Auto CMD12 and Auto CMD23.

The system test register (MMCHS_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the MMCHS_CON[4] MODE bit = 1) for boundary connectivity verification.

The MMCHS_HCTL[7] CDSS and MMCHS_HCTL[6] CDTL bits enable manual control of MMCHS_PSTATE[16] CINS and interrupt generating indicated in MMCHS_STAT[7] CREM and MMCHS_STAT[6] CINS.

25.4.17 eMMC/SD/SDIO Hardware Status Features

Table 25-21 describes the eMMC/SD/SDIO hardware status features.

Table 25-21. eMMC/SD/SDIO Hardware Status Features

Feature	Type	Register/Bit Field	Description
Interrupt flags		See Section 25.4.4, *Interrupt Requests.*	
CMD line signal level	Status	MMCHS_PSTATE[24] CLEV	Indicates the level of the command line
DAT lines signal level	Status	MMCHS_PSTATE[23:20] DLEV	Indicates the level of the data lines
Write protect switch pin level	Status	MMCHS_PSTATE[19] WP	Indicates whether the SD card is write protected or not.
Card detect pin level	Status	MMCHS_PSTATE[18] CDPL	Indicates the level of the mmci_sdcd signal/pad

Table 25-21. eMMC/SD/SDIO Hardware Status Features (continued)

Feature	Type	Register/Bit Field	Description
Card State Stable	Status	MMCHS_PSTATE[17] CSS	Used for testing. Indicates mmci_sdcd stable state
Card inserted	Status	MMCHS_PSTATE[16] CINS	Indicates whether the SD card is inserted
Buffer read enable	Status	MMCHS_PSTATE[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	MMCHS_PSTATE[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	MMCHS_PSTATE[9] RTA	Used to detect completion of a read transfer.
Write transfer active	Status	MMCHS_PSTATE[8] WTA	Indicates a write transfer active
Re - Tuning Request	Status	MMCHS_PSTATE[3] RTR	Indicates whether the sampling clock needs re - tuning or not.
Data line active	Status	MMCHS_PSTATE[2] DLA	Indicates whether the data lines are active
Command Inhibit (DAT lines)	Status	MMCHS_PSTATE[1] DATI	Indicates whether issuing of command using data lines is allowed. For example, commands with busy mechanism (that is, R1b response), data transfer commands.
Command inhibit (CMD line)	Status	MMCHS_PSTATE[0] CMDI	Indicates whether issuing of command using command line is allowed

Table 25-22 describes the eMMC/SD/SDIO preset value features.

Table 25-22. eMMC/SD/SDIO Preset Value Registers

Feature	Type	Register	Description
Preset value register	Status	MMCHS_PVINITSD	Preset Values for Initialization and Default Speed modes
Preset value register	Status	MMCHS_PVHSSDR12	Preset Values for High Speed and SDR12 speed modes
Preset value register	Status	MMCHS_PVSDR25SDR50	Preset Values for SDR25 and SDR50 speed modes
Preset value register	Status	MMCHS_PVSDR104DDR50	Preset Values for SDR104 and DDR50 speed modes

25.5 eMMC/SD/SDIO Programming Guide

25.5.1 Low-Level Programming Models

25.5.1.1 Global Initialization

25.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module must be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the eMMC/SD/SDIO modules. For more information, see Section 25.3, *eMMC/SD/SDIO Integration*, and Section 25.2, *eMMC/SD/SDIO Environment*.Table 25-23 shows the global initialization of surrounding modules.

Table 25-23. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing and configuration must be set in the control module. See *Control Module* .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
Device DMAs	Device DMAs configuration must be done to enable the module DMA channel requests.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see *Interrupt Controllers*

25.5.1.1.2 eMMC/SD/SDIO Host Controller Initialization Flow

Table 25-24 shows the general boot process.

Table 25-24. eMMC/SD/SDIO Controller Meta Initialization Steps

Step	Access Type	Register/Bit Field/Programming Model	Value
Initialize clocks.		See Section 25.5.1.1.2.1, *Enable Interface and Functional Clock for MMC Controller.*	
Software reset of the controller.		See Section 25.5.1.1.2.2, *MMCHS Soft Reset Flow*.	
Set module hardware capabilities.		See Section 25.5.1.1.2.3,*Set MMCHS Default Capabilities*.	
Set module idle and wake-up modes.		See Section 25.5.1.1.2.4, *Wake-Up Configuration*.	

25.5.1.1.2.1 Enable Interface and Functional Clock for MMC Controller

Before any MMCHS register access, the MMCHS interface clock and functional clock in the PRCM module registers must be enabled. See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.

25.5.1.1.2.2 MMCHS Soft Reset Flow

Figure 25-34 shows the soft reset process of the MMCHS controller.

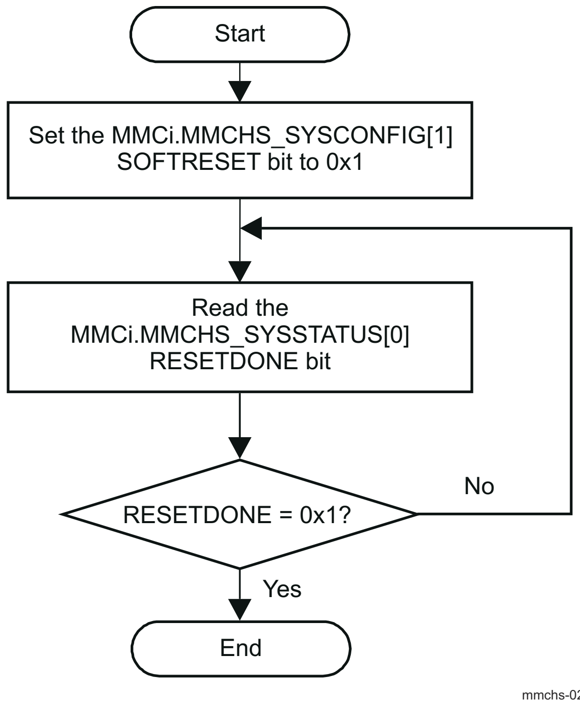

Figure 25-34. eMMC/SD/SDIO Controller Software Reset Flow

Table 25-25. Register Call Summary for Main Sequence – Software Reset Flow

Register Name	Register Name
MMCHS_SYSCONFIG	MMCHS_SYSSTATUS

25.5.1.1.2.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM, for example) and is allowed to set (write) the MMCi.MMCHS_CAPA[26:24] and MMCi.MMCHS_CUR_CAPA[23:0] bit fields before the eMMC/SD/SDIO host driver is started.

25.5.1.1.2.4 Wake-Up Configuration

Table 25-26 describes the MMCHS controller wake-up configuration.

Table 25-26. eMMC/SD/SDIO Controller Wake-Up Configuration

Step	Access Type	Register/Bit Field/Programming Model	Value
Configure wake-up bit (if necessary).	W	MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP	0x1
Enable wake-up events on SD card interrupt (if necessary).	W	MMCi.MMCHS_HCTL[24] IWE	0x1
SDIO card only: Enable card interrupt (if necessary).	W	MMCi.MMCHS_IE[8] CIRQ_ENABLE	0x1

25.5.1.1.2.5 MMC Host and Bus Configuration

Figure 25-35 shows the MMC bus configuration process.

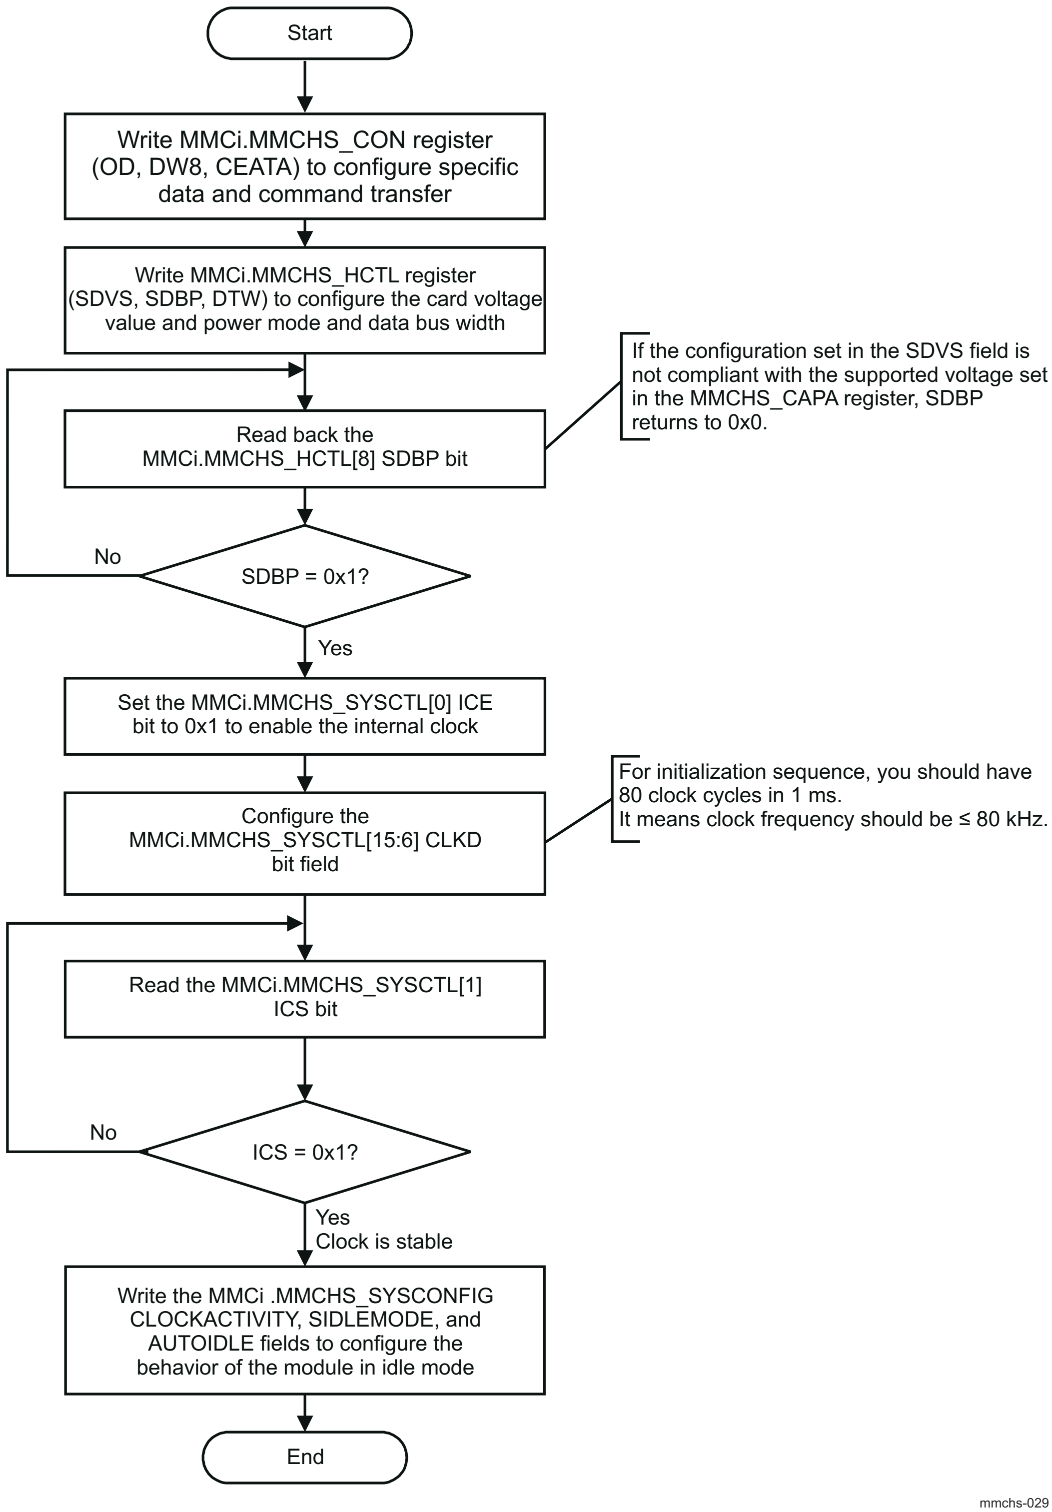

Figure 25-35. eMMC/SD/SDIO Controller Bus Configuration

Table 25-27. Register Call Summary for Main Sequence – Bus Configuration

Register Name	Register Name
MMCHS_CON	MMCHS_HCTL
MMCHS_SYSCONFIG	MMCHS_SYSCTL

25.5.1.2 Operational Modes Configuration

25.5.1.2.1 Basic Operations for eMMC/SD/SDIO Host Controller

The eMMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

25.5.1.2.1.1 Card Detection, Identification, and Selection

Figure 25-36 and Figure 25-37 show the card detection, identification and selection process.

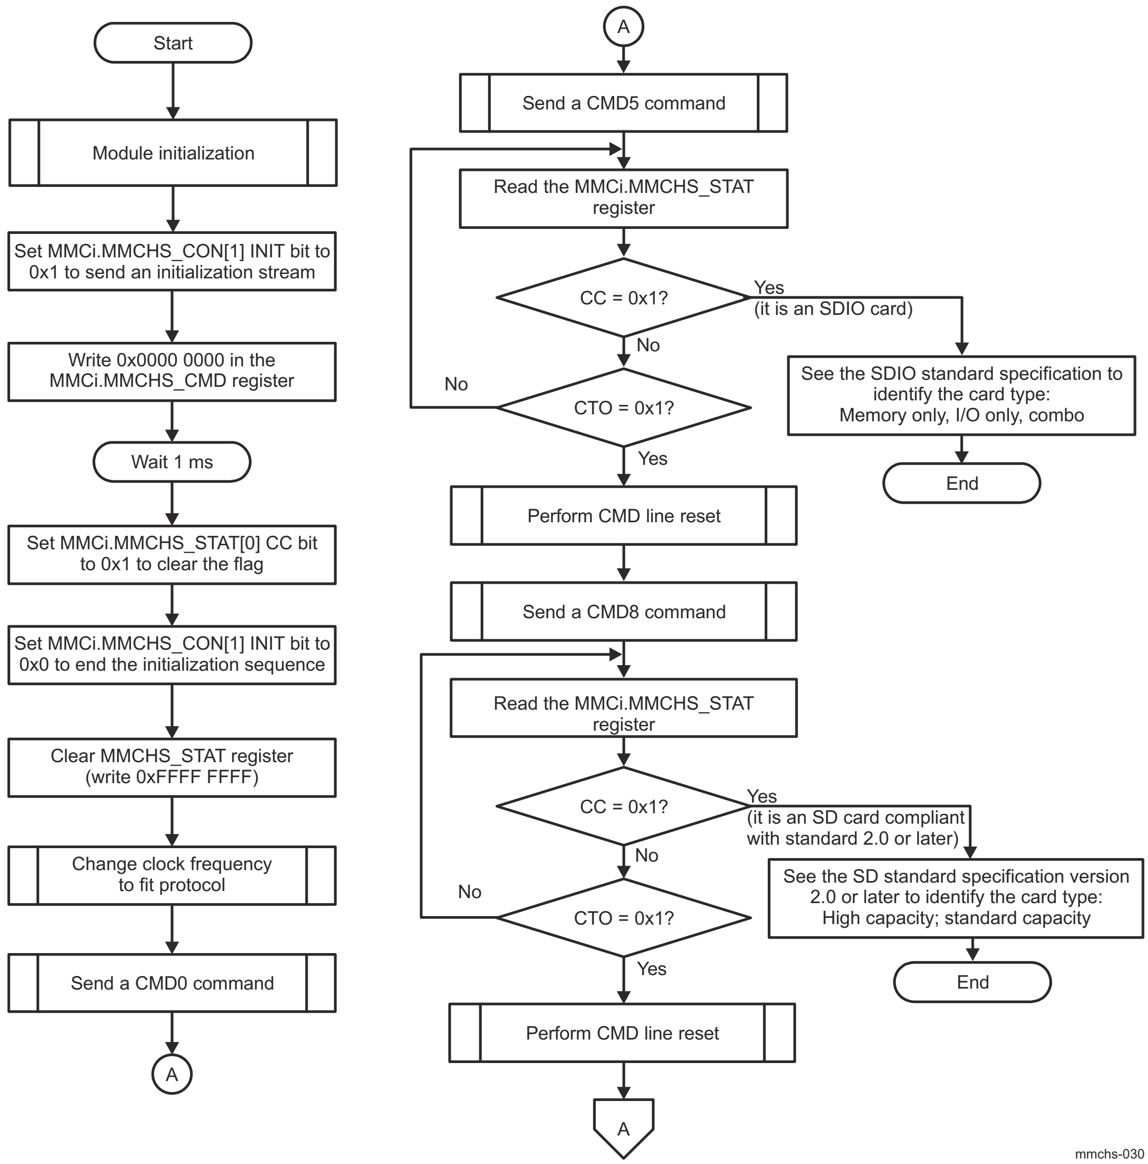

Figure 25-36. eMMC/SD/SDIO Controller Card Identification and Selection – Part 1

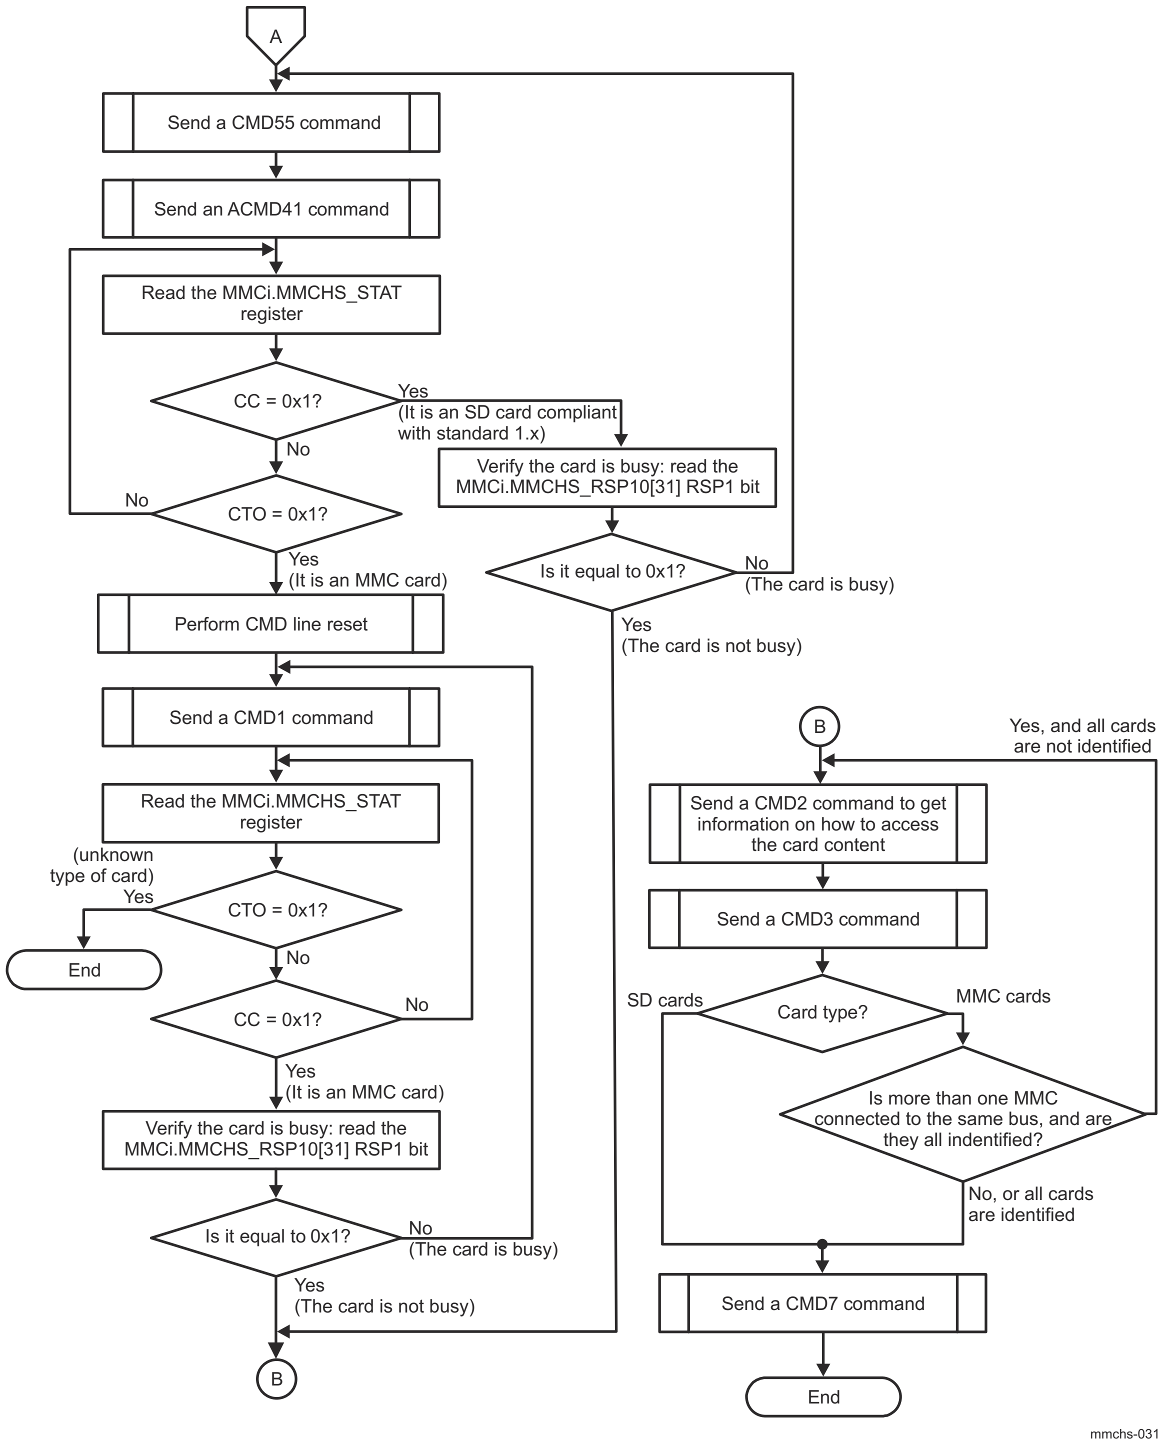

Figure 25-37. eMMC/SD/SDIO Controller Card Identification and Selection – Part 2

Table 25-28. Register Call Summary for Main Sequence – Card Identification and Selection

Register Name	Register Name	Register Name
MMCHS_CON	MMCHS_CMD	MMCHS_STAT
MMCHS_SYSCTL	MMCHS_RSP10	

Table 25-29 lists the subprocess call summary.

Table 25-29. Subprocess Call Summary for Main Sequence – Card Identification and Selection

Subprocess Name	Cross-Reference
Initialize module.	See Section 25.5.1.1.2 , *eMMC/SD/SDIO Host Controller Initialization Flow*.
Change clock frequency to fit protocol.	See Section 25.5.1.2.1.7.2, *MMCHS Clock Frequency Change*.
Send a command.	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.
Perform CMD line reset.	See Section 25.5.1.2.1.1.1, *CMD Line Reset Procedure*.

25.5.1.2.1.1.1 CMD Line Reset Procedure

Table 25-30lists the CML line reset.

Table 25-30. CMD Line Reset

Step	Access Type	Register/Bit Field/Programming Model	Value
Initiate CMD line reset.	W	MMCi.MMCHS_SYSCTL[25] SRC	0x1
Poll the SRC bit until it is set to 0x1.	R	MMCi.MMCHS_SYSCTL[25] SRC	= 0x1
Wait until the SRC bit returns to 0x0 (reset procedure is completed).	R	MMCi.MMCHS_SYSCTL[25] SRC	= 0x0

25.5.1.2.1.2 Read/Write Transfer Flow in DMA Mode With Interrupt

Figure 25-38 shows the read and write protocol in DMA slave mode with interrupt signaling.

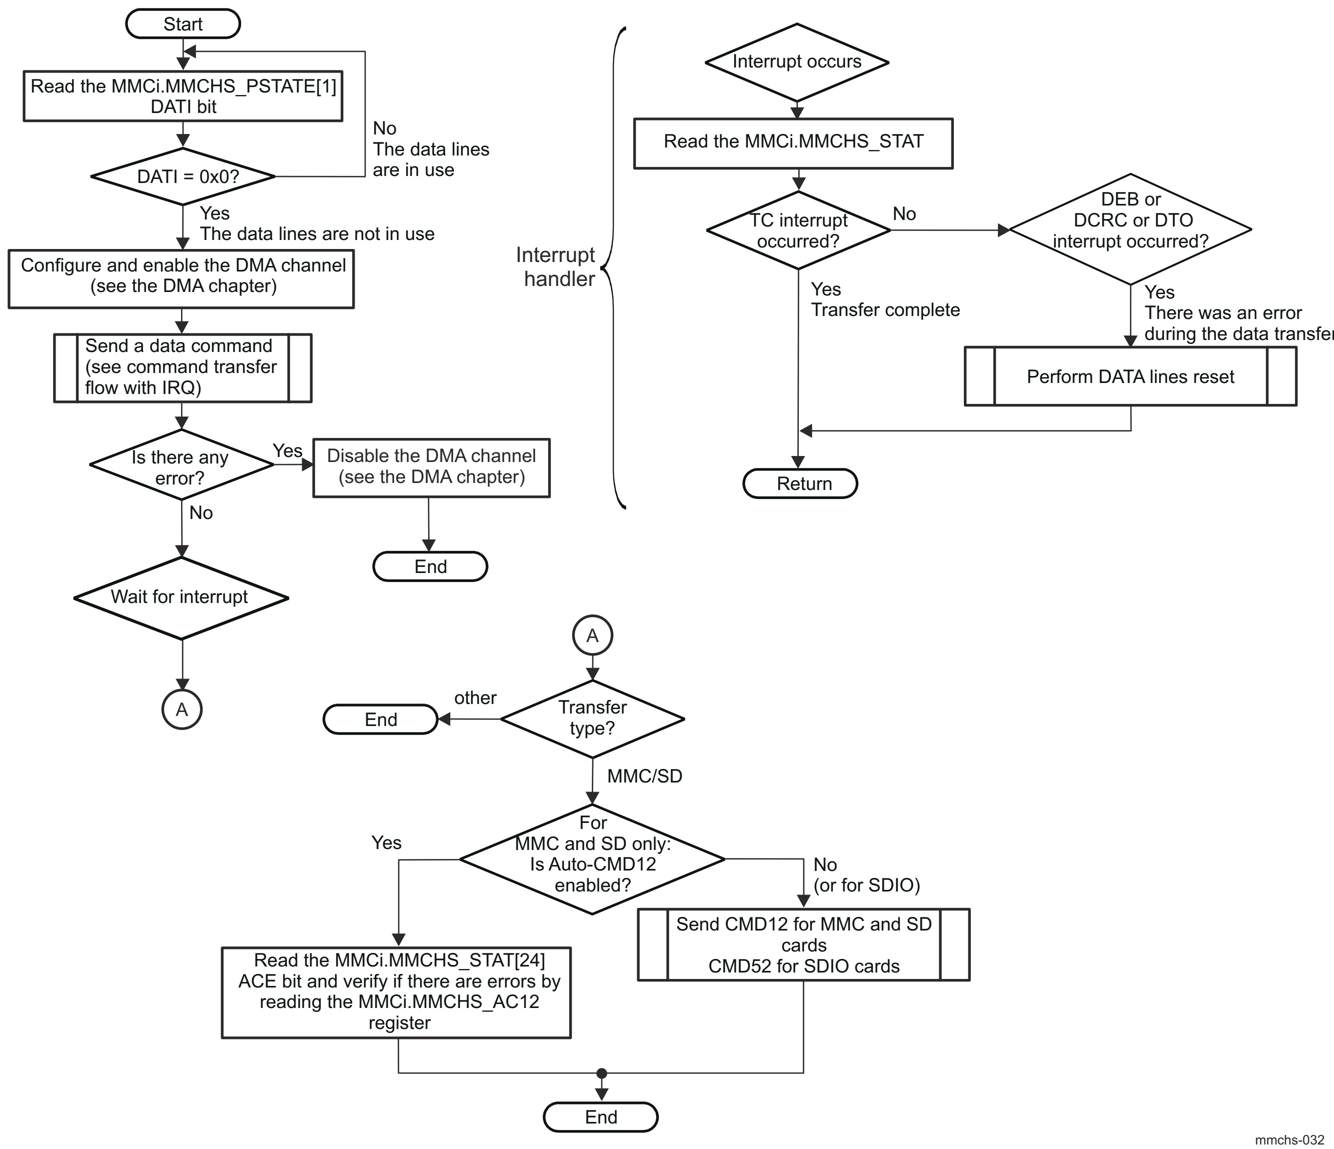

Figure 25-38. eMMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Slave Mode With interrupt

Table 25-31. Register Call Summary for Main Sequence – Read/Write Transfer Flow in DMA Mode With interrupt

MMCHS_PSTATE	MMCHS_CON	MMCHS_IE
MMCHS_CMD	MMCHS_STAT	
MMCHS_ARG	MMCHS_SYSCTL	

Table 25-39. Subprocess Call Summary for Main Sequence – Read/Write in CE-ATA Mode

Subprocess Name	Cross-Reference
Perform CMD line reset.	See Section 25.5.1.2.1.1.1, *CMD Line Reset Procedure*.
Perform DATA lines reset.	See Section 25.5.1.2.1.2.1, *DATA Lines Reset Procedure*.

CAUTION

CE-ATA protocol is supported only by MMC cards.

In CE-ATA mode, issuing a command during the transfer (except a CCSD command) is not allowed.

In CE-ATA mode, infinite transfers are not allowed; only finite transfers are permitted.

25.5.1.2.1.6 Suspend-Resume Flow

The suspend-and-resume feature is supported only by SDIO cards.

25.5.1.2.1.6.1 Suspend Flow

Figure 25-42 shows the suspend flow for SDIO cards.

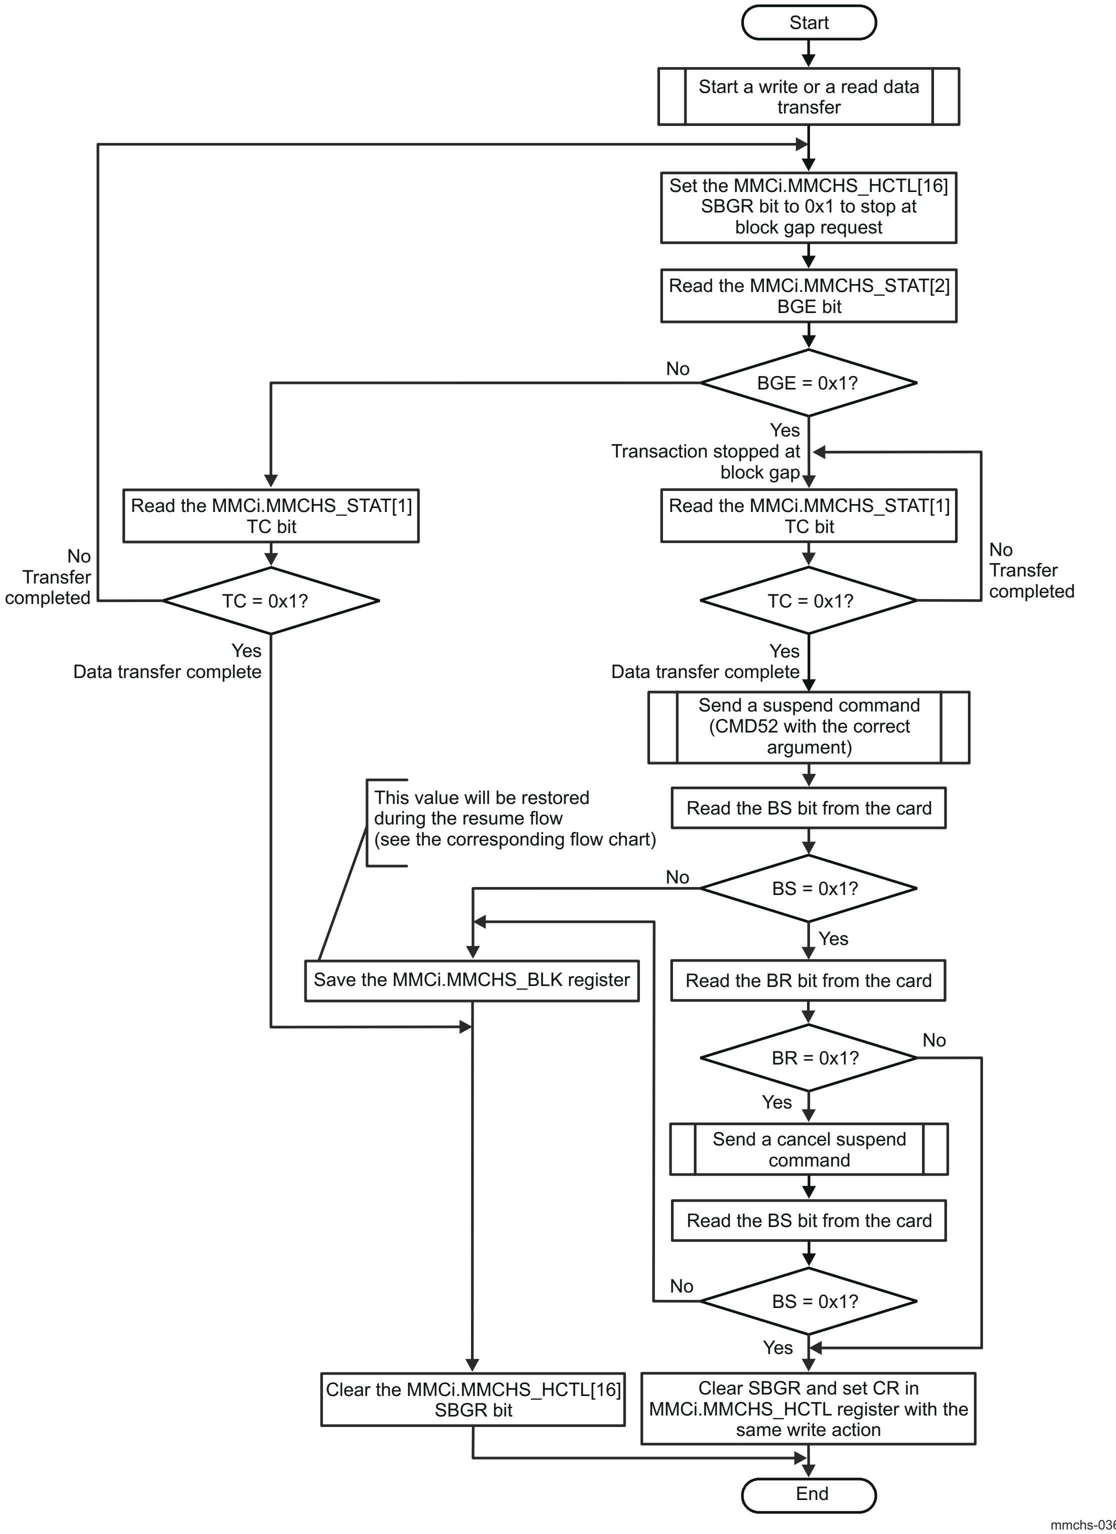

Figure 25-42. eMMC/SD/SDIO Controller Suspend Flow

Table 25-40. Register Call Summary for Main Sequence – Suspend Flow

Register Name	Register Name	Register Name
MMCHS_HCTL	MMCHS_STAT	MMCHS_BLK

Table 25-41. Subprocess Call Summary for Main Sequence – Suspend Flow

Subprocess Name	Cross-Reference
Start a write or a read data transfer.	See Section 25.5.1.2.1, *Basic Operations for eMMC/SD/SDIO Host Controller*.
Send a suspend command (CMD52 with the correct argument).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.
Send a cancel suspend command.	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.1.6.2 Resume Flow

Figure 25-43 shows the resume flow for SDIO cards.

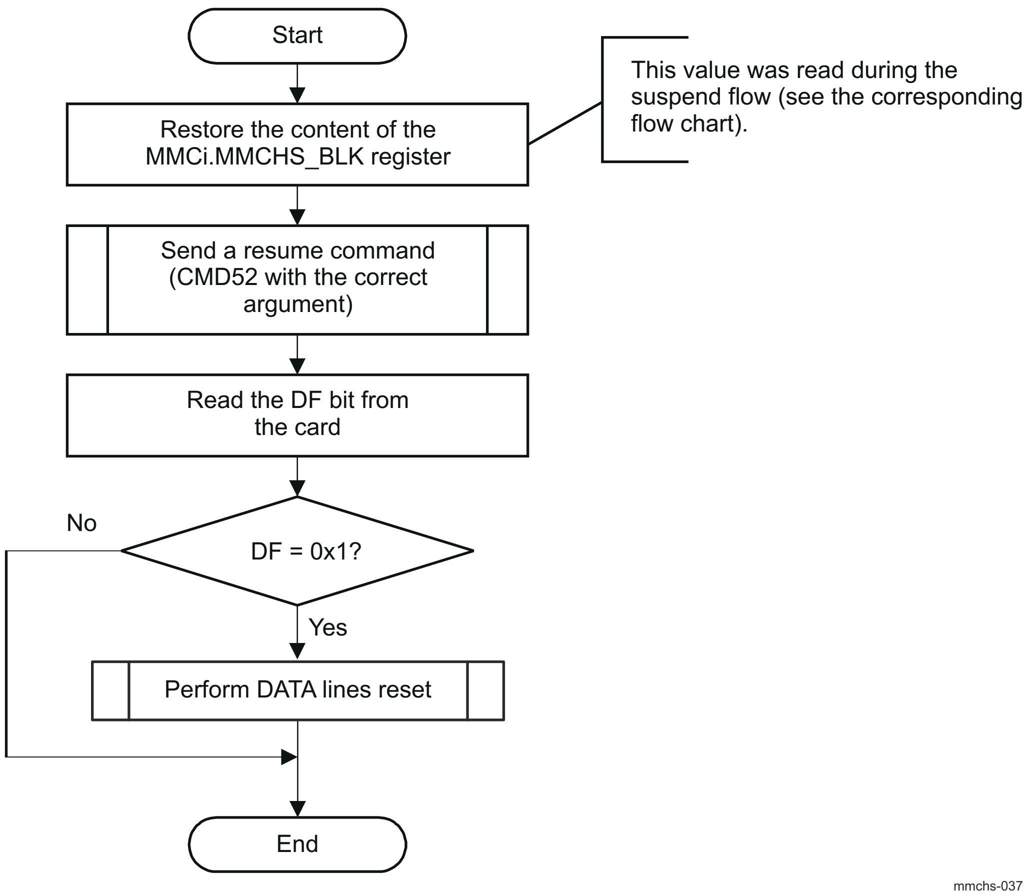

Figure 25-43. eMMC/SD/SDIO Controller Resume Flow

Table 25-42. Register Call Summary for Main Sequence - Resume Flow

Register Name	Register Name

MMCHS_RSP76	MMCHS_CON	MMCHS_HCTL

Table 25-50. Subprocess Call Summary for Main Sequence – Bus Width Configuration Flow

Subprocess Name	Cross-Reference
Initialize module and card.	See Section 25.5.1.1.2, *eMMC/SD/SDIO Host Controller Initialization Flow*. See Section 25.5.1.2.1.1, *Card Detection, Identification, and Selection*.
Send a SEND_CSD command (CMD9).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.
Send SWITCH command (CMD6).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.2 Bus Voltage Selection

The eMMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.3 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns, those pads must have an internal bias voltage reference to operate. The PBIAS module supplies this bias voltage, depending on the settings of the CTRL_CORE_CONTROL_PBIAS register.

For more information about the PBIAS cell, see *PBIAS Cell And MMC1 I/O Cells Control Registers*, in *Control Module*.

Figure 25-48 shows how to configure the MMC1 controller to fit with power switching sequence.

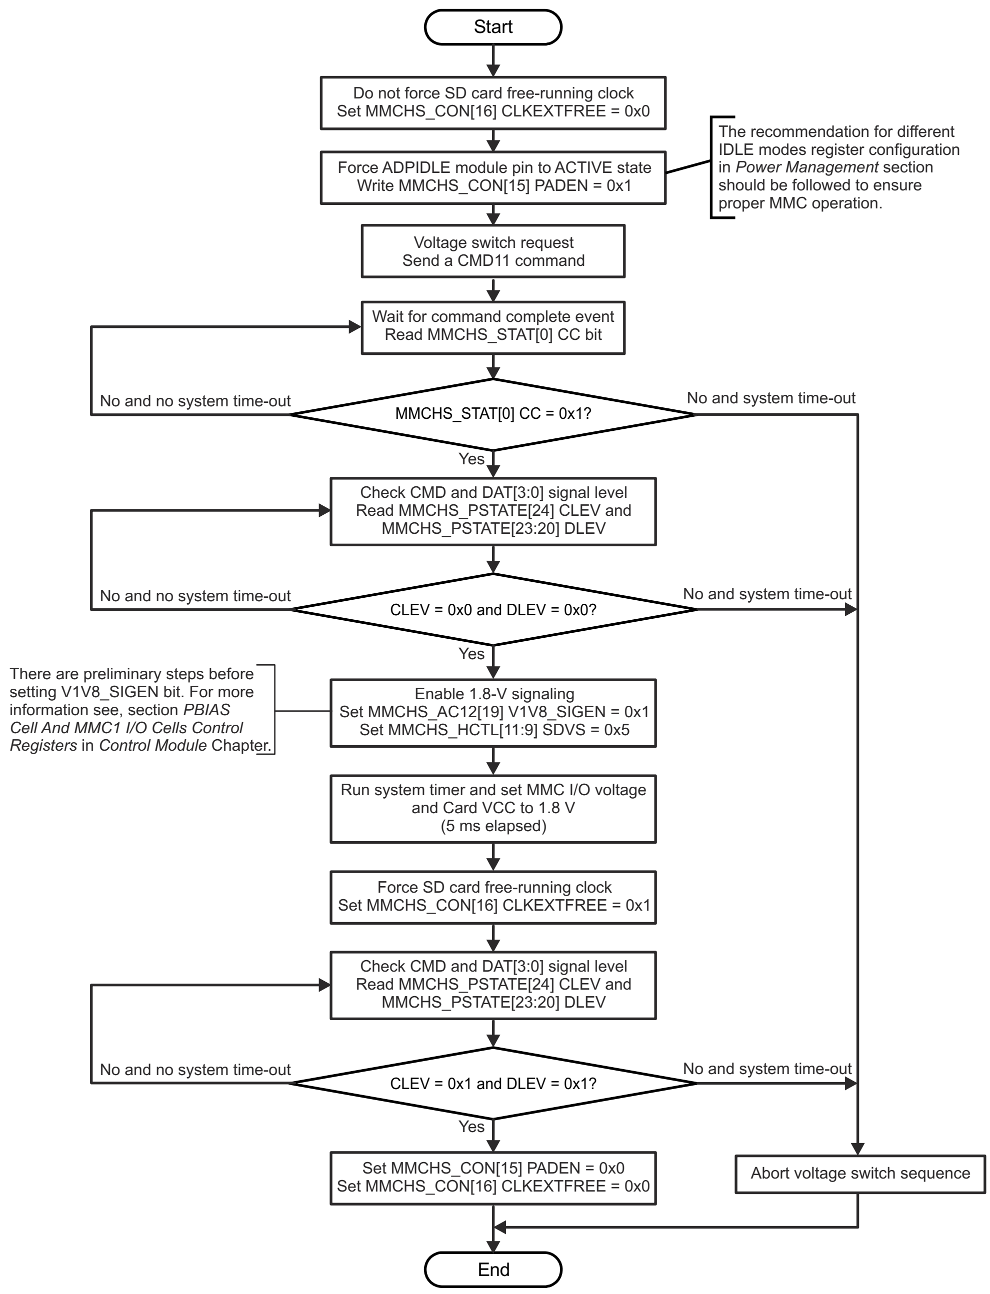

Figure 25-48. eMMC/SD/SDIO Power Switching Procedure

Table 25-51. Register Call Summary for Main Sequence – Power Switching Procedure

Register Name	Register Name
MMCHS_STAT	MMCHS_PSTATE
MMCHS_CMD	MMCHS_CON

Table 25-52. Subprocess Call Summary for Main Sequence – Power Switching Procedure

Subprocess Name	Cross-Reference
Send a READ_DAT_UNTIL_STOP command (CMD11).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.3 Boot Mode Configuration

The following sections describe the two possible ways to issue a boot command: issue a CMD0 or drive the CMD line to 0 during the whole boot phase.

25.5.1.2.3.1 Boot Using CMD0

Figure 25-49 shows the necessary steps to configure the controller boot mode using CMD0.

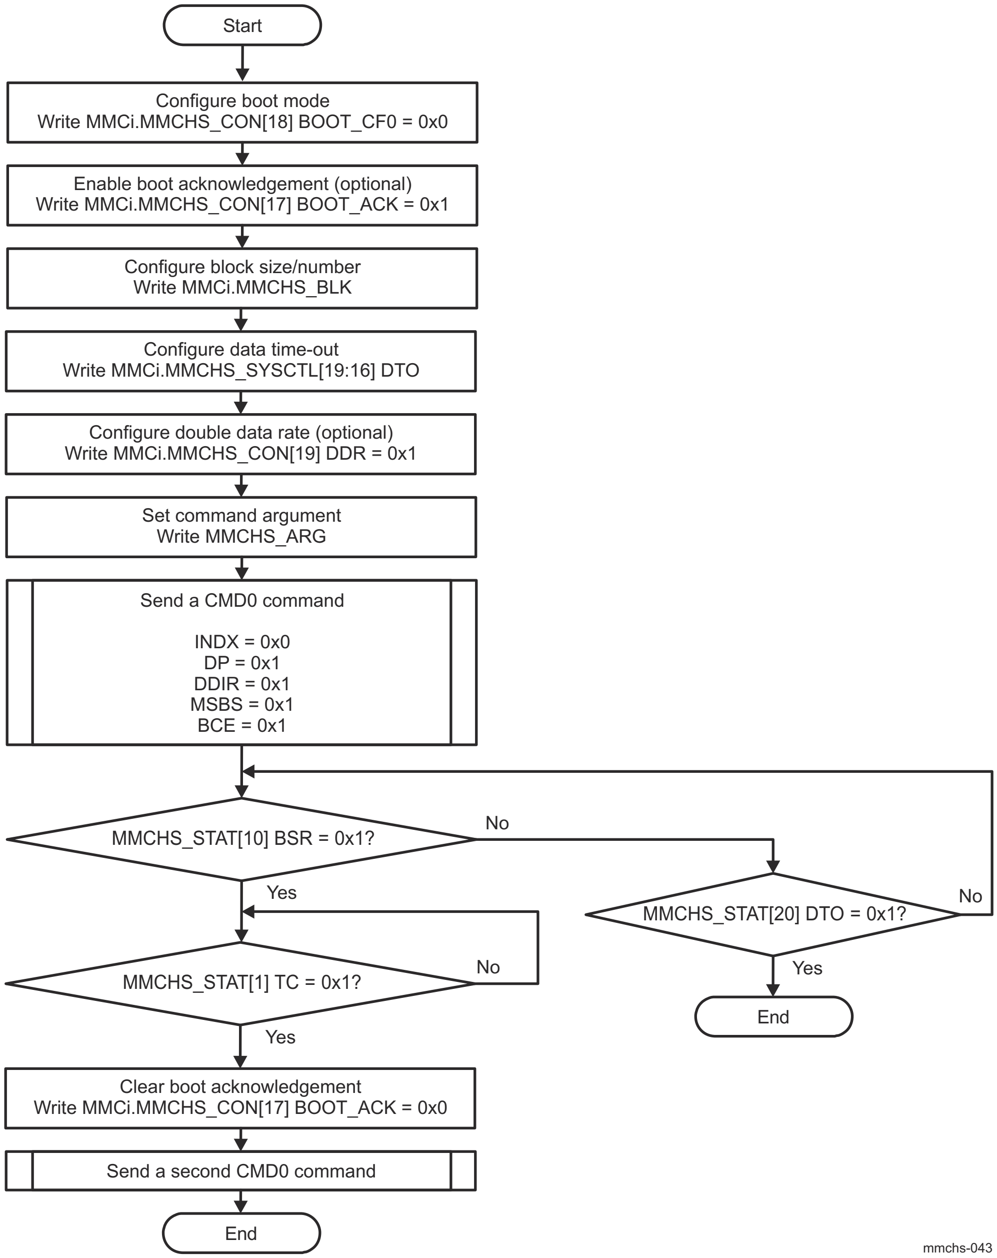

Figure 25-49. eMMC/SD/SDIO Controller Boot Using CMD0

To abort a boot sequence, the system must issue a CMD0 with the MMCHS_CMD[23:22] CMD_TYPE bit field set to 0x3 (the MMCHS_CON[17] BOOT_ACK bit previously cleared to 0x0) during the transfer to abort the transfer and enable the card to exit from boot state.

Table 25-53. Register Call Summary for Main Sequence – Boot Using CMD0

Register Name	Register Name	Register Name
MMCHS_CON	MMCHS_BLK	MMCHS_SYSCTL
MMCHS_ARG	MMCHS_STAT	

Table 25-54. Subprocess Call Summary for Main Sequence – Boot Using CMD0

Subprocess Name	Cross-Reference
Send a CMD0 command.	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.3.2 Boot With CMD Line Tied to 0

Figure 25-50 shows the necessary steps to configure the controller in this mode; the driver must follow this sequence.

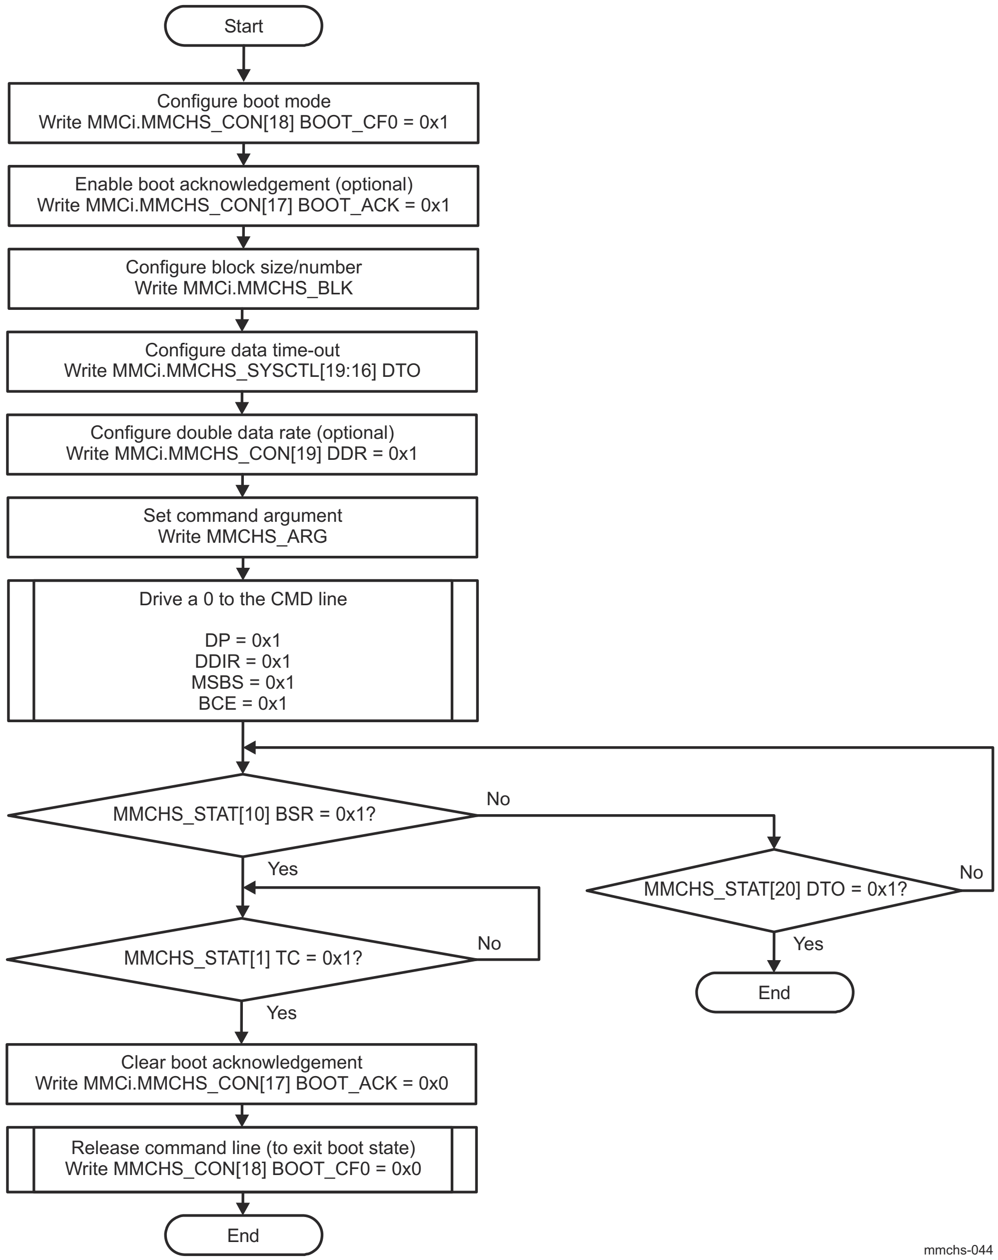

Figure 25-50. eMMC/SD/SDIO Controller Boot With CMD Line Tied to 0

To abort the boot sequence, the system must clear the MMCHS_CON[18] BOOT_CF0 bit to 0x0 during the transfer to abort the transfer and enable the card to exit from boot state.

Table 25-55. Register Call Summary for Main Sequence – Boot Using CMD0

Register Name	Register Name	Register Name
MMCHS_CON	MMCHS_BLK	MMCHS_SYSCTL
MMCHS_ARG	MMCHS_STAT	MMCHS_CMD

Table 25-56. Subprocess Call Summary for Main Sequence – Boot Using CMD0

Subprocess Name	Cross-Reference
Send a CMD0 command.	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.4 SDR104/HS200 DLL Tuning Procedure

Figure 25-51 shows the DLL tuning procedure when SDR104 and HS200 modes are used.

Note

The BRR interrupt has to be enabled during tuning for functionality to succeed. The other error flags in MMCHS_IE can also be enabled for debug purposes. The MMCHS_SYSCTL[25] SRC bit can be set for command related interrupts, but caution has to be taken such that the MMCHS_SYSCTL[26] SRD bit is not set even when DAT related errors occurred, until after tuning completion.

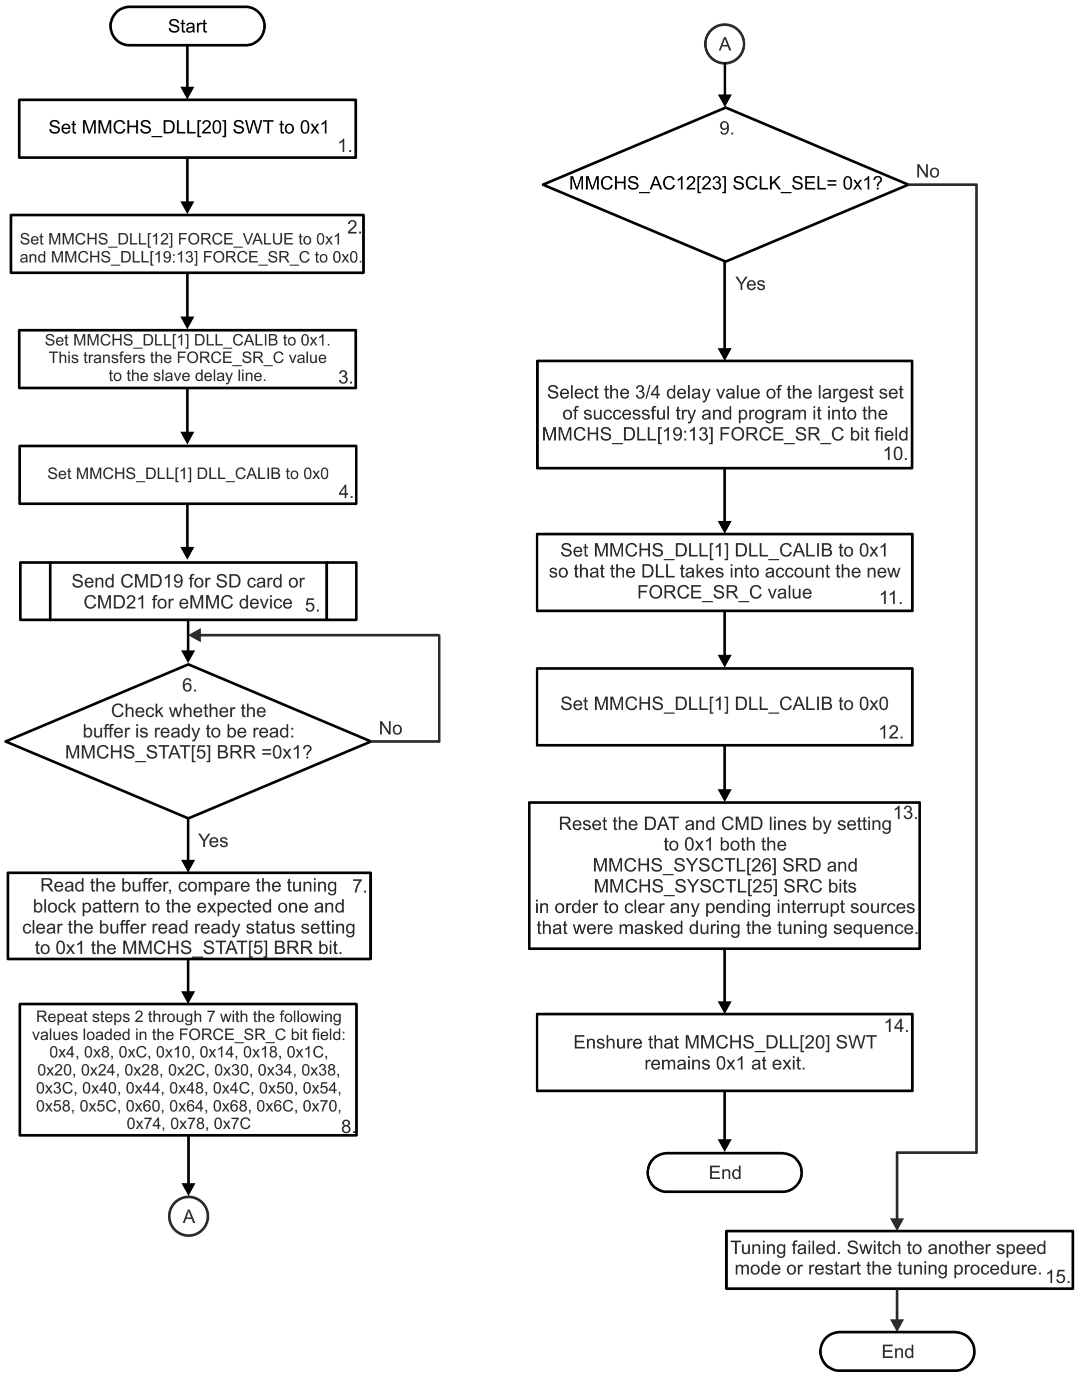

Figure 25-51. SDR104/HS200 DLL Tuning Procedure

25.6 eMMC/SD/SDIO Register Manual

25.6.1 eMMC/SD/SDIO Instance Summary

Table 25-57 lists the eMMC/SD/SDIO instances.

Description	Clock Management Configuration Register		
Type	RW		

31–6	5–4	3–2	1	0
RESERVED	STANDBYMODE	IDLEMODE	FREEEMU	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x000 0000
5:4	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: local initiator is unconditionally placed in standby state.Backup mode, for debug only. 0x1: No-standby mode: local initiator is unconditionally placed out of standby state.Backup mode, for debug only. 0x3: Smart-Standby wakeup-capable mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator. IP module may generate (master-related) wakeup events when in standby state.Mode is only relevant if the appropriate IP module "mwakeup" output is implemented. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator.IP module shall not generate (initiator-related) wakeup events.	RW	0x2

Bits	Field Name	Description	Type	Reset
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's idle state follows (acknowledges) the system's IDLE requests unconditionally, i.e. regardless of the IP module's internal requirements.Backup mode, for debug only. 0x1: No-idle mode: local target never enters idle state.Backup mode, for debug only. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module shall not generate (IRQ- or DMA-request-related) wakeup events.	RW	0x2
1	FREEEMU	Sensitivity to emulation (debug) suspend input signal. Functionality NOT implemented in MMCHS. 0x0: IP module is sensitive to emulation suspend 0x1: IP module is not sensitive to emulation suspend	RW	0
0	SOFTRESET	Software reset. (Optional) Write 0x0: No action Write 0x1: Initiate software reset Read 0x1: Reset (software or other) ongoing Read 0x0: Reset done, no pending action	RW	0

Table 25-63. MMCHS_SYSCONFIG

Address Offset	0x0000 0110

31:14	RESERVED		R	0x0 0000

Bits	Field Name	Description	Type	Reset
13:12	STANDBYMODE	Master interface power Management, standby/wait control. The bit field is only useful when generic parameter MMCHS_HL_HWINFO[0] MADMA_EN (Master ADMA enable) is set as active, otherwise it is a read only register read a '0'. 0x0: Force-standby. Mstandby is forced unconditionnaly. 0x1: No-standby. Mstandby is never asserted. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator.IP module shall not generate (initiator-related) wakeup events.	RW	0x2
11:10	RESERVED		R	0x0
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period. Bit8: Interface clock Bit9: Functional clock 0x0: Interface and Functional clock may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched-off. 0x3: Interface and Functional clocks are maintained. 0x2: Functional clock is maintained. Interface clock may be switched-off.	RW	0x0
7:5	RESERVED	This bit is initialized to zero, and writes to it are ignored. Reads return 0.	R	0x0
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the MMCHS acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally de-asserted. 0x1: If an IDLE request is detected, the request is ignored and the module keeps on behaving normally. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module shall not generate (IRQ- or DMA-request-related) wakeup events.	RW	0x2
2	ENAWAKEUP	Wakeup feature control 0x0: Wakeup capability is disabled 0x1: Wakeup capability is enabled	RW	1
1	SOFTRESET	Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0. Write 0x0: No effect. Write 0x1: Trigger a module reset. Read 0x1: The module is reset. Read 0x0: Normal mode	RW	0

Bits	Field Name	Description	Type	Reset
0	AUTOIDLE	Internal Clock gating strategy 0x0: Clocks are free-running 0x1: Automatic clock gating strategy is applied, based on the Interconnect and MMC interface activity	RW	1

Table 25-64. MMCHS_SYSSTATUS

Address Offset	0x0000 0114

Table 25-65. MMCHS_CSRE

Address Offset	0x0000 0124		
Physical Address	0x4809 C124 0x480B 4124 0x480A D124 0x480D 1124	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	Card Status Response Error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCHS_CSRE[i] is set to 1, if the corresponding bit at the same position in the response MMCHS_RSP0[i] is set to 1, the host controller indicates a card error (MMCHS_STAT[CERR]) interrupt status to avoid the host driver reading the response register (MMCHS_RSP0). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCHS_RESP76) for possible card errors.

Table 25-66. MMCHS_SYSTEST (continued)

Physical Address	0x4809 C128 0x480B 4128 0x480A D128 0x480D 1128	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	System Test Register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCHS_BLK[BLEN]) and the Blocks count for current transfer (MMCHS_BLK[NBLK]) are needed to generate a Buffer write ready interrupt (MMCHS_STAT[BWR]) or a Buffer read ready interrupt (MMCHS_STAT[BRR]) and DMA requests if enabled.

31:22	21	20	19	18	17	16	15	14	13	12	11	10:9	8	7	6	5	4	3	2	1	0
RESERVED	SDMA_LNE	DMA_MNS	DDR	BOOT_CF0	BOOT_ACK	CLKEXTFREE	PADEN	OBIE	OBIP	CEATA	CTPL	DVAL	WPP	CDP	MIT	DW8	MODE	STR	HR	INIT	OD

Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x000

Bits	Field Name	Description	Type	Reset
21	SDMA_LNE	Slave DMA Level/Edge Request: The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to MMCHS_DATA register or late de-assertion, request remains active until last allowed data written into MMCHS_DATA. 0x0: Slave DMA edge sensitive, Early DMA de-assertion 0x1: Slave DMA level sensitive, Late DMA de-assertion	RW	0
20	DMA_MNS	DMA Master or Slave selection: When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory).This option is only available if generic parameter MADMA_EN is asserted to '1'. 0x0: The controller is slave on data transfers with system. 0x1: The controller is master on data exchange with system, controller must be configured as using DMA.	RW	0
19	DDR	Dual Data Rate mode: When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of MMCHS_SYSCTL[CLKD], it is insensitive to MMCHS_HCTL[HSPE] setting. 0x0: Standard mode : data are transmitted on a single edge depending on MMCHS_HCTRL[HSPE]. 0x1: Data Bytes and CRC are transmitted on both edge.	RW	0
18	BOOT_CF0	Boot status supported: This register is set when the CMD line need to be forced to '0' for a boot sequence. CMD line is driven to '0' after writing in MMCHS_CMD. The line is released when this bit field is de-asserted and abort data transfer in case of a pending transaction. Write 0x0: CMD line is released when it was previously forced to '0' by a boot sequence. Write 0x1: CMD line forced to '0' is enabled and will be active after writing into MMCHS_CMD Read 0x1: CMD line forced to '0' is enabled Read 0x0: CMD line not forced	RW	0
17	BOOT_ACK	Boot acknowledge received: When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated. 0x0: No acknowledge to be received 0x1: A boot status will be received on DAT0 line after issuing a command.	RW	0
16	CLKEXTFREE	External clock free running: This register is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if MMCHS_SYSCTL[CEN] is set. 0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if MMCHS_SYSCTL[CEN] is set.	RW	0

Bits	Field Name	Description	Type	Reset
15	PADEN	Control Power for MMC Lines: This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control MMCHS_CON[CTPL] bit. 0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. 0x1: ADPIDLE module pin is forced to active state.	RW	0
14	OBIE	Out-of-Band Interrupt Enable MMC cards only: This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Out-of-Band interrupt detection disabled 0x1: Out-of-Band interrupt detection enabled	RW	0
13	OBIP	Out-of-Band Interrupt Polarity MMC cards only: This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Active high level 0x1: Active low level	RW	0
12	CEATA	CE-ATA control mode MMC cards compliant with CE-ATA:By default, this bit is set to 0. It is used to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. 0x0: Standard MMC/SD/SDIO mode. 0x1: CE-ATA mode next commands are considered as CE-ATA commands.	RW	0
11	CTPL	Control Power for DAT[1] line MMC and SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers. 0x0: Disable all the input buffers outside of a transaction. 0x1: Disable all the input buffers except the buffer of DAT[1] outside of a transaction.	RW	0

Bits	Field Name	Description	Type	Reset
10:9	DVAL	Debounce filter value All cards This register is used to define a debounce period to filter the card detect input signal (mmci_sdcd). The usage of the card detect input signal (mmci_sdcd) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: 33 us debounce period 0x1: 231 us debounce period 0x3: 8,4 ms debounce period 0x2: 1 ms debounce period	RW	0x3
8	WPP	Write protect polarity For SD and SDIO cards only This bit selects the active level of the write protect input signal (mmci_sdwp). The usage of the write protect input signal (mmci_sdwp) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level 0x1: Active low level	RW	0
7	CDP	Card detect polarity All cards This bit selects the active level of the card detect input signal (mmci_sdcd). The usage of the card detect input signal (mmci_sdcd) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active low level 0x1: Active high level	RW	0
6	MIT	MMC interrupt command Only for MMC cards. This bit must be set to 1, when the next write access to the command register (MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0x0: Command timeout enabled 0x1: Command timeout disabled	RW	0
5	DW8	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification 4.x (see section 3.6). 0x0: 1-bit or 4-bit Data width (DAT[0] used, MMC, SD cards) 0x1: 8-bit Data width (DAT[7:0] used, MMC cards)	RW	0

Bits	Field Name	Description	Type	Reset
4	MODE	Mode select All cards This bit select between Functional mode and SYSTEST mode. 0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the CMD register. 0x1: SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.	RW	0
3	STR	Stream command Only for MMC cards. This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer 0x1: Stream oriented data transfer	RW	0
2	HR	Broadcast host response Only for MMC cards. This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core (see section 4.3, "Interrupt Mode", in the MMC specification). In order to have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1. When MMCHS_CON[CEATA] is set to 1 and MMCHS_ARG set to 0x00000000 when writing 0x00000000 into MMCHS_CMD register, the host controller performs a 'command completion signal disable' token i.e. CMD line held to '0' during 47 cycles followed by a 1. 0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.	RW	0
1	INIT	Send initialization stream All cards. When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCHS_SYSCTL[CLKD]) should be set to ensure that 80 clock periods are greater than 1ms. (see section 9.3, "Power-Up", in the MMC card specification, or section 6.4 in the SD card specification). Note: in this mode, there is no command sent to the card and no response is expected 0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.	RW	0

Bits	Field Name	Description	Type	Reset
0	OD	Card open drain mode. Only for MMC cards. This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCHS_CON[HR]) 0x0: No Open Drain 0x1: Open Drain or Broadcast host response	RW	0

SDMA_ARG2																															

Bits	Field Name	Description	Type	Reset
31:0	SDMA_ARG2	SDMA System Address / Argument 2 This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23. (1) SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. (2) Argument 2 This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without AMDA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.	RW	0x0000 0000

Table 25-71. MMCHS_BLK

Address Offset	0x0000 0204

Description	Transfer Length Configuration Register MMCHS_BLK[BLEN] is the block size register. MMCHS_BLK[NBLK] is the block count register. This register shall be used for any card.		

Table 25-71. MMCHS_BLK (continued)

Type RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NBLK																RESERVED				BLEN											

Bits	Field Name	Description	Type	Reset
31:16	NBLK	Blocks count for current transfer This register is enabled when Block count Enable (MMCHS_CMD[BCE]) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e, after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count. 0xFFFF: 65535 blocks 0x0: Stop count 0x1: 1 block 0x2: 2 blocks	RW	0x0000
15:12	RESERVED		R	0x0
11:0	BLEN	Transfer Block Size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (MMCHS_STAT[TC] set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched. 0x1: 1 byte block length 0x7FF: 2047 bytes block length 0x0: No data transfer 0x1FF: 511 bytes block length 0x800: 2048 bytes block length 0x2: 2 bytes block length 0x3: 3 bytes block length 0x200: 512 bytes block length	RW	0x000

23:22	CMD_TYPE	Command type This register specifies three types of special command: Suspend, Resume and Abort.	RW	0x0

Bits	Field Name	Description	Type	Reset
		These bits shall be set to 00b for all other commands. 0x0: Others Commands 0x1: CMD52 for writing "Bus Suspend" in CCCR 0x3: Abort command CMD12, CMD52 for writing " I/O Abort" in CCCR 0x2: CMD52 for writing "Function Select" in CCCR		
21	DP	Data present select This register indicates that data is present and DAT line shall be used. It must be set to 0 in the following conditions: - command using only CMD line - command with no data transfer but using busy signal on DAT[0] - Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCHS_STAT[CIE] set to1). **Note:** The register CICE cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCHS_STAT[CCRC] set to 1). **Note:** The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable	RW	0
18	RESERVED		R	0
17:16	RSP_TYPE	Response type This bits defines the response type of the command 0x0: No response 0x1: Response Length 136 bits 0x3: Response Length 48 bits with busy after response 0x2: Response Length 48 bits	RW	0x0
15:6	RESERVED		R	0x000
5	MSBS	Multi/Single block select This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0.	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: Single block. If this bit is 0, it is not necessary to set the register MMCHS_BLK[NBLK]. 0x1: Multi block. When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer.		
4	DDIR	Data transfer Direction Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host)	RW	0
3:2	ACEN	Auto CMD Enable - SD card only. This field determines use of auto command functions. There are two methods to stop Multiple-block read and write operation 1. Auto CMD12 Enable When this field is set to 01b, the Host Controller issues CMD12 automatically when last block transfer is completed. Auto CMD12 error is indicated to the Auto CMD Error Status register (MMCHS_AC12). The Host Driver shall not set this bit if the command does not require CMD12. In particular, secure commands defined in the Part 3 File Security specification do not require CMD12. 2. Auto CMD23 Enable When this bit field is set to 10b, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register. The Host Controller Version 3.00 and later shall support this function. The following conditions are required to use the Auto CMD23. – Auto CMD23 Supported (Host Controller Version is 3.00 or later) – A memory card that supports CMD23 (SCR[33]=1) – If DMA is used, it shall be ADMA. –Only when CMD18 or CMD25 is issued (**Note:** the Host Controller does not check command index.) Auto CMD23 can be used with or without ADMA. By writing the Command register, the Host Controller issues a CMD23 first and then issues a command specified by the Command Index in Command register. If response errors of CMD23 are detected, the second command is not issued. A CMD23 error is indicated in the Auto CMD Error Status register (MMCHS_AC12). 32-bit block count value for CMD23 is set to SDMA System Address / Argument 2 register (MMCHS_SDMASA). 0x0: Auto Command Disabled 0x1: Auto CMD12 enable or CCS detection enabled. 0x3: Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x2: Auto CMD23 Enable		
1	BCE	Block Count Enable Multiple block transfers only. This bit is used to enable the block count register (MMCHS_BLK[NBLK]). When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks	RW	0
0	DE	DMA Enable This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

Description	Data Register This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x00
24	CLEV	CMD line signal level This status is used to check the CMD line level to recover from errors, and for debugging. The value of this register after reset depends on the CMD line level at that time. Read 0x1: The CMD line level is 1. Read 0x0: The CMD line level is 0.	R	-
23:20	DLEV	DAT[3:0] line signal level DAT[3] => bit 23 DAT[2] => bit 22 DAT[1] => bit 21 DAT[0] => bit 20 This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The value of these registers after reset depends on the DAT lines level at that time.	R	0x-
19	WP	Write protect switch pin level For SDIO cards only. This bit reflects the write protect input pin (mmci_sdwp) level. The value of this register after reset depends on the protect input pin (mmci_sdwp) level at that time. Read 0x1: If MMCHS_CON[WPP] is set to 0 (default), the card is not write protected, otherwise the card is protected. Read 0x0: If MMCHS_CON[WPP] is set to 0 (default), the card is write protected, otherwise the card is not protected.	R	-

Bits	Field Name	Description	Type	Reset
18	CDPL	Card detect pin level This bit reflects the inverse value of the card detect input pin (mmci_sdcd), debouncing is not performed on this bit and bit is valid only when Card State Stable (MMCHS_PSTAE[CSS]) is set to 1. Use of this bit is limited to testing since it must be debounced y software. The value of this register after reset depends on the card detect input pin (mmci_sdcd) level at that time. Read 0x1: The value of the card detect input pin (mmci_sdcd) is 0 Read 0x0: The value of the card detect input pin (mmci_sdcd) is 1	R	-
17	CSS	Card State Stable This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (MMCHS_PSTATE[CDPL]). Debouncing is performed on the card detect input pin (mmci_sdcd) to detect card stability. This bit is not affected by a software reset. Read 0x1: No card or card inserted Read 0x0: Reset or Debouncing	R	0
16	CINS	Card inserted This bit is the debounced value of the card detect input pin (mmci_sdcd). An inactive to active transition of the card detect input pin (mmci_sdcd) will generate a card insertion interrupt (MMCHS_STAT[CINS]). A active to inactive transition of the card detect input pin (mmci_sdcd) will generate a card removal interrupt (MMCHS_STAT[REM]). This bit is not affected by a software reset. Read 0x1: If MMCHS_CON[CDP] is set to 1, the card has been inserted from the card slot. If MMCHS_CON[CDP] is set to 0, no card is detected. The card may have been removed from the card slot. Read 0x0: If MMCHS_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot. If MMCHS_CON[CDP] is set to 0, the card has been inserted.	R	0
15:12	RESERVED		R	0x0
11	BRE	Buffer read enable This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCHS_BLK[BLEN] has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCHS_STAT[BRR]). Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer. Read 0x0: Read BLEN bytes disable	R	0
10	BWE	Buffer Write enable This status is used for non-DMA write transfers. It indicates if space is available for write data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data. Read 0x0: There is no room left in the buffer to write BLEN bytes of data.	R	0

Bits	Field Name	Description	Type	Reset
9	RTA	Read transfer active This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request. Read 0x1: read data transfer on going. Read 0x0: No valid data on the DAT lines.	R	0
8	WTA	Write transfer active This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request. Read 0x1: Write data transfer on going. Read 0x0: No valid data on the DAT lines.	R	0
7:4	RESERVED		R	0x0
3	RTR	Re-Tuning Request Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This bit is cleared when a command is issued with setting MMCHS_AC12[22] ET. This bit isn't set to 1 if MMCHS_AC12[23] SCLK_SEL is set to 0 (using fixed sampling clock). Refer to MMCHS_CAPA2[15:14] RTM for more detail. Read 0x1: Sampling clock needs re-tuning Read 0x0: Fixed or well tuned sampling clock	R	0
2	DLA	DAT line active This status bit indicates whether one of the DAT line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. Read 0x1: DAT Line active Read 0x0: DAT Line inactive	R	0

Bits	Field Name	Description	Type	Reset
1	DATI	Command inhibit(DAT) This status bit is generated if either DAT line is active (MMCHS_PSTATE[DLA]) or Read transfer is active (MMCHS_PSTATE[RTA]) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCHS_STAT[TC]). Read 0x1: Issuing of command using DAT lines is not allowed Read 0x0: Issuing of command using the DAT lines is allowed	R	0
0	CMDI	Command inhibit(CMD) This status bit indicates that the CMD line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is set to 0 in either the following cases: - After the end bit of the command response, excepted if there is a command conflict error (MMCHS_STAT[CCRC] or MMCHS_STAT[CEB] set to 1) or a Auto CMD12 is not executed (MMCHS_AC12[ACNE]). - After the end bit of the command without response (MMCHS_CMD[RSP_TYPE] set to "00") In case of a command data error is detected (MMCHS_STAT[CTO] set to 1), this register is not automatically cleared. Read 0x1: Issuing of command using CMD line is not allowed Read 0x0: Issuing of command using CMD line is allowed	R	0

Bits	Field Name	Description	Type	Reset
31:28	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
27	OBWE	Wakeup event enable for 'Out-of-Band' Interrupt. This bit enables wakeup events for 'Out-of-Band' assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). The write to this register is ignored when MMCHS_CON[OBIE] is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt 0x1: Enable wakeup on 'Out-of-Band' Interrupt	RW	0
26	REM	Wakeup event enable on SD card removal This bit enables wakeup events for card removal assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card removal 0x1: Enable wakeup on card removal	RW	0
25	INS	Wakeup event enable on SD card insertion This bit enables wakeup events for card insertion assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card insertion 0x1: Enable wakeup on card insertion	RW	0
24	IWE	Wakeup event enable on SD card interrupt This bit enables wakeup events for card interrupt assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt	RW	0
23:20	RESERVED		R	0x0
19	IBG	Interrupt block at gap This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode	RW	0
18	RWC	Read wait control The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCHS_HCTL[SBGR]) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line. 0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control	RW	0

Bits	Field Name	Description	Type	Reset
17	CR	Continue request This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCHS_HCTL[SBGR]). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e DAT line is active (MMCHS_PSTATE[DLA]) or transferring data (MMCHS_PSTATE[WTA]). The Stop at block gap request must be disabled (MMCHS_HCTL[SBGR]=0) before setting this bit. 0x0: No affect 0x1: transfer restart	RW	0
16	SBGR	Stop at block gap request This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCHS_HCTL[CR]) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCHS_STAT[TC] set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCHS_DATA). 0x0: Transfer mode 0x1: Stop at block gap	RW	0
15:12	RESERVED		R	0x0
11:9	SDVS	SD bus voltage select All cards. The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system (MMCHS_CAPA[VS18,VS30,VS33]) before starting a transfer. 0x6: 3.0V (Typical) 0x7: 3.3V (Typical) 0x5: 1.8V (Typical)	RW	0x0
8	SDBP	SD bus power Before setting this bit, the host driver shall select the SD bus voltage (MMCHS_HCTL[SDVS]). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage MMCHS_HCTL[SDVS] is not supported according to capability register (MMCHS_CAPA[VS*]). 0x0: Power off 0x1: Power on	RW	0
7	CDSS	Card Detect Signal Selection This bit selects source for the card detection.When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupts caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing. 0x0: mmci_sdcd is selected (for normal use) 0x1: MMCHS_HCTL[6] CDTL is selected (for test purpose)	RW	0

Bits	Field Name	Description	Type	Reset
6	CDTL	Card Detect Test Level: This bit is enabled while MMCHS_HCTL[7] CDSS is set to 1 and it indicates whether the card is inserted or not. 0x0: No Card 0x1: Card Inserted	RW	0
5	RESERVED		R	0
4:3	DMAS	DMA Select Mode: One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register MMCHS_CAPA . Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MADMA_EN is set to 1. When MADMA_EN is set to 0 the bit field is read only and returned value is 0. 0x0: Reserved 0x1: Reserved 0x3: Reserved 0x2: 32-bit Address ADMA2 is selected	RW	0x0
2	HSPE	Before setting this bit, the Host Driver shall check the MMCHS_CAPA[21] HSS. This bit shall not be set when dual data rate mode is activated in MMCHS_CON[DDR]. 0x0: The Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock 0x1: The Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock **NOTE: Do not set this bit to 0x1 because device was timing closed with HSPE bit set to 0x0 for all supported modes of operation.**	RW	0
1	DTW	Data transfer width For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with MMC standard specification 4.x (see section 3.6). This register has no effect when the MMC 8-bit mode is selected (register MMCHS_CON[DW8] set to1), For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (DAT[0] used) 0x1: 4-bit Data width (DAT[3:0] used)	RW	0
0	LED	Reserved bit. LED control feature is not supported This bit is initialized to zero, and writes to it are ignored.	R	0

Bits	Field Name	Description	Type	Reset
31:27	RESERVED		R	0x00
26	SRD	Software reset for DAT line This bit is set to 1 for reset and released to 0 when completed. For more information about SRD bit manipulation, see *DATA Lines Reset Procedure*. DAT finite state machine in both clock domain are also reset. Here below are the registers cleared by MMCHS_SYSCTL[SRD]: - MMCHS_DATA - MMCHS_PSTATE: BRE, BWE, RTA, WTA, DLA and DATI - MMCHS_HCTL: SBGR and CR - MMCHS_STAT: BRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. 0x0: Reset completed 0x1: Software reset for DAT line	RW	0
25	SRC	Software reset for CMD line For more information about SRC bit manipulation, see *CMD Line Reset Procedure*. This bit is set to 1 for reset and released to 0 when completed. CMD finite state machine in both clock domain are also reset. Here below the registers cleared by MMCHS_SYSCTL[SRC]: - MMCHS_PSTATE: CMDI - MMCHS_STAT: CC Interconnect and MMC command status management is reinitialized. 0x0: Reset completed 0x1: Software reset for CMD line	RW	0
24	SRA	Software reset for all This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the capabilities registers (MMCHS_CAPA and MMCHS_CUR_CAPA). 0x0: Reset completed 0x1: Software reset for all the design	RW	0
23:20	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
19:16	DTO	Data timeout counter value and busy timeout. This value determines the interval by which DAT lines timeouts are detected. The host driver needs to set this bitfield based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCHS_CAPA[TCF]). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCHS_STA[DTO]). The MMCHS_SYSCTL[DTO] register is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0xF: Reserved 0x0: TCF x 2^13 0x1: TCF x 2^14 0xE: TCF x 2^27	RW	0x0
15:6	CLKD	Clock frequency select These bits define the ratio between MMCi_FCLK and the output clock frequency on the CLK pin of either the memory card (MMC, SD or SDIO). 0x0: MMCi_FCLK bypass 0x1: MMCi_FCLK bypass 0x2: MMCi_FCLK / 2 0x3: MMCi_FCLK / 3 0x3FF: MMCi_FCLK / 1023	RW	0x000
5	CGS	Clock Generator Select - For SD cards Host Controller Version 3.00 supports this bit. This bit is used to select the clock generator mode in MMCHS_SYSCTL[15:6] CLKD. If the Programmable Clock Mode is supported (non-zero value is set to MMCHS_CAPA2[23:16] CM), this bit attribute is RW, and if not supported, this bit attribute is RO and zero is read. This bit depends on the setting of MMCHS_AC12[31] PV_ENABLE. If PV_ENABLE = 0, this bit is set by Host Driver. If PV_ENABLE = 1, this bit is automatically set to a value specified in one of Preset Value registers, see, Table 25-22.	R	0
4:3	RESERVED		R	0x0
2	CEN	Clock enable This bit controls if the clock is provided to the card or not. 0x0: The clock is not provided to the card . Clock frequency can be changed . 0x1: The clock is provided to the card and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCHS_SYSCTL[ICS]).	RW	0

Bits	Field Name	Description	Type	Reset
1	ICS	Internal clock stable (status) This bit indicates either the internal clock is stable or not. Read 0x1: The internal clock is stable after enabling the clock (MMCHS_SYSCTL[ICE]) or after changing the clock ratio (MMCHS_SYSCTL[CLKD]). Read 0x0: The internal clock is not stable.	R	0
0	ICE	Internal clock enable This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wakeup events) and the interface clock (used for reads and writes to the module register map) are not affected by this register. 0x0: The internal clock is stopped (very low power state). 0x1: The internal clock oscillates and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value) .	RW	0

Bits	Field Name	Description	Type	Reset
28	CERR	Card error This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCHS_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read MMCHS_RSP76 register to detect error bits in the command response. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card error Read 0x0: No Error	RW	0
27	RESERVED		R	0
26	TE	Tuning Error This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure (Occurrence of an error during tuning procedure is indicated by Sampling Select). By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning. To reset tuning circuit, Sampling Clock shall be set to 0 before executing tuning procedure. The Tuning Error is higher priority than the other error interrupts generated during data transfer. By detecting Tuning Error, the Host Driver should discard data transferred by a current read/write command and retry data transfer after the Host Controller retrieved from tuning circuit error. The bit is set if the lock is lost (but not during the tuning process) or if the lock counter expires without the lock being asserted. If the latter happens, the SW can decide to ignore the interrupt and wait some more for the lock to be set. 0x0: No Error 0x1: Error	RW	0
25	ADMAE	ADMA Error: This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register.In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: ADMA error Read 0x0: No Interrupt.	RW	0

Bits	Field Name	Description	Type	Reset
24	ACE	Auto CMD error Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register (MMCHS_AC12) has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Auto CMD error Read 0x0: No Error.	RW	0
23	RESERVED		R	0
22	DEB	Data End Bit error This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data end bit error Read 0x0: No Error	RW	0
21	DCRC	Data CRC Error This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data CRC error Read 0x0: No Error.	RW	0
20	DTO	Data timeout error This bit is set automatically according to the following conditions: - busy timeout for R1b, R5b response type - busy timeout after write CRC status - write CRC status timeout - read data timeout Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Time out Read 0x0: No error.	RW	0
19	CIE	Command index error This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable in MMCHS_CMD[CICE] register. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command index error Read 0x0: No error.	RW	0

Bits	Field Name	Description	Type	Reset
18	CEB	Command end bit error This bit is set automatically when detecting a 0 at the end bit position of a command response. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command end bit error Read 0x0: No error.	RW	0
17	CCRC	Command CRC Error This bit is set automatically when there is a CRC7 error in the command response depending on the enable in MMCHS_CMD[CCCE] register. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command CRC error Read 0x0: No Error.	RW	0
16	CTO	Command Timeout Error This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Time Out Read 0x0: No error	RW	0
15	ERRI	Error Interrupt If any of the bits in the Error Interrupt Status register (MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. Read 0x1: Error interrupt event(s) occurred Read 0x0: No Interrupt.	R	0
14:11	RESERVED		R	0x0
10	BSR	Boot status received interrupt This bit is set automatically when MMCHS_CON[BOOT] is set 0x1 or 0x2 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Boot status received interrupt. Read 0x0: No Interrupt.	RW	0
9	OBI	Out-Of-Band interrupt This bit is set automatically when MMCHS_CON[OBIE] is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCHS_CON[OBIP]. This interrupt is only useful for MMC card. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Interrupt Out-Of-Band occurs Read 0x0: No Out-Of-Band interrupt.	RW	0

Bits	Field Name	Description	Type	Reset
8	CIRQ	Card interrupt This bit is only used for SD and SDIO and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives CMD line to zero during one cycle after data transmission end.All modes above are fully exclusive. The controller interrupt must be clear by setting MMCHS_IE[CIRQ] to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCHS_IE[CIRQ] is set to 1. Writes to this bit are ignored. Read 0x1: Generate card interrupt Read 0x0: No card interrupt	R	0
7	CREM	Card removal This bit is set automatically when MMCHS_PSTATE[CINS] changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card removed Read 0x0: Card state stable or Debouncing	RW	0
6	CINS	Card insertion This bit is set automatically when MMCHS_PSTATE[CINS] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card inserted Read 0x0: Card state stable or debouncing	RW	0
5	BRR	Buffer read ready This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by MMCHS_BLK[BLEN] is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Ready to read buffer Read 0x0: Not Ready to read buffer	RW	0

Bits	Field Name	Description	Type	Reset
4	BWR	Buffer write ready This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCHS_BLK[BLEN]. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Ready to write buffer Read 0x0: Not Ready to write buffer	RW	0
3	DMA	DMA interrupt : This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: No dma interrupt Read 0x0: Dma interrupt detected	RW	0
2	BGE	Block gap event When a stop at block gap is requested (MMCHS_HCTL[SBGR]), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. This event does not occur when the stop at block gap is requested on the last block. In read mode, a 1-to-0 transition of the DAT Line active status (MMCHS_PSTATE[DLA]) between data blocks generates a Block gap event interrupt. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Transaction stopped at block gap Read 0x0: No block gap event	RW	0
1	TC	Transfer completed This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCHS_HCTL[SBGR]). In Read mode: This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[RTA]). In write mode: This bit is set automatically on completion of the DAT line use (MMCHS_PSTATE[DLA]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data transfer complete Read 0x0: No transfer complete	RW	0

Bits	Field Name	Description	Type	Reset
0	CC	Command complete This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[CMDI]) If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCHS_STAT[CTO]) has higher priority than command complete (MMCHS_STAT[CC]). If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command complete Read 0x0: No Command complete	RW	0

Table 25-85. MMCHS_AC12

Address Offset	0x0000 023C		
Physical Address	0x4809 C23C 0x480B 423C 0x480A D23C 0x480D 123C	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	Host Control 2 Register and Auto CMD Error Status Register This register is used to indicate CMD12 response error of Auto CMD12 and CMD23 response error of Auto CMD23. The Host driver can determine what kind of Auto CMD12 / CMD23 errors occur by this register. Auto CMD23 errors are indicated only in bits[4:1]. Bits[7:0] are valid only when the MMCHS_CMD[3:2] ACEN bitfield is configured to enable Auto CMD and the Auto CMD Error bit (MMCHS_STAT[24]ACE) is set.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PV_ENABLE	AI_ENABLE	RESERVED	SCLK_SEL	ET	DS_SEL	V18_SIGEN	UHSMS	RESERVED	CNI	RESERVED	ACIE	ACEB	ACCE	ACTO	ACNE

Bits	Field Name	Description	Type	Reset
31	PV_ENABLE	Preset Value Enable Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set, automatic SDCLK frequency generation and driver strength selection is performed without considering system specific conditions. This bit enables the functions defined in the Preset Value registers, see, Table 25-22. If this bit is set to 0, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Driver. If this bit is set to 1, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Controller as specified in the Preset Value registers, see, Table 25-22. 0x0: SDCLK and Driver Strength (DS_SEL) are controlled by Host Driver. 0x1: Automatic Selection by Preset Value are Enabled.	RW	0
30	AI_ENABLE	Asynchronous Interrupt Enable This bit can be set to 1 if a card supports asynchronous interrupts and MMCHS_CAPA[29] AIS is set to 1. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver the Card Interrupt to the host when it is asserted by the Card. 0x0: Disabled 0x1: Enabled	RW	0
29:24	RESERVED		R	0x00
23	SCLK_SEL	Sampling Clock Select Host Controller uses this bit to select sampling clock to receive CMD and DAT. This bit is set by tuning procedure and valid after the completion of tuning (when MMCHS_AC12[22] ET is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting MMCHS_AC12[22] ET. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to compete re-tuning sequence in a short time. Change of this bit is not allowed while the Host Controller is receiving response or a read data block. 0x0: Fixed clock is used to sample data 0x1: Tuned clock is used to sample data	RW	0

Bits	Field Name	Description	Type	Reset
22	ET	Execute Tuning This bit is set to 1 to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to MMCHS_AC12[23] SCLK_SEL. Tuning procedure is aborted by writing 0. This is Read-Write with automatic clear register 0x0: Not Tuned or Tuning Completed 0x1: Execute Tuning	RW	0
21:20	DS_SEL	Driver Strength Select Host Controller output driver in 1.8V signaling is selected by this bit. In 3.3V signaling, this field is not effective. This field can be set depending on Driver Type A, C and D support bits (DTA, DTC and DTD respectively) in the MMCHS_CAPA2 register. This bit depends on setting of Preset Value Enable. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set by a value specified in the one of Preset Value registers, see, Table 25-22. 0x0: Driver Type B is selected (Default) 0x1: Driver Type A is selected 0x3: Driver Type D is selected 0x2: Driver Type C is selected	RW	0x0
19	V1V8_SIGEN	1.8V Signaling Enable This bit controls voltage regulator for I/O cell. 3.3V is supplied to the card regardless of signaling voltage. Setting this bit from 0 to 1 starts changing signal voltage from 3.3V to 1.8V. 1.8V regulator output shall be stable within 5ms. Host Controller clears this bit if switching to 1.8V signaling fails. Clearing this bit from 1 to 0 starts changing signal voltage from 1.8V to 3.3V. 3.3V regulator output shall be stable within 5ms. Host Driver can set this bit to 1 when Host Controller supports 1.8V signaling (One of support bits is set to 1: SDR50, SDR104 or DDR50 in MMCHS_CAPA2 register) and the card or device supports UHS-I (S18A=1. Refer to Bus Signal Voltage Switch Sequence in the Physical Layer Specification Version 3.0x). 0x0: 3.3V Signaling 0x1: 1.8V Signaling	RW	0

Bits	Field Name	Description	Type	Reset
18:16	UHSMS	UHS Mode Select This field is used to select one of UHS-I modes or eMMC HS200 mode and is effective when 1.8V Signaling Enable is set to 1. If MMCHS_AC12[31] PV_ENABLE is set to 1, Host Controller sets MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL according to Preset Value registers, see, Table 25-22. In this case, one of preset value registers is selected by this field. Host Driver needs to reset MMCHS_SYSCTL[2] CEN before changing this field to avoid generating clock glitch. After setting this field, Host Driver sets MMCHS_SYSCTL[2] CEN again. When SDR50, SDR104 or DDR50 is selected for SDIO card, interrupt detection at the block gap shall not be used. Read Wait timing is changed for these modes. Refer to the SDIO Specification Version 3.00 for more detail. 0x0: SDR12 0x1: SDR25 0x2: SDR50 0x3: SDR104/HS200 0x4: DDR50 0x5: Reserved 0x6: Reserved 0x7: Reserved	RW	0x0
15:8	RESERVED		R	0x00
7	CNI	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. Read 0x1: Command not issued Read 0x0: No error	R	0
6:5	RESERVED		R	0x0
4	ACIE	Auto CMD Index Error - For Auto CMD12 and Auto CMD23 This bit is set if the Command Index error occurs in response to a command. Read 0x1: Error Read 0x0: No error	R	0
3	ACEB	Auto CMD End Bit Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting that the end bit of command response is 0. Read 0x1: End bit Error Generated Read 0x0: No error	R	0
2	ACCE	Auto CMD CRC Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting a CRC error in the command response. Read 0x1: CRC Error Generated Read 0x0: No error	R	0

Bits	Field Name	Description	Type	Reset
1	ACTO	Auto CMD Timeout Error - For Auto CMD12 and Auto CMD23 This bit is set if no response is returned within 64 SDCLK cycles from the end bit of command. If this bit is set to1, the other error status bits (D04-D02) are meaningless. Read 0x1: Auto CMD Time Out Read 0x0: No error	R	0
0	ACNE	Auto CMD12 Not Executed If memory multiple block data transfer is not started due to command error, this bit is not set because it is not necessary to issue Auto CMD12. Setting this bit to 1 means the Host Controller cannot issue Auto CMD12 to stop memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (D04-D01) are meaningless. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. Read 0x1: Auto CMD12 Not Executed Read 0x0: Auto CMD12 Executed	R	0

Table 25-86. MMCHS_CAPA

28	BIT64	64 Bit System Bus Support Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus. Read 0x1: 64 bit System bus address Read 0x0: 32 bit System bus address	R	0
27	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
26	VS18	Voltage support 1.8V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 1.8V Not supported Write 0x1: 1.8V Supported Read 0x1: 1.8V Supported Read 0x0: 1.8V Not Supported	RW	0
25	VS30	Voltage support 3.0V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 3.0V Not supported Write 0x1: 3.0V Supported Read 0x1: 3.0V Supported Read 0x0: 3.0V Not Supported	RW	0
24	VS33	Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 3.3V Not supported Write 0x1: 3.3V Supported Read 0x1: 3.3V Supported Read 0x0: 3.3V Not Supported	RW	0
23	SRS	Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/ Resume functionality. Read 0x0: The Host controller does not Suspend/ Resume functionality.	R	1
22	DS	DMA support This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x1: DMA Supported Read 0x0: DMA Not Supported	R	1
21	HSS	High speed support This bit indicates that the host controller supports high speed operations and can supply an up-to maximum card frequency. Read 0x1: High Speed Supported Read 0x0: High Speed Not Supported **NOTE: High Speed modes are supported, but MMCHS_HCTL[HSPE] bit must always be set to 0x0 because device was timing closed with HSPE bit set to 0x0 for all supported modes of operation.**	R	1
20	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
19	AD2S	ADMA2 Support This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN Read 0x1: ADMA2 Supported Read 0x0: ADMA2 not Supported	R	0
18	RESERVED		R	0
17:16	MBL	Maximum block length This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. This value depends on definition of generic parameter with a max value of 2048 bytes. The host controller supports 512 bytes and 1024 bytes block transfers. Read 0x2: 2048 bytes Read 0x1: 1024 bytes Read 0x0: 512 bytes	R	0x1
15:8	BCF	Base Clock Frequency For SD Clock This value indicates the base (maximum) clock frequency for the SD Clock. 8-bit Base Clock Frequency This mode is supported by the Host Controller Version 3.00. Unit values are 1MHz. The supported clock range is 10MHz to 255MHz. FFh : 255MHz .... : .... 02h : 2MHz 01h : 1MHz 00h : Get information via another method If the real frequency is 16.5MHz, the lager value shall be set 0001 0001b (17MHz) because the Host Driver use this value to calculate the clock divider value (Refer to MMCHS_SYSCTL[15:6] CLKD) and it shall not exceed upper limit of the SD Clock frequency. If these bits are all 0, the Host System has to get information via another method. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method.	R	0x00
7	TCU	Timeout clock unit This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCHS_STAT[DTO]). Read 0x1: MHz Read 0x0: KHz	R	1
6	RESERVED		R	0
5:0	TCF	Timeout clock frequency The timeout clock frequency is used to detect Data Timeout Error (MMCHS_STAT[DTO]). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.	R	0x00

23:16	CM	Clock Multiplier This field indicates clock multiplier value of programmable clock generator. Refer to MMCHS_SYSCTL [15:0]. Setting 00h means that Host Controller does not support programmable clock generator. 00h : Clock Multiplier is Not Supported 01h : Clock Multiplier M = 2 02h : Clock Multiplier M = 3 .... : .... FFh : Clock Multiplier M = 256	R	0x00

Bits	Field Name	Description	Type	Reset
15:14	RTM	Re-Tuning Modes This field selects re-tuning method and limits the maximum data length. Bit47-46 Re-Tuning Mode Re-Tuning Method Data Length There are two re-tuning timings: Re-Tuning Request controlled by the Host Controller and expiration of a Re-Tuning Timer controlled by the Host Driver. By receiving either timing, the Host Driver executes the re-tuning procedure just before a next command issue. The maximum data length per read/write command is restricted so that re-tuning procedures can be inserted during data transfers. (1) Re-Tuning Mode 1 The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MiB. (2) Re-Tuning Mode 2 The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MiB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. (3) Re-Tuning Mode 3 The host controller has the capability to take care of the re-tuning during data transfer (Auto Re-Tuning). Re-Tuning Request shall not be generated during data transfers and there is no limitation to data length per read/write command. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. Re-Tuning Timer Control Example for Re-Tuning Mode 1 The initial value of re-tuning timer is provided by Timer Count for Re-Tuning field in this register. The timer starts counting by loading the initial value. When the timer expires, the Host Driver marks an expiration flag. On receiving a command request, the Host driver checks the expiration flag. If the expiration flag is set, then the Host Driver should perform the re-tuning procedure before issuing a command. If the expiration flag is not set, then the Host Driver issues a command without performing the re-tuning procedure. Every time the re-tuning procedure is performed, the timer loads the new initial value and the expiration flag is cleared. Re-Tuning Timer Control Example for Re-Tuning Mode 2 and Mode 3 The timer control is almost the same as Re-Tuning Mode 1 except the timer loads the new initial value after data transfer (when receiving Transfer Complete). In case of Mode 3, Timer Count for Re-Tuning is set either smaller value: Tuning effective time after re-tuning procedure or after data transfer. If a Host System goes into power down mode, the Host Driver should stop the re-tuning timer and set the expiration flag to 1 when the Host System resumes from power down mode. Read 0x3: Reserved Read 0x2: Auto Re-Tuning (for transfer) - Timer and Re-Tuning Request Read 0x1: Timer and Re-Tuning Request - Max data length 4 MiB Read 0x0: Timer - Max data length 4 MiB	R	0x0

Bits	Field Name	Description	Type	Reset
13	TSDR50	Use Tuning for SDR50 If this bit is set to 1, this Host Controller requires tuning to operate SDR50. (Tuning is always required to operate SDR104.) Read 0x1: SDR50 requires tuning. Read 0x0: SDR50 does not require tuning.	R	0
12	RESERVED		R	0
11:8	TCRT	Timer Count for Re-Tuning This field indicates an initial value of the Re-Tuning Timer for Re-Tuning Mode 1 to 3. Setting to 0 disables Re-Tuning Timer. Table 25-90. MMCHS_FE (continued)

Description	Force Event Register for Auto CMD Error Status and Error Interrupt status The Force Event Register is not a physically implemented register. Rather, it is an address at which the Auto CMD Error Status Register (MMCHS_AC12) can be written. Writing 1 : set each bit of the Auto CMD Error Status Register Writing 0 : no effect Rather, it is an address at which the Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register if the corresponding bit of the Error Interrupt Status Enable Register is set. Writing 1 : set each bit of the Error Interrupt Status Register Writing 0 : no effect Note: By setting this register, the Error Interrupt can be set in the Error Interrupt Status register. In order to generate interrupt signal, both the Error Interrupt Status Enable and Error Interrupt Signal Enable shall be set.

Table 25-91. MMCHS_ADMAES (continued)

Description	ADMA Error Status Register When ADMA Error Interrupt is occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows: ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address ST_FDS: Current location set in the ADMA System Address register is the error descriptor address ST_CADR: This sate is never set because do not generate ADMA error in this state. ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address In case of write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

Chapter 26

Shared PHY Component Subsystem

This chapter describes the shared PHY component subsystems of the device.

26.1 SATA PHY Subsystem 6520
26.2 USB3_PHY Subsystem 6539
26.3 USB3 PHY and SATA PHY Register Manual 6558
26.4 PCIe PHY Subsystem 6577

26.1 SATA PHY Subsystem

This chapter describes the features and functions of the serial advanced technology attachment (SATA) PHY subsystem of the device.

26.1.1 SATA PHY Subsystem Overview

The physical layer (PHY) is responsible for transmitting and receiving the parallel 8b/10b encoded information as a serial data stream on the wire.

The SATA host controller subsystem instantiates a single serializer (transmitter), SATA_PHY_TX, and a single deserializer (receiver), SATA_PHY_RX. Together the transmitter and receiver are also signified as SATA_PHY throughout this chapter. The role of the TX and RX components is to adapt SATA Link parallel 10-bit input/output (I/O) data stream for a serialized differential transmission and reception over SATA electrical interface, respectively.

The high speed transmission clock is generated by and integrated into the SATA host subsystem dpll (DPLL_SATA).

The DPLL_SATA is configured and controlled through a SATA dedicated PLL controller (DPLLCTRL_SATA) with associated registers, accessible over a L4_CFG interface adapter.

The components (SATA_PHY_RX, SATA_PHY_TX, DPLL_SATA, DPLLCTRL_SATA, and DPLLCTRL_SATA L4-interface adapter) build the SATA PHY subsystem. This subsystem is responsible for PHY components clock generation and physical layer transmission/reception within the device SATA subsystem.

Figure 26-1 gives an overview of the SATA PHY subsystem. As shown in Figure 26-1, at one side the SATA_PHY components directly interface the attached to host controller SATA mass storage device (over TXP/TXN transmission and RXP/RXN reception interface I/Os) and on the other side they interface the SATA controller, described in detail in Section 24.8, *SATA Controller*.

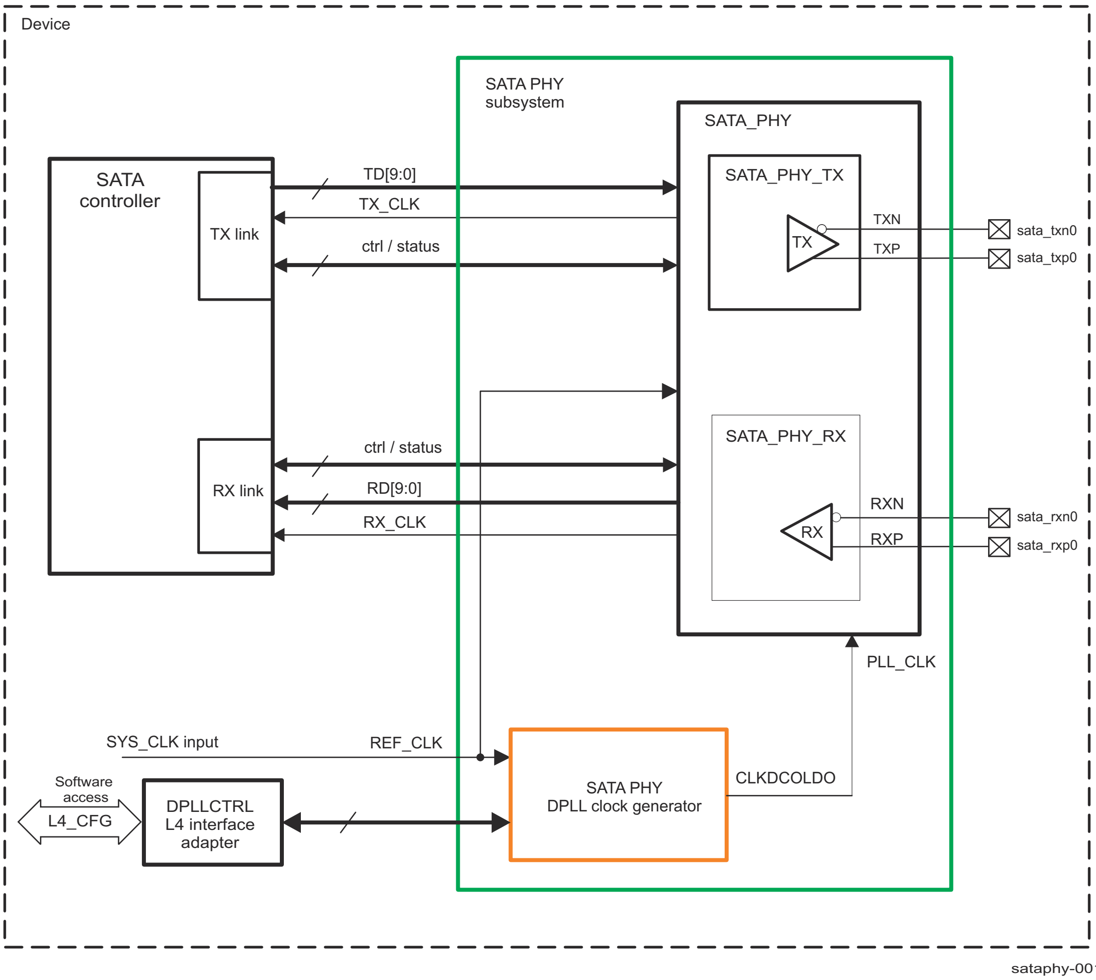

Figure 26-1. SATA PHY Subsystem Overview

26.1.2 SATA PHY Subsystem Environment

26.1.2.1 SATA PHY I/O Signals

Table 26-1 lists the module pins and their corresponding signal names at the device level, and also specifies their links to functions.

Table 26-1. SATA PHY I/O Signals

Module Signal	Device Pin	I/O[(1)]	Description	Pin Reset Value
TXP	sata_txp0	O	TXP output of the SATA PHY differential transmission lane	HiZ
TXN	sata_txn0	O	TXN output of the SATA PHY differential transmission lane	HiZ
RXP	sata_rxp0	I	RXP input of the SATA PHY differential reception lane	HiZ
RXN	sata_rxn0	I	RXN input of the SATA PHY differential reception lane	HiZ

(1) I = Input; O = Output

Figure 26-2 shows module pin signals mapping to SATA PHY I/O signals visible at device pad level.

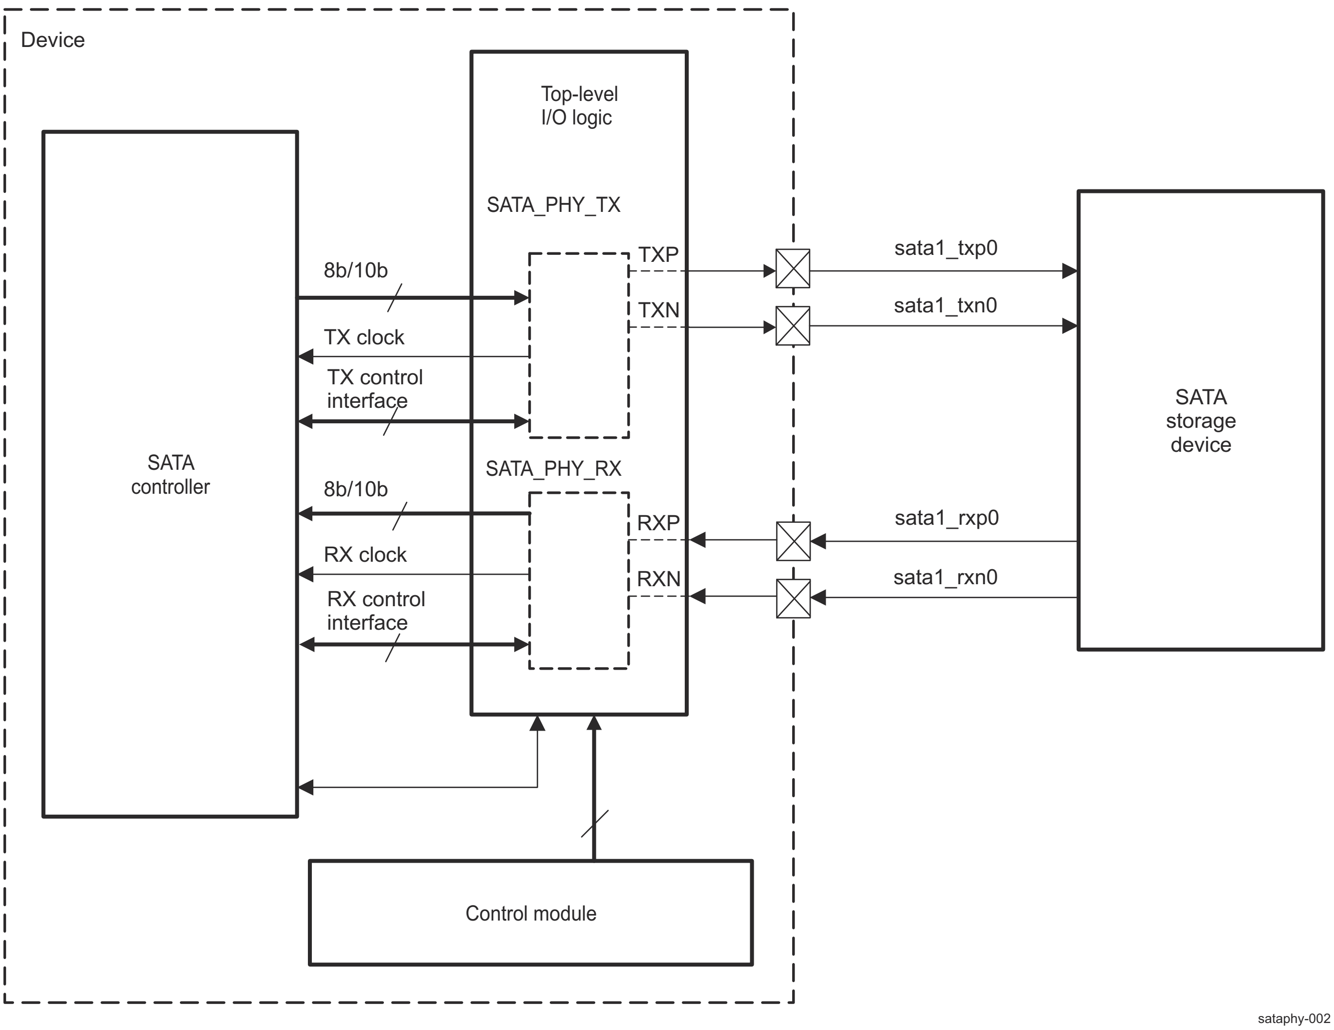

Figure 26-2. SATA PHY I/O Signals

Note

The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers. See *Control Module*, for more information.

26.1.3 SATA PHY Subsystem Integration

This section describes the SATA PHY subsystem-related components (SATA_PHY, DPLL_SATA, DPLLCTRL_SATA, OCP2SCP3) integration in the device, including information about clocks, resets, and hardware requests.

Figure 26-3 shows the SATA_PHY integration.

The SATA_PHY module integration features are:

- A low-power nonretention reset, L3INIT_RST
- A DPLL reference input clock, PLL_CLK
- Parallel 10-bit TD[9:0] (SATA_PHY_TX) and 10-bit RD[9:0] (SATA_PHY_RX) data interfaces to SATA controller
- TX_CLK output clock for the parallel TX data interface between SATA_PHY.SATA_PHY_TX and SATA controller
- RX_CLK output clock for the parallel RX data interface between SATA_PHY.SATA_PHY_RX and SATA controller
- REF_CLK clock input (SATA_REF_GFCLK)
- A device core control module command port to the SATA_PHY integrated power sequencer

The DPLL_SATA integration features are:

- A low-power nonretention reset, L3INIT_RST
- A power, reset, and clock management (PRCM) gated version of SYS_CLK (SATA_REF_GFCLK) supplying the DPLL_SATA.CLKINP pin
- A single high-frequency clock output (DPLL_SATA.CLKDCOLDO to the SATA_PHY TX/RX components)
- No high-speed (HS) divider integration
- Idle signaling implementation
- LDO and DCO PWRDNZ monitoring signals
- A DPLL_LOCK locked status indication output to SATA_PHY and the SATA controller

The DPLLCTRL_SATA integration features are:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SCP3) Interconnect adapter target interface
- Configuration/control programming interface to the DPLL_SATA
- No direct gate control for DPLL_SATA.CLKINP and CLKDCOLDO

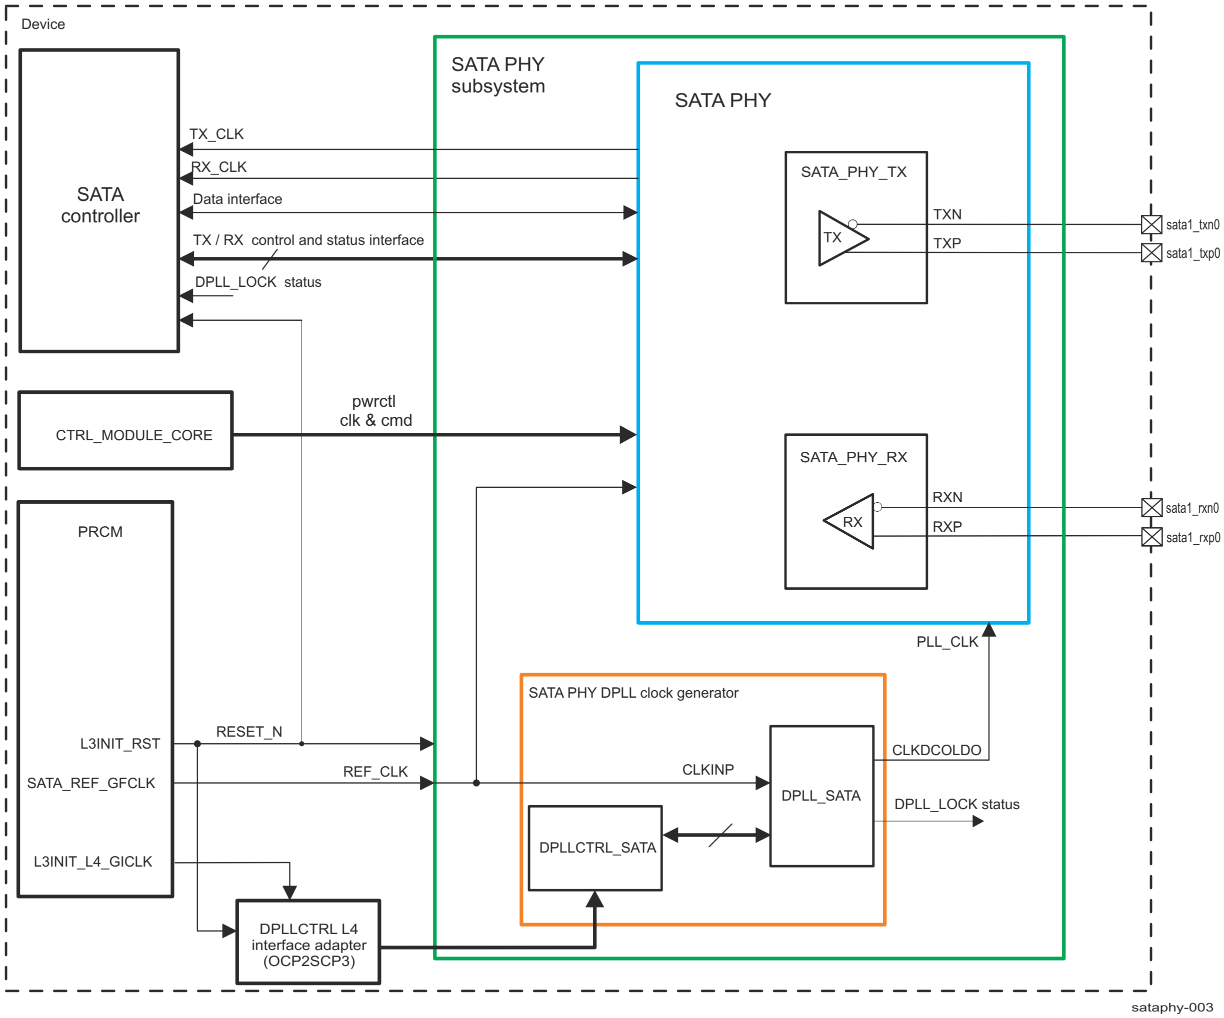

Figure 26-3. SATA PHY Subsystem Integration

Table 26-2 through Table 26-4 summarize the integration of the module in the device.

Table 26-2. SATA PHY Integration Attributes

Module Instance	Attributes	
	Power Domain	**Interconnect**
DPLLCTRL_SATA	PD_L3INIT	OCP2SCP3 adapter SCP interconnects

Table 26-4. SATA PHY Resets

Resets

Table 26-4. SATA PHY Resets (continued)

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SATA_PHY subsystem	RESET_N	L3INIT_RST	PRCM	A nonretention reset to all SATA_PHY subsystem components

Note

The SATA_PHY, DPLL_SATA, and DPLLCTRL_SATA modules do not generate DMA, interrupt, or wakeup hardware requests to the surrounding modules integrated in the device.

26.1.4 SATA PHY Subsystem Functional Description

26.1.4.1 SATA PLL Controller L4 Interface Adapter Functional Description

The L4_CFG interconnect adapter (OCP2SCP3), allows user software to configure the DPLLCTRL_SATA registers over the L4_CFG port. Hence it is expected that this adapter is configured to operate before any programming of the DPLLCTRL_SATA.

Aa value of 0x6 or more should be written to the register bitfield OCP2SCP_TIMING[3:0] SYNC2.

L4_CFG interconnect adapter software reset is performed via writing OCP2SCP_SYSCONFIG[1] SOFTRESET to 0b1. The software reset completion is observed in bit OCP2SCP_SYSSTATUS[0] RESETDONE.

By default a smart-idle power mode is selected for OCP2SCP3. The smart-idle mode supported by OCP2SCP3 is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP3 by setting the OCP2SCP_SYSCONFIG [4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

By default OCP2SCP_SYSCONFIG[0] AUTOIDLE =0x1, which defines that the PLLCTRL L4 interface adapter automaticaly gates its L4 input clock based on L4_CFG interconnect activity. To enable a free-running clock, one should set bit AUTOIDLE to 0x0.

26.1.4.2 SATA PHY Serializer and Deserializer Functional Descriptions

26.1.4.2.1 SATA PHY Reset

No software reset is applicable to SATA_PHY. L3INIT reset assertion is automatically managed by hardware.

26.1.4.2.2 SATA_PHY Clocking

26.1.4.2.2.1 SATA_PHY Input Clocks

A standard high-speed 1.5 GHz input clock of SATA_PHY is provided by the DPLL_SATA.CLKDCOLDO output. PRCM. SATA_REF_GFCLK (derived from the SYS_CLK) should be enabled, to provide the necessary DPLL_SATA and SATA_PHY clocking within the SATA subsystem.

Depending on the SATA_REF_GFCLK (SYS_CLK derived) frequency, following settings should be made in the CTRL_MODULE_CORE.CONTROL_PHY_POWER_SATA[31:22] SATA_PWRCTL_CLK_FREQ bitfield for proper operation:

- 0x26: If SYSCLK = 38.4 MHz
- 0x1A: If SYSCLK = 26.0 MHz
- 0x13: If SYSCLK = 19.2 MHz
- 0x10: If SYSCLK = 16.8 MHz
- 0x0C: If SYSCLK = 12.0 MHz

26.1.4.2.2.2 SATA_PHY Output Clocks

The 10-bit data parallelly transmitted data between SATA_PHY_TX and SATA controller link logic is sampled with respect to the TX_CLK. Frequency of this clock is obtained as the SATA_PHY.PLL_CLK clock frequency:

- Divided by 10 if a 1.5-Gbps limit is negotiated by software setting DWC_ahsata.SATA_PxSCTL[7:4] SPD = 0x1
- Divided by 5 if a 3-Gbps limit is negotiated by software setting DWC_ahsata.SATA_PxSCTL[7:4] SPD = 0x0 or 0x2

The actually negotiated between host and the attached SATA device speed is indicated in the read-only SATA controller.SATA_PxSSTS[7:4] SPD bit field. For more information, see Section 24.8.6, *SATA Controller Register Manual*, in Section 24.8, *SATA Controller*.

RX_CLK: The SATA_PHY_RX output RX_CLK is a clock that is recovered from the serial data received over the RXP/RXN lanes serial data. The RX_CLK clock supplies the SATA controller link parallel 10-bit data reception logic.

26.1.4.2.3 SATA_PHY Power Management

The SATA_PHY power sequencer receives a power-up/power-down command input from the device general core control module. The power sequencer takes care to execute different stages of the SATA_PHY_TX and SATA_PHY_RX power-up/-down processes. Besides a power-up/-down functionality, the SATA PHY accepts power transition commands/states (Ready state, Partial or Slumber states) from the SATA controller link power management port .

26.1.4.2.3.1 SATA_PHY Power-Up/-Down Sequences

Powering up/down the SATA_PHY_TX and SATA_PHY_RX modules is triggered by software writing corresponding power-up/-down commands in the CTRL_MODULE_CORE. CONTROL_PHY_POWER_SATA register of the device core control module, as follows:

- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x0 (default value), commands both SATA_PHY_TX and SATA_PHY_RX to power-down (OFF) state.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x1, powers up the SATA_PHY_RX only.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x2, powers up the SATA_PHY_TX only.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x3, simultaneously powers up the SATA_PHY_RX and the SATA_PHY_TX.

For more information, see *Control Module*.

26.1.4.2.3.2 SATA_PHY Low-Power Modes

Setting the DWC_ahsata.SATA_PxSCTL[3:0] DET bit field to 0x4 automatically puts the SATA_PHY_RX deserializer in offline mode. This software operation has no impact over the SATA_PHY_TX serializer.

Note

The SATA controller transition to partial or slumber mode has no impact over the SATA_PHY_RX deserializer.

Note

The SATA_PHY_TX.TX_CLK output clock is a free-running clock and cannot be gated, even when the transmitter is disabled by a SATA controller.

26.1.4.2.4 SATA_PHY Hardware Requests

No DMA, interrupt or wake-up requests are generated by the SATA_PHY to the surrounding SATA controller subsystem components.

26.1.4.3 SATA Clock Generator Subsystem Functional Description

The DPLL_SATA, which is located outside the PRCM boundaries and is part of the SATA host controller subsystem, directly injects a high-speed clock into the SATA_PHY serializer/deserializer input, PLL_CLK. The DPLL generator is controlled through a programmable interface from a dedicated PLL controller, DPLLCTRL_SATA.

26.1.4.3.1 SATA DPLL Clock Generator Overview

The SCP interface of the SATA PLL controller (the DPLLCTRL_SATA instance) is used to set the configuration of the digital phase-locked loop (DPLL) modules, primarily the various counter values. Figure 26-4 is an overview of the DPLL clock generator embedded into the SATA host controller subsystem.

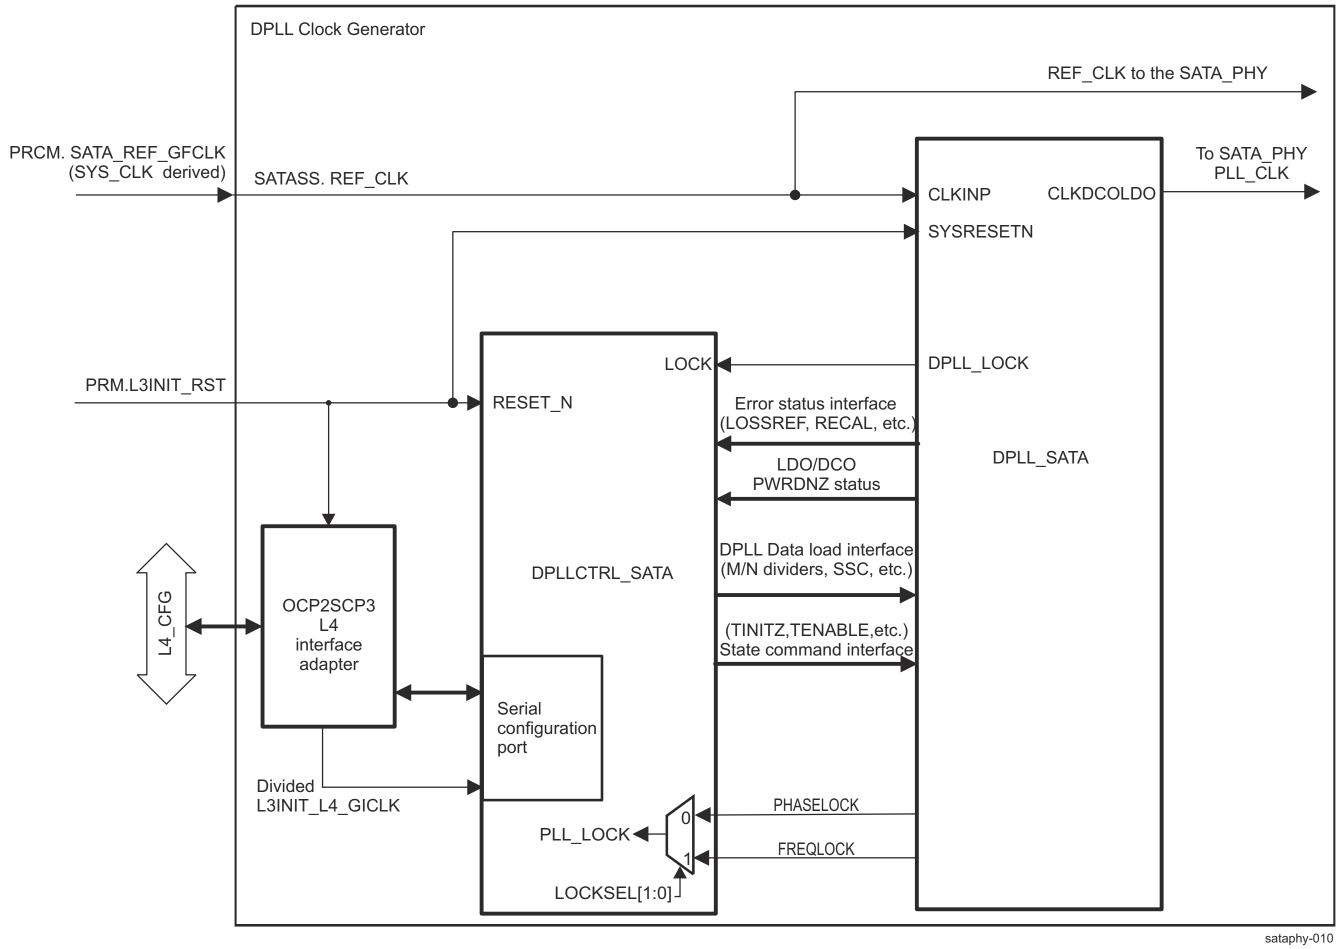

Figure 26-4. SATA DPLL Clock Generator Overview

Note

The DPLLCTRL_SATA module is user accessible on the L4_CFG interconnect. However, to make access possible, the user must configure the OCP2SCP3 instance prior to accessing the DPLLCTRL_SATA registers.

The DPLL_SATA features are:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Digital control and loop filter
- Internal oscillator output clock on internal LDO domain (CLKDCOLDO output)
- DPLL output clock spread spectrum clocking (SSC) support
- No retention capabilities
- No idle-bypass fast relock capabilities
- Idle-bypass low-power mode
- M/N bypass mode
- Relock from standby

The DPLLCTRL_SATA components features are:

- DPLL error and status notification
- DPLL initialization and configuration
- DPLL lock criteria selectable between frequency and phase lock

- Idle command implementation
- No software reset implementation

26.1.4.3.2 SATA DPLL Clock Generator Reset

The SATA PLL controller and SATA DPLL clock generator share a common hardware nonretention reset (L3INIT_RST) which comes from the device power and reset manager. When the DPLL_SATA hardware reset completes, the DPLLCTRL_SATA.PLL_STATUS[0] PLLCTRL_RESET_DONE bit is automatically updated to 1. For more information on the hardware reset source, see *Reset Domains*, in *Power, Reset, and Clock Management*.

The DPLLCTRL_SATA itself has no software reset capabilities.

The DPLLCTRL_SATA performs a software reset sequence on the DPLL_SATA in hardware (through the TINITZ signal activation).

26.1.4.3.3 SATA DPLL Low-Power Modes

The power-management port (PMP) is not integrated for DPLLCTRL_SATA. The DPLL_SATA has no retention capabilities. This means the DPLL digital power supply remains switched on during all modes of operation.

The low-power (LP) modes supported by DPLL_SATA are idle-bypass low power and MN-bypass modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKDCOLDO output pulled low

For more details on the PLL settings and conditions necessary to enter idle-bypass and MN-bypass low-power modes, see Section 26.1.4.3.6.4, *SATA DPLL Idle-Bypass Low-Power Mode*, and Section 26.1.4.3.6.5, *SATA DPLL MN-Bypass Mode*.

DPLL_SATA is held in a similar low-power state (DCO and LDO switched off, with CLKDCOLDO = 0) after POR, before the first PLL_GO command has been software-triggered on the PLL controller. See Section 26.1.4.3.6.1, *SATA Clock Generator Power Up*.

26.1.4.3.4 SATA DPLL Clocks Configuration

26.1.4.3.4.1 SATA DPLL Input Clock Control

The DPLL_SATA accepts the functional clock (SATA_REF_GFCLK) on its CLKINP pin (REF_CLK input at SATA SS level) directly from the device PRCM, without involving any DPLLCTRL_SATA interactions. The SATA_REF_GFCLK is derived from SYS_CLK1, and can be optionally software-gated by setting the PRCM.CM_L3INIT_SATA_CLKCTRL[8] OPTFCLKEN_REF_CLK bit. The status of the SATA_REF_GFCLK clock can be monitored in the PRCM.CM_L3INIT_CLKSTCTRL[19] CLKACTIVITY_SATA_REF_GFCLK bit. See *Clock Domain Module Attributes* in *Power, Reset, and Clock Management*.

If CLKINP signal is lost for some time, the LOSSREF output signal, which serves as a feedback to DPLLCTRL_SATA, is asserted high. When CLKINP resumes, the LOSSREF signal goes low (LOSSREF inactive state). The LOSSREF status signal can be monitored by software in the DPLLCTRL_SATA.PLL_STATUS[3] PLL_LOSSREF bit.

26.1.4.3.4.2 SATA DPLL Output Clock Configuration

Only the DPLL_SATA output, CLKDCOLDO, is used to provide the high-speed clock at the PLL_CLK pin of the SATA_PHY. Only the REGM, REGN, and SD divider values are used within the DPLL clock generator subsystem to adjust the CLKDCOLDO output clock frequency. This is done by programming the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM, DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN, and DPLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD bit fields, respectively. The SATA DPLL CLKOUT and CLKOUTLDO outputs are not used, and internal REGM2 and REGM1 dividers are not software controllable.

Note

At the DPLL/PLLCTRL integration level, the PLL_REGM1[3:0] and PLL_REGM2[6:0] divider control signals are tied-off by hardware to 0x0 and 0x1, respectively.

For more details on output clock settings sequence, see Section 26.1.4.3.7.2, *SATA DPLL Clock Programming Sequence*.

26.1.4.3.4.2.1 SATA DPLL Output Clock Gating

There is no direct software gate control for the DPLL_SATA.CLKDCOLDO output.

The DPLL_SATA.CLKDCOLDO clock output is automatically gated (CLKDCOLDO pulled low) in the following scenarios:

- DPLL power-up sequence. For more information on the power-up sequence, see Section 26.1.4.3.6.1, *SATA Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on the relocking sequence, see Section 26.1.4.3.6.2, *SATA DPLL Sequences*.
- DPLL entering idle-bypass low-power mode. For more information on idle-bypass mode, see Section 26.1.4.3.6.4, *SATA DPLL Idle-Bypass Mode*.
- DPLL entering MN-bypass mode. For more information on MN-bypass mode, see Section 26.1.4.3.6.5, *SATA DPLL MN Bypass Mode*.

26.1.4.3.5 SATA DPLL Subsystem Architecture

Figure 26-5 is a simplified block diagram of the DPLL_SATA instance integration in the SATA clock generator subsystem.

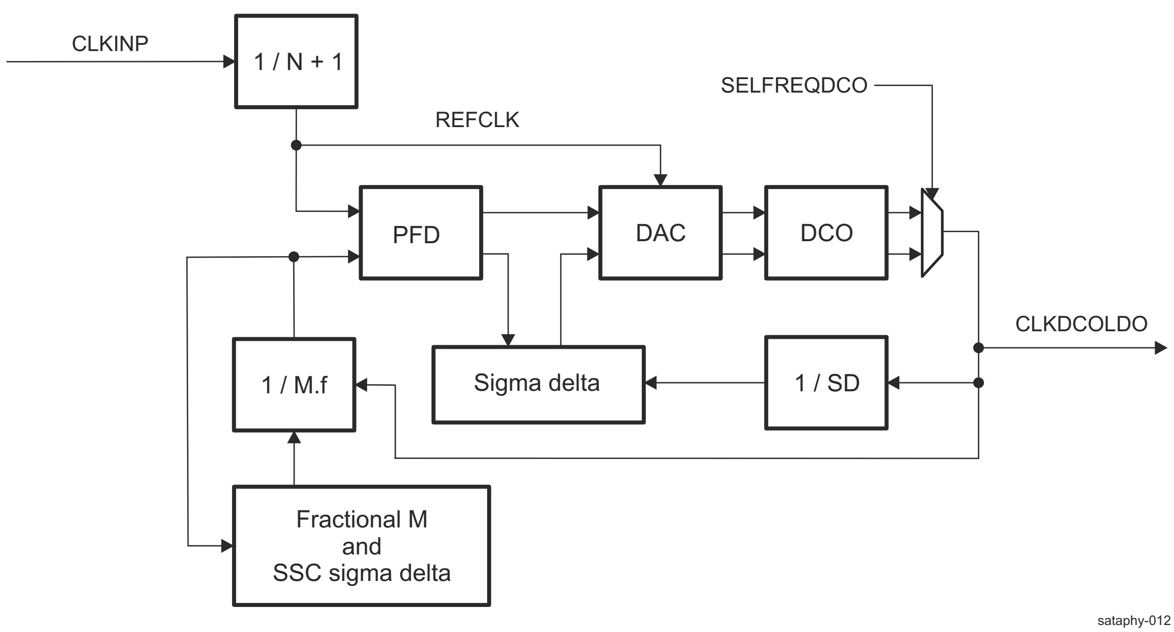

Figure 26-5. DPLL_SATA Functional Block Diagram

The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

The frequency ranges for the DPLL_SATA input clock (CLKINP) and the DPLL internal reference clock (REFCLK = CLKINP/N + 1) are:

- 0.62 to 60 MHz for CLKINP

- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKDCOLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP × M/(N + 1). For that purpose the feedback multiplier M must be configured through the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL_SATA module supports fractional synthesis (that is, the frequency multiplication factor M can be programmed as fractional). This is achieved by having a sigma delta feedback divider (M). A fractional value (Fractional M) of 18 bits is supported enabling control for a better accuracy. Programming the 18-bit Fractional M value is done by setting the DPLLCTRL_SATA.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field (similar to REGM). To enable integer only division Fractional M should be set to 000…0.

Note

Fractional synthesis is not supported for M > 4093.

26.1.4.3.6 SATA DPLL Clock Generator Modes and State Transitions

The DPLL_SATA can be set in different modes during operation. PLLCTRL triggers DPLL_SATA state transitions to different static modes by means of TINITZ and TENABLE hardware control signals.

26.1.4.3.6.1 SATA Clock Generator Power Up

After power up, the DPLL_SATA.SYSRESETN input is automatically pulled low by PRM, together with DPLLCTRL_SATA.RESET_N input. Because PRM.L3INIT_RST is an asynchronous reset, the DPLL_SATA input clock (DPLL_SATA.CLKINP) is not demanded upon reset. The LOSSREF signal, which monitors the presence of CLKINP clock, remains 1 during SYSRESETN = 0 irrespective of presence/absence on the CLKINP clock. If CLKINP is present upon reset assertion, the LOSSREF signal is deasserted to 0, a certain time after the hardware reset completion. During DPLL power-up mode, CLKDCOLDO clock is maintained inactive (pulled low). After POR, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too.

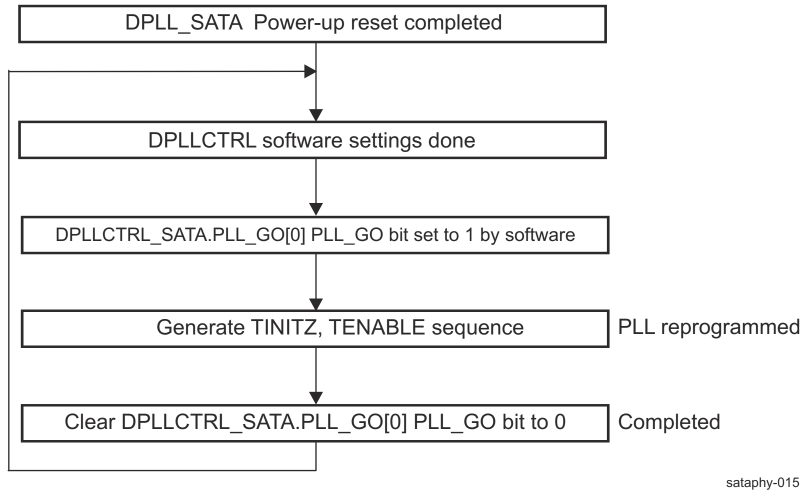
26.1.4.3.6.2 SATA DPLL Sequences

Once all the configuration values have been initially programmed into the DPLLCTRL_SATA registers (see Section 26.1.4.3.7.2, *SATA DPLL Clock Programming Sequence*), the DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit should be set to update the configuration values and start the DPLL calibration and locking sequence.

After DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit is set high in software, the DPLLCTRL_SATA state-machine takes the following action:

1. Sets TINITZ signal to 0. TINITZ acts as a soft reset to DPLL_SATA. This starts the DPLL initialization procedure. During initialization mode, the CLKDCOLDO, FREQLOCK, and PHASELOCK signals are kept at 0 and the BYPASSACK signal is kept at 1.
   VDDA power supply of DPLL should be active before DPLL_SATA initialization is performed, but it is not required to be switched on immediately after device power up.
2. The TENABLE signal is asserted high by the PLLCTRL hardware to load the user-programmed values of REGM, REGN, REGSD, and SELFREQDCO into DPLL registers.
3. After TENABLE is asserted, TINITZ is driven high (disabled) by the PLLCTRL to trigger a DPLL calibration and lock sequence after the loop control values are loaded. The module calibration-lock sequence will begin from the first CLKINP edge after TINITZ is disabled.

Figure 26-6 summarizes the software and hardware sequences flow of DPLL_SATA.



All thick-outlined blocks in Figure 26-6 show operations performed by software. Other blocks show operations performed by hardware.

Figure 26-6. SATA PLL GO Sequence

DPLL_SATA Relock Sequence: When DPLL leaves a lost clock condition (LOSSREF = 1 → 0) or idle-bypass mode it enters relock sequence from the first CLKINP edge (after bypass mode leaving). Relock sequence is the same as calibration-lock sequence already described.

A DPLL relock sequence is also software triggered by setting DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit to 0b1 for DPLL parameters update.

When DPLL_SATA enters a relock sequence, CLKDCOLDO is pulled low. FREQLOCK and PHASELOCK status signals are also low. CLKDCOLDO output clock is activated after FREQLOCK or PHASELOCK signal goes high, depending on the selected locking criteria.

The DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit can be used by software to monitor if PLLCTRL locking process is still pending (PLL_GO = 0b1).

26.1.4.3.6.3 SATA DPLL Locked Mode

When DPLL_SATA finishes calibration and lock sequences it enters the LOCKED state. During the LOCKED state, LOSSREF is deasserted, BYPASSACK is deasserted, and the FREQLOCK or PHASELOCK signals are asserted.

DPLL lock event criteria (FREQLOCK or PHASELOCK) is software selectable through the DPLLCTRL_SATA.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL bit field.

The DPLL indicates it is in the LOCKED state to the DPLLCTRL_SATA, SATA controller core controller, and SATA_PHY through assertion of the DPLL_LOCK signal, which reflects the internal lock loop status. The user software can monitor the DPLL locked event in the DPLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit, which is active high.

26.1.4.3.6.4 SATA DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_SATA.

DPLL_SATA supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the DPLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE bit to 0x1. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and DCO oscillator.

In idle-bypass low-power mode, the PHASELOCK and FREQLOCK output signals are asserted low and CLKDCOLDO goes low, respectively. Also, the internal reference clock REFCLK = CLKINP/N + 1 is gated inside the DPLL digital control logic to save power.

In the functional mode, DPLL_SATA.TICOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal DCO oscillator. The internal DCO oscillator is powered down in idle-bypass mode or during period from SYSRESETN 0 → 1 to module initialization. The DCO oscillator exits power down (TICOPWDN goes low) whenever the module internally tries to lock or relock after initialization or exiting idle-bypass mode.

In the functional mode, DPLL_SATA.LDOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal LDO. LDOPWDN goes high as soon as the internal LDO is powered down. LDOPWDN goes low after the LDO output voltage is stable. The internal LDO is powered down in period from SYSRESETN 0 → 1 to module initialization or when entering into idle-bypass mode. LDOPWDN is cleared whenever the module internally tries to lock or relock after initialization or exiting idle-bypass mode after the internal LDO output voltage has stabilized.

The DCO and LDO power ON/OFF states are reflected within the read-only DPLLCTRL_SATA.PLL_STATUS[16] PLL_TICOPWDN and DPLLCTRL_SATA.PLL_STATUS[15] LDOPWDN monitor bits.

To exit idle-bypass mode and restore clock generation, the user should set DPLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE to 0x0, which deasserts the IDLE signal and DPLL_SATA automatically enters a relock sequence. The CLKDCOLDO output clock is activated after the FREQLOCK or PHASELOCK signal goes high, depending on selected locking criteria.

26.1.4.3.6.5 SATA DPLL MN-Bypass Mode

The MN-Bypass mode will be activated if REGM = 0 or 1 is loaded into the module on the rising edge of TENABLE. TINITZ also should be pulsed to enter MN-Bypass mode. The module enters a low-power mode by gating all its internal clocks (REFCLK) and powering down the internal LDO (LDOPWDN = 1) and DCO (DCOPWDN = 1). CLKDCOLDO remains gated (low) during this mode.

Note

When the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field is updated to 0x0 or 0x1, the CLKDCOLDO output clock is gated.

26.1.4.3.6.6 SATA DPLL Error Conditions

The PLL lock and recalibration signals can be monitored to detect the loss of lock condition and the DPLL requirement to recalibrate (caused by a large temperature change since the last lock request):

- The DPLLCTRL_SATA.PLL_STATUS[2] PLL_RECAL bit informs whether the DPLL_SATA must be recalibrated.

The PLL reference clock (CLKINP) loss status and PLL-in-high-jitter condition can also be monitored:

- The DPLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit gives the SATA PLL LOCKED state.
- The DPLLCTRL_SATA.PLL_STATUS[3] PLL_LOSSREF bit informs whether the DPLLCTRL_SATA has lost the reference clock.
- The DPLLCTRL_SATA.PLL_STATUS[5] PLL_HIGHJITTER bit informs whether the PLL has entered a high-jitter condition.

26.1.4.3.7 SATA PLL Controller Functions

26.1.4.3.7.1 SATA PLL Controller Register Access

The configuration registers are accessed through the OCP2SCP3 L4 adapter register space using the SCP interface of the DPLLCTRL_SATA. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

Note

Because the SATA_PHY directly provides parallel data interface clocks RX_CLK and TX_CLK to the SATA controller, the DPLLCTRL_SATA and DPLL_SATA must be configured before any data transfer between the SATA controller and an external SATA storage device.

26.1.4.3.7.2 SATA DPLL Clock Programming Sequence

The DPLL_SATA factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

- The REGM factor is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- The fractional part of REGM factor is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field.
- The REGN factor is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- The DCO frequency range is set in the DPLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field.
  - PLL_SELFREQDCO should be set to 0x2, if 750 MHz < CLKDCOLDO [MHz] < 1500 MHz
  - PLL_SELFREQDCO should be set to 0x4, if 1250 MHz < CLKDCOLDO [MHz] < 2500 MHz
- The SD divider is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD bit field. The DPLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field should be programmed depending on the value of CLKDCOLDO = CLKINP × M/(N + 1). The formulas are shown in Figure 26-7.

Figure 26-7 shows the programming sequence.

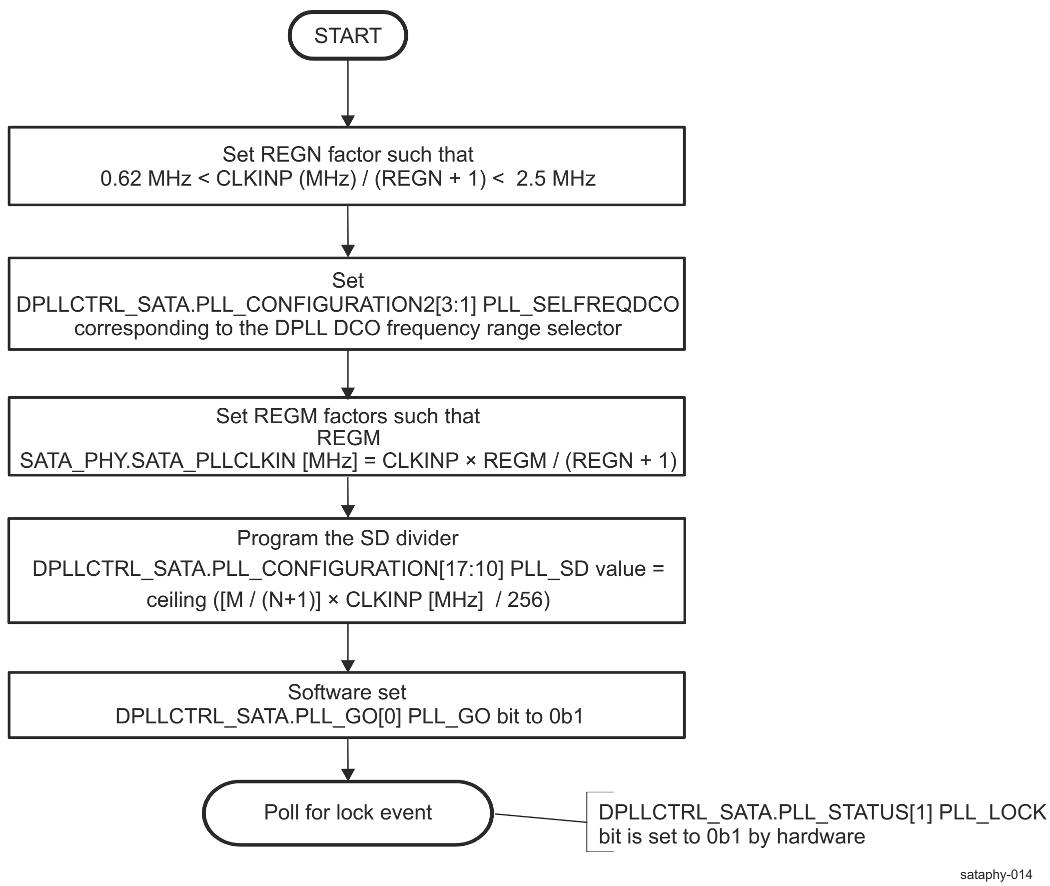


Figure 26-7. SATA PLL Programming Sequence

Note

- The equation for SATA_PHY_TX/SATA_PHY_RX (MHz) applies to the CLKDCOLDO of the DPLL_SATA.
- For normal operation CLKDCOLDO output frequency of the DPLL_SATA should be either 750 MHz (SATA-1 mode) or 1500 MHz (SATA-2 mode).

Table 26-5 summarizes the registers for the DPLLCTRL_SATA programming sequence.

Table 26-5. Register Call Summary for SATA PLL Programming Sequence

Register Name	Register Name	Register Name	Register Name
DPLLCTRL_SATA.PLL_CONFIGURATION2	DPLLCTRL_SATA.PLL_GO	DPLLCTRL_SATA.PLL_STATUS	DPLLCTRL_SATA.PLL_CONFIGURATION3

26.1.4.3.7.3 SATA DPLL Recommended Values

Table 26-6 lists the DPLL_SATA recommended values.

Table 26-6. Recommended Programming Values

Field Name	Value	Description
DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM	See (1).	Feedback clock divider
DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN	See (1).	Reference clock divider
DPLLCTRL_SATA.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL	0x-	Criteria to lock the PLL
DPLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO	See (1).	Program based on the PLL choice and lock frequency.
DPLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE	0	PLL active
DPLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD	See (1).	Ceiling { [PLL_REGM/(PLL_REGN + 1)] × CLKINP(MHz)/256 }
DPLLCTRL_SATA.PLL_GO[0] PLL_GO	0x1	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.

(1) The value of the bit field must be set according to the desired clock frequencies – 750 MHz for SATA-1 and 1.5 GHz for SATA-2 speeds.

26.1.5 SATA PHY Subsystem Low-Level Programming Model

Table 26-7 summarizes the low-level programming sequence to set up the SATA PHY subsystem for SATA I/O operations.

Table 26-7. SATA PHY Subsystem Low-Level Programming Sequence

Step	Description	Comment
1.	Set the startup low-performance OPP in the appropriate PRCM registers.	For more information regarding demanded OPP, see the device *Data Manual*.
2.	Enable the PRCM.SATA_REF_GFCLK.	See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
3.	Enable the PRCM.L3INIT_L4_GICLK clock to enable the OCP2SCP3 interface adapter operation.	See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
4.	Software reset the OCP2SCP3 and poll until soft reset completion is indicated in status.	See Section 26.1.4.1.
5.	Set up division ratio between the OCP clock (PRCM.L3INIT_L4_GICLK) and SCP clock to supply the serial configuration register domains of the DPLLCTRL_SATA.	See Section 26.1.4.1.
6.	Set up necessary SYNC1 and SYNC2 timings to ensure no blocking of transactions over the SCP bus.	. See Section 26.1.4.1.After this step user is ready to access DPLLCTRL_SATA .
7.	Configure DPLL_SATA to generate frequency (CLKDCOLDO) = 1.5 GHz.	See Section 26.1.4.3.7.2 and Table 26-8.
8.	Soft assert bit DPLLCTRL_SATA.PLL_GO[0] PLL_GO to 0x1.	Start the DPLL lock with desired parameters.
9.	Poll DPLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit until it is seen 1.	DPLL locked event
10.	Perform a SATA_PHY tuning required for SATA i/f operation	Follow steps described in Table 26-9, *SATA PHY Tuning Table*.
11.	Software trigger the SATA_PHY_TX power-up sequence.	For more details, see Section 26.1.4.2.3.1, *SATA_PHY Power-Up/-Down Sequences*.
12.	Software trigger the SATA_PHY_RX power-up sequence.	For more details, see Section 26.1.4.2.3.1, *SATA_PHY Power-Up/-Down Sequences*.

Table 26-8. DPLL CLKDCOLDO Recommended Settings

Parameter	Setting				
F(CLKDCOLDO) MHz	1500				
SYS_CLK (MHz)	12	16.8	19.2	26	38.4
N	4	6	7	12	15
SELFREQDCO[2:0]	100	100	100	100	100
M	625	625	625	750	625
Frac	0	0	0	0	0
SD	6	7	6	6	6

Table 26-9. SATA PHY Tuning Table

Physical address[(2)] [bits to modify]	Preferred value setting[(1)]
0x4A09 600C [31:27]	0b01000 for SATA 1.5 Gbps mode 0b00100 for SATA 3 Gbps mode
0x4A09 600C [17:14]	0b1010 for SATA-Gen1x and SATA-Gen2x[(3)] 0b0101 for SATA-Gen1m and SATA-Gen2m
0x4A09 6028 [23:19]	0b11100 if spread-spectrum is ON 0b00001 if spread-spectrum is OFF
0x4A09 6028 [18:11]	0b01100110 (regardless of spread-spectrum being ON or OFF)
0x4A09 600C [6:5]	0b00
0x4A09 601C [31:30]	0b01

Table 26-9. SATA PHY Tuning Table (continued)

Physical address[2] [bits to modify]	Preferred value setting[1]
0x4A09 6024 [31:30]	0b10
0x4A09 6038 [31:16]	0x0000
0x4A09 6038 [15:7]	0b111110000
0x4A09 6038 [2:1]	0b11
0x4A09 6044 [10:9]	0b00

(1) These are the preferred settings of SATA_PHY, in case that SATA PHY PLL_CLK=1.5 GHz.
(2) Accesses to these locations have to be done in 32-bits only. User must NOT modify SATA PHY bits different than those described in Table 26-9.
(3) For SATA Genx and Genm description, please refer to *Serial ATA II Electrical Specification 1.0.*

26.2 USB3_PHY Subsystem

This chapter describes the features and functions of the USB3_PHY subsystem of the device.

26.2.1 USB3_PHY Subsystem Overview

The USB3.0 physical layer (PHY) is responsible for transmitting the USB1 controller media access layer (MAC) 32-bit parallel data output as a serial data stream over a differential pair (TXP/TXN) and converting the differentially received serial data (RXP/RXN) to 32-bit parallel input data demanded by the MAC receiver logic.

The USB3_PHY component operates with a 2.5 GHz-source clock, to achieve the USB 3.0 super-speed throughput of 5 Gbps. The USB3_PHY serializer/deserializer source clock is generated by a DPLL clock generator (DPLL_USB_OTG_SS) which isintegrated into the USB1 host subsystem.

The DPLL_USB_OTG_SS is configured and controlled through the USB3_PHY dedicated PLL controller (DPLLCTRL_USB_OTG_SS) with associated serial configuration port (SCP) accessible registers.

A common interconnect adapter component, OCP2SCP1, lets the user program the USB3_PHY serializer/deserializer and DPLLCTRL_USB_OTG_SS through the L4_CFG interconnect.

Figure 26-8 gives an overview of the USB3_PHY subsystem. Figure 26-8 shows that the USB3_PHY serializer and deserializer directly interract with the attached to USB OTG SS controller USB3.0 compatible device (over TXP/TXN transmission and RXP/RXN reception interface I/Os). The PIPE port interracts with the USB1 MAC port, described in details in Section 24.7, *SuperSpeed USB DRD*.

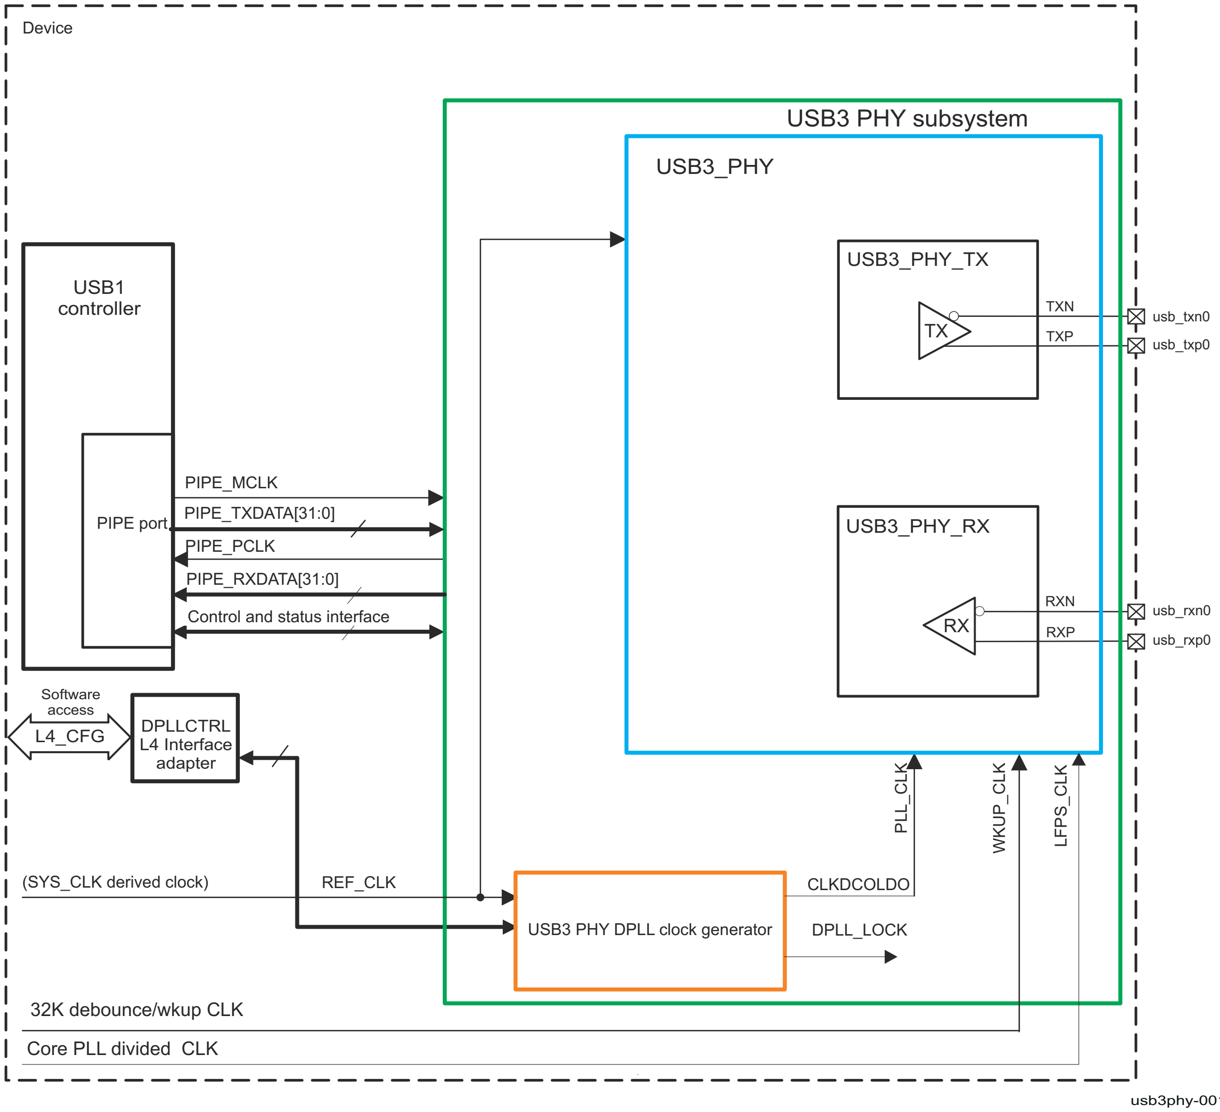

Figure 26-8. USB3_PHY Subsystem Overview

26.2.2 USB3_PHY Subsystem Environment

26.2.2.1 USB3_PHY I/O Signals

Table 26-10 represents module pins and their corresponding signal names at the device level, and also specifies their links to functions.

Table 26-10. USB3_PHY I/O Signals

Module Pin Name	Device-Level Signal Name	I/O(1)	Description	Module Pin Reset Value(2)
TXP	usb_txp0	O	TX output of the USB3_PHY differential transmission line	0
TXN	usb_txn0	O	TY output of the USB3_PHY differential transmission line	0
RXP	usb_rxp0	I	RX input of the USB3_PHY differential reception line	HiZ
RXN	usb_rxn0	I	RY input of the USB3_PHY differential reception line	HiZ

(1) I = Input; O = Output
(2) HiZ = High impedance

Figure 26-9 shows module pin signals mapping to USB3_PHY signals visible at the device pad level.

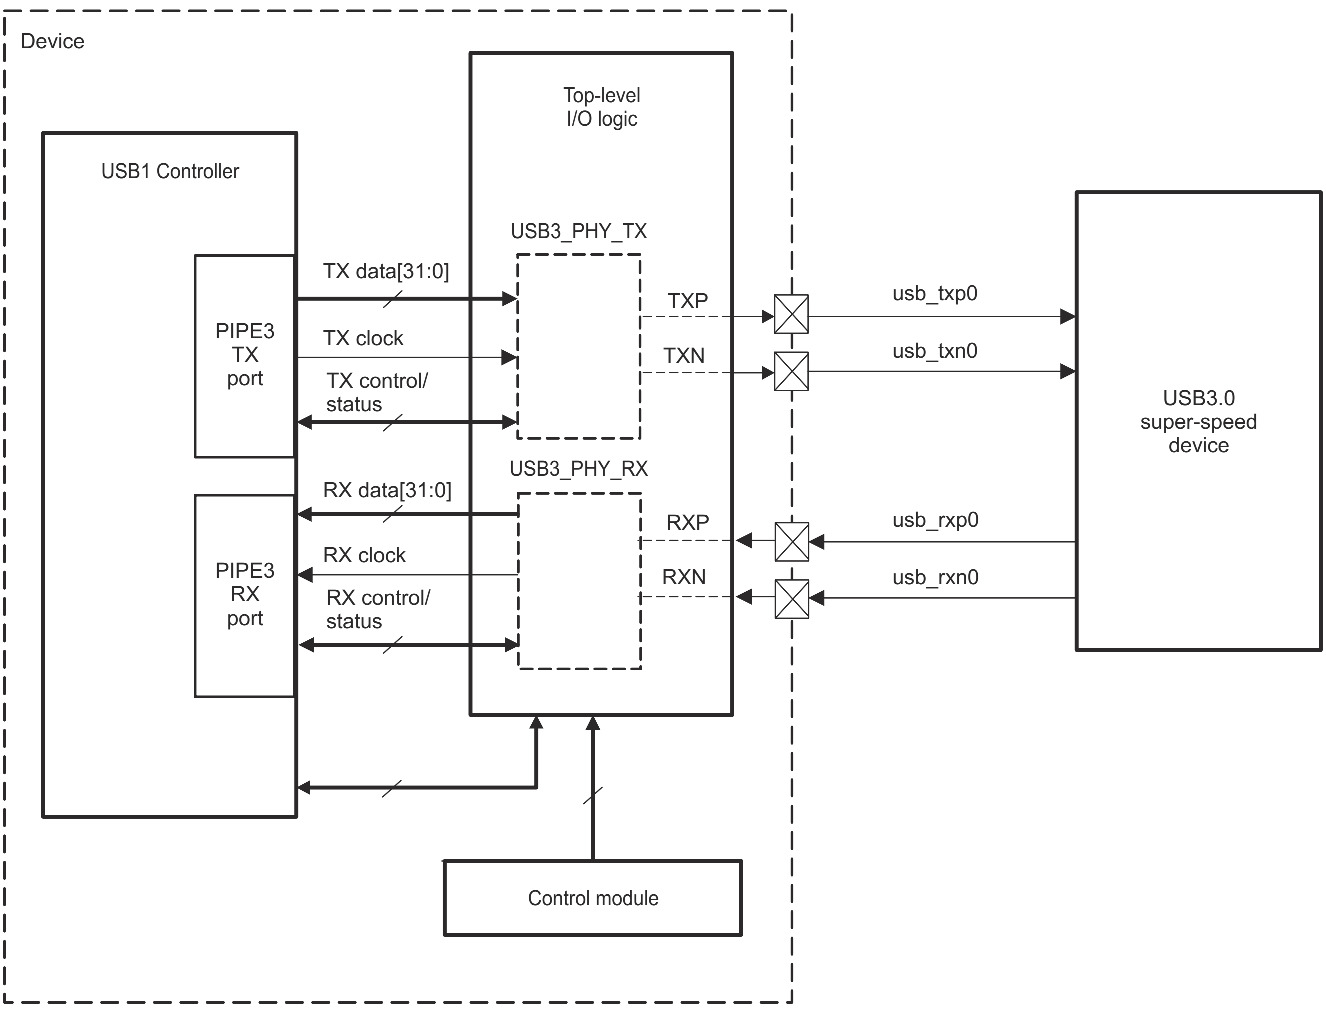

Figure 26-9. USB3_PHY I/O Signals

26.2.3 USB3_PHY Subsystem Integration

This section describes the USB3_PHY subsystem-related components (USB3_PHY module, DPLL_USB_OTG_SS, DPLLCTRL_USB_OTG_SS, and OCP2SPC1) integration in the device, including information about clocks, resets, and hardware requests.

Figure 26-10 shows the USB3_PHY integration.

The USB3_PHY module integration features:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SPC1) Interconnect adapter target interface
- A high-frequency input clock (PLL_CLK) tied to the DPLL_USB_OTG_SS.CLKDCOLDO output
- A local port connected to the USB1 MAC PIPE3 port
- A clock output (PIPE_PCLK) to the USB1 PIPE port
- A clock output (PIPE_MCLK) from the USB1 PIPE port
- A common clock from PRCM - REF_CLK, to supply DPLL and PHY RX/TX logic
- PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK clock tied to the USB3_PHY_TX
- A device CORE CONTROL MODULE command port to the power sequencer

The DPLL_USB_OTG_SS integration features:

- A low-power nonretention reset, L3INIT_RST
- A PRCM gated version of the device SYS_CLK (USB_OTG_SS_REF_CLK) supplying DPLL_USB_OTG_SS.CLKINP pin
- A single high-frequency clock output, DPLL_USB_OTG_SS.CLKDCOLDO, to the PLL_CLK input of the USB3_PHY_TX/RX components.
- No HS divider integration
- IDLE signaling implementation
- LDO and DCO PWRDNZ monitoring signals
- A DPLL_LOCK LOCKED status indication

The DPLLCTRL_USB_OTG_SS integration features:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SPC1) Interconnect adapter target interface also providing the input SCP clock to the DPLLCTRL_USB_OTG_SS
- Configuration/control programming interface to the DPLL_USB_OTG_SS
- No direct gate control for DPLL_USB_OTG_SS.CLKINP and CLKDCOLDO

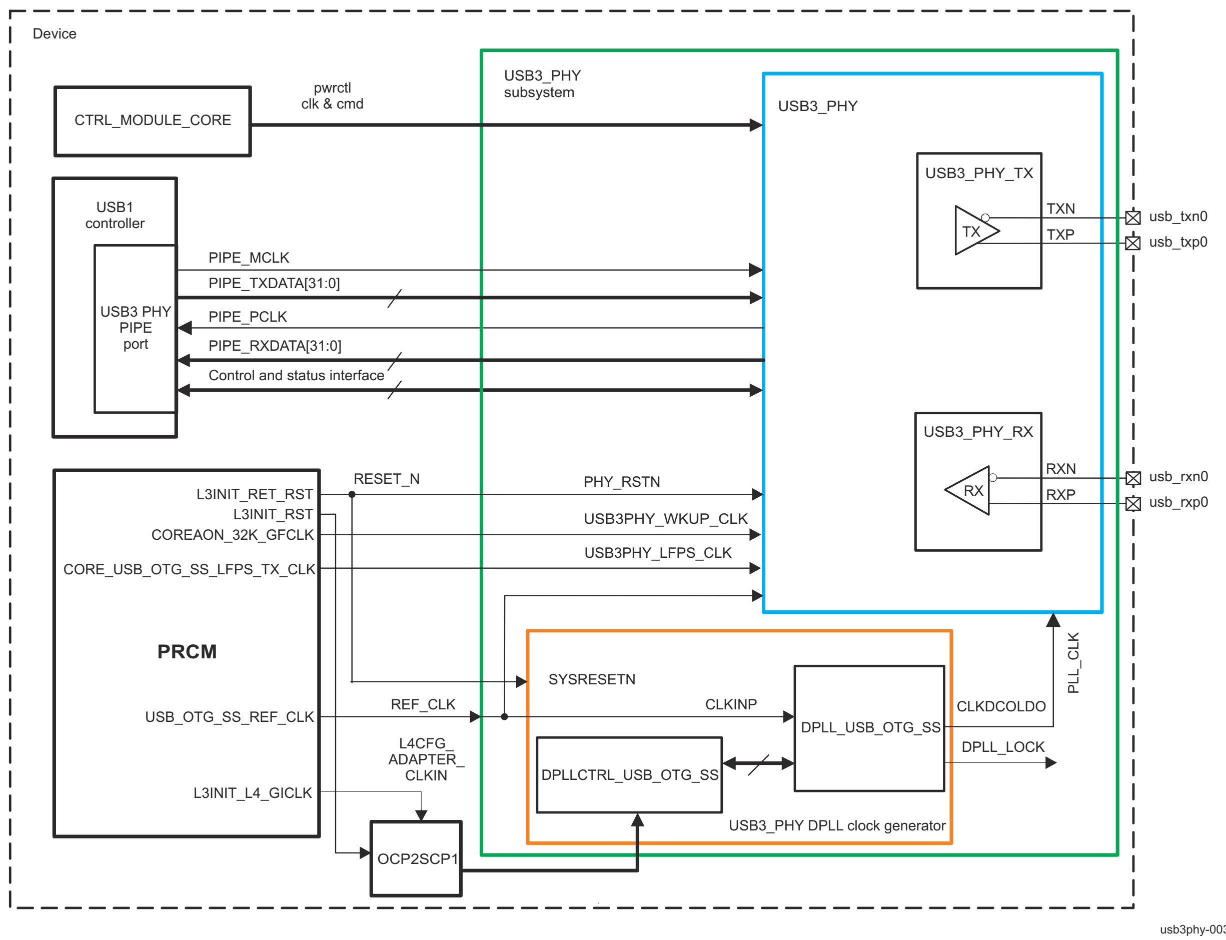

Figure 26-10. USB3_PHY Subsystem Integration

Table 26-11 through Table 26-13 summarize the integration of the module in the device.

Table 26-11. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
USB3_PHY_TX	PD_L3INIT	OCP2SCP1 SCP interconnects
USB3_PHY_RX		OCP2SCP1 SCP interconnects
USB3_PHY (wrapper)		CTRL_CORE_MODULE power control
DPLLCTRL_USB_OTG_SS		OCP2SCP1 adapter SCP interconnect
DPLL_USB_OTG_SS	PD_COREAON	
OCP2SCP1		L4_CFG

Table 26-12. Clocks

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DPLL_USB_OTG_SS	CLKINP	USB_OTG_SS_REF_CLK[1]	PRCM	DPLL_USB_OTG_SS reference functional clock (SYS_CLK based)
USB3_PHY	USB3PHY_PWRS_CLK	USB_OTG_SS_REF_CLK	PRCM	USB3_PHY wrapper power sequencer functional clock (SYS_CLK)

Table 26-12. Clocks (continued)

USB3_PHY_TX	USB3PHY_LFPS_CLK	CORE_USB_OTG_SS_LFPS_TX_CLK	PRCM	Fixed frequency USB3TX functional clock used for LFPS pattern generation
USB3_PHY_RX	USB3PHY_WKUP_CLK	COREAON_32K_GFCLK	PRCM	I/O wakeup and debounce 32-kHz functional clock at USB3_PHY_RX Receiver side
OCP2SCP1	L4CFG_ADAPTER_CLKIN	L3INIT_L4_GICLK	PRCM	L4_CFG adapter interface clock

(1) This clock is connected to a single clock input pin - REF_CLK at the USB3_PHY subsystem level

Table 26-13. Resets

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
USB3_PHY subsystem	RESET_N	L3INIT_RST	PRCM	A nonretention reset to all USB3_PHY subsystem components

Note

The USB3_PHY_RX generates a hardware wakeup request to the PRCM module.

26.2.4 USB3_PHY Subsystem Functional Description

26.2.4.1 Super-Speed USB PLL Controller L4 Interface Adapter Functional Description

The L4_CFG interconnect adapter (OCP2SCP1), allows user software to configure the DPLLCTRL_USB_OTG_SS registers over the L4_CFG port. Hence it is expected that this adapter is configured to operate before any programming of the DPLLCTRL_USB_OTG_SS.

Before initiating any software reset to this adapter, a value >= 0x6 should be written to the register bitfield OCP2SCP_TIMING[3:0] SYNC2.

L4_CFG interconnect adapter software reset is performed via writing OCP2SCP_SYSCONFIG[1] SOFTRESET to 0b1. The software reset completion is observed in bit OCP2SCP_SYSSTATUS[0] RESETDONE.

By default a smart-idle power mode is selected for OCP2SCP1. The smart-idle mode supported by OCP2SCP1 is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP1 by setting the OCP2SCP_SYSCONFIG [4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

By default OCP2SCP_SYSCONFIG[0] AUTOIDLE =0x1, which defines that the DPLLCTRL L4 interface adapter automaticaly gates its L4 input clock based on L4_CFG interconnect activity. To enable a free-running clock, one should set bit AUTOIDLE to 0x0.

26.2.4.2 USB3_PHY Serializer and Deserializer Functional Descriptions

26.2.4.2.1 USB3_PHY Module Resets

26.2.4.2.1.1 Hardware Reset

The USB3_PHY active low reset which is sourced from PRCM module. L3INIT_RST is hardware-asserted upon power up. For more information on the hardware reset source , see *Reset Domains*, in *Power, Reset, and Clock Management*.

26.2.4.2.1.2 Software Reset

The USB3_PHY PIPE i/f logic is software reset from USB1 over PIPE port by software assertion of the USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST bit to 0x1. The user must set USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x1 before triggering the serializer and deserializer power-up sequence in the CTRL_CORE_PHY_POWER_USB register. For more information on power-up sequence, see Section 26.2.4.2.3.1, *USB3_PHY Power-Up/Down Sequences*.

The user should deassert USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x0, after the serializer and deserializer power-up sequence completes. For more information, see Section 26.2.4.2.3.1, *USB3_PHY Power-Up/Down Sequences*.

26.2.4.2.2 USB3_PHY Subsystem Clocking

26.2.4.2.2.1 USB3_PHY Subsystem Input Clocks

The USB3_PHY component receives a feedback clock, PIPE_MCLK, which is the reflected version of the PIPE_PCLK (PIPE port synchronizing clock) generated by the USB3_PHY component. The clock is turned on/off according to the PIPE power-down port states. As PIPE port works in source-synchronous mode, all data movement from the MAC layer to the PIPE interface is synchronous to PIPE_PCLK.

The USB3_PHY.PLL_CLK high-speed transmission (2.5 GHz) clock input pin is connected to the DPLL_USB_OTG_SS clock output, CLKDCOLDO. For more information on the DPLL_USB_OTG_SS.CLKDCOLDO output clock settings, see Section 26.2.4.3.4.2, *USB3_PHY DPLL Output Clock Configuration*.

As shown in Figure 26-11, the same PRCM-sourced clock (USB_OTG_SS_REF_CLK), tied at the USB3_PHY subsystem REF_CLK input, supplies the USB3_PHY RX/TX components and the DPLL_USB_OTG_SS.CLKINP inputs.

The PHY associated power sequencer receives PRCM.USB_OTG_SS_REF_CLK as a functional clock . Software must notify the PHY logic about which REF_CLK frequency is selected by writing the CTRL_CORE_PHY_POWER_USB[31:22] USB_PWRCTL_CLK_FREQ bit field, as follows:

- 0x26: If SYSCLK = 38.4 MHz
- 0x1A: If SYSCLK = 26.0 MHz
- 0x13: If SYSCLK = 19.2 MHz
- 0x10: If SYSCLK = 16.8 MHz
- 0x0C: If SYSCLK = 12.0 MHz

The USB3PHY_LFPS_CLK clock input is used to support different USB3_PHY functions, such as the low-frequency periodic signaling (LFPS) generator. This USB3_PHY_TX clock input is tied to the PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK functional clock.

The USB3_PHY_RX deserializer I/O wake-up logic is supported by the PRCM.COREAON_32K_GFCLK clock, applied at the USB3PHY_WKUP_CLK input.

26.2.4.2.2.2 USB3_PHY Subsystem Output Clocks

- PIPE_PCLK: The PIPE interface is source-synchronous. A PIPE_PCLK clock is generated by the USB3_PHY component, used to synchronize USB1 PIPE port inputs, and reflected back as the PIPE_MCLK along with the PIPE outputs. The clock is turned on/off according to the power control port. All data movement from the PIPE interface to the USB1 MAC layer is synchronous to this clock.

The PIPE_PCLK clock which drives the PIPE3 logic is sourced by the on-chip USB3_PHY. The PIPE interface is source-synchronous (that is, the clock is received from the PHY), used to synchronize USB1 PIPE inputs, and reflected back along with the PIPE outputs as the PIPE_MCLK. The PIPE_PCLK clock is turned on/off according to the USB3_PHY power control port. For more details, see Section 26.2.4.2.3, *USB3_PHY Power Management*.

26.2.4.2.3 USB3_PHY Power Management

From one side the control over power up/down states of the USB3_PHY is provided through a power sequencer module tightly integrated with the the USB3_PHY physical layer TX/RX components.

26.2.4.2.3.1 USB3_PHY Power-Up/-Down Sequences

Powering-up/-down the USB3_PHY_TX and USB3_PHY_RX modules is triggered through software writing corresponding power-up/down commands in the CTRL_CORE_PHY_POWER_USB register of the device core control module, as follows:

- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x0 (default value) commands both USB3_PHY_TX and USB3_PHY_RX to power-down (OFF) state.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x1 powers up the USB3_PHY_RX only.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x2 powers up the USB3_PHY_TX only.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x3 simultaneously powers up the USB3_PHY_RX and the USB3_PHY_TX

For more information, see *Control Module*.

26.2.4.2.3.2 USB3_PHY Low-Power Modes

An implemented powerdown control port allows USB3_PHY to support four low-power states:

- 0b00: P0, normal operation (used for all Polling, Configuration, Recovery, Loopback, and Hot_Reset states, and U0 state),
- 0b01: P1, low recovery time latency, power saving state (used for U1 state)
- 0b10: P2, longer recovery time latency, lower power state (used for U2, Rx.Detect and SS.Inactive states)
- 0b11: P2, lowest power state (used for SS.disabled and U3)

The USB3_PHY transitions from P0-active mode to low-power P1, or either of the two P2 states, is synchronized with USB1 transitions from U0 active state to U1, U2, and U3 low-power states through the input PIPE_POWERDOWN[1:0]. The PIPE port low-power behavior is configured from various bit fields inside the USB1.USB_GUSB3PIPECTL register. For more information on PIPE port low-power (LP) configuration, see *USB Register Description* in Section 24.7, *SuperSpeed USB DRD*.

26.2.4.2.3.3 Clock Gating

The USB3_PHY component high-speed clocks, PLL_CLK and PIPE_PCLK, are gated during the P1 low-power state.

26.2.4.2.4 USB3_PHY Hardware Requests

An asynchronous wake-up request is generated to the PRCM module by the USB3_PHY_RX I/Os (RXP, RXN). When the wake-up request is acknowledged, the DPLL_USB_OTG_SS and PIPE_PCLK are restarted.

Neither interrupt nor DMA requests are generated.

26.2.4.3 USB3_PHY Clock Generator Subsystem Functional Description

The DPLL_USB_OTG_SS, which is located outside the PRCM boundaries and is part of the USB1 controller subsystem, directly injects a high-speed clock into the USB3_PHY serializer/deserializer input, PLL_CLK. The DPLL generator is controlled through a programmable interface from a dedicated PLL controller, DPLLCTRL_USB_OTG_SS.

26.2.4.3.1 USB3_PHY DPLL Clock Generator Overview

The SCP interface of the USB3_PHY PLL controller (DPLLCTRL_USB_OTG_SS instance) is used to set the configuration of the DPLL modules, primarily the various counter values. Figure 26-11 is an overview of the DPLL clock generator embedded into the USB1 controller subsystem.

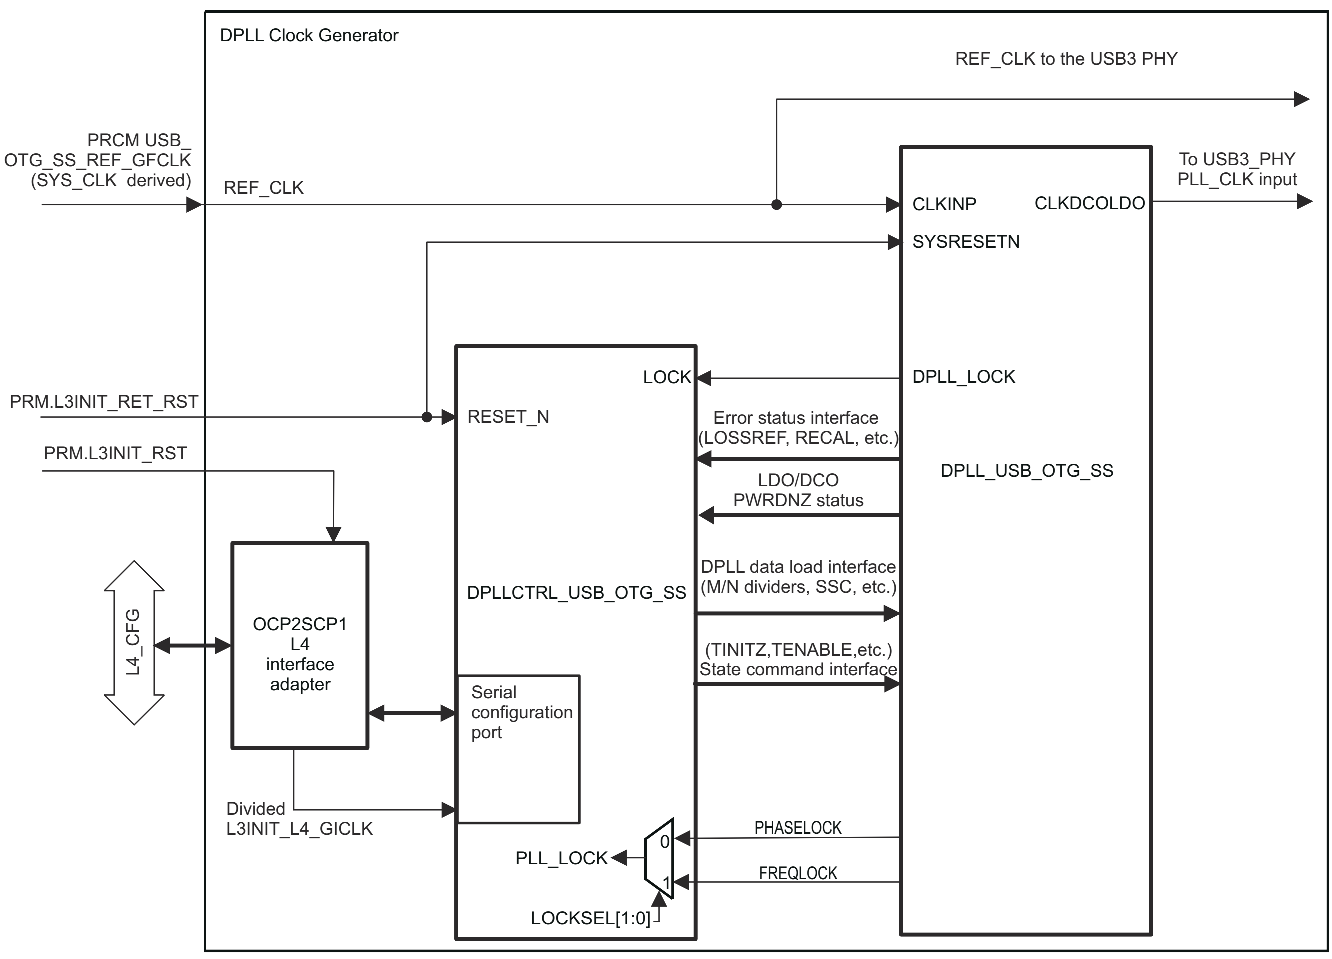

Figure 26-11. USB3_PHY DPLL Clock Generator Overview

The DPLL_USB_OTG_SS features:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Digital control and loop filter
- Internal oscillator output clock on internal LDO domain (CLKDCOLDO output)
- DPLL output clock SSC (spread spectrum clocking) support
- No retention capabilities
- No Idle-bypass fast relock capabilities
- Idle-bypass low-power mode
- M/N bypass mode
- Relock from standby

The DPLLCTRL_USB_OTG_SS components features:

- DPLL error and status notification
- DPLL initialization and configuration
- DPLL lock criteria selectable between frequency and phase lock
- Idle command implementation
- No software reset implementation
- Automatic enable/disable control, synchronized with USB1 controller PIPE port commands to set USB3_PHY to P1, P2, and P3 low-power states

26.2.4.3.2 USB3_PHY DPLL Clock Generator Reset

The USB3_PHY PLL controller and USB3_PHY DPLL clock generator share a common hardware nonretention reset, L3INIT_RST, which comes from the device power and reset manager. Upon DPLL_USB_OTG_SS hardware reset completion, the DPLLCTRL_USB_OTG_SS.PLL_STATUS[0] PLLCTRL_RESET_DONE bit is automatically updated to 1. For more information on the hardware reset source, see *Reset Domains* in *Power, Reset, and Clock Management*.

The DPLLCTRL_USB_OTG_SS itself has no software reset capabilities.

DPLLCTRL_USB_OTG_SS performs a software reset sequence on the DPLL_USB_OTG_SS in hardware (through the TINITZ signal activation).

26.2.4.3.3 USB3_PHY DPLL Low-Power Modes

The power-management port (PMP) is not integrated for DPLLCTRL_USB_OTG_SS. The DPLL_USB_OTG_SS has no retention capabilities. This means, the DPLL digital power supply remains switched on during all modes of operation.

The low-power modes supported by DPLL_USB_OTG_SS are Idle-bypass low-power and MN-bypass modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKDCOLDO output pulled low

For more details on the PLL settings and conditions necessary to enter Idle-bypass and MN-bypass low-power modes, see Section 26.2.4.3.6.4, *USB3_PHY DPLL Idle-bypass low-power Mode* , and Section 26.2.4.3.6.5, *USB3_PHY DPLL MN-Bypass Mode*.

DPLL_USB_OTG_SS is held in a similar low-power state (DCO and LDO switched off, with CLKDCOLDO = 0) after Power-up Reset, before first PLL_GO command has been software triggered on the PLL controller. See Section 26.2.4.3.6.1, *USB3_PHY Clock Generator Power Up*.

26.2.4.3.4 USB3_PHY DPLL Clocks Configuration

26.2.4.3.4.1 USB3_PHY DPLL Input Clock Control

The DPLL_USB_OTG_SS accepts the functional clock, USB_OTG_SS_REF_CLK, on its CLKINP pin (REF_CLK input at USB3_PHY subsystem level) directly from the device PRCM, without involving any DPLLCTRL_USB_OTG_SS interactions. The USB_OTG_SS_REF_CLK is derived from SYS_CLK1. See *Clock Domain Module Attributes* in *Power, Reset, and Clock Management*.

If the CLKINP signal is lost for some time, the LOSSREF output signal, which serves as a feedback to DPLLCTRL_USB_OTG_SS, is asserted high. When CLKINP resumes, LOSSREF goes low (LOSSREF inactive state). The LOSSREF status signal can be software-monitored in the DPLLCTRL_USB_OTG_SS.PLL_STATUS[3] PLL_LOSSREF bit.

Note

DPLLCTRL_USB_OTG_SS has no software or hardware mechanisms to control DPLL_USB_OTG_SS input clock (CLKINP).

26.2.4.3.4.2 USB3_PHY DPLL Output Clock Configuration

Only the DPLL_USB_OTG_SS output, CLKDCOLDO, is used to provide the high-speed clock at the PLL_CLK pin of the USB3_PHY. Only the REGM, REGN, and SD divider values are used within the DPLL clock generator subsystem to adjust the CLKDCOLDO output clock frequency. This is done through programming the DPLLCTRL_USB_OTG_SS.DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9], PLL_REGM, DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1], PLL_REGN, and DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD bit fields, respectively. The USB3_PHY DPLL CLKOUT and CLKOUTLDO outputs are not used, and internal REGM2 and REGM1 dividers are not software controllable.

Note

At DPLL/DPLLCTRL integration level the PLL_REGM1[3:0] and PLL_REGM2[6:0] divider control signals are hardware tie-off to 0x0 and 0x1, respectively.

For more details on output clock settings sequence, see Section 26.2.4.3.7.3, *USB3_PHY DPLL Clock Programming Sequence*.

26.2.4.3.4.2.1 USB3_PHY DPLL Output Clock Gating

There is no direct software gate control for the DPLL_USB_OTG_SS.CLKDCOLDO output.

DPLL_USB_OTG_SS.CLKDCOLDO clock output is automatically gated (CLKDCOLDO pulled low) in the following scenarios:

- DPLL power-up sequence. For more information on power-up sequence, see Section 26.2.4.3.6.1, *USB3_PHY Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on relocking sequence, see Section 26.2.4.3.6.2, *USB3_PHY DPLL Sequences*.
- DPLL entering Idle-bypass low-power mode. For more information on idle-bypass mode, see Section 26.2.4.3.6.4, *USB3_PHY DPLL Idle-Bypass Mode*.
- DPLL entering MN-bypass mode. For more information on MN-bypass mode, see Section 26.2.4.3.6.5, *USB3_PHY DPLL MN-Bypass Mode*.

26.2.4.3.5 USB3_PHY DPLL Subsystem Architecture

Figure 26-12 is a simplified block diagram of the DPLL_USB_OTG_SS instance integration in the USB3_PHY clock generator subsystem.

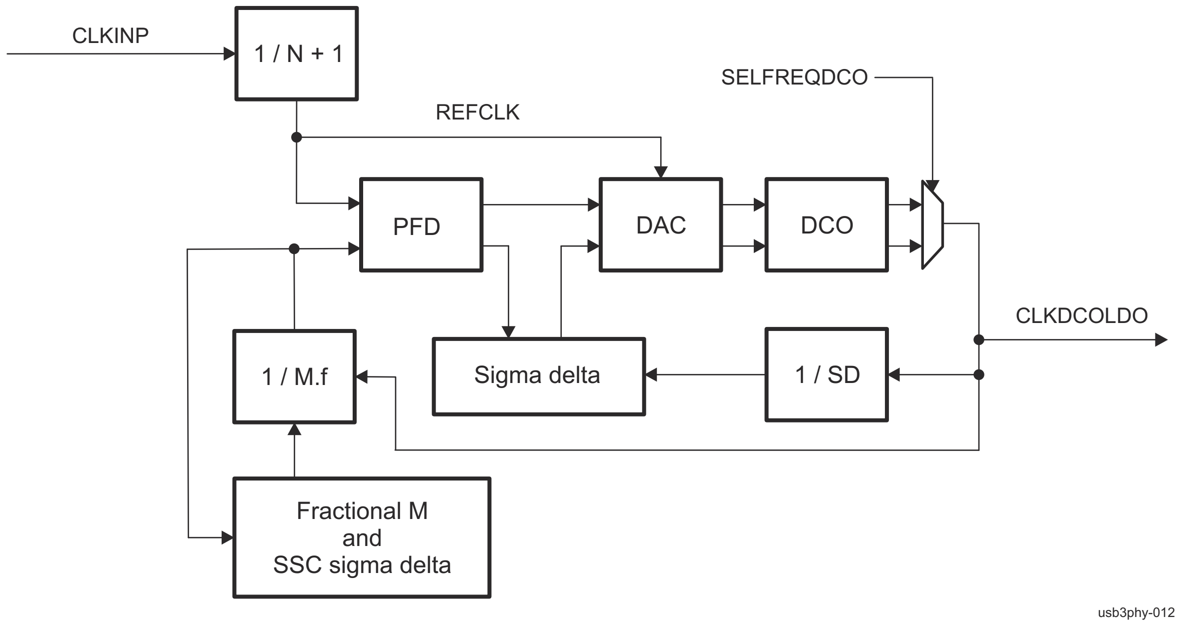

Figure 26-12. DPLL_USB_OTG_SS Functional Block Diagram

The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

The frequency ranges for the DPLL_USB_OTG_SS input clock - CLKINP and the DPLL internal reference clock, REFCLK = CLKINP/N + 1 are:

- 0.62 to 60 MHz for CLKINP
- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKDCOLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP×M/(N + 1). For that purpose the feedback multiplier M must be configured through the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL_USB_OTG_SS module supports fractional synthesis (that is, the frequency multiplication factor M can be programmed as fractional). This is achieved by having a sigma delta feedback divider (M). A fractional value (Fractional M) of 18 bits is supported, thus enabling control for a better accuracy. Programming the 18-bit Fractional M value is done by setting the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field (similar to REGM). To enable integer only division, Fractional M should be set to 000…0.

Note

Fractional synthesis is not supported for M > 4093.

The module also supports SSC on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce any electromagnetic interference (EMI). When SSC is enabled, the clock spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread (df) and the modulation frequency (fm); that is, {10×log10(df/fm)} dB.

The SSC is performed by changing the feedback divider (M) in a triangular pattern, which means the frequency of the output clock varies in a triangular pattern. The frequency of the triangular pattern is modulation frequency (fm). The peak (dM) or the amplitude of the triangular pattern as a percent of M is equal to the percent of the frequency spread (df); that is, $dM/M = df/F_{OUT}$.

Because this is in-band modulation for the DPLL_USB_OTG_SS, the modulation frequency must be within the loop bandwidth of the DPLL. A higher modulation frequency would result in less spreading in the output clock.

The SSC can be enabled and disabled by asserting the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION1[0] EN_SSC bit. The acknowledge signal SSCACK, observed by the DPLLCTRL_USB_OTG_SS.PLL_STATUS[12] SSC_EN_ACK bit, notifies the exact start and end of SSC. When EN_SSC is deasserted, SSC is disabled only after completion of one full cycle of the triangular pattern given by the modulation frequency. This is done to maintain the average frequency.

The modulation frequency (fm) can be programmed as a ratio of REFCLK/4; that is, the value programmed in the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field must be = REFCLK/(4×fm).The ModFreqDivider is split into Mantissa and 2^{Exponent} (ModFreqDivider = ModFreqDividerMantissa × $2^{\text{ModFreqDividerExponent}}$).

- The Mantissa is controlled by bits [29:23] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.
- The Exponent is controlled by bits [22:20] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.

Although the same value of ModFreqDivider could be obtained by different combinations of Mantissa and Exponent values, it is preferred to get the target ModFreqDivider by programming maximum Mantissa and minimum Exponent values.

To define the frequency spread (df), dM must be controlled as previously explained. To define dM, the step size of M for each REFCLK during the triangular pattern must be programmed.This is defined as follows:

- dM =($2^{\text{ModFreqDividerExponent}}$) × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent <= 3
- dM = 8 × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent > 3

DeltaMStep value is split into integer part and fractional part, as follows:

- The MSB of 3-bit integer part, DeltaMStepInteger, is controlled by the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[30] DELTAM2 bit and the remaining LSBs by bits [19:18] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.
- The 18-bit fractional part, DeltaMStepFraction, is controlled by bits [17:0] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.

If the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION1[2] DOWNSPREAD bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0 (except for 20 percent overshot).

26.2.4.3.6 USB3_PHY DPLL Clock Generator Modes and State Transitions

The DPLL_USB_OTG_SS can be set in different modes during operation. DPLLCTRL triggers DPLL_USB_OTG_SS state transitions to different static modes by means of the TINITZ and TENABLE hardware control signals.

26.2.4.3.6.1 USB3_PHY Clock Generator Power Up

After power up, the DPLL_USB_OTG_SS.SYSRESETN input is automatically pulled low by the PRM, together with the DPLLCTRL_USB_OTG_SS.RESET_N input. Because PRM.L3INIT_RST is an asynchronous reset, the DPLL_USB_OTG_SS input clock (DPLL_USB_OTG_SS.CLKINP) is not demanded upon reset. The LOSSREF signal, which monitors the presence of CLKINP clock, remains 1 during SYSRESETN = 0 irrespective of presence/absence of the CLKINP clock. If CLKINP is present when reset is asserted, the LOSSREF signal is deasserted to 0, a certain time after the hardware reset completes. During DPLL power-up mode, CLKDCOLDO clock is maintained inactive (pulled low). After power-up reset, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too.

26.2.4.3.6.2 USB3_PHY DPLL Sequences

Once all the configuration values have been initially programmed into the DPLLCTRL_USB_OTG_SS registers (see Section 26.2.4.3.7.3) , the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit should be set to update the configuration values and start the DPLL calibration and locking sequence.

After the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit is set high in software, the DPLLCTRL_USB_OTG_SS state-machine takes the following action:

1. Sets the TINITZ signal to 0, which acts as a soft reset to DPLL_USB_OTG_SS. This starts the DPLL initialization procedure. During initialization mode, the CLKDCOLDO, FREQLOCK, and PHASELOCK signals are kept at 0 and the BYPASSACK signal is kept at 1.
   VDDA power supply of DPLL should be active before DPLL_USB_OTG_SS Initialization is performed, but it is not required to be switched on immediately after device power up.
2. The TENABLE signal is asserted high by DPLLCTRL hardware to load the user-programmed values of REGM, REGN, REGSD, and SELFREQDCO into DPLL registers.
3. After TENABLE is asserted, TINITZ is driven high (disabled) by the DPLLCTRL to trigger a DPLL calibration and lock sequence after the loop control values are loaded. The module calibration-lock sequence will begin from the first CLKINP edge after TINITZ is disabled.

Figure 26-13 summarizes the software and hardware sequences flow of DPLL_USB_OTG_SS.

Note

All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

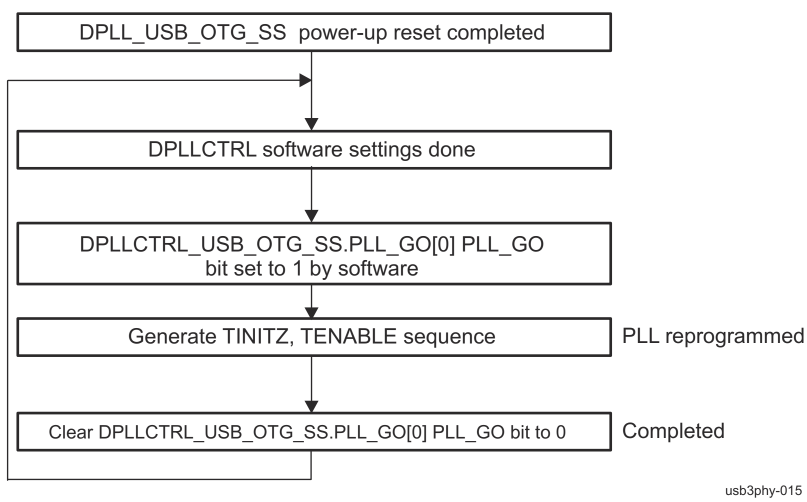

Figure 26-13. USB3_PHY PLL GO Sequence

DPLL_USB_OTG_SS relock sequence:

When the DPLL leaves a lost clock condition (LOSSREF = 1 → 0) or idle-bypass mode it enters relock sequence from the first CLKINP edge (after bypass mode leaving). Relock sequence is the same as calibration-lock sequence already described.

A DPLL relock sequence is also software triggered by setting the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit to 0b1 for DPLL parameters update.

When DPLL_USB_OTG_SS enters a relock sequence, CLKDCOLDO is pulled low. FREQLOCK and PHASELOCK status signals are also low. CLKDCOLDO output clock is activated after the FREQLOCK or PHASELOCK signal goes high, depending on the selected locking criteria.

The DPLLCTRL_USB_OTG_SS.PLL_GOUSB3PHY_PLL_GO[0] PLL_GO bit can be used by software to monitor if DPLLCTRL locking process is still pending (PLL_GO = 0b1).

26.2.4.3.6.3 USB3_PHY DPLL Locked Mode

When DPLL_USB_OTG_SS finishes calibration and lock sequences it enters a locked state. During the locked state, LOSSREF and BYPASSACK are deasserted, FREQLOCK or PHASELOCK is asserted.

DPLL lock event criteria (FREQLOCK or PHASELOCK) is software-selectable through the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL bit field.

The DPLL signalizes the locked state to DPLLCTRL_USB_OTG_SS, USB_OTG_SS core controller, and USB3_PHY through assertion of the DPLL_LOCK signal, which reflects the internal lock loop status. The user software can monitor the DPLL locked event in the DPLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit, which is active high.

26.2.4.3.6.4 USB3_PHY DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_USB_OTG_SS.

DPLL_USB_OTG_SS supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the DPLLCTRL_USB_OTG_SS.DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE bit to 0x1. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and the DCO oscillator.

In idle-bypass low-power mode, the PHASELOCK and FREQLOCK output signals are asserted low and CLKDCOLDO goes low. Also, the internal reference clock REFCLK = CLKINP/N + 1 is gated inside the DPLL digital control logic to save power.

In the functional mode, the DPLL_USB_OTG_SS.TICOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal DCO oscillator. The internal DCO oscillator is powered down in idle-bypass mode or during period from SYSRESETN 0->1 to module initialization. The DCO oscillator exits power-down (TICOPWDN goes low) whenever the module internally tries to lock/relock after initialization or exiting idle-bypass mode.

In the functional mode, DPLL_USB_OTG_SS.LDOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal LDO. LDOPWDN goes high as soon as the internal LDO is powered down. LDOPWDN goes low after the LDO output voltage is stable. The internal LDO is powered down in the period from SYSRESETN 0 → 1 to module initialization or when entering into idle-bypass mode. LDOPWDN is cleared whenever the module internally tries to lock/relock after initialization or exiting idle-bypass mode after the internal LDO output voltage has stabilized.

The DCO and LDO power ON and OFF states are reflected within the read-only DPLLCTRL_USB_OTG_SS.PLL_STATUS[16] PLL_TICOPWDN and DPLLCTRL_USB_OTG_SS.PLL_STATUS[15] LDOPWDN monitor bits.

To exit idle-bypass mode and restore clock generation, the user should write DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE to 0x0, which deasserts the IDLE signal, and DPLL_USB_OTG_SS automatically enters a relock sequence. CLKDCOLDO output clock is activated after the FREQLOCK or the PHASELOCK signal goes high, depending on selected locking criteria.

26.2.4.3.6.5 USB3_PHY DPLL MN-Bypass Mode

The MN-bypass mode will be activated if REGM = 0 or 1 is loaded into the module on the rising edge of TENABLE. TINITZ also should be pulsed to enter MN-bypass mode. The module enters a low-power mode by gating all its internal clocks (REFCLK) and powering down internal LDO (LDOPWDN = 1) and DCO (DCOPWDN = 1). CLKDCOLDO remains gated (low) during this mode.

Note

When the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field is updated to 0x0 or 0x1, the CLKDCOLDO is gated.

26.2.4.3.6.6 USB3_PHY DPLL Error Conditions

The PLL lock and recalibration signals can be monitored to detect the loss-of-lock condition and the DPLL requirement to recalibrate (caused by a large temperature change since the last lock request):

- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[2] PLL_RECAL bit informs whether the DPLL_USB_OTG_SS must be recalibrated.

The PLL reference clock (CLKINP) loss status and PLL-in-high-jitter condition can also be monitored:

- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit gives the USB3_PHY PLL lock state.
- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[3] PLL_LOSSREF bit informs whether the DPLLCTRL_USB_OTG_SS has lost the reference clock.
- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[5] PLL_HIGHJITTER bit informs whether the PLL has entered a high-jitter condition.

26.2.4.3.7 USB3_PHY PLL Controller Functions

26.2.4.3.7.1 USB3_PHY PLL Controller Register Access

The configuration registers are accessed through the OCP2SCP1 L4 adapter register space using the SCP interface of the DPLLCTRL_USB_OTG_SS. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

Note

Because the USB3_PHY directly provides parallel data interface clocks RX_CLK and TX_CLK to the USB1 MAC controller, the DPLLCTRL_USB_OTG_SS and DPLL_USB_OTG_SS must be configured before any data transfer between the USB1 controller MAC layer and an external USB3 device.

26.2.4.3.7.2

26.2.4.3.7.3 USB3_PHY DPLL Clock Programming Sequence

The DPLL_USB_OTG_SS factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

- REGM factor is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- Fractional part of REGM factor is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field.
- REGN factor is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- DCO frequency range is set in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field.
  - PLL_SELFREQDCO should be set to 0x2 if 750 MHz < CLKDCOLDO [MHz] < 1500 MHz.
  - PLL_SELFREQDCO should be set to 0x4 if 1250 MHz < CLKDCOLDO [MHz] < 2500 MHz.
- SD divider is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD bit field. The DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO register bit field should be programmed depending on the value of CLKDCOLDO = CLKINP × M/(N + 1).

Figure 26-14 shows the formulae and programming sequence.

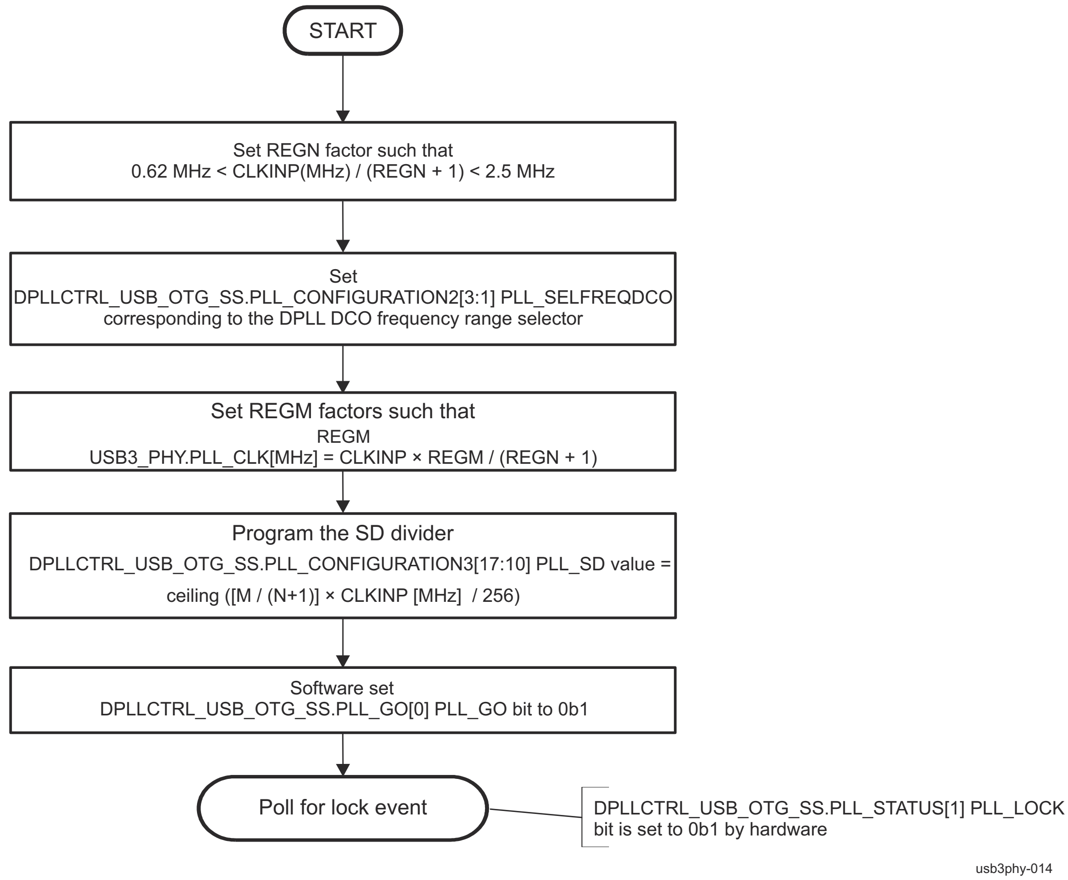

Figure 26-14. USB3_PHY PLL Programming Sequence

Note

- The equation for USB3_PHY_TX/USB3_PHY_RX (MHz) applies to the CLKDCOLDO of the DPLL_USB_OTG_SS.
- CLKDCOLDO output frequency of the DPLL_USB_OTG_SS should be programmed to 2.5 GHz, for the super-speed USB (5 Gbps) mode.

Table 26-14 summarizes the registers for the DPLLCTRL_USB_OTG_SS programming sequence.

Table 26-14. Register Call Summary for USB3_PHY PLL Programming Sequence

Register Name	Register Name	Register Name	Register Name
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2	DPLLCTRL_USB_OTG_SS.PLL_GO	DPLLCTRL_USB_OTG_SS.PLL_STATUS	DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3

26.2.4.3.7.4 USB3_PHY DPLL Recommended Values

Table 26-15 lists the DPLL_USB_OTG_SS recommended values.

Table 26-15. Recommended Programming Values

Field Name	Value	Description
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM	See [1].	Feedback clock divider
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN	See [1].	Reference clock divider

Table 26-15. Recommended Programming Values (continued)

Field Name	Value	Description
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL	0x-	Criteria to lock the PLL
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO	See (1).	Program based on the PLL choice and lock frequency.
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE	0	PLL active
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD	See (1).	Ceiling { [PLL_REGM/(PLL_REGN+1)] × CLKINP(MHz)/256 }
DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO	0x1	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.

(1) The value of the bit field must be set according to the desired clock frequency.

26.2.5 USB3_PHY Subsystem Low-Level Programming Model

The low-level programming sequence to set up the USB3_PHY subsystem for USB superspeed I/O operations is summarized in the Table 26-16

Table 26-16. USB3_PHY Subsystem Low-Level Programming Sequence

Step	Description	Comment
1.	Set the startup low performance OPP in the appropriate PRCM registers.	For more information regarding demanded OPP, see the device *Data Manual*.
2.	Enable the PRCM.USB_OTG_SS_REF_CLK.	See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
3.	Enable the PRCM.L3INIT_L4_GICLK to enable the OCP2SCP1 interface adapter operation.	See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
4.	Software reset the OCP2SCP1 and poll until soft reset completion is indicated in status.	See Section 26.2.4.1.
5.	Set up division ratio between the OCP clock (PRCM.L3INIT_L4_GICLK) and SCP clock to supply the serial configuration register domains of the DPLLCTRL_USB_OTG_SS .	See Section 26.2.4.1.
6.	Set up necessary SYNC1 and SYNC2 timings to ensure no blocking of transactions over the SCP bus.	See Section 26.2.4.1. After this step, the user is ready to access the DPLLCTRL_USB_OTG_SS registers.
7.	Configure DPLL_USB_OTG_SS to generate frequency (CLKDCOLDO) = 2.5 GHz.	See Section 26.2.4.3.7.3.
8.	Software-assert the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit to 0x1	Start the DPLL lock with desired parameters.
9.	Poll the DPLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit until it reads 1.	DPLL locked event
10.	Perform a USB3_PHY tuning required for the Super-Speed OTG USB i/f operation	Follow steps described in Table 26-17, *USB3_PHY Tuning Table*.
11.	Set USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x1	Software reset the USB3_PHY over USB OTG SS controller PIPE port. Note that this reset does not impact settings made in step 10.
12.	Software-trigger the USB3_PHY_TX power-up sequence.	For more details, see Section 26.2.4.2.3.1.
13.	Software-trigger the USB3_PHY_RX power-up sequence.	For more details, see Section 26.2.4.2.3.1.
14.	Clear USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x0	Deassert the software reset bit after power-up sequence completion is indicated

Table 26-17. USB3_PHY Tuning Table

Physical address[(2)] [bits to modify]	Preferred value setting[(1)]
0x4A08 440C [31:27]	0b10000
0x4A08 440C [17:14]	0b1010

Table 26-17. USB3_PHY Tuning Table (continued)

Physical address(2) [bits to modify]	Preferred value setting(1)
0x4A08 4428 [23:11]	0b1110001100110
0x4A08 4428 [28:26]	0b001
0x4A08 440C [6:5]	0b00
0x4A08 441C [31:30]	0b10
0x4A08 4424 [31:30]	0b11
0x4A08 4438 [10:7]	0b1001
0x4A08 4438 [2]	0b0

(1) These are the preferred settings of USB3_PHY, in case that USB3_PHY PLL_CLK=2.5 GHz.
(2) Accesses to these locations have to be done in 32-bits only. User must not modify USB3_PHY bits different than those described in Table 26-17.

26.3 USB3 PHY and SATA PHY Register Manual

This chapter summarizes and describes the registers for USB3 PHY and SATA PHY subsystems.

26.3.1 USB3 PHY and SATA PHY Instance Summary

Note

For OCP2SCP1 registers, please refer to Section 26.4.6 , *PCIe PHY Subsystem Register Manual*.

Table 26-18. USB3 PHY and SATA PHY Instance Summary

Module Name	Module Base Address	Size
USB3_PHY_RX	0x4A08 4400	128 bytes
USB3_PHY_TX	0x4A08 4800	100 bytes
DPLLCTRL_USB_OTG_SS	0x4A08 4C00	64 bytes
DPLLCTRL_SATA	0x4A09 6800	64 bytes

26.3.2 USB3_PHY_RX Registers

26.3.2.1 USB3_PHY_RX Register Summary

26.3.2.2 USB3_PHY_RX Register Description

Table 26-20. USB3PHYRX_ANA_PROGRAMMABILITY_REG1

Address Offset	0x0000 000C		
Physical Address	0x4A08 440C	**Instance**	USB3_PHY_RX
Description	Some programmability for different analog circuits in the PHY.		
Type	RW		

31:8	7	6:5	4:0
MEM_ANAMODE	RESERVED	MEM_PLLDIV	RESERVED

Bits	Field Name	Description	Type	Reset
31:8	MEM_ANAMODE	Programmability for Analog circuits in the IP. The top 5 bits - MEM_ANAMODE[31:27] indicate the serial Interface using this PHY module. To select USB Super-Speed interface mode, user must set bit MEM_ANAMODE [31] to '0b1', and the other bits must be written to '0b0', as follows: **MEM_ANAMODE[31:27] = '0b10000' for the USB Super-Speed.** Bits [17:14] of the MEM_ANAMODE bitfield are used to control loss-of-signal detection (LOSD) threshold.	RW	0x00 0000
7	RESERVED		RW	0
6:5	MEM_PLLDIV	This is a test mode. SoC Users are requested to leave this at default value. The input PLL_CLK (after being muxed with PLLBYPCLK) is divided by the following factors indicated by this register. 00=1 01=2 10=4 11=RESERVED. All references to PLL_CLK in this register descriptions are AFTER considering this division.	RW	0x0
4:0	RESERVED		R	0x00

Table 26-21. USB3PHYRX_TRIM_REG4

Address Offset	0x0000 001C		
Physical Address	0x4A08 441C	**Instance**	USB3_PHY_RX
Description	The IP requires some values to be remembered in EFUSE. This register provides an alternative to EFUSE.		
Type	RW		

31	30:0
MEM_DLL_TRIM_SEL	RESERVED

Bits	Field Name	Description	Type	Reset
31:30	MEM_DLL_TRIM_SEL	Determines which of the 4 EFUSE registers EFUSE_dll_rateN_coarsetrim should be used as the trim code by the DLL. This feature is so that the user may find and store the trim codes corresponding to different (at most 4) DLL frequencies (PLL_CLK (after the bypassing by MEM_EN_PLLBYP and the division by MEM_PLLDIV) frequencies) and at wake-up, instruct the IP to choose one of these available trim values depending on the Application's frequency requirement. 00 selects dll_rate0_coarsetrim 01 selects dll_rate1_coarsetrim 10 selects dll_rate2_coarsetrim 11 selects dll_rate3_coarsetrim.	RW	0x0
29:0	RESERVED		RW	0x0000 0000

Table 26-22. USB3PHYRX_DLL_REG1

Address Offset	0x0000 0024		
Physical Address	0x4A08 4424	**Instance**	USB3_PHY_RX
Description	This register is used to program DLL settings.		
Type	RW		

31	30	29–0
MEM_DLL_PHINT_RATE		RESERVED

Bits	Field Name	Description	Type	Reset
31:30	MEM_DLL_PHINT_RATE	Programs the DLL and the Phase Interpolator analog circuits to work with different clock frequencies. The frequency of PLL_CLK (after the bypassing by MEM_EN_PLLBYP and the division by MEM_PLLDIV) should be indicated by this register. 00=0.625GHz to 0.75GHz 01=RESERVED 10=1.25GHz to 1.5GHz 11=2.5GHz to 2.9GHz.	RW	0x3
29:0	RESERVED		R	0x00A4 1915

Table 26-23. USB3PHYRX_DIGITAL_MODES_REG1

Address Offset	0x0000 0028		
Physical Address	0x4A08 4428	**Instance**	USB3_PHY_RX
Description	This register contains control bits which affect different circuits in digital section of the PHY.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MEM_INV_RXPN_PAIR	MEM_OVRD_INV_RXPN_PAIR	RESERVED	MEM_HS_RATE	MEM_OVRD_HS_RATE	RESERVED	MEM_CDR_FASTLOCK	MEM_CDR_LBW	MEM_CDR_STEPCNT	MEM_CDR_STL	MEM_CDR_THR	MEM_CDR_THR_MODE	MEM_CDR_2NDO_SDM_MODE	RESERVED

Bits	Field Name	Description	Type	Reset
31	MEM_INV_RXPN_PAIR	If '1', interchanges RXP and RXN effectively by inverting the received data samples.	RW	0
30	MEM_OVRD_INV_RXPN_PAIR	Pin override control. See register bit MEM_INV_RXPN_PAIR.	RW	0
29	RESERVED		R	0
28:27	MEM_HS_RATE	Determines the ratio of PLL_CLK (after the bypassing by MEM_EN_PLLBYP and the division by MEM_PLLDIV) frequency and the output data rate. Full Rate means PLL_CLK (after the bypassing by MEM_EN_PLLBYP and the division by MEM_PLLDIV) frequency = Data Rate/2 00=Full Rate 01=Half Rate 10=Quarter Rate 11=RESERVED. This takes effect only if register bit MEM_OVRD_HS_RATE is '1', else the same is controlled by input pins hs_rate.	RW	0x0
26	MEM_OVRD_HS_RATE	Pin override control. See register bit MEM_HS_RATE.	RW	0
25:24	RESERVED		R	0x2
23	MEM_CDR_FASTLOCK	'1' to reduce lock time of CDR (clock-data-recovery circuit).	RW	1
22:21	MEM_CDR_LBW	CDR band-width control.	RW	0x3
20:19	MEM_CDR_STEPCNT	CDR 2nd order setting.	RW	0x0
18:16	MEM_CDR_STL	CDR settling time. Determines the number of vote clocks to blank ELV (Early-Late-Voter circuit) after update of phase.	RW	0x3
15:13	MEM_CDR_THR	CDR 1st order threshold. Determines how much early/ late votes should differ by before a phase change in the receiver sampling clock is triggered.	RW	0x1
12	MEM_CDR_THR_MODE	CDR 1st order threshold.	RW	1
11	MEM_CDR_2NDO_SDM_MODE	If '1', the 2nd Order CDR block uses a 1st order Sigma Delta Modulator to accomplish frequency offset If '0', a simple rate transformer is used for the same purpose.	RW	0
10:0	RESERVED		R	0x000

Table 26-24. USB3PHYRX_EQUALIZER_REG1

Address Offset	0x0000 0038		
Physical Address	0x4A08 4438	**Instance**	USB3_PHY_RX

Table 26-24. USB3PHYRX_EQUALIZER_REG1 (continued)

Description	The IP has an Equalizer (with analog and digital parts) which addresses Inter Symbol Interference (ISI). This register is for its controllability. The equalizer can be configured via the EQCTL bits which are part of the SCP register. The options are: No adaptive equalisation. The equalizer provides a flat response at the maximum gain. This setting may be appropriate if jitter at the receiver occurs predominantly as a result of crosstalk rather than frequency dependent loss. Fully adaptive equalisation. Both the low frequency gain and zero position of the equalizer are determined algorithmically by analysing the data patterns and transition positions in the received data. This setting should be used for most applications. Partially adaptive equalisation. The low frequency gain of the equalizer is determined algorithmically by analysing the data patterns and transition positions in the received data. The zero position is fixed in one of eight zero positions. When enabled, the receiver equalization logic analyzes data patterns and transition times to determine whether the low frequency gain of the equalizer should be increased or decreased. For the fully adaptive setting (EQCTL = 0001), if the low frequency gain reaches the minimum value, the zero frequency is then reduced. Likewise, if it reaches the maximum value, the zero frequency is then increased.

26.4 PCIe PHY Subsystem

This chapter describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) physical layer (PHY) subsystem.

26.4.1 PCIe PHY Subsystem Overview

The device has two PCI Express physical ports - PCIe 0 and PCIe 1. Each of the two device PCIe ports has an associated PMA (physical media attachment) component pair of a high-speed operating differential transmitter (serializer) and a differential receiver (de-serializer). While the device PCIe port 0 PHY is always mapped to device PCIe_SS1 controller, the device PCIe port 1 PHY can be software multiplexed to the PCIe_SS1 (dual-lane configuration) or to the PCIe_SS2 (single-lane configuration) . In addition, the PCIe shared PHY subsystem encompasses a PCIe PCS (physical coding sublayer), a PCIe power management logic, APLL, a DPLL reference clock generator and an APLL low-jitter clock buffer.

- PCIe PCS (a physical coding sublayer component) converts an 8-bit portion of parallel data over a PCIe lane to a 10-bit parallel data to adapt the process of serialization and deserialization in the TX/RX PHYs to various requirements. At the same time it transforms the transmission rate to maintain the PCIe Gen2 bandwidth. A PCS component is hardware mapped to each of the PCIe_SS1 (16-bit) and PCIe_SS2 controller (32-bit) PIPE ports.
- A programmable multiplexing logic which maps either PCIe_SS1 or PCIe_SS2 PCS logic to PCIe port 1 PHY.
- PHY serializer (TX) and deserializer (RX) components with associated power control logic, building the so called PMA (physical media attachment) part.
- DPLL_PCIe_REF is a DPLL clock source, controlled from the device PRCM, that provides (typically 20 MHz/100 MHz) clock to the PCIe PHY serializer/de-serializer components reference clock inputs.
- Contains an integrated APLL (APLLPCIe) which multiplies the DPLL_PCIe_REF clock to 2.5 GHz.
- The APLLPCIe low-jitter buffer and additional logic takes care to provide the PCIe APLL reference input clock.
- An L4_CFG interface adapter - OCP2SCP3 enables accessing the PCIe PHY serial configuration protocol compatible (SCP) registers via L4_CFG interconnect accesses.

Figure 26-15 shows an overview of the device PCIe subsystem with its integrated components.

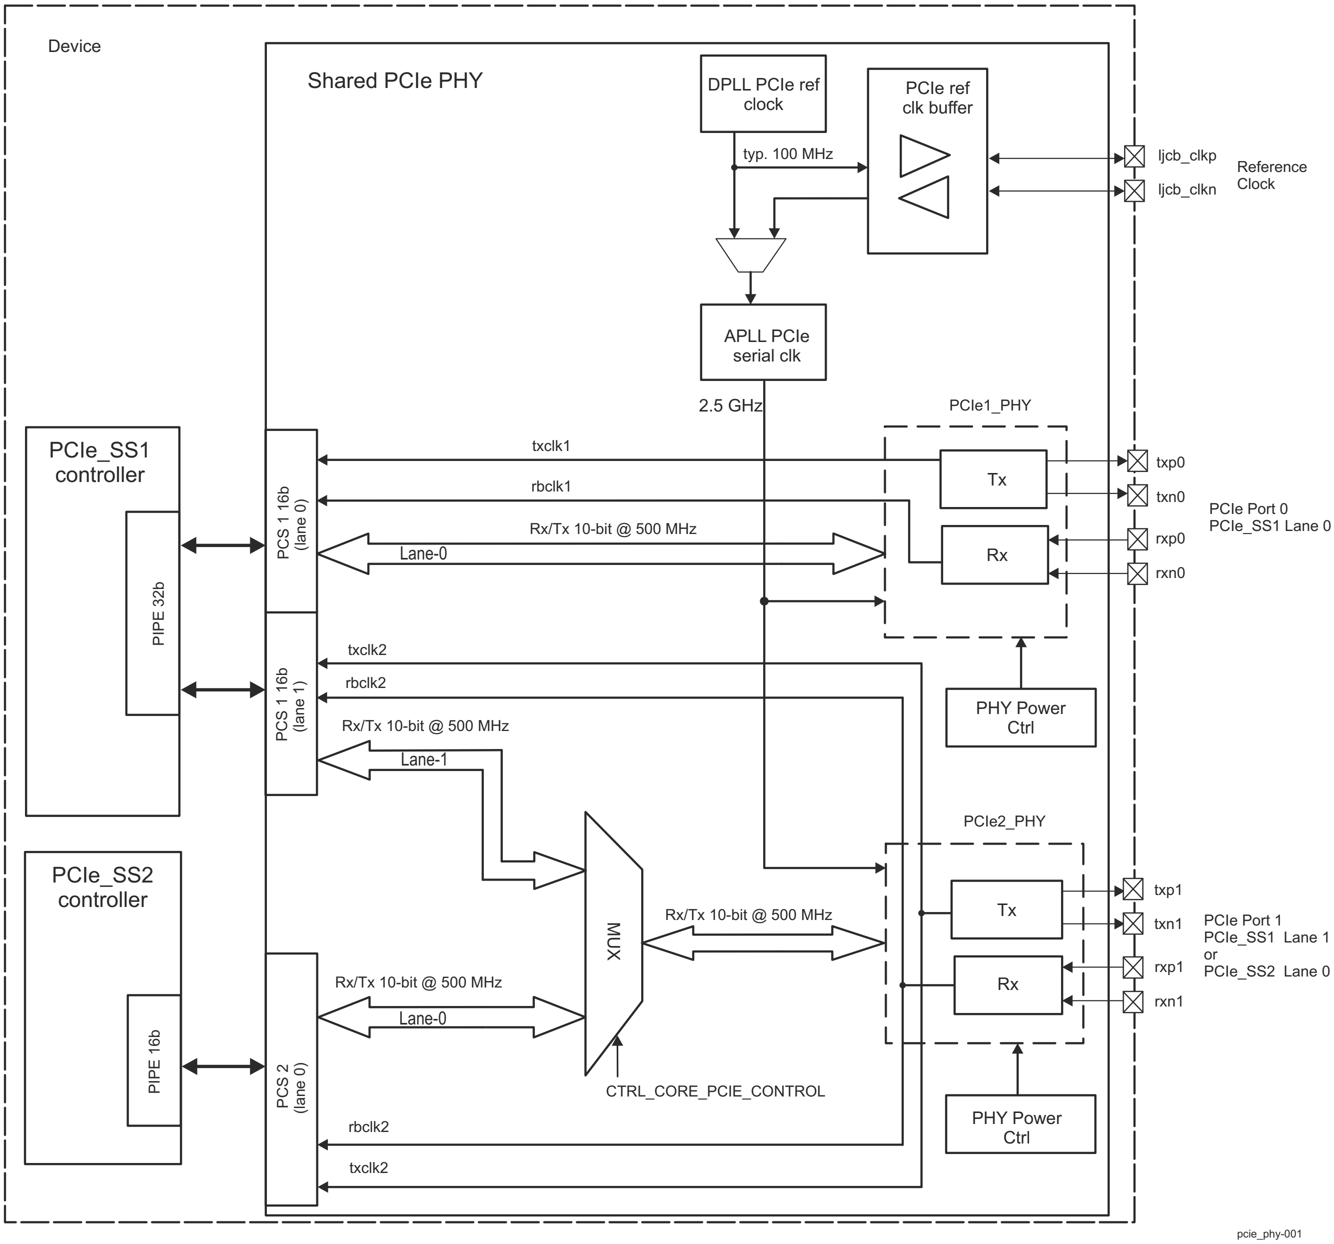

Figure 26-15. PCIe Controller Subsystem Overview

26.4.1.1 PCIe PHY Subsystem Key Features

This section describes the features supplied by the PCIe PHY subsystem. The device integrated PCIe PHY comply with the following standard:

- *PHY Interface for PCI Express Gen 2 and USB3.0 architectures (PIPE for USB3)*

The device supports PCI express interface in the following configurations:

- The PCIe PHYs can be mapped either as 2-lane to one controller (PCIe_SS1) or two separate lanes to two controllers (PCIe_SS1 and PCIe_SS2), as follows:
  - One 2x-lane functional (Gen2) PCIe port, built on the device two PCIe PHY ports (0 and 1), using the dual-lane PCIe_SS1 controller (the PCIe_SS1 controller)

  - Two 1x-lane (Gen2) PCIe ports - PCIe port 0 and PCIe port 1, mapped to the PCIe_SS1 and PCIe_SS2 controllers, each configured to operate in a single-lane mode, respectively. In this case the two device PCIe PHY ports function independently from each other.
- A power control module for each PCIe port which:
  - ensures the Rx/Tx PHYs power-up sequence
  - ensures the Rx/Tx PHYs power-down sequence
- Embedded PCIe DPLL generator, software controlled in device PRCM
- A PLL reference clock - (typically 20MHz or 100MHz), which can be programmed to be:
  - an externally supplied differential clock
  - internally supplied by DPLL_PCIE_REF generated clock, controlled from device PRCM
  - output to external systems when supplied by the DPLL_PCIE_REF
- A bidirectional low-jitter asynchronous buffer which:
  - is used to supply an external reference clock to the PCIe APLL.
  - can output DPLL_PCIE_REF clock to external chips
  - can be bypassed, when DPLL clock is used but NOT output to external chips.
- Polarity inversion on receiver

26.4.2 PCIe PHY Subsystem Environment

26.4.2.1 PCIe PHY I/O Signals

Table 26-49 represents module pins and their corresponding signal names at the device level, and also specifies their links to functions.

Table 26-49. PCIe PHY I/O Signals

Module Pin Name	Device-Level Signal Name	I/O(1)	Description	Pin Reset Value(2)
TXP0	pcie_txp0	O	TXP output of the PCIe Port 0 PHY differential transmission line	0
TXN0	pcie_txn0	O	TXN output of the PCIe Port 0 PHY differential transmission line	0
RXP0	pcie_rxp0	I	RXP input of the PCIe Port 0 PHY differential reception line	HiZ
RXN0	pcie_rxn0	I	RXN input of the PCIe Port 0 PHY differential reception line	HiZ
TXP1	pcie_txp1	O	TXP output of the PCIe Port 1 PHY differential transmission line	0
TXN1	pcie_txn1	O	TXN output of the PCIe Port 1 PHY differential transmission line	0
RXP1	pcie_rxp1	I	RXP input of the PCIe Port 1 PHY differential reception line	HiZ
RXN1	pcie_rxn1	I	RXN input of the PCIe Port 1 PHY differential reception line	HiZ
LJCB_CLKP	ljcb_clkp	I/O	Differential input/output of reference clock buffer (positive)	HiZ
LJCB_CLKN	ljcb_clkn	I/O	Differential input/output of reference clock buffer (negative)	HiZ

(1) I = Input, O = Output
(2) HiZ = High-impedance

To swap polarity of the PHY_TX serializer outputs - TXP and TXN such that, TXP becomes the negative and TXN becomes the positive terminal, user software has to assert bit PCIEPHYTX_FUNC_CONFIG_REG[31] MEM_INVPAIR to 0b1.

To swap polarity of the PHY_RX de-serializer inputs - RXP and RXN, such that, RXP becomes the negative and RXN becomes the positive terminal, user software has to:

- First assert the bit PCIEPHYRX_DIGITAL_MODES_REG1[30] MEM_OVRD_INV_RXPN_PAIR to 0b1, in order to be able to override the internal HW polarity control of the de-serializer.
- Assert bit PCIEPHYRX_DIGITAL_MODES_REG1[31] MEM_INV_RXPN_PAIR to 0b1.

For more information on the necessary SCP register access configuration refer to Section 26.4.6, *PCIe PHY Subsystem Register Manual* and Section 26.4.5, *PCIePHY Subsystem Low-Level Programming Model*.

Figure 26-16 shows module pin signals mapping to PCIe PHY signals visible at the device pad level.

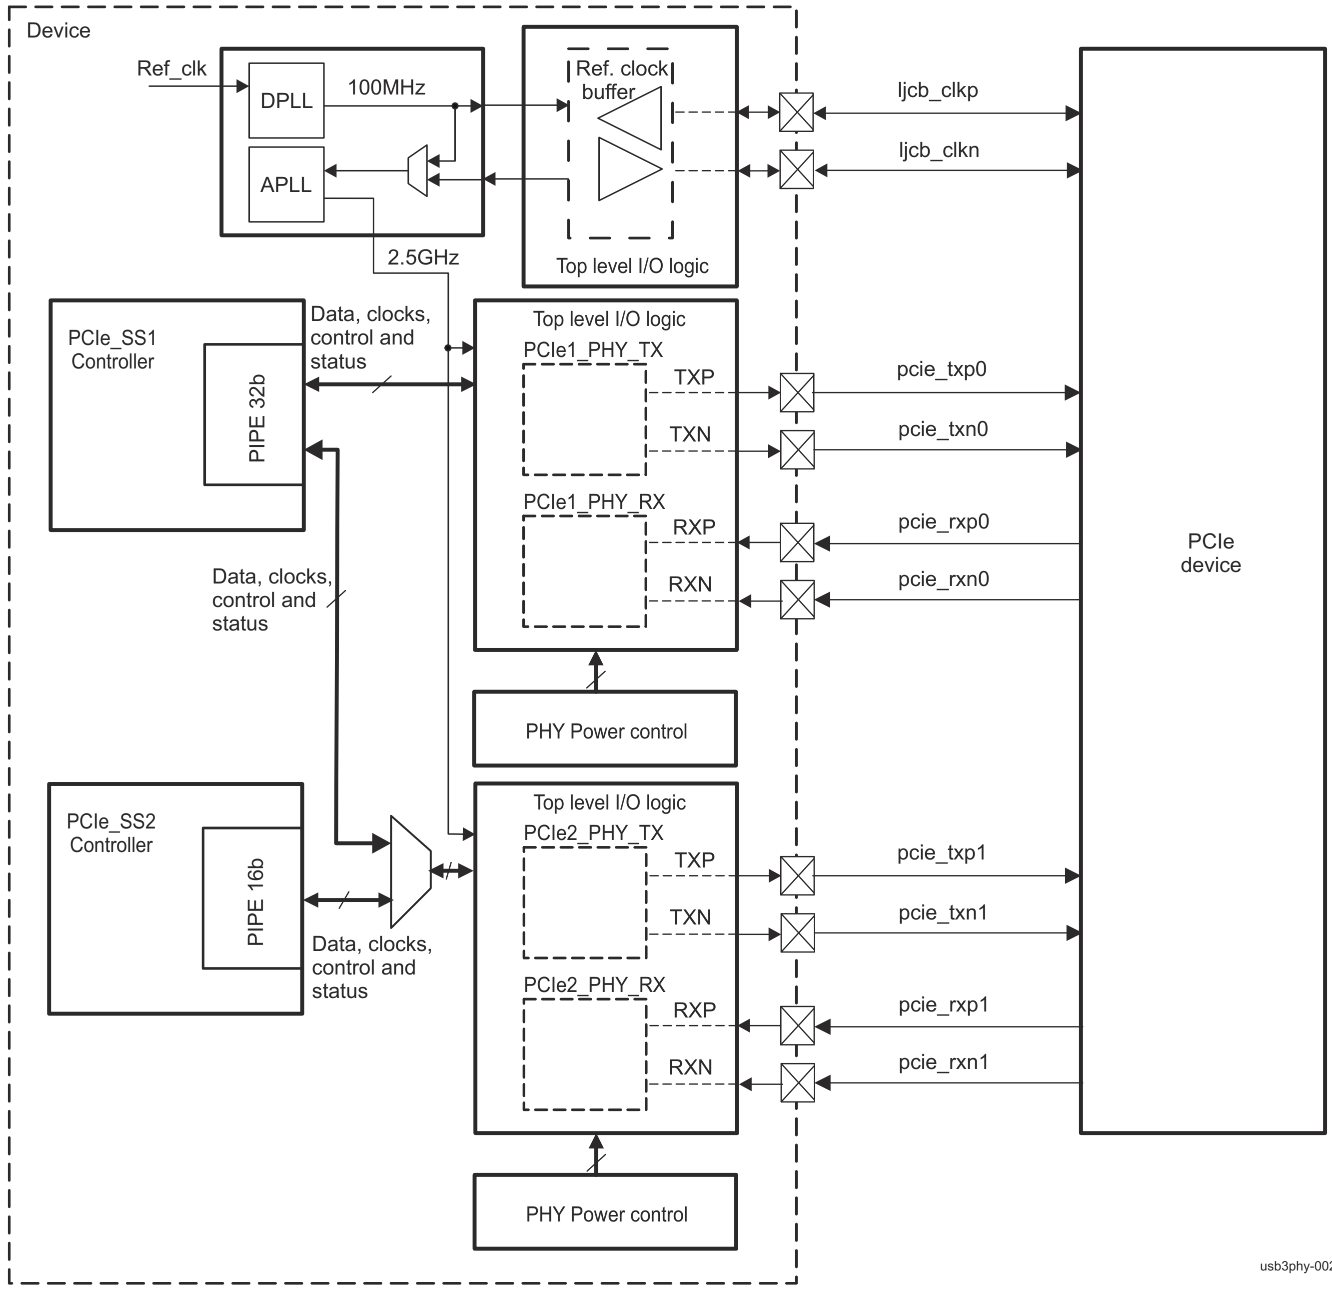

Figure 26-16. PCIe PHY I/O Signals

Note

The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and can be programmed in the control module registers. For more information, see *Pad Configuration Registers* and *Control Module Register Manual* in *Control Module*.

26.4.3 PCIe Shared PHY Subsystem Integration

This section describes the PCIe PHY subsystem-related components (PCIe_PHY, DPLL_PCIE_REF, APLL_PCIE, and OCP2SPC3) integration in the device, including information about clocks, resets, and hardware requests.

Figure 26-17 shows the PCIe PHY integration.

The PCIe PHY module integration features:

- A low-power non retention reset, L3INIT_RST
- A low power non retention Power-on Reset, L3INIT_PWRON_RST
- Interconnect adapter target interface (OCP2SCP3)
- A high-frequency input clock for RX module PCIE_PHY_GCLK, tied to the PCIE_APLL.CLKVCOLDO output
- A high frequency divided input clock for TX module PCIE_PHY_DIV_GCLK, tied to PCIE_APLL.CLKVCOLDO_DIV output
- A local PCIE PHY PIPE compatible port connected to the PCIe_SS1 controller PIPE port
- A clock output (PIPE_PCLK) to the PCIe_SS module PIPE port
- A clock input (PIPE_MCLK) from the PCIe_SS module PIPE port
- A power control logic integrated for PCIe PHY reciever/transmiter pair
- PRCM.PCIE_32K_GFCLK for debounce and wakeup logic inside the PCIe1_PHY_RX
- PRCM.PCIE_REF_GFCLK clock (based on PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK clock) tied to the PCIe1_PHY_TX and PCIe2_PHY_TX input
- PRCM.PCIE_SYS_GFCLK clock tied to power control module clock input
- A device CORE CONTROL MODULE command port to the power control module

The DPLL_PCIE_REF integration features:

- A low-power non retention reset, COREAON_PWRON_RST
- A gated version of the device SYS_CLK1 - PCIE_DPLL_CLK supplying DPLL_PCIE_REF.CLKINP pin.
- A single clock output, DPLL_PCIE_REF.CLKOUTLDO, to the APLL_PCIE input multiplexer
- No HS divider integration
- Direct PRCM register control

The APLL_PCIE integration features:

- A low-power non retention reset, COREAON_PWRON_RST
- Direct PRCM register control
- Selectable input clock from DPLL_PCIE_REF.CLKOUTLDO or external differential input clock conducted from device PCIe ljcb_clkp/n pads via the ACSPCIE buffer
- High frequency output clock on APLL_PCIE.CLKVCOLDO output tied to PCIE PHY RX modules
- High frequency divided output clock on APLL_PCIE.CLKVCOLDO_DIV output tied to PCIE PHY TX modules

The ACSPCIE integration features:

- A difirential clock input from the device pads or differential output to device pads supplied from DPLL_PCIE_REF.CLKOUTLDO.
- Single ended clock output to APLL_PCIE input multiplexer

The OCP2SCP3 (interconnect adapter) integration features:

- L4_CFG slave configuration interface
- One interface clock, L3INIT_L4_GICLK
- A nonretention reset, L3INIT_RST

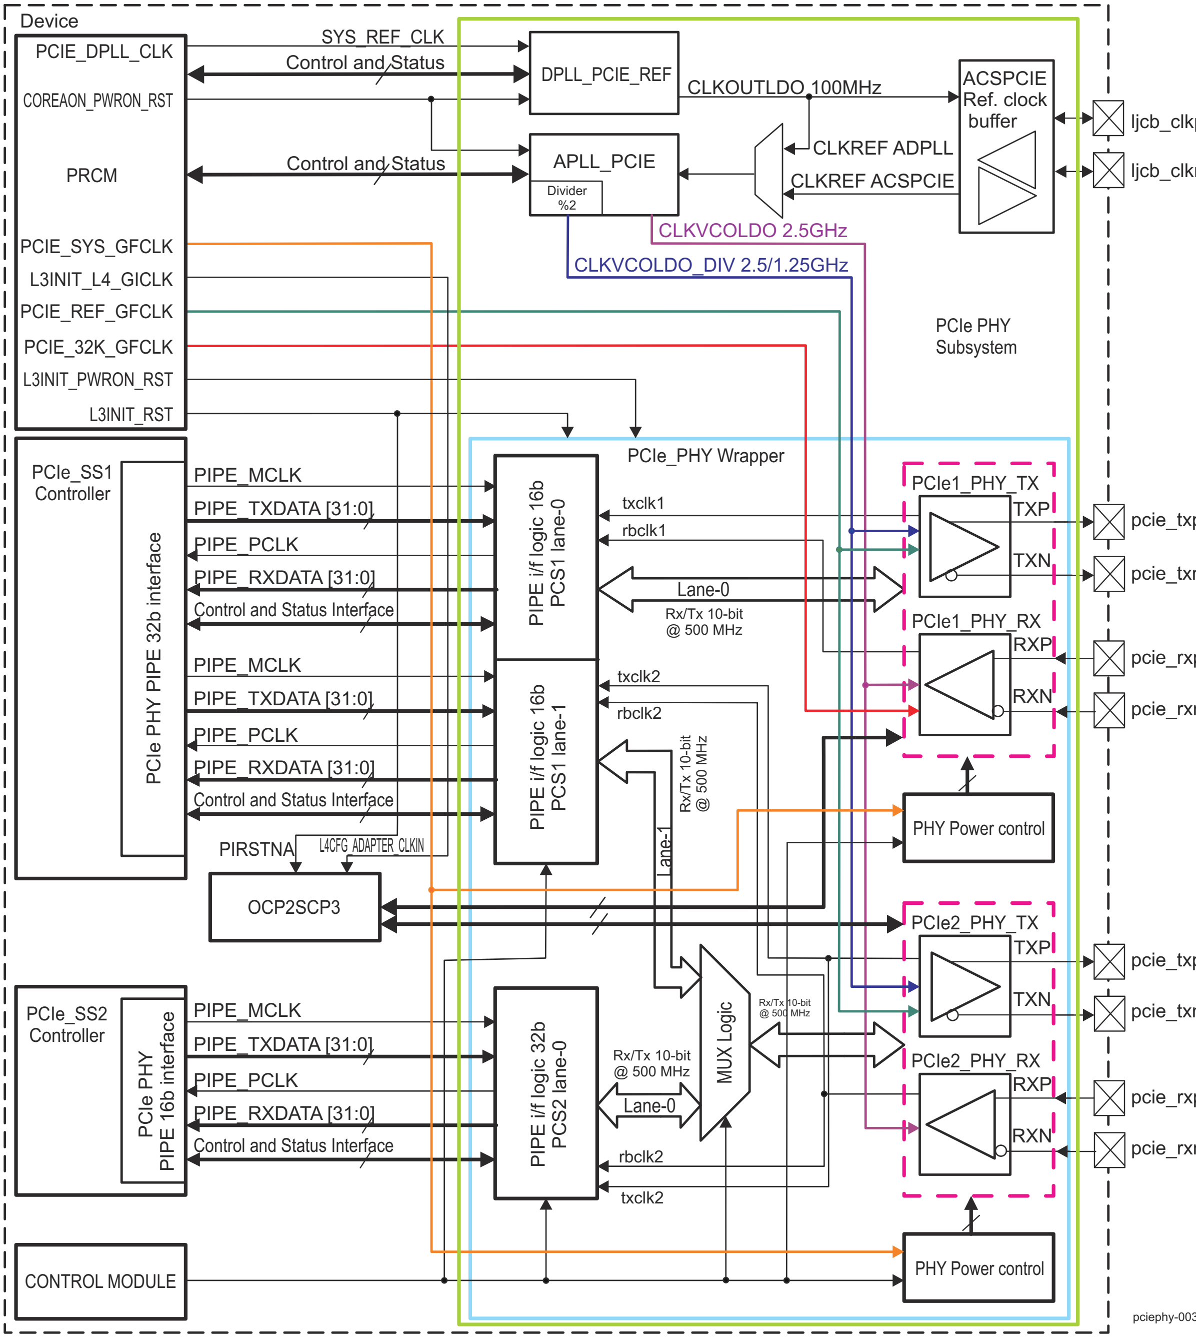

Figure 26-17. PCIe PHY Subsystem Integration

Table 26-50 through Table 26-52 summarize the integration of the module in the device.

Table 26-50. Integration Attributes

Module Instance	Attributes	
	Power Domain	**Interconnect**
PCIe1_PHY_TX	PD_L3INIT	OCP2SCP3 SCP interconnects
PCIe1_PHY_RX	PD_L3INIT	OCP2SCP3 SCP interconnects
PCIe2_PHY_TX	PD_L3INIT	OCP2SCP3 SCP interconnects
PCIe2_PHY_RX	PD_L3INIT	OCP2SCP3 SCP interconnects

Table 26-50. Integration Attributes (continued)

PCIE PHY (wrapper power controller)	PD_L3INIT	A device CTRL_CORE_MODULE power control bus
OCP2SCP3	PD_COREAON	L4_CFG
DPLL_PCIE_REF	PD_COREAON	Direct PRCM module register control
APLL_PCIE	PD_COREAON	Direct PRCM module register control

Table 26-51. Clocks

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DPLL_PCIE_REF	REF_CLK	PCIE_DPLL_CLK	PRCM	DPLL_PCIE_REF reference functional clock (SYS_CLK1 based)
PCIe1_PHY	PCIE1_PWR_CLK	PCIE_SYS_GFCLK	PRCM	PCIE power control logic reference functional clock (SYS_CLK1 based)
PCIe2_PHY	PCIE2_PWR_CLK	PCIE_SYS_GFCLK	PRCM	PCIE power control logic reference functional clock (SYS_CLK1 based)
PCIe1_PHY_TX	PCIE1_REF_CLKIN	PCIE_REF_GFCLK(1)	PRCM	Fixed frequency PCIE functional clock used for LFPS pattern generation (CORE_USB_OTG_SS_LFPS_TX_CLK based)
PCIe2_PHY_TX	PCIE2_REF_CLKIN	PCIE_REF_GFCLK(1)	PRCM	Fixed frequency PCIE functional clock used for LFPS pattern generation (CORE_USB_OTG_SS_LFPS_TX_CLK based)
PCIe1_PHY_RX	PCIE1_PHY_WKUP_CLK	PCIE_32K_GFCLK	PRCM	I/O wakeup and debounce 32-kHz functional clock at PCIe1_PHY_RX Receiver side
OCP2SCP3	L4CFG_ADAPTER_CLKIN	L3INIT_L4_GICLK	PRCM	L4_CFG adapter interface clock

(1) This clock is connected to a single clock input pin - REF_CLKIN at the PCIE PHY subsystem level

Table 26-52. Resets

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
OCP2SCP3	PIRSTNA	L3INIT_RST	PRCM	A non retention reset to L4_CFG interface adapter
PCIe_PHY	PHY_RSTN_MAIN	L3INIT_RST	PRCM	A non retention reset to the PCIe_PHY
	PHY_RSTN_POR	L3INIT_PWRON_RST	PRCM	A non retention POR reset to the PCIe_PHY
DPLL_PCIE_REF	SYSRESETN	COREAON_PWRON_RST	PRCM	A non retention POR reset to DPLL reference clock generator
APLL_PCIE	APLLRESETN	COREAON_PWRON_RST	PRCM	A non retention POR reset to APLL clock generator

Note

The PCIe1_PHY_RX generates a hardware wakeup request to the PRCM module.

26.4.4 PCIe PHY Subsystem Functional Description

26.4.4.1 PCIe PHY Subsystem Block Diagram

Figure 26-18 shows a block diagram of the PCIe PHY subsystem.

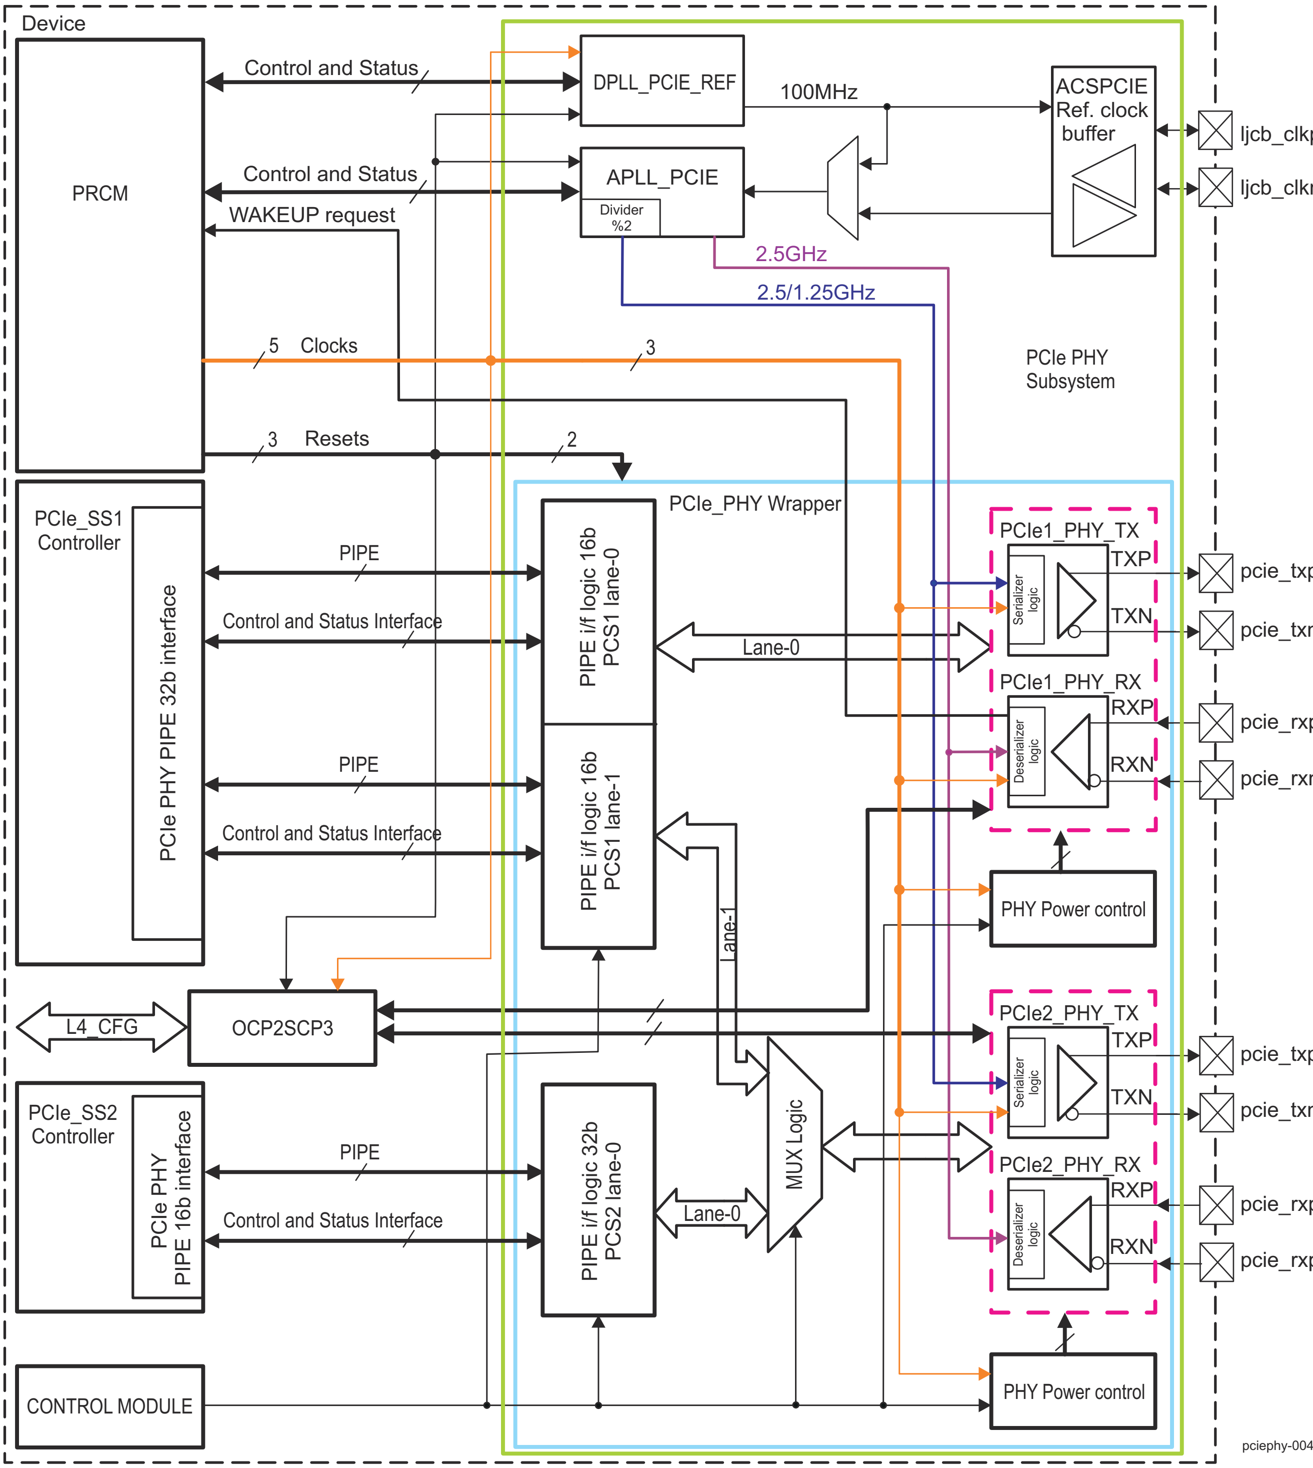

Figure 26-18. PCIe PHY Subsystem Block Diagram

26.4.4.2 OCP2SCP Functional Description

The OCP2SCP3 module (OCP2SCP instantiation 3), allows user software to configure the PCIe_PHY over the L4_CFG port. All PCIe_PHY_TX and PCIe_PHY_RX configuration registers are accessible through OCP2SCP3.

26.4.4.2.1 OCP2SCP Reset

26.4.4.2.1.1 Hardware Reset

The module receives an asynchronous hardware reset (L3INIT_RST) upon power-on reset (POR) at its active low PIRSTNA input. Table 26-52 lists the OCP2SCP3 system reset signal. For more information on the hardware reset source, see *Reset Domains* in *Power Reset and Clock Management*.

26.4.4.2.1.2 Software Reset

Setting the OCP2SCP_SYSCONFIG[1] SOFTRESET bit to 1 triggers a software reset on the OCP2SCP interconnect adapter. The OCP2SCP_SYSSTATUS[0] RESETDONE bit is used by software to monitor the status of reset completion. Hardware keeps this bit at 0 while the reset is being executed. A RESETDONE bit transition from 0 to 1 indicates OCP2SCP reset completion.

26.4.4.2.2 OCP2SCP Power Management

The OCP2SCP features idle acknowledgement protocol with the PRCM module.

26.4.4.2.2.1 Idle Mode

The smart-idle mode supported by OCP2SCP is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP by setting the OCP2SCP_SYSCONFIG[4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

For more information, see *Module-Level Clock Management* in *Power, Reset, and Clock Management*.

Note

Software must take the OCP2SCP module out of IDLE state by setting the OCP2SCP_SYSCONFIG[4:3] IDLEMODE bit field to 0x1, once smart-idle mode has been selected (OCP2SCP_SYSCONFIG[4:3] IDLEMODE = 0x2).

26.4.4.2.2.2 Clock Gating

The OCP2SCP module has local support for an automatic clock gating based on L4_CFG interconnect activity. This feature is enabled by setting the OCP2SCP_SYSCONFIG[0] AUTOIDLE bit to 0x1, otherwise the module interface clock is free running.

For more information, see *Clock Domain-Level Clock Management* in *Power, Reset, and Clock Management*.

26.4.4.2.3 OCP2SCP Timing Registers

The timing configuration register sets various parameters controlling the timing constraints of the OCP2SCP module.

The division ratio between the L4_CFG interconnect clock (L3INIT_L4_GICLK) and the serial configuration port output clock is set through the OCP2SCP_TIMING[9:7] DIVISIONRATIO bit field, with a valid range of 0x1 to 0x7.

The OCP2SCP_TIMING[6:4] SYNC1 timing information is programmable in the range 0 to 7 clock cycles, and shows the acceptable delay between the enable and command availability on SCP. The value of OCP2SCP_TIMING[3:0] SYNC2 is also programmable in the range of 1 to 15 clock cycles, measured from the moment the command is available on SCP until data is accessible.

Note

When the value 000 is programmed for the SCP clock division ratio, and the transaction to be made is a valid transaction on the SCP interface, the value of the DIVISIONRATIO bit field is set internally to 0x7 (to avoid a block on the L4_CFG interconnect interface).

Note

When the value 0000 is programmed for the SYNC2 bit field, and the transaction to be made is a valid transaction on the SCP interface, the value of SYNC2 is set to the minimum allowed 0x0001 (to avoid a block on the L4_CFG interconnect interface).

CAUTION

To ensure correct operation, DIVISIONRATIO must not be modified and the value of SYNC2 must be set to 0x6 or more. See OCP2SCP_TIMING register for details.

26.4.4.3 PCIe PHY Serializer and Deserializer Functional Descriptions

26.4.4.3.1 PCIe PHY Module Resets

26.4.4.3.1.1 Hardware Reset

The PCIe PHY Serializer and Deserializer modules recives two active low non-retention resets from PRCM modules.

- The Power-on reset L3INIT_PWRON_RST
- The main reset L3INIT_RST

For more information on the hardware reset source, see *Reset Domains*, in *Power, Reset, and Clock Management*.

26.4.4.3.1.2 Software Reset

No software reset is available for PCIe PHY Serializer and Deserializer modules.

26.4.4.3.2 PCIe PHY Subsystem Clocking

There are two clock domains within the PCIe PHY:

- PCIe_PHY PIPE port clock domain (PIPE_PCLK and PIPE_MCLK), where 32/16 bit-data is transferred between PCIe_SS controller and PCIe_PHY
- txclk/rbclk functional clock domain in which PCIe PHY generates clock: txclk for 10-bit parallel data transmission, and recovers the rbclk from serially received data.

26.4.4.3.2.1 PCIe PHY Subsystem Input Clocks

The PCIe PHY component receives a feedback clock, PIPE_MCLK, which is the loopback version of the PIPE_PCLK (PIPE port synchronizing clock) generated by the PCIe PHY component. The clock is turned on/off according to the PIPE power-down port states. As PIPE port works in source-synchronous mode, all data movement from the MAC layer to the PIPE interface is synchronous to PIPE_PCLK.

The high speed transmission clock input of the PCIe_PHY serializer and deserializer are connected to APLL_PCIE output pins. The PHY_RX module input clock pin is tied to APLL_PCIE_REF.CLKVCOLDO (PCIE_PHY_GCLK) clock. The PHY_TX input clock pin is tied to divided APLL_PCIE_REF.CLKVCOLDO_DIV (PCIE_PHY_DIV_GCLK) output clock. For more information on the APLL_PCIE_REF.CLKVCOLDO and APLL_PCIE_REF.CLKVCOLDO_DIV output clocks settings, see Section 26.4.4.4.1.4.2, *PCIe PHY APLL Output Clock Configuration*.

In two lane mode when both PCIe1_PHY and PCIe2_PHY modules are connected to PCIe_SS1 as Lane-0 and Lane-1, there is a requirement for the clocking of the transmitter parts PCIe1_PHY_TX and PCIe2_PHY_TX. Both input clocks of the transmitters of all ports has to be in phase, including the by-2-dividers used when operating in 2.5GT/s. This is implemented by providing the same pre-divided clock to the PCIe1_PHY_TX and PCIe2_PHY_TX, coming from the APLL_PCIE's own by-2-divider, and bypassing the by-2-dividers inside each PCIe1_PHY_TX and PCIe2_PHY_TX. In this way the PCIe1_PHY_TX and PCIe2_PHY_TX receive one high speed clock and are allways in phase. The receivers PCIe1_PHY_RX and PCIe2_PHY_RX do not need synchronization in two lane mode.

The high speed clock APLL_PCIE_REF.CLKVCOLDO_DIV (PCIE_PHY_DIV_GCLK) could be divided by 2 on two places, in the APLL_PCIE own by-2-divider or in the PHY_TX internal by-2-divider. These dividers support force-bypass mode where the divider is bypassed and no division is performed. The dividers of the APLL_PCIE and of the PHY_TX are cascaded: one divider should always be bypassed, and the other active. For one lane operation the APLL_PCIE divider could be force-baypassed and only internal PCIe_PHY divider to be active.

The APLL_PCIE by-2-divider bypass is controlled in PRCM register CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS bit.

The PCIe1_PHY_TX by-2-divider bypass mode is controlled by PCIe1_PHY_TX.PCIEPHYTX_DRIVER_DATA_CONFIG1 register bits as follows:

- Bypassed not forced: FB=0 (default mode):

  PCIEPHYTX_DRIVER_DATA_CONFIG1[1] MEM_OVRD_HS_RATE_ANA_OVERRIDE = 0b0
- Bypassed forced: FB=1:

  PCIEPHYTX_DRIVER_DATA_CONFIG1[1] MEM_OVRD_HS_RATE_ANA_OVERRIDE = 0b1

  PCIEPHYTX_DRIVER_DATA_CONFIG1[3:2] MEM_HS_RATE_ANA_OVERRIDE = 0b00

The receivers PCIe1_PHY_RX and PCIe2_PHY_RX are allways supplied with non divided clock APLL_PCIE_REF.CLKVCOLDO (PCIE_PHY_GCLK) and the internal dividers are always active and controlled by the PCIe controllers.

The APLL_PCIE input clock is MUX selectable between DPLL_PCIE_REF.CLKOUTLDO output and ACSPCIE output derived from device differential clock input pins.

The DPLL_PCIE_REF input clock pin CLKINP is tied to PRCM.PCIE_DPLL_CLK (SYS_CLK1 based) clock.

As shown in Table 26-51, the PCIe PHY Power control module clock input is supplied from SYS_CLK1 based clock PRCM.PCIE_SYS_GFCLK.

Software must notify the PHY logic about which clock frequency is selected by writing CTRL_CORE_PHY_POWER_PCIESS1[31:22] PCIESS1_PWRCTL_CLKFREQ bit field and CTRL_CORE_PHY_POWER_PCIESS2[31:22] PCIESS2_PWRCTL_CLKFREQ bit field.

The REF_CLKIN clock input is used to support different PCIe_PHY functions. REF_CLKIN clock input is tied to the PRCM.PCIE_REF_GFCLK (CORE_USB_OTG_SS_LFPS_TX_CLK based) functional clock.

The PCIE1_PHY_RX deserializer I/O wake-up logic is supported by the PRCM.PCIE_32K_GFCLK clock, applied at the logic clock input.

The input clock for PCIe_PHY SCP port configuration interface is delivered from the OCP2SCP3 interface adaclockpter.

The SCP port clock input of PCIe_PHY is driven by the OCP2SCP3 gateable output . The ratio of the OCP2SCP3 gateable output clock to the OCP2SCP3 input clock (L3INIT_L4_GICLK) is controlled through the OCP2SCP_TIMING[9:7] DIVISIONRATIO bit field. For more information, see Section 26.4.4.2.3, *OCP2SCP3 Timing Registers*.

26.4.4.3.2.2 PCIe PHY Subsystem Output Clocks

- PIPE_PCLK: The PIPE interface is source-synchronous. A PIPE_PCLK clock is generated by the PCIe_PHY components, used to synchronize PCIe_SS PIPE port inputs, and reflected back as the PIPE_MCLK along with the PIPE outputs. The clock is turned on/off according to the power control port. All data movement from the PIPE interface to the PCIe_SS MAC layer is synchronous to this clock.

- txclk1: Some clock division is performed over the high frequency PCIE_PHY_DIV_GCLK signal before its derivative txclk1 clock is output from the PCIe1_PHY_TX.
- txclk2: Some clock division is performed over the high frequency PCIE_PHY_DIV_GCLK signal before its derivative txclk2 clock is output from the PCIe2_PHY_TX.
- rbclk1: The PCIe1_PHY_RX output rbclk1 is the clock recovered by the PCIe1_PHY_RX on base of the serial data, received over the RXP0 and RXN0 lines from the attached to the PCIe PHY external device. The rbclk1 clock supplies the PCS1 link parallel 10-bit data reception logic.
- rbclk2: The PCIe2_PHY_RX output rbclk2 is the clock recovered by the PCIe2_PHY_RX on base of the serial data, received over the RXP1 and RXN1 lines from the attached to the PCIe PHY external device. The rbclk2 clock supplies the PCS1 or PCS2 link parallel 10-bit data reception logic.

The PIPE_PCLK clock which drives the PIPE logic is sourced by the on-chip PCIe_PHY. The PIPE interface is source-synchronous (that is, the clock is received from the PHY), used to synchronize PCIe_SS1 and PSIe_SS2 PIPE inputs, and reflected back along with the PIPE outputs as the PIPE_MCLK. The PIPE_PCLK clock is turned on/off according to the PCIe_PHY power control port. For more details, see Section 26.4.4.3.3, *PCIe PHY Power Management*.

26.4.4.3.3 PCIe PHY Power Management

From one side the control over power up/down states of the USB3_PHY is provided through a Power control modules tightly integrated with the the PCIe1_PHY and PCIe2_PHY physical layer TX/RX components. On the other side, the PCIe_PHY PIPE i/f logic of the PCIe_PHY wrapper conveys power transition commands/ states (L0–L3) from the PCIe_SS1 and PCIe_SS2 MAC PIPE power management-ports to the PCIe1_PHY and PCIe2_PHY components as their corresponding P0 (active) and P0s, P1, P2 (low-power) states.

26.4.4.3.3.1 PCIe PHY Power-Up/-Down Sequences

The PHY power control module receives a power-up/power-down command input from the device general core control module. The power control module takes care to execute different stages of the PHY_TX and PHY_RX power-up/-down processes and ensures that the necessary timing intervals are applied between these stages.

Powering-up/-down the PHY_TX and PHY_RX modules is triggered through software writing corresponding power-up/down commands in the CTRL_CORE_PHY_POWER_PCIESS1 and CTRL_CORE_PHY_POWER_PCIESS2 registers of the device core control module.

For more information, see *Control Module*.

26.4.4.3.3.2 PCIe PHY Low-Power Modes

An implemented powerdown control port allows PCIe_PHY to support four low-power states:

- **P0 (pipe_powerdown = 0b00): active state**, for high-speed (HS) data transmission and reception. Used for L0 link state.
- **P0s (pipe_powerdown = 0b01):** active HS receiver, suspended transmitter. Used for L0s link state.
- **P1 (pipe_powerdown = 0b10):** Suspended HS receiver and transmitter, but PIPE clock still running.
- **P2 (pipe_powerdown = 0b11):** Suspended HS receiver and transmitter, PIPE clock stopped (i.e. asynchronous mode). Th to transmit and receive the "beacon".

The PCIe PHY power transitions are managed from connected PCIe_SS controller power management state machines according to desired Link and physical layer power states via signal PIPE_POWERDOWN[1:0]. For more information see Section 24.9.4.5 *PCIe Controller Power Management* in Section 24.9 *PCIe Controllers* chapter.

26.4.4.3.3.3 Clock Gating

The PCIe_PHY component high-speed clocks, PLL_CLK and PIPE_PCLK, are gated during the P2 low-power state.

26.4.4.3.4 PCIe PHY Hardware Requests

An asynchronous wake-up request is generated to the PRCM module by the PCIe1_PHY_RX I/Os (RXP0, RXN0).

Neither interrupt nor DMA requests are generated.

26.4.4.4 PCIe PHY Clock Generator Subsystem Functional Description

The clock generator subsystem of PCIe PHY module consists of integrated DPLL generator DPLL_PCIE_REF, an APLL high frequency generator for PHY transmision clocks APLL_PCIE and ACSPCIE input/output reference low-jitter clock buffer for connecting with external PCIe device. Figure 26-19 shows the block diagram of Clock Generator Subsistem of PCIe PHY module.

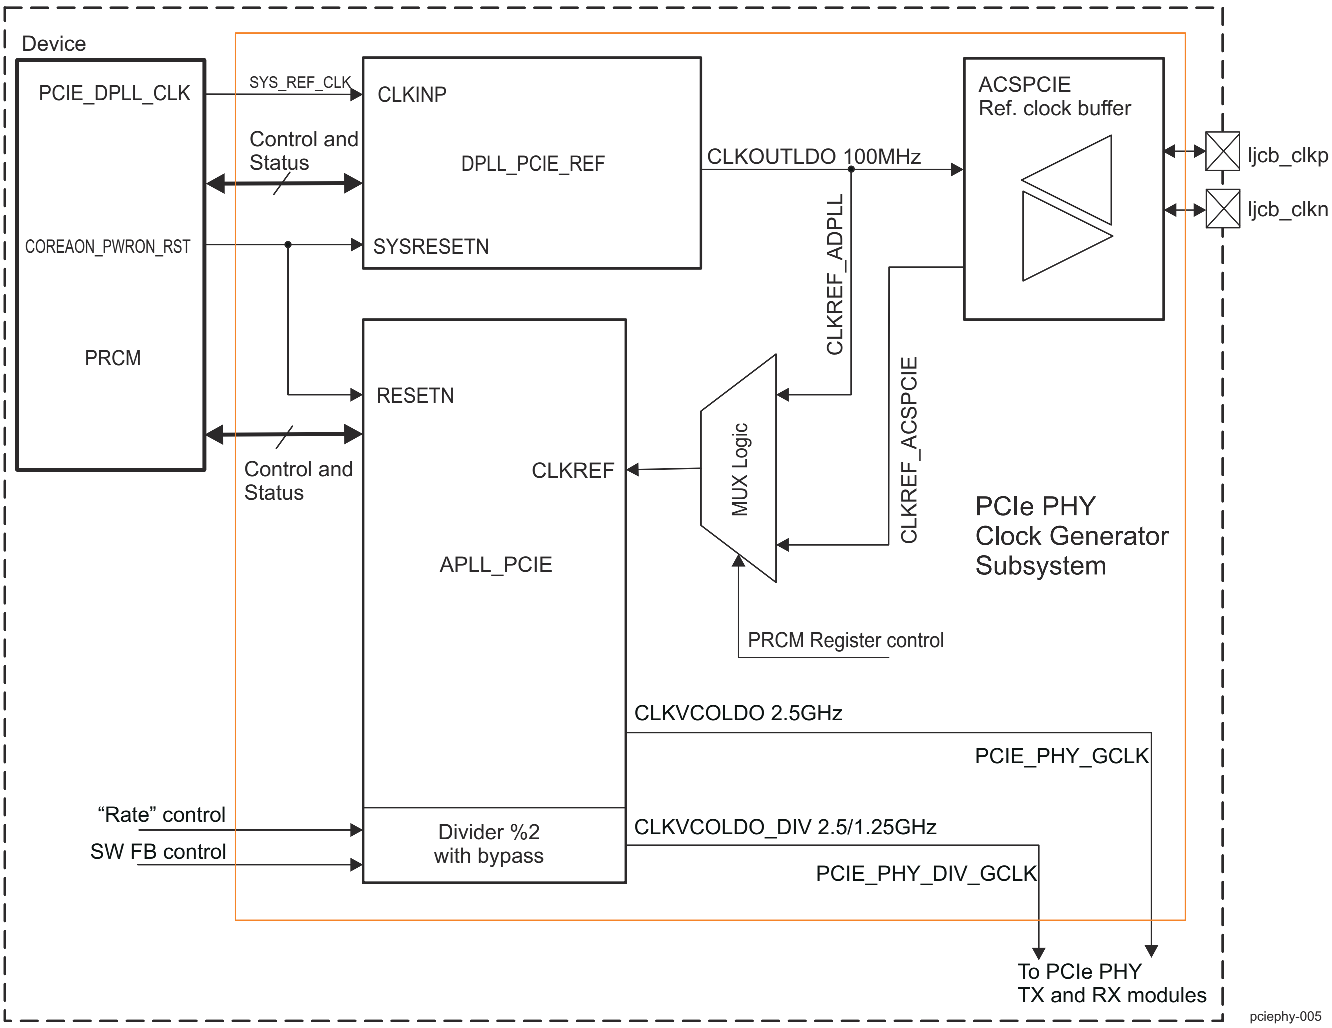

Figure 26-19. PCIe PHY Clock Generator Overview

The DPLL_PCIE_REF clock generator receives its input clock directly from PRCM as PCIE_DPLL_CLK (SYS_CLK1 based). The status and control registers for DPLL_PCIE_REF are located in the PRCM module and allow direct programming of the DPLL_PCIE_REF. The output clock of DPLL_PCIE_REF is on output pin CLKOUTLDO and is fed directly in the APLL_PCIE input clock multiplexer. In input mode, the reference low-jitter clock buffer ACSPCIE receives his clock from diferential input pins directly from outside device and after only buffering feeds this clock to the APLL_PCIE input clock multiplexer.

The APLL_PCIE input clock multiplexer chooses the input clock for APLL_PCIE according to register programming and feeds it to the input of APLL_PCIE. The selection of clock source is made by the register PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL bit as follows:

PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL = 0b0 - input clock CLKREF_ADPLL, APLL reference input clock is from DPLL_PCIE_REF

PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL = 0b1 - input clock CLKREF_ACSPCIE, APLL reference input clock is from ACSPCIE

The APLL_PCIE has two output high frequency transmission clocks. The main undivided clock PCIE_PHY_GCLK is delivered from output CLKVCOLDO and is fed directly to the PHY RX module. The second divided clock PCIE_PHY_DIV_GCLK is delivered after passing the main APLL output clock through a by-2-divider (with baypass capabilities) and is outputed on CLKVCOLDO_DIV output. This clock is fed to the PCIe PHY TX modules and delivers sinchronization of the TX modules in two lane mode.

26.4.4.4.1 PCIe PHY DPLL Clock Generator

This section describes the PCIe PHY DPLL reference clock generator DPLL_PCIE_REF.

26.4.4.4.1.1 PCIe PHY DPLL Clock Generator Overview

The DPLL module integrated in the PCIe PHY is a single instance high speed clock generator, used to deliver the reference clock to the main clock generator APLL_PCIE. The DPLL_PCIE_REF is directly controlled from the PRCM module and all the necessary control and status signals are exported by the subsystem.

The DPLL_PCIE_REF features:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer multiplier: M
- A programmable 7-bit integer post divider M2
- Digital control and loop filter
- Internal oscillator divided output clock (CLKOUTLDO output)
- Idle-bypass low-power mode
- Low Power Stop mode

26.4.4.4.1.2 PCIe PHY DPLL Clock Generator Reset

The PCIe PHY DPLL clock generator receive hardware non-retention reset, COREAON_PWRON_RST, which comes from the device power and reset manager. For more information on the hardware reset source, see *Reset Domains* in *Power, Reset, and Clock Management*.

The DPLL_PCIE_REF itself has no software reset capabilities.

26.4.4.4.1.3 PCIe PHY DPLL Low-Power Modes

The DPLL_PCIE_REF module supports two types of low power mode controlled by the PRCM register PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bits.

The low-power modes supported by DPLL_PCIE_REF are Idle-bypass low-power and Low Power Stop modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKOUTLDO output pulled low

For more details on the DPLL settings and conditions necessary to enter Idle-bypass and Low Power Stop modes, see Section 26.4.4.4.1.6.4, *PCIe PHY DPLL Idle-bypass low-power Mode*, and Section 26.4.4.4.1.6.5, *PCIe PHY DPLL Low Power Stop Mode*.

DPLL_PCIE_PHY is held in a similar low-power state (DCO and LDO switched off, with CLKOUTLDO = 0) after Power-up Reset.

26.4.4.4.1.4 PCIe PHY DPLL Clocks Configuration

26.4.4.4.1.4.1 PCIe PHY DPLL Input Clock Control

The DPLL_PCIE_REF accepts the functional clock, PCIE_DPLL_CLK, on its CLKINP pin directly from the device PRCM, without involving any control interactions. The PCIE_DPLL_CLK is derived from SYS_CLK1. See *Clock Domain Module Attributes* in *Power, Reset, and Clock Management*.

26.4.4.4.1.4.2 PCIe PHY DPLL Output Clock Configuration

Only the DPLL_PCIE_REF output CLKOUTLDO is used to supply the reference clock to the APLL input multiplexer. To adjust the output clock frequency and jitter, the following values must be programmed, dividers SD, N and M2 and the multiplier M. The values for these parameters must be programmed in the corresponding registers in PRCM as follows:

PRCM.CM_CLKSEL_DPLL_PCIE_REF[31:24] DPLL_SD_DIV - Sigma-Delta divider SD, must be set by software to ensure optimum jitter performance.

PRCM.CM_CLKSEL_DPLL_PCIE_REF[19:8] DPLL_MULT - multiplier M, multiplier factor (2 to 4095).

PRCM.CM_CLKSEL_DPLL_PCIE_REF[7:0] DPLL_DIV - dvider N, input clock divider factor (0 to 255) (actual division factor is N+1).

PRCM.CM_DIV_M2_DPLL_PCIE_REF[6:0] DIVHS - divider M2, output clock post-divider factor (1 to 127).

The state of the output clock CLKOUTLDO is indicated by the PRCM.CM_DIV_M2_DPLL_PCIE_REF[10] CLKLDOST bit.

For more details on output clock settings sequence, see Section 26.4.4.4.1.6.6, *PCIe PHY DPLL Clock Programming Sequence*.

26.4.4.4.1.4.2.1 PCIe PHY DPLL Output Clock Gating

There is no direct software gate control for the DPLL_PCIE_REF.CLKOUTLDO output.

DPLL_PCIE_REF.CLKOUTLDO clock output is automatically gated (CLKOUTLDO pulled low) in the following scenarios:

- DPLL power-up sequence. For more information on power-up sequence, see Section 26.4.4.4.1.6.1, *PCIe PHY Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on relocking sequence, see Section 26.4.4.4.1.6.2, *PCIe PHY DPLL Sequences*.
- DPLL entering Idle-bypass low-power mode. For more information on idle-bypass mode, see Section 26.4.4.4.1.6.4, *PCIe PHY DPLL Idle-Bypass Mode*.
- DPLL entering Low Power Stop mode. For more information on Low Power Stop mode, see Section 26.4.4.4.1.6.5, *PCIe PHY DPLL Low Power Stop Mode*.

26.4.4.4.1.5 PCIe PHY DPLL Subsystem Architecture

Figure 26-20 is a simplified block diagram of the DPLL_PCIE_REF instance integrated in the PCIe PHY clock generator subsystem.

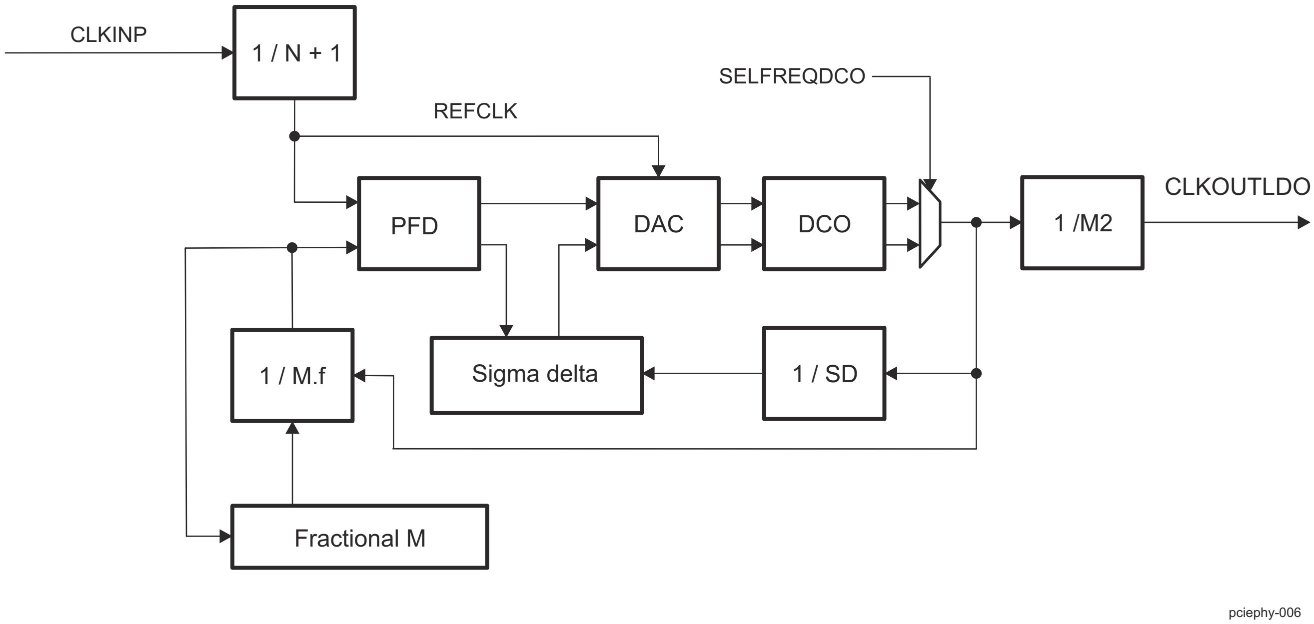

Figure 26-20. DPLL_PCIE_REF Functional Block Diagram

The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the PRCM.CM_CLKSEL_DPLL_PCIE_REF[7:0] DPLL_DIV bit field.

The frequency ranges for the DPLL_PCIE_REF input clock - CLKINP and the DPLL internal reference clock, REFCLK = CLKINP/N + 1 are:

- 0.62 to 60 MHz for CLKINP
- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKOUTLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range divided by the M2 value. The CLKOUTLDO frequency can be given with CLKOUTLDO = [CLKINP×M/(N + 1)]/M2. For that purpose the feedback multiplier M must be configured through the PRCM.CM_CLKSEL_DPLL_PCIE_REF[19:8] DPLL_MULT bit field and the output clock divider M2 must be configured through the PRCM.CM_DIV_M2_DPLL_PCIE_REF[6:0] DIVHS bit field.

Note

Fractional synthesis is not supported for M.

26.4.4.4.1.6 PCIe PHY DPLL Clock Generator Modes and State Transitions

The DPLL_PCIE_REF can be set in different modes during operation. PRCM triggers DPLL_PCIE_REF state transitions to different static modes by setting the bit field of the PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN. Automatic state transitions could be enabled if corresponding bits in PRCM.CM_AUTOIDLE_DPLL_PCIE_REF register are set. The DPLL_PCIE_REF then can automaticly enter the low power condition as follows:

If PRCM.CM_AUTOIDLE_DPLL_PCIE_REF[2:0] AUTO_DPLL_MODE is set to 0x0 - automatic control is disabled.

If PRCM.CM_AUTOIDLE_DPLL_PCIE_REF[2:0] AUTO_DPLL_MODE is set to 0x1- The DPLL is automatically put in Low Power Stop mode when its DPLL generated clocks are not required anymore. It is also restarted automatically.

If PRCM.CM_AUTOIDLE_DPLL_PCIE_REF[2:0] AUTO_DPLL_MODE is set to 0x5 - The DPLL is automatically put in Idle Bypass Low Power mode when its DPLL generated clocks are not required anymore. It is also restarted automatically.

For more information see *Power, Reset, and Clock Management*.

26.4.4.4.1.6.1 PCIe PHY Clock Generator Power Up

After power up, the DPLL_PCIE_REF.SYSRESETN input is automatically pulled low by the PRM, together with the APLL_PCIE.RESETN input. Because PRM.COREAON_PWRON_RST is an asynchronous reset, the DPLL_PCIE_REF input clock (DPLL_PCIE_REF.CLKINP) is not demanded upon reset. During DPLL power-up mode, CLKOUTLDO clock is maintained inactive (pulled low). After power-up reset, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too. The default value of the mode select register bit field PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN puts the DPLL_PCIE_REF in Idle Bypass Low Power mode. It is software responability to change the state of the DPLL_PCIE_REF to desired mode after PRCM reset.

26.4.4.4.1.6.2 PCIe PHY DPLL Sequences

Once all the configuration values have been initially programmed into the PRCM registers controlling DPLL_PCIE_REF (see Section 26.4.4.4.1.4.2), the PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bit should be set to 0x7 to start the DPLL calibration and locking sequence. After performing the locking sequence a lock status is indicated for DPLL_PCIE_REF by PRCM.CM_IDLEST_DPLL_PCIE_REF[0] ST_DPLL_CLK bit asserted to 0b1.

26.4.4.4.1.6.3 PCIe PHY DPLL Locked Mode

When DPLL_PCIE_REF finishes calibration and lock sequences it enters a locked state. DPLL_PCIE_REF locked state is indicated by PRCM.CM_IDLEST_DPLL_PCIE_REF[0] ST_DPLL_CLK bit asserted to 0b1. In locked mode all the parameters of DPLL_PCIE_REF are set and the loop is running. The output clock CLKOUTLDO is active.

26.4.4.4.1.6.4 PCIe PHY DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_PCIE_REF.

DPLL_PCIE_REF supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bit field to 0x5. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and the DCO oscillator. This mode is also the default state after PRCM reset for the DPLL_PCIE_REF.

In idle-bypass low-power mode, the CLKOUTLDO goes low. Also, the internal reference clock REFCLK = CLKINP/N + 1 is gated inside the DPLL digital control logic to save power, the internal LDO and the DCO are turned off.

To exit idle-bypass mode and restore clock generation, the user should write PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bit field to 0x7, which deasserts the IDLE signal, and DPLL_PCIE_REF automatically enters a relock sequence. CLKOUTLDO output clock is activated after DPLL_PCIE_REF enters locked mode.

26.4.4.4.1.6.5 PCIe PHY DPLL Low Power Stop Mode

The Low Power Stop mode will be activated if software writes PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bit field to 0x1. The module enters a low Power Stop mode by gating all its internal clocks (REFCLK) and powering down internal LDO and DCO. CLKOUTLDO remains gated (low) during this mode.

Note

When the DPLL_PCIE_REF is in Low Power Stop mode, the input clock on CLKINP pin is not needed.

26.4.4.4.1.6.6 PCIe PHY DPLL Clock Programming Sequence

The DPLL_PCIE_REF factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

The values that must be considered during programming are:

- The internal reference frequence REFCLK. Must be kept in the range of 0.62 to 2.5 MHz. The value is calculated as REFCLK = CLKINP/(N+1).
- The Sigma-Delta divider to ensure optimum jitter performance. Must ensure that the sigma-delta operation frequency is as close as possible, but less than 250MHz for optimal performance. The value is calculated as SD = CEILING([(M)/(N+1)] × CLKINP/250) where CLKINP is the input clock of the DPLL in MHz.
- The output clock CLKOUTLDO frequency. This frequency must be programmed to 100 MHz fixed value for correct PCIe operation. The value is calculated as CLKOUTLDO = [CLKINP×M/(N + 1)]/M2
- The DCO frequency range must be set according to needed DCO output clock DCOCLK = CLKINP × [M/(N+1)]. The value of the SELFREQDCO[2:0] DPLL input selects the DCO internal oscilator ICO1 or ICO2 as follows:
  – If 750 < DCOCLK < 1500, SELFREQDCO[2:0] must be set to 0b010 (HS2 mode, ICO2 selected)
  – If 1250 < DCOCLK < 2500, SELFREQDCO[2:0] must be set to 0b100 (HS1 mode, ICO1 selected)
  – All other combinations of SELFREQDCO[2:0] are reserved

The following registers set the requred parameters values for the DPLL_PCIE_REF.

- PRCM.CM_CLKSEL_DPLL_PCIE_REF[7:0] DPLL_DIV - sets dvider N, input clock divider factor (0 to 255) (actual division factor is N+1)
- PRCM.CM_CLKSEL_DPLL_PCIE_REF[21] DPLL_SELFREQDCO bit sets DCO frequency range.
  – DPLL_SELFREQDCO should be set to 0b0 if 750 MHz < CLKDCOLDO [MHz] < 1500 MHz (SELFREQDCO[2:0] set to 0b010)
  – DPLL_SELFREQDCO should be set to 0b1 if 1250 MHz < CLKDCOLDO [MHz] < 2500 MHz (SELFREQDCO[2:0] set to 0b100).
- PRCM.CM_CLKSEL_DPLL_PCIE_REF[19:8] DPLL_MULT - sets multiplier M, multiplier factor (2 to 4095).
- PRCM.CM_DIV_M2_DPLL_PCIE_REF[6:0] DIVHS - sets divider M2, output clock post-divider factor (1 to 127).
- PRCM.CM_CLKSEL_DPLL_PCIE_REF[31:24] DPLL_SD_DIV - sets Sigma-Delta divider SD, must be set by software to ensure optimum jitter performance.

To maintain proper PCIe operation of the PCIe PHY submodule a set of parameters values are recomended. The DCO frequency of the PCIe reference DPLL is not used directly, so it can be changed to optimize jitter, power, or lock time. Only the divided-by-M2 CLKOUTLDO output clock is a required. The tables below give ratios that have been verified to meet PCIe jitter requirements. Other ratios combinations exist, to obtain a lower DCO frequency and lower power, but they should be checked against the PCIe standard.

Table 26-53. DPLL_PCIE_REF Recommended Configuration

CLKINP (MHz)	N	N+1	REFCLK (MHz)	M	DCOCLK (GHz)	DPLL_SELF REQDCO	M2	CLKOUTLDO (MHz)
20	9	10	2	750	1.5	0	15	100

Figure 26-21 shows the programming sequence for DPLL_PCIE_REF.

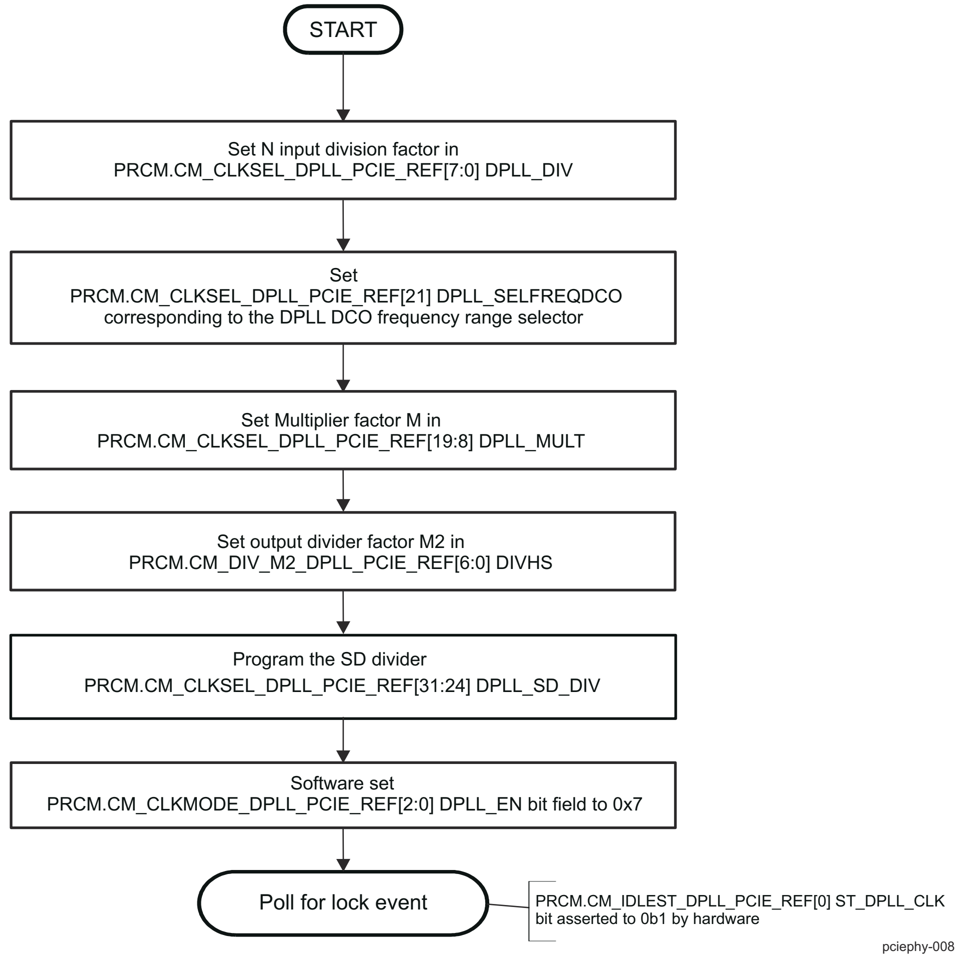

Figure 26-21. DPLL_PCIE_REF Programming Sequence

Note

- The sequence applies to the CLKOUTLDO output of the DPLL_PCIE_REF.
- CLKOUTLDO output frequency of the PLL_PCIE_REF should be programmed to 100 MHz, for the proper PCIe operation.

Table 26-54 summarizes the PRCM registers for the DPLL_PCIE_REF programming sequence.

Table 26-54. Register Call Summary for DPLL_PCIE_REF Programming Sequence

Register Name	Register Name	Register Name
CM_CLKSEL_DPLL_PCIE_REF	CM_DIV_M2_DPLL_PCIE_REF	CM_CLKMODE_DPLL_PCIE_REF

26.4.4.4.1.6.7 PCIe PHY DPLL Recommended Values

Table 26-55 lists the DPLL_PCIE_REF setup registers in PRCM recommended values.

Table 26-55. Recommended Programming Values

Field Name	Value	Description
CM_CLKSEL_DPLL_PCIE_REF[7:0] DPLL_DIV	See Table 26-53	Sets dvider N, input clock divider factor (0 to 255) (actual division factor is N+1)
CM_CLKSEL_DPLL_PCIE_REF[21] DPLL_SELFREQDCO	See Table 26-53	Sets DCO frequency range

Table 26-55. Recommended Programming Values (continued)

Field Name	Value	Description
CM_CLKSEL_DPLL_PCIE_REF[19:8] DPLL_MULT	See Table 26-53	Sets multiplier M, multiplier factor (2 to 4095)
CM_DIV_M2_DPLL_PCIE_REF[6:0] DIVHS	See Table 26-53	Sets divider M2, output clock post-divider factor (1 to 127)
CM_CLKSEL_DPLL_PCIE_REF[31:24] DPLL_SD_DIV	See [1]	Sets Sigma-Delta divider SD, SD = CEILING([(M)/(N+1)] × CLKINP/250)
CM_CLKSEL_DPLL_PCIE_REF[2:0] DPLL_EN	0x7	Enables the DPLL in Lock mode
CM_IDLEST_DPLL_PCIE_REF[0] ST_DPLL_CLK	=1	Poll this bit for DPLL lock status. Set by hardware.

(1) The value of the bit field must be set according to the desired clock frequency and M, N and input frequency values.

26.4.4.4.2 PCIe PHY APLL Clock Generator

This section describes the PCIe PHY APLL high speed clock generator APLL_PCIE.

26.4.4.4.2.1 PCIe PHY APLL Clock Generator Overview

The APLL module integrated in the PCIe PHY is a single instance high speed clock generator, used to deliver the high speed clocks to the PCIe PHY RX and TX modules. The APLL_PCIE is directly controlled from the PRCM module and all the necessary control and status signals are exported by the subsystem.

The APLL_PCIEF features:

- Fixed multiplication ratio to generate 2.5 GHz output clock
- High frequency direct output CLKVCOLDO
- High frequency divided output CLKVCOLDO_DIV
- A bypass feature of by-2-divider of CLKVCOLDO_DIV
- Internal voltage controlled oscilator VCO
- Auto Idle mode

26.4.4.4.2.2 PCIe PHY APLL Clock Generator Reset

The PCIe PHY APLL_PCIE clock generator receive hardware non-retention reset, COREAON_PWRON_RST, which comes from the device power and reset manager. For more information on the hardware reset source, see *Reset Domains* in *Power, Reset, and Clock Management*.

The APLL_PCIE itself has no software reset capabilities.

26.4.4.4.2.3 PCIe PHY APLL Low-Power Mode

The APLL_PCIE module supports one type of low power mode controlled by the PRCM register PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT bits.

The low-power mode supported by APLL_PCIE is Auto Idle mode.

26.4.4.4.2.4 PCIe PHY APLL Clocks Configuration

26.4.4.4.2.4.1 PCIe PHY APLL Input Clock Control

The APLL_PCIE accepts the functional clock from its input multiplexer, which selects between the DPLL_PCIE_REF output clock CLKREF_ADPLL and the clock from the reference clock buffer ACSPCIE output (delivered from outside the device) CLKREF_ACSPCIE. The selection is made by PRCM register PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL bit as folows:

- PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL = 0b0 - input clock CLKREF_ADPLL, APLL reference input clock is from DPLL_PCIE_REF
- PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL = 0b1 - input clock CLKREF_ACSPCIE, APLL reference input clock is from ACSPCIE

The APLL module does not have software capabilitites for gating the input clock.

26.4.4.4.2.4.2 PCIe PHY APLL Output Clock Configuration

Two high frequency output clocks are available from APLL_PCIE. The direct output CLKVCOLDO supplies 2.5 GHz high speed transmision clock for the PCIe PHY RX module and the divided by 2 clock output CLKVCOLDO_DIV supplies high speed transmision clock (1.25 or 2.5 GHz) for the PCIe PHY TX module. The internal parameters of APLL (multipliers, dividers) are fixed and do not need programming to generate the output clocks. The output clock CLKVCOLDO_DIV is by default the divided by 2 version of the CLKVCOLDO. The divider is controlled by the RATE signal from the PCIe_SS controller. The by-2-divider has a bypass feature to ignore the division control from PCIe_SS and to output a clock with same frequency like CLKVCOLDO. This bypass feature is controlled by PRCM.CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS bit as follows:

- PRCM.CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS = 0b0 - the division by 2 is controlled from Rate signal from PCIe_SS controller;
- PRCM.CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS = 0b1 - the CLKOUTLDO_DIV is not divided by 2 and has same frequency like CLKVCOLDO. Select this option for the current device.

The frequency of CLKVCOLDO_DIV can be changed on-the-fly, but glitches can occur on the clock. Best approach is to disable the CLKVCOLDO_DIV when changing the frequency. See Section 26.4.4.4.2.4.2.1 *PCIe PHY APLL Output Clock Gating* for CLKVCOLDO_DIV gating options.

The availability of the APLL_PCIE output clocks can be monitored in PRCM.CM_CLKVCOLDO_APLL_PCIE register as follows:

- PRCM.CM_CLKVCOLDO_APLL_PCIE[9] CLKST bit gives the status (gated or enabled) of CLKVCOLDO clock
- PRCM.CM_CLKVCOLDO_APLL_PCIE[10] CLK_DIVST bit gives the status (gated or enabled) of CLKVCOLDO_DIV clock.

26.4.4.4.2.4.2.1 PCIe PHY APLL Output Clock Gating

Because the APLL_PCIE.CLKVCOLDO and APLL_PCIE.CLKVCOLDO_DIV are implemented as optional functional clocks the PRCM has software control on them. The two clocks can be controlled by PRCM registers corresponding to the implemented PCIe_SS controllers.

PRCM.CM_PCIE_PCIESS1_CLKCTRL[9] OPTFCLKEN_PCIEPHY_CLK bit controls the CLKVCOLDO clock for the PCIe PHY modules.

PRCM.CM_PCIE_PCIESS1_CLKCTRL[10] OPTFCLKEN_PCIEPHY_CLK_DIV bit controls the CLKVCOLDO_DIV clock for the PCIe PHY modules.

The same controls are duplicated in the registers below:

PRCM.CM_PCIE_PCIESS2_CLKCTRL[9] OPTFCLKEN_PCIEPHY_CLK bit controls the CLKVCOLDO clock for the PCIe PHY modules.

PRCM.CM_PCIE_PCIESS2_CLKCTRL[10] OPTFCLKEN_PCIEPHY_CLK_DIV bit controls the CLKVCOLDO_DIV clock for the PCIe PHY modules.

APLL_PCIE.CLKVCOLDO and APLL_PCIE.CLKVCOLDO_DIV clock outputs are automatically gated (pulled low) in the following scenarios:

- APLL power-up sequence. For more information on power-up sequence, see Section 26.4.4.4.2.6.1, *PCIe PHY APLL Clock Generator Power Up* .
- APLL entering Auto Idle mode.

26.4.4.4.2.5 PCIe PHY APLL Subsystem Architecture

Figure 26-22 is a simplified block diagram of the APLL_PCIE instance integrated in the PCIe PHY clock generator subsystem.

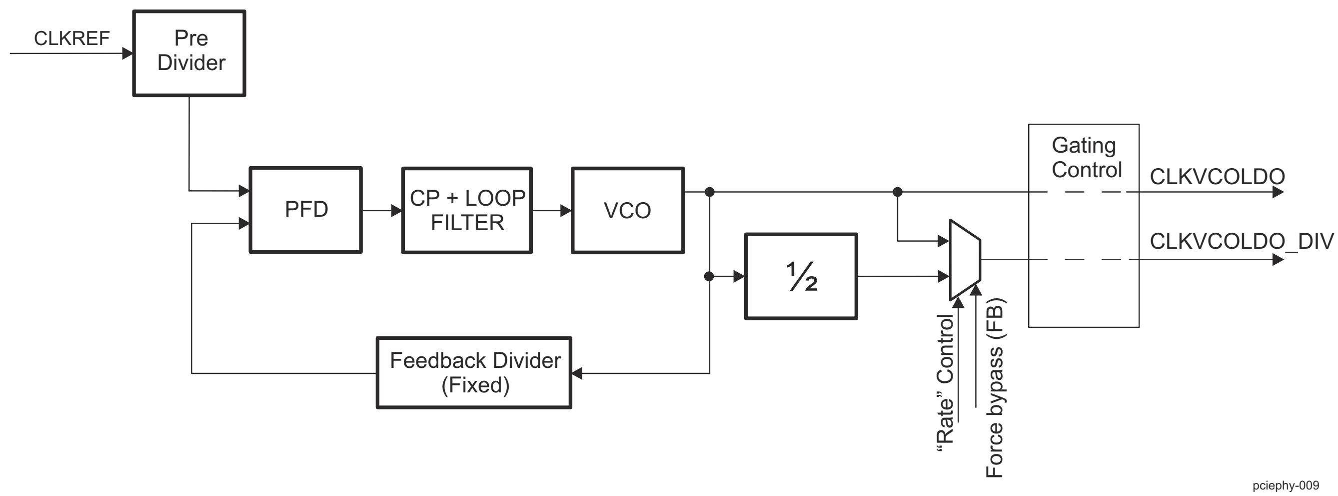

Figure 26-22. APLL_PCIE Functional Block Diagram

The input clock CLKINP goes to a predivider with fixed value. Then goes to the clock generation loop with fixed Feedback Divider. The output of the VCO is split in two. One path directly goes out on CLKVCOLDO output. The other path passes the internal divider by 2 and then goes to bypass multiplexor where is selected the output frequency of the CLKVCOLDO_DIV output. The selection is made either from "Rate" signal from PCIe_SS controller or with higher priority from Force bypass signal controlled from PRCM.CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS bit.

The frequency of the VCO output is fixed to 2.5 GHz and is not programmable in software. No changes could be made on the internal parameters of the APLL_PCIE. Output clocks are controllable through PRCM registers and can be gated by software. See Section 26.4.4.4.2.4.2.1 *PCIe PHY APLL Output Clock Gating* for more information.

26.4.4.4.2.6 PCIe PHY APLL Clock Generator Modes and State Transitions

Note

In order to disable the APLL_PCIE, the user needs to disable PCIe_SSx (where x = 1 or 2) using the CM_PCIE_PCIESSx_CLKCTRL[1:0] MODULEMODE registers. When PCIe_SS is disabled, the PRCM module automatically disables the APLL_PCIE. Please note that setting CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT bitfield to 0x0 does not disable the APLL_PCIE.

The APLL_PCIE can be set in different modes during operation. PRCM triggers APLL_PCIE state transitions to different static modes by setting the bit field of the PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT. Only two static modes are available for APLL_PCIE:

- PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT = 0x1 – APLL_FORCE_LOCK_MODE is set. This puts the APLL in Force Lock mode
- PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT = 0x2 – APLL_FORCE_IDLE_MODE is set. This puts the APLL in Auto Idle mode

For more information see *Power, Reset, and Clock Management*.

26.4.4.4.2.6.1 PCIe PHY APLL Clock Generator Power Up

After power up, the APLL_PCIE.RESETN input is automatically pulled low by the PRM, together with the DPLL_PCIE_REF.SYSRESETN input. Because PRM.COREAON_PWRON_RST is an asynchronous reset, the DPLL_PCIE_REF input clock (DPLL_PCIE_REF.CLKINP) is not demanded upon reset. During APLL power-up mode, CLKVCOLDO and CLKVCOLDO_DIV clocks are maintained inactive (pulled low). After power-up reset, the APLL_LOCK (internal lock loop) signal is maintained deasserted, too. The default value of the mode select register bit field PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT = 0x0 puts the DPLL_PCIE_REF in unknown state. It is software responability to change the state of the APLL_PCIE to desired mode after PRCM reset.

26.4.4.4.2.6.2 PCIe PHY APLL Sequences

After setting the APLL_PCIE in Force Lock mode, a inital lock sequence is started and the module enters working state. The output clocks CLKVCOLDO and CLKVCOLDO_DIV are gated until the lock sequence is finished and APLL_LOCK signal is aserted. After that all clocks are operational and their states depend on the software control.

26.4.4.4.2.6.3 PCIe PHY APLL Locked Mode

When APLL_PCIE finishes calibration and lock sequences it enters a locked state. APLL_PCIE locked state is indicated by PRCM.CM_IDLEST_APLL_PCIE[0] ST_APLL_CLK bit asserted to 0b1. In locked mode all the parameters of DPLL_PCIE_REF are set and the loop is running. The output clocks CLKVCOLDO and CLKVCOLDO_DIV are active under software control.

26.4.4.4.3 ACSPCIE reference clock buffer

The ACSPCIE module is a clock buffer circuit, which has both receive (RX) and transmission (TX) mode. This clock buffer is used to provide low jitter input clock to APLL. In receive mode it takes in an external differential clock and converts it to single-ended CMOS level clock signal. In transmission mode it takes in an internal single-ended clock and converts it to differential HCSL[1] level (in presence of external terminations). The I/O pins of ACSPCIE are *ljcb_clkp* and *ljcb_clkn* differential pair.

- Receive mode: RX is a clock slicer that receives HCSL or LVDS differential clock (typically from on-board Crystal Oscillator) between ljcb_clkp and ljcb_clkn and converts it to CMOS single-ended output CLKREF_ACSPCIE. This CMOS clock signal is the input clock for APLL.
- Transmission mode: TX is a current switching driver that receives CMOS single-ended clock CLKREF_ADPLL at it's input pin from DPLL_PCIE_REF and converts it to HCSL differential-ended output ljcb_clkp and ljcb_clkn. The termination for TX is on-board and 50 Ohms single-ended or 100 Ohms differential.

The ACSPCIE module has two modes of operation:

- Functional mode: The module is powered up automatically and acts as either an input or output buffer.
- Power-down mode: The module is powered down. RX output is held low and TX output is tri-stated/ terminated.

26.4.5 PCIePHY Subsystem Low-Level Programming Model

The low-level programming sequence to set up the PCIe PHY subsystem is summarized in the Table 26-56.

Note

Registers prefixed with CM_ are system Clock Manager registers and are described in *Power, Reset, and Clock Management*.

Registers prefixed with CTRL_ are system Control Module registers and are described in *Control Module*.

Table 26-56. PCIePHY Subsystem Low-Level Programming Sequence

Step	Register/Bit Field/Programming Model	Value
Start a software forced wake-up transition on the PCIE clock domain	CM_PCIE_CLKSTCTRL[1:0] CLKTRCTRL	0x2
Start a software forced wake-up transition on the L3INIT clock domain	CM_L3INIT_CLKSTCTRL[1:0] CLKTRCTRL	0x2
Configure the PCIESS1 module to be explicitly enabled	CM_PCIE_PCIESS1_CLKCTRL[1:0] MODULEMODE	0x2
Poll for PCIESS1 module fully functional?	CM_PCIE_PCIESS1_CLKCTRL[17:16] IDLEST	=0x0

Table 26-56. PCIePHY Subsystem Low-Level Programming Sequence (continued)

Step	Register/Bit Field/Programming Model	Value
Optional: Configure the PCIESS2 module to be explicitly enabled	CM_PCIE_PCIESS2_CLKCTRL[1:0] MODULEMODE	0x2
Optional: Poll for PCIESS2 module fully functional?	CM_PCIE_PCIESS2_CLKCTRL[17:16] IDLEST	=0x0
Configure the OCP2SCP3 module to be managed automatically by hardware according to clock domain transition	CM_L3INIT_OCP2SCP3_CLKCTRL[1:0] MODULEMODE	0x1
Perform a software reset on OCP2SCP3	OCP2SCP_SYSCONFIG[1] SOFTRESET	1
Wait until reset is finished?	OCP2SCP_SYSSTATUS[0] RESETDONE	=1
Configure the OCP2SCP3 Division Ratio and SYNC values	OCP2SCP_TIMING	0x8F
Configure DPLL_PCIE_REF registers to select CLKOUTLDO = 100 MHz. Lock the PLL.	See Section 26.4.4.4.1.6.7, *PCIe PHY DPLL Recommended Values*.	
Select the desired direction of the ACSPCIE buffer (connected to the ljcp_clkn/ljcp_clkp pins)	CTRL_CORE_SMA_SW_6[17:16] PCIE_TX_RX_CONTROL	0x1 (output) 0x2 (input)
Select the APLL_PCIE 100MHz reference clock source	CM_CLKMODE_APLL_PCIE[7] REFSEL	0 (DPLL_PCIE) 1 (ACSPCIE)
Configure APLL_PCIE registers to select CLKVCOLDO = 2.5 GHz and CLKVCOLDO_DIV = 2.5 GHz	See Section 26.4.4.4.2.4, *PCIe PHY APLL Clocks Configuration*.	
Request the APLL_PCIE Force Lock mode	CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT	0x1
Wait for APLL_PCIE Lock	CM_IDLEST_APLL_PCIE[0] ST_APLL_CLK	=1
Configure the PCIE PHYs to ×1 or ×2 mode	CTRL_CORE_PCIE_CONTROL[3:2] PCIE_B1C0_MODE_SEL	0x0 (×1 mode) 0x1 (×2 mode)
	CTRL_CORE_PCIE_CONTROL[0] PCIE_B0_B1_TSYNCEN	0 (×1 mode) 1 (×2 mode)
Enable the CLKVCOLDO clock for the PCIESS1 PHY	CM_PCIE_PCIESS1_CLKCTRL[9] OPTFCLKEN_PCIEPHY_CLK	1
Enable the CLKVCOLDO_DIV clock for the PCIESS1 PHY	CM_PCIE_PCIESS1_CLKCTRL[10] OPTFCLKEN_PCIEPHY_CLK_DIV	1
IF: PCIESS2 is enabled	Software test condition	
Enable the CLKVCOLDO clock for the PCIESS2 PHY	CM_PCIE_PCIESS2_CLKCTRL[9] OPTFCLKEN_PCIEPHY_CLK	1
Enable the CLKVCOLDO_DIV clock for the PCIESS2 PHY	CM_PCIE_PCIESS2_CLKCTRL[10] OPTFCLKEN_PCIEPHY_CLK_DIV	1
ENDIF		
Configure the PCIESS1 Power Control clock frequency to match SYS_CLK1 in MHz	CTRL_CORE_PHY_POWER_PCIESS1[31:22] PCIESS1_PWRCTL_CLKFREQ	0x14 (20 MHz)
Power up PCIESS1_PHY_TX and PCIESS1_PHY_RX	CTRL_CORE_PHY_POWER_PCIESS1[21:14] PCIESS1_PWRCTL_CMD	0x3
IF: Either PCIESS1 Second Lane or PCIESS2 is required	Software test condition	
Configure the PCIESS2 Power Control clock frequency to match SYS_CLK1 in MHz	CTRL_CORE_PHY_POWER_PCIESS2[31:22] PCIESS2_PWRCTL_CLKFREQ	0x14 (20 MHz)
Power up PCIESS2_PHY_TX and PCIESS2_PHY_RX	CTRL_CORE_PHY_POWER_PCIESS2[21:14] PCIESS2_PWRCTL_CMD	0x3
ENDIF		
Configure the proper Delay Count	CTRL_CORE_PCIE_PCS[23:16] PCIESS_PCS_RC_DELAY_COUNT	0x96
Configure PCIe_PHY_RX SCP Settings	See PCIe_PHY_RX preferred SCP settings in Table 26-57.	
PHY_TX settings must remain at default values.	No additional tuning in PHY_TX SCP registers is required.	

Table 26-57. Preferred PCIe_PHY_RX SCP Register Settings

Register	Preferred Value Setting
PCIEPHYRX_ANA_PROGRAMMABILITY_REG1[31:27] MEM_ANATESTMODE	0b00001

26.4.6.1.1.2 PCIe_PHY_RX Register Description

Table 26-61. PCIEPHYRX_ANA_PROGRAMMABILITY_REG1

Address Offset	0x0000 000C		
Physical Address	0x4A09 400C 0x4A09 500C	**Instance**	PCIe1_PHY_RX PCIe2_PHY_RX
Description	Programmability for different analog circuits in the PHY.		
Type	RW		

31–8	7	6–5	4–0
MEM_ANATESTMODE	RESERVED	MEM_PLLDIV	RESERVED

Bits	Field Name	Description	Type	Reset
31:8	MEM_ANATESTMODE	Programmability for Analog circuits in the PHY. The top 5 bits - MEM_ANATESTMODE[31:27] indicate the serial Interface using this PHY module. Bits [17:14] are used to control loss-of-signal detection (LOSD) threshold.	RW	0x00 0000
7	RESERVED		RW	0

Bits	Field Name	Description	Type	Reset
6:5	MEM_PLLDIV	This is a test mode. SoC Users are requested to leave this at default value. The input PLL_CLK (after being muxed with PLLBYPCLK) is divided by the following factors indicated by this register. 00=1 01=2 10=4 11=RESERVED. All references to PLL_CLK in this register descriptions are AFTER considering this division.	RW	0x0
4:0	RESERVED		R	0x00

Table 26-62. PCIEPHYRX_TRIM_REG4

Address Offset	0x0000 001C		
Physical Address	0x4A09 401C 0x4A09 501C	**Instance**	PCIe1_PHY_RX PCIe2_PHY_RX
Description	The IP requires some values to be remembered in EFUSE. This register provides an alternative to EFUSE.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEM_DLL_TRIM_SEL		RESERVED																													

Bits	Field Name	Description	Type	Reset
31:30	MEM_DLL_TRIM_SEL	Determines which of the 4 EFUSE registers EFUSE_dll_rateN_coarsetrim should be used as the trim code by the DLL. This feature is so that the user may find and store the trim codes corresponding to different (at most 4) DLL frequencies (pll_clk pll_clk (after the bypassing by MEM_en_pllbyp and the division by MEM_plldiv) frequencies) and at wake-up, instruct the IP to choose one of these available trim values depending on the Application's frequency requirement. 00 selects dll_rate0_coarsetrim 01 selects dll_rate1_coarsetrim 10 selects dll_rate2_coarsetrim 11 selects dll_rate3_coarsetrim.	RW	0x0
29:0	RESERVED		RW	0x0000 0000

Table 26-63. PCIEPHYRX_DLL_REG1

Address Offset	0x0000 0024		
Physical Address	0x4A09 4024 0x4A09 5024	**Instance**	PCIe1_PHY_RX PCIe2_PHY_RX
Description	This register is used to program DLL settings.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEM_DLL_PHINT_RATE		RESERVED																													

Bits	Field Name	Description	Type	Reset
31:30	MEM_DLL_PHINT_RATE	Programs the DLL and the Phase Interpolator analog circuits to work with different clock frequencies. The frequency of pll_clk (after the bypassing by MEM_en_pllbyp and the division by MEM_plldiv) should be indicated by this register. 00=0.625GHz to 0.75GHz 01=RESERVED 10=1.25GHz to 1.5GHz 11=2.5GHz to 2.9GHz.	RW	0x3
29:0	RESERVED		R	0x00A4 1915

Table 26-64. PCIEPHYRX_DIGITAL_MODES_REG1

Address Offset	0x0000 0028		
Physical Address	0x4A09 4028 0x4A09 5028	**Instance**	PCIe1_PHY_RX PCIe2_PHY_RX
Description	This register contains control bits which affect different circuits in digital section		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEM_INV_RXPN_PAIR	MEM_OVRD_INV_RXPN_PAIR	RESERVED	MEM_HS_RATE		MEM_OVRD_HS_RATE	RESERVED		MEM_CDR_FASTLOCK	MEM_CDR_LBW		MEM_CDR_STEPCNT		MEM_CDR_STL			MEM_CDR_THR			MEM_CDR_THR_MODE	MEM_CDR_2NDO_SDM_MODE	RESERVED										

Bits	Field Name	Description	Type	Reset
31	MEM_INV_RXPN_PAIR	If '1', interchanges RXP and RXN effectively by inverting the received data samples.	RW	0
30	MEM_OVRD_INV_RXPN_PAIR	Pin override control. See register bit MEM_inv_rxpn_pair.	RW	0
29	RESERVED		R	0
28:27	MEM_HS_RATE	Determines the ratio of pll_clk (after the bypassing by MEM_en_pllbyp and the division by MEM_plldiv) frequency and the output data rate. Full Rate means pll_clk (after the bypassing by MEM_en_pllbyp and the division by MEM_plldiv) frequency = Data Rate/2 00=Full Rate 01=Half Rate 10=Quarter Rate 11=RESERVED. This takes effect only if register bit MEM_ovrd_hs_rate is '1', else the same is controlled by input pins hs_rate.	RW	0x0
26	MEM_OVRD_HS_RATE	Pin override control. See register bit MEM_hs_rate.	RW	0
25:24	RESERVED		R	0x2
23	MEM_CDR_FASTLOCK	'1' to reduce lock time of CDR (clock-data-recovery circuit).	RW	1
22:21	MEM_CDR_LBW	CDR band-width control.	RW	0x3
20:19	MEM_CDR_STEPCNT	CDR 2nd order setting.	RW	0x0

Bits	Field Name	Description	Type	Reset
18:16	MEM_CDR_STL	CDR settling time. Determines the number of vote clocks to blank ELV (Early-Late-Voter circuit) after update of phase.	RW	0x3
15:13	MEM_CDR_THR	CDR 1st order threshold. Determines how much early/ late votes should differ by before a phase change in the receiver sampling clock is triggered.	RW	0x1
12	MEM_CDR_THR_MODE	CDR 1st order threshold.	RW	1
11	MEM_CDR_2NDO_SDM_MODE	If '1', the 2nd Order CDR block uses a 1st order Sigma Delta Modulator to accomplish frequency offset If '0', a simple rate transformer is used for the same purpose.	RW	0
10:0	RESERVED		R	0x000

Table 26-65. PCIEPHYRX_EQUALIZER_REG1

Address Offset	0x0000 0038		
Physical Address	0x4A09 4038 0x4A09 5038	**Instance**	PCIe1_PHY_RX PCIe2_PHY_RX
Description	The module has an Equalizer (with analog and digital parts) which addresses Inter Symbol Interference (ISI). The equalizer can be configured via the EQCTL bits. The options are: No adaptive equalization. The equalizer provides a flat response at the maximum gain. This setting may be appropriate if jitter at the receiver occurs predominantly as a result of crosstalk rather than frequency dependent loss. Fully adaptive equalization. Both the low frequency gain and zero position of the equalizer are determined algorithmically by analysing the data patterns and transition positions in the received data. This setting should be used for most applications. Partially adaptive equalization. The low frequency gain of the equalizer is determined algorithmically by analysing the data patterns and transition positions in the received data. The zero position is fixed in one of eight zero positions. When enabled, the receiver equalization logic analyzes data patterns and transition times to determine whether the low frequency gain of the equalizer should be increased or decreased. For the fully adaptive setting (EQCTL = 0001), if the low frequency gain reaches the minimum value, the zero frequency is then reduced. Likewise, if it reaches the maximum value, the zero frequency is then increased.		
Type	RW		

31:16	15:11	10:8	7:3	2	1	0

31–10	9–7	6–4	3–0
RESERVED	DIVISIONRATIO	SYNC1	SYNC2

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reserved.	R	0x00 0000
9:7	DIVISIONRATIO(1)	Division Ration of the SCP clock in relation to OCP input clock.	RW	0x0
6:4	SYNC1	Number of SCPclock cycles defining SYNC1	RW	0x0
3:0	SYNC2	Number of SCPclock cycles defining SYNC2	RW	0x1

(1) When value “000” is programmed for the SCP clock division ratio, and the transaction to be made is a valid transaction on the SCP interface, the DIVISIONRATIO value is set internally to 0x7 (to avoid a block on the OCP interface).

CAUTION

To ensure correct operation, DIVISIONRATIO must not be modified. CAUTION: To ensure correct operation, the value of SYNC2 must be set to 0x6 or more.

Chapter 27

General-Purpose Interface

Texas Instruments

This chapter describes the general-purpose interface for the device.

27.1 General-Purpose Interface Overview.......... 6615
27.2 General-Purpose Interface Environment.......... 6618
27.3 General-Purpose Interface Integration.......... 6623
27.4 General-Purpose Interface Functional Description.......... 6628
27.5 General-Purpose Interface Programming Guide.......... 6643
27.6 General-Purpose Interface Register Manual.......... 6645

27.1 General-Purpose Interface Overview

The general-purpose interface combines eight general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 256 (8 × 32) pins. Some of the pins may be reserved in this Device. For more information of the supported number of GPIO pins, see the device Data Manual.

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pullup/down control, open-drain feature). For more information, see *Pad Configuration Registers,* in *Control Module*.

Figure 27-1 is an overview of the general-purpose interface.

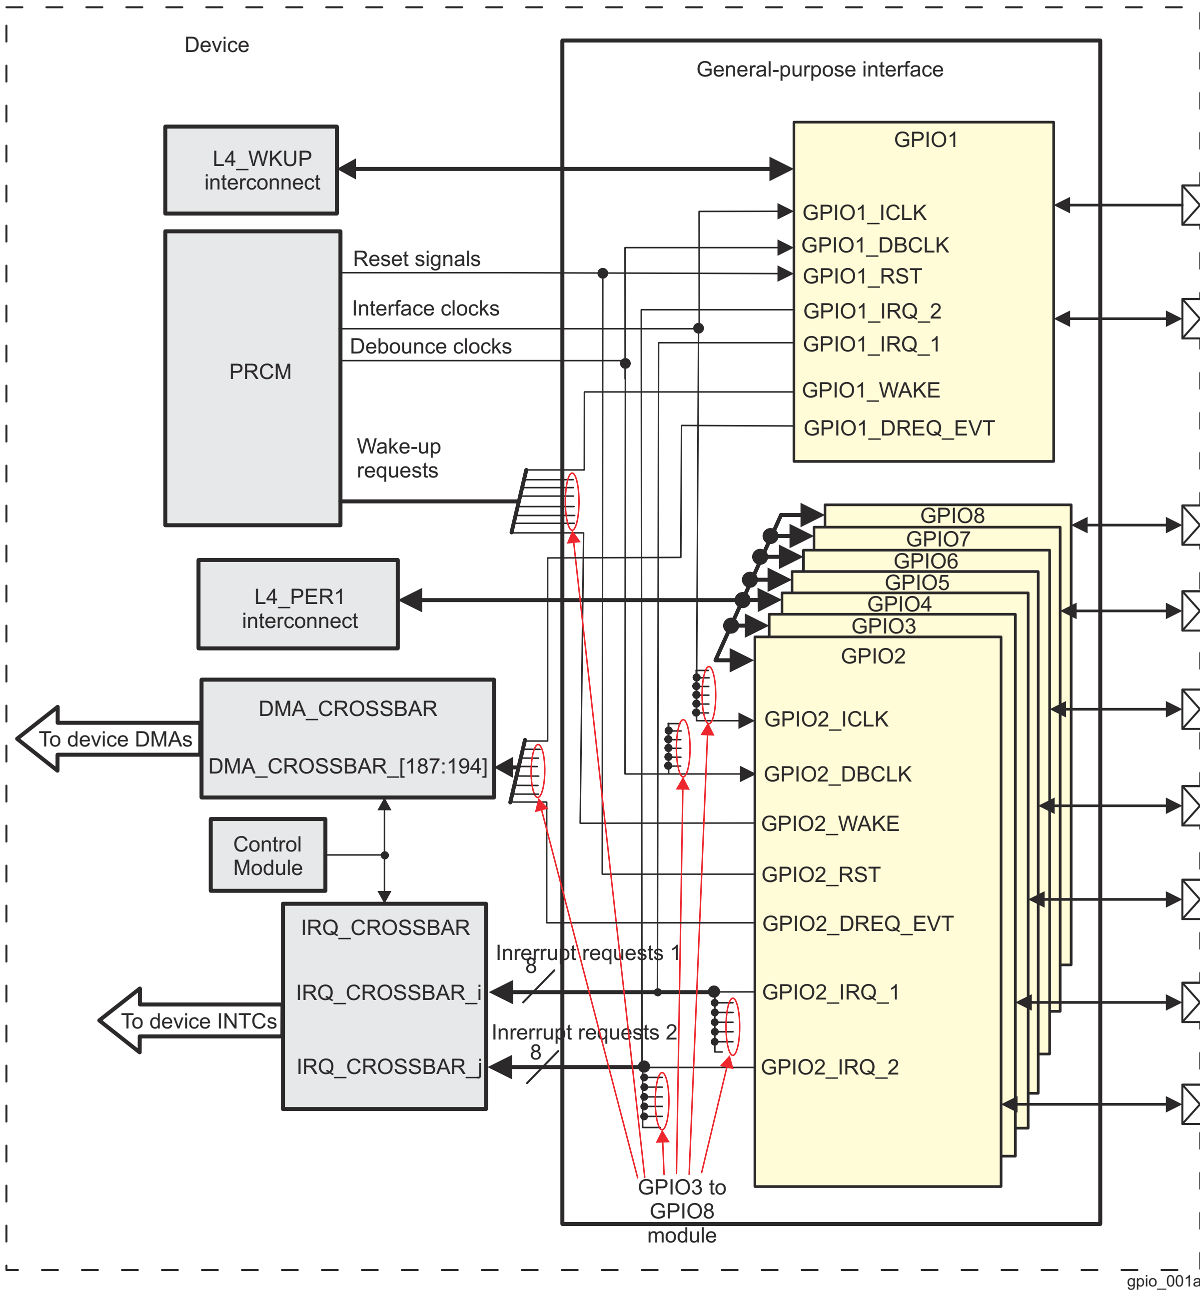

Figure 27-1. General-Purpose Interface Overview

The GPIO modules include the following global features:

- Two identical submodules can process synchronous interrupt requests from each channel to be used independently in a biprocessor environment. Each submodule controls its own synchronous interrupt request line. Each submodule also has its own interrupt-enable and interrupt status registers. The interrupt-enable register (GPIO_IRQSTATUS_SET_x [where x = 0 or 1]) selects the channel considered for the interrupt request generation. The interrupt status register (GPIO_IRQSTATUS_RAW_x) determines which channel has activated the interrupt request. Event detection on GPIO channels is reflected into GPIO_IRQSTATUS_RAW independently from the content of the interrupt-enable registers.
- Wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)

- Power-management support

The general-purpose interface has 16 interrupt lines (two interrupt lines on GPIO1 through GPIO8 modules).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Each channel in the GPIO modules has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the level 4 (L4_WKUP and L4_PER1) interconnect.
- The input line can be fed to the GPIO module through an optional and configurable debounce cell. (Because the debouncing time value is global for all ports of one GPIO module, up to five different debouncing time values are possible.)
- The value of the input line is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 (L4_WKUP and L4_PER1) interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level used (logical 0, logical 1, or both) can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the data-output register (GPIO_DATAOUT). For this register, the module implements the set-and-clear protocol register update (see Section 27.4.9, *General-Purpose Interface Set-and-Clear Protocol*).

All module registers are 8-, 16-, or 32-bit accessible through the OCP-compatible interface (little-endian encoding)

27.2 General-Purpose Interface Environment

The general-purpose interface combines eightGPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The GPIO allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 27-2 shows a typical application using the general-purpose interface.

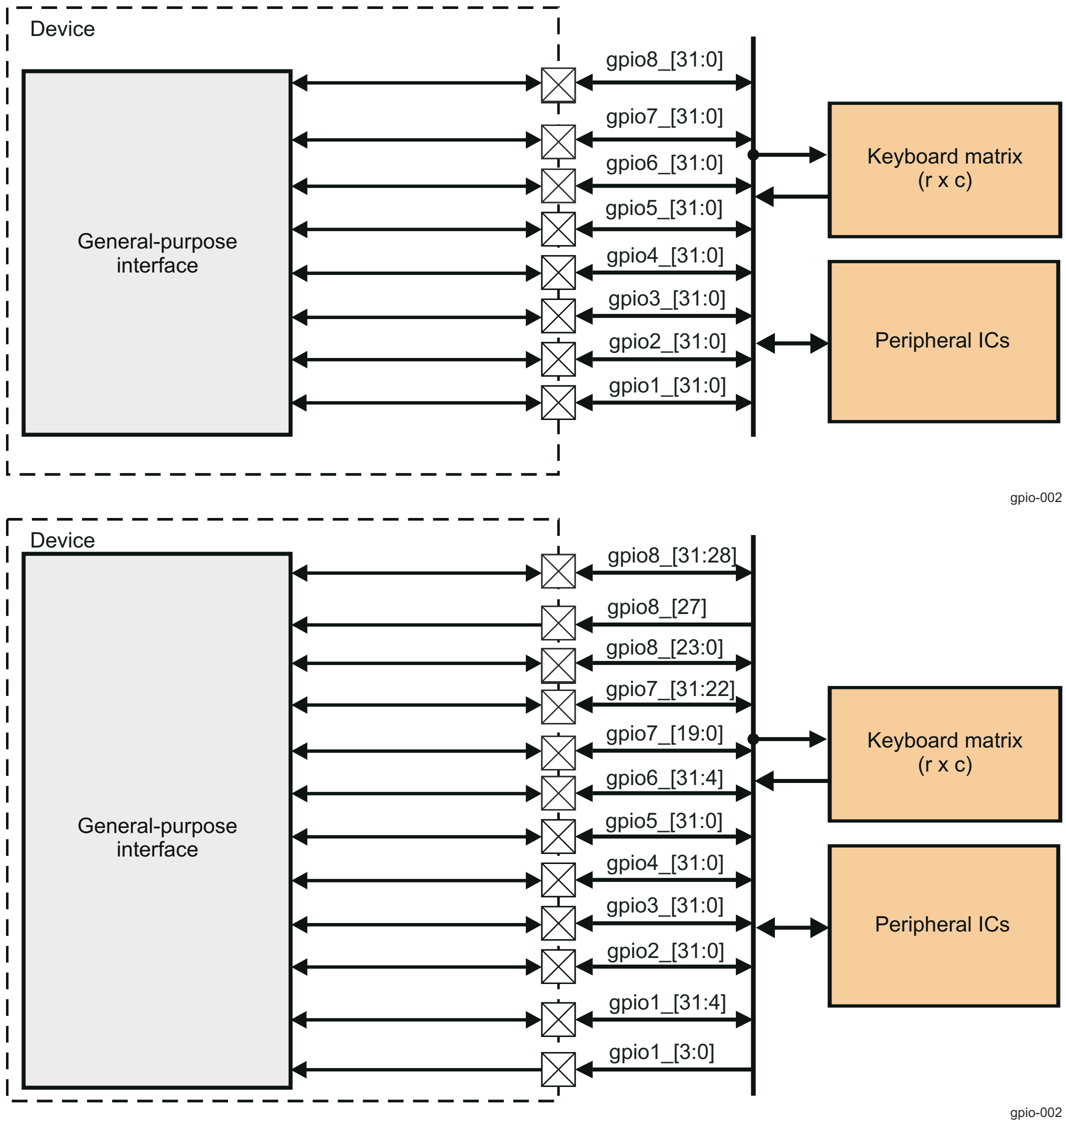

Figure 27-2. General-Purpose Interface Typical Application

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

27.2.1 General-Purpose Interface as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. Channels can be dedicated based on the keyboard matrix (r × c). Figure 27-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

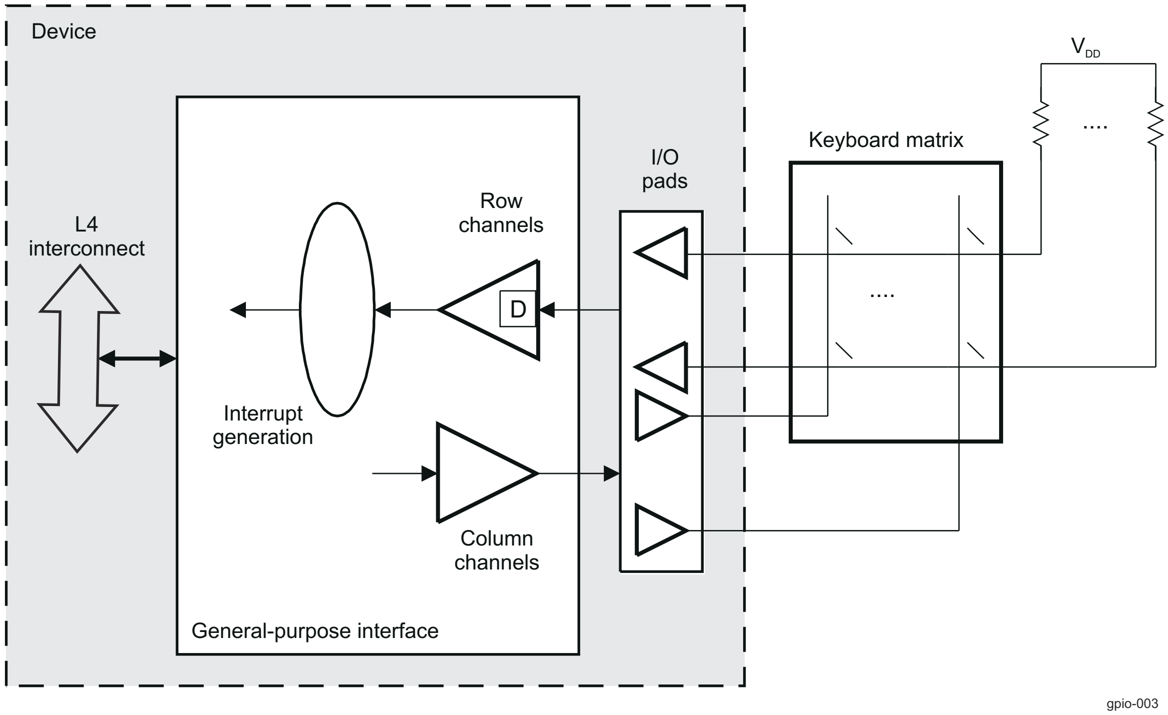

Figure 27-3. General-Purpose Interface Used as a Keyboard Interface

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 27.4.6, *Interrupt and Wake-up Requests*).

When the keyboard interrupt is received, the processor (microprocessor unit [MPU] and/or digital signal processor [DSP] subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

27.2.2 General-Purpose Interface Signals

Table 27-1 describes the module signals.

Table 27-1. I/O Description

Signal	I/O[1]	Description	Reset Value[2]
gpio1_[0:3]	I	GPIO (inputs only)	Hi-Z
gpio1_[4:31]	I/O	GPIO	Hi-Z
gpio2_[0:31]	I/O	GPIO	Hi-Z
gpio3_[0:31]	I/O	GPIO	Hi-Z
gpio4_[0:31]	I/O	GPIO	Hi-Z
gpio5_[0:31]	I/O	GPIO	Hi-Z
gpio6_[4:31]	I/O	GPIO	Hi-Z
gpio7_[0:19]	I/O	GPIO	Hi-Z
gpio7_[22:31]	I/O	GPIO	Hi-Z
gpio8_[0:23]	I/O	GPIO	Hi-Z

Table 27-1. I/O Description (continued)

Signal	I/O[1]	Description	Reset Value[2]
gpio8_27	I	GPIO (input only)	Hi-Z
gpio8_[28:31]	I/O	GPIO	HI-Z

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High Impedance

Figure 27-4 shows the signal connections of GPIO1.

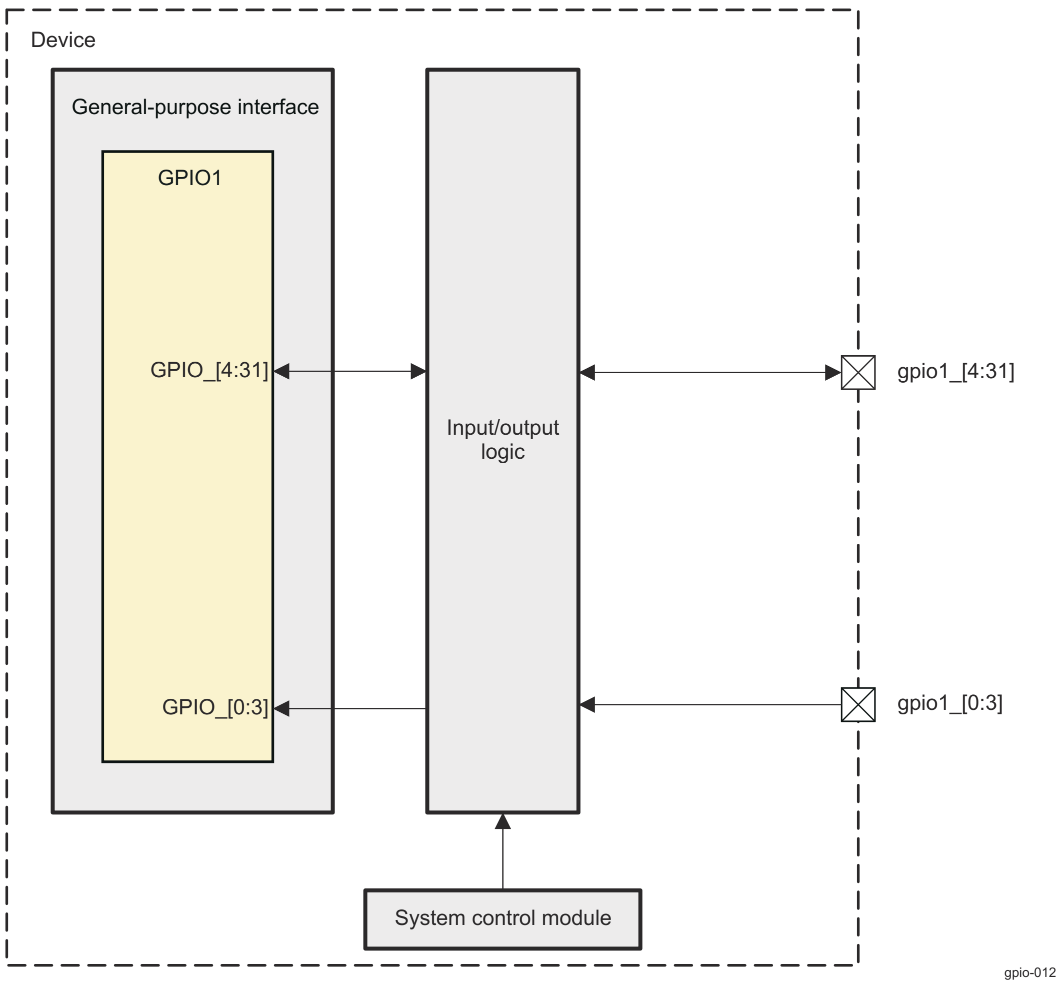

Figure 27-4. GPIO1 Signal Connections

Figure 27-5 shows the signal connections of GPIO2 through GPIO8.

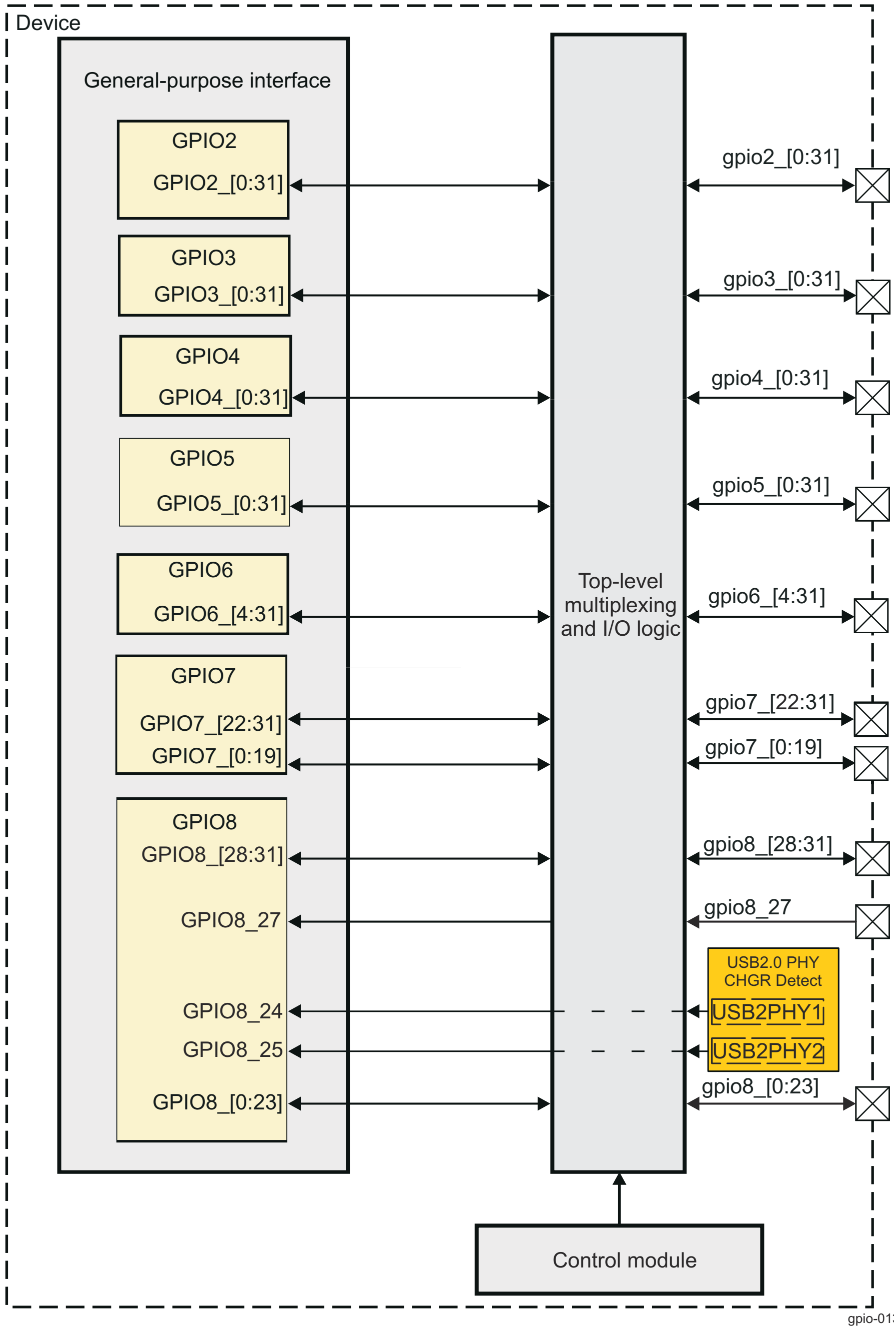

Figure 27-5. GPIO2 Through GPIO8 Signal Connections

Note

For more information about the GPIO1 through GPIO8 signals and channel description, see Section 27.4.7, *General-Purpose Interface Channels Description.*

Note

For more information about GPIO signal multiplexing, see *Pad Configuration Registers, and* in *Control Module*.

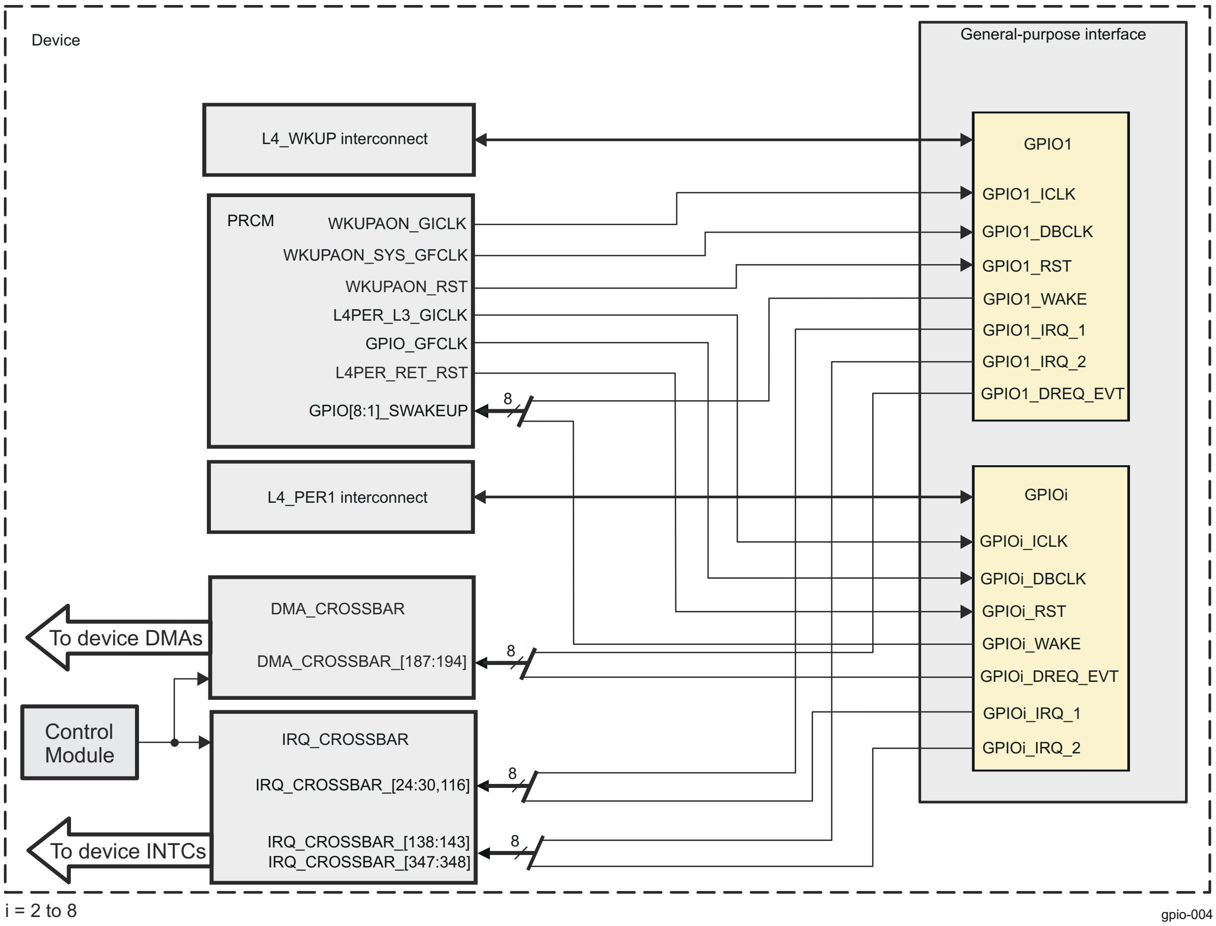
Note

GPIO pins can directly snoop device pads even if those are configured in the other modes. For GPIO output user needs to set pad mux.

27.3 General-Purpose Interface Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 27-6 shows this module integration.



i = 2 to 8
IRQ_CROSSBAR_[24:30] - GPIO1 to GPIO7 interrupt line 1
IRQ_CROSSBAR_116 - GPIO8 interrupt line 1
IRQ_CROSSBAR_[138:143] - GPIO1 to GPIO6 interrupt line 2
IRA_CROSSBAR_[347:348] - GPIO7 and GPIO8 interrupt line 2

Figure 27-6. GPIO Integration

Note

For more information about the slave idle protocol and the wake-up request, see *Clock Management*, in *Power, Reset, and Clock Management*.

Table 27-2 through Table 27-4 summarize the integration of the module in the device.

Table 27-2. GPIO Integration Attributes

Module Instance	Attributes

Table 27-4. GPIO Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
GPIO1	GPIO1_IRQ_2	IRQ_CROSSBAR_138	N/A	GPIO1 interrupt request (secont interrupt line). This IRQ source signal is not mapped by default to any device INTC.
	GPIO1_IRQ_1	IRQ_CROSSBAR_24	MPU_IRQ_29	GPIO1 interrupt request to MPU (first interrupt line)
			DSP1_IRQ_55	GPIO1 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_55	GPIO1 interrupt request to DSP2 (first interrupt line)
			IPU1_IRQ_51	GPIO1 interrupt request to IPU1 (first interrupt line)
			IPU2_IRQ_51	GPIO1 interrupt request to IPU2 (first interrupt line)
GPIO2	GPIO2_IRQ_2	IRQ_CROSSBAR_139	N/A	GPIO2 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO2_IRQ_1	IRQ_CROSSBAR_25	MPU_IRQ_30	GPIO2 interrupt request to MPU (first interrupt line)
			DSP1_IRQ_56	GPIO2 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_56	GPIO2 interrupt request to DSP2 (first interrupt line)
			IPU1_IRQ_52	GPIO2 interrupt request to IPU1 (first interrupt line)
			IPU2_IRQ_52	GPIO2 interrupt request to IPU2 (first interrupt line)
GPIO3	GPIO3_IRQ_2	IRQ_CROSSBAR_140	N/A	GPIO3 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO3_IRQ_1	IRQ_CROSSBAR_26	MPU_IRQ_31	GPIO3 interrupt request to MPU (first interrupt line)
			DSP1_IRQ_57	GPIO3 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_57	GPIO3 interrupt request to DSP2 (first interrupt line)
GPIO4	GPIO4_IRQ_2	IRQ_CROSSBAR_141	N/A	GPIO4 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO4_IRQ_1	IRQ_CROSSBAR_27	MPU_IRQ_32	GPIO4 interrupt request to MPU (first interrupt line)
			DSP1_IRQ_58	GPIO4 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_58	GPIO4 interrupt request to DSP2 (first interrupt line)

Table 27-4. GPIO Hardware Requests (continued)

Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
GPIO5	GPIO5_IRQ_2	IRQ_CROSSBAR_142	N/A	GPIO5 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO5_IRQ_1	IRQ_CROSSBAR_28	MPU_IRQ_33	GPIO5 interrupt request to MPU (first interrupt line)
			DSP1_IRQ_59	GPIO5 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_59	GPIO5 interrupt request to DSP2 (first interrupt line)
GPIO6	GPIO6_IRQ_2	IRQ_CROSSBAR_143	N/A	GPIO6 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO6_IRQ_1	IRQ_CROSSBAR_29	MPU_IRQ_34	GPIO6 interrupt request to MPU (first interrupt line)
			DSP1_IRQ_60	GPIO6 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_60	GPIO6 interrupt request to DSP2 (first interrupt line)
GPIO7	GPIO7_IRQ_2	IRQ_CROSSBAR_347	N/A	GPIO7 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO7_IRQ_1	IRQ_CROSSBAR_30	MPU_IRQ_35	GPIO7 interrupt request to MPU (first interrupt line)
			DSP1_IRQ_61	GPIO7 interrupt request to DSP1 (first interrupt line)
			DSP2_IRQ_61	GPIO7 interrupt request to DSP2 (first interrupt line)
GPIO8	GPIO8_IRQ_2	IRQ_CROSSBAR_348	N/A	GPIO8 interrupt request (second interrupt line). This IRQ source signal is not mapped by default to any device INTC
	GPIO8_IRQ_1	IRQ_CROSSBAR_116	MPU_IRQ_121	GPIO8 interrupt request to MPU (first interrupt line)
		DMA Requests		
Module Instance	**Source Signal Name**	**Destination DMA_CROSSBAR Input**	**Default Mapping**	**Description**
GPIO1	GPIO1_DREQ_EVT	DMA_CROSSBAR_187	N/A	GPIO1 module - event/ interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.
GPIO2	GPIO2_DREQ_EVT	DMA_CROSSBAR_188	N/A	GPIO2 module - event/ interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.
GPIO3	GPIO3_DREQ_EVT	DMA_CROSSBAR_189	N/A	GPIO3 module - event/ interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.
GPIO4	GPIO4_DREQ_EVT	DMA_CROSSBAR_190	N/A	GPIO4 module - event/ interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.

Table 27-4. GPIO Hardware Requests (continued)

GPIO5	GPIO5_DREQ_EVT	DMA_CROSSBAR_191	N/A	GPIO5 module - event/ interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.
GPIO6	GPIO6_DREQ_EVT	DMA_CROSSBAR_192	N/A	GPIO6 module - event/ interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.
GPIO7	GPIO7_DREQ_EVT	DMA_CROSSBAR_193	N/A	GPIO7 module - event/ interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.
GPIO8	GPIO8_DREQ_EVT	DMA_CROSSBAR_194	N/A	GPIO8 module - event/ interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.

Note

The “**Default Mapping**” column in Table 27-4 *GPIO Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For the description of the interrupt source, see Section 27.4.6, *Interrupt and Wake-Up Requests.*

27.4 General-Purpose Interface Functional Description

27.4.1 General-Purpose Interface Block Diagram

Figure 27-7 shows the general-purpose interface block diagram.

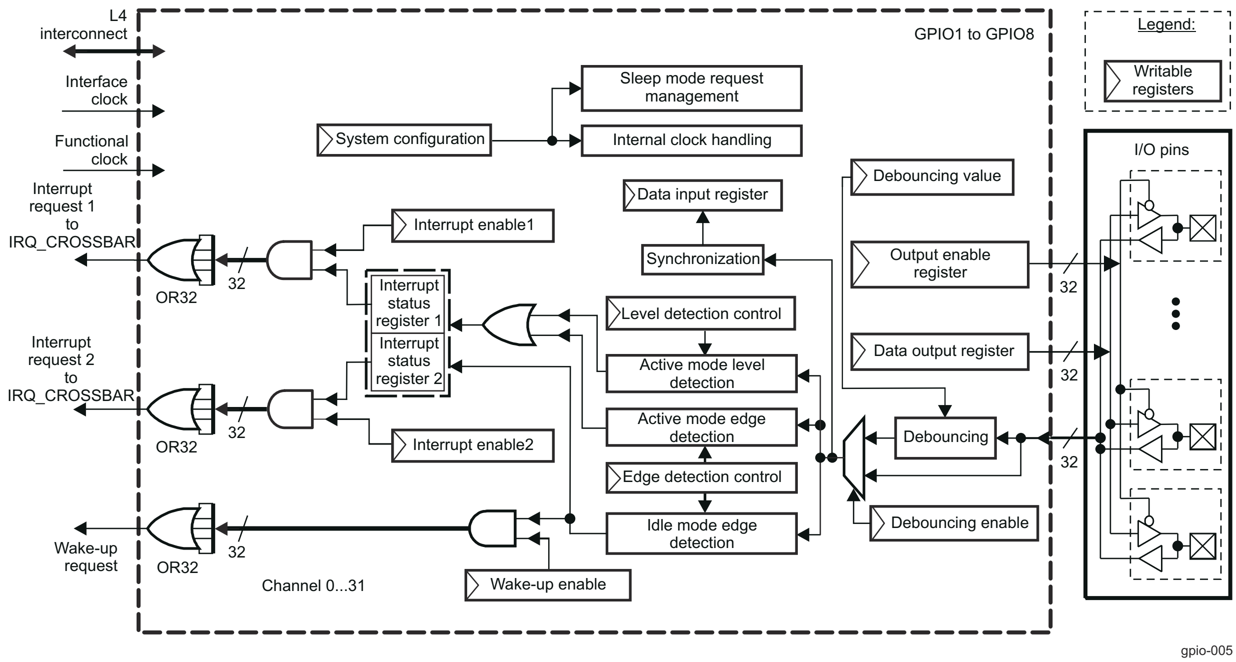

Figure 27-7. General-Purpose Interface Block Diagram

Figure 27-7 shows the details of the GPIO modules in the general-purpose interface block diagram, including their configuration registers and main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO. Synchronous interrupt request lines 1 and 2 are active based on their respective interrupt-enable1 and 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1). See Figure 27-8.

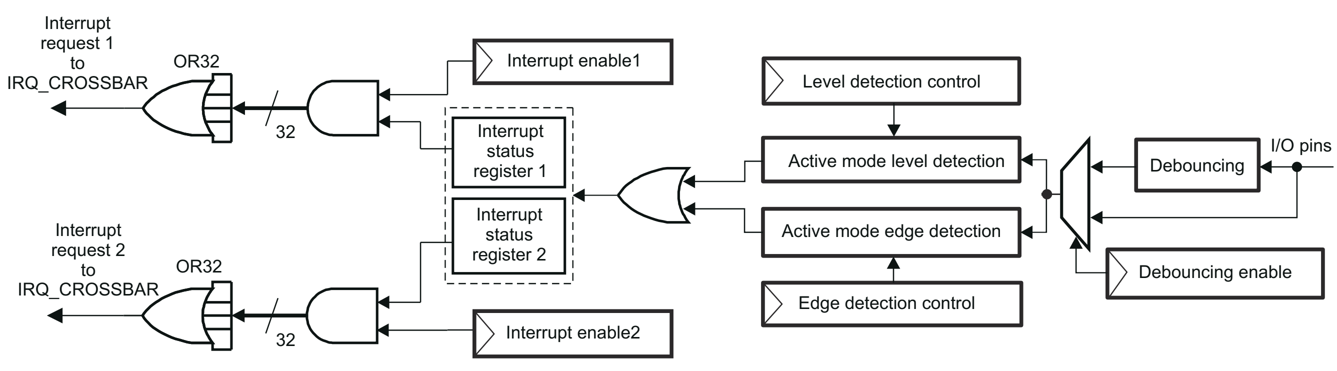

Figure 27-8. Synchronous Path

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO. The asynchronous wake-up request line is active based on the wake-up-enable register. See Figure 27-9.

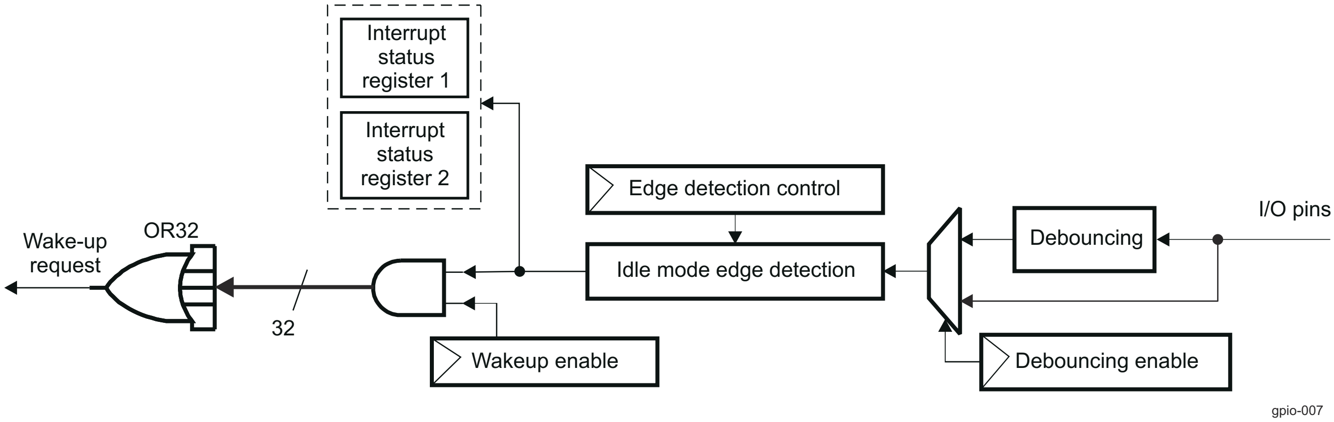

Figure 27-9. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode)

27.4.2 General-Purpose Interface Interrupt and Wake-Up Features

27.4.2.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 16 interrupt lines (two interrupt lines per GPIO module instance). The 16 interrupt signals are GPIOi_IRQ_1 (used by the MPU, DSP and IPU subsystems) and GPIOi_IRQ_2 (used by the CROSSBAR), where i = 1 to 8.

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the CROSSBAR subsystem on one side and by the MPU, IPU, and DSP subsystems on the other side. Each submodule controls its own synchronous interrupt request line and has its own interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1) and interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW_1). The interrupt-enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt-enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see Section 27.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see Section 27.4.5.2.4, *Module Power Saving*). When an event matches the programmed settings (see Section 27.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), the corresponding bit in the interrupt status register (GPIO_IRQSTATUS_RAW_x [where x = 0 or 1]) is set to 1, and on the following interface clock cycle, interrupt lines 1 and/or 2 are activated (depending on the interrupt-enable registers GPIO_IRQSTATUS_SET_x [where x = 0 or 1]).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (that is, *N* times the interface clock period; see Section 27.4.5.2.4, *Module Power Saving*). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed three internally gated interface clock cycles plus two interface clock cycles when the debounce feature is not used.

When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) (see Section 27.4.3, *General-Purpose Interface Clock Configuration*) and is less than three internally gated interface clock cycles plus two interface clock cycles plus GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles plus three debounce clock cycles.

Synchronous interrupt request line 1 is default mapped on the MPU, IPU, DSP subsystems.

Synchronous interrupt request line 2 is mapped on the CROSSBAR.

Figure 27-10 is an overview of the interrupt request generation.

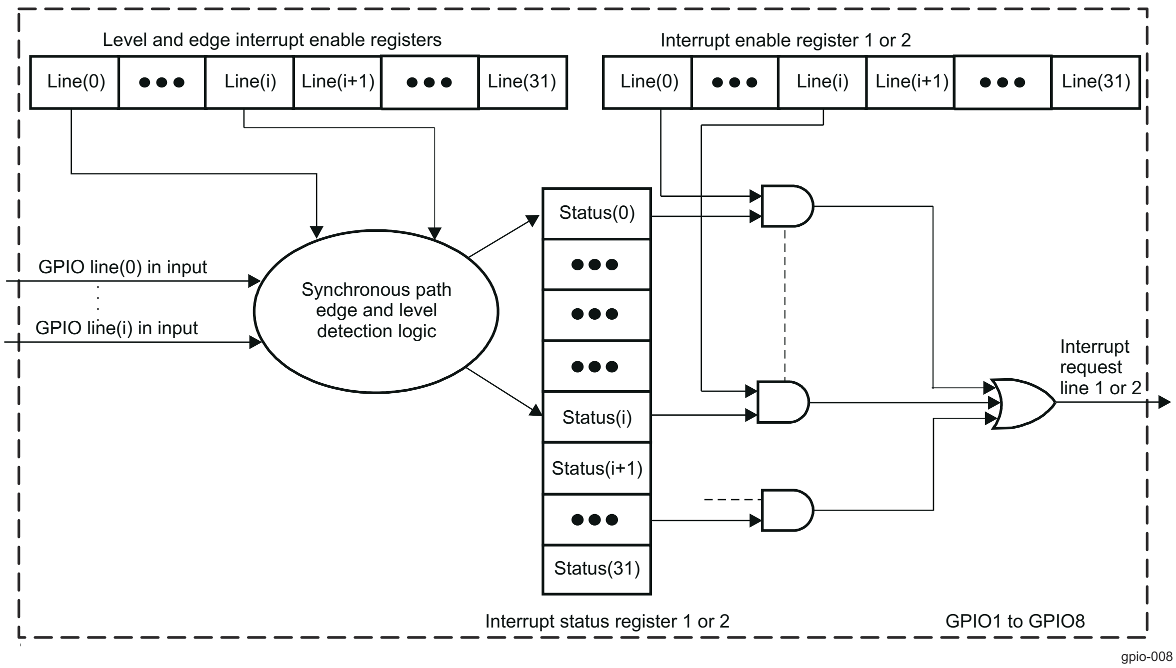

Figure 27-10. Interrupt Request Generation

27.4.2.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has eight wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wake-up-enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) select the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW_1).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 27.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi_SWAKEUP [where i = 1 to 8), if the wake-up-enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW). On the following internal clock cycle, interrupt lines 1 and/or 2 are active (active high) when the corresponding bits are set in the interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

Note

- If the debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request, because there is no sampling operation.
- If the debouncing is used, the minimum pulse width is set by the debouncing specified time.
- The ENAWAKEUP bit of the GPIO_SYSCONFIG register allows the enabling or disabling of the GPIO wake-up feature globally: if this bit is set to 0, GPIO_IRQWAKEN_x has no effect

Figure 27-11 is an overview of the wake-up request generation.

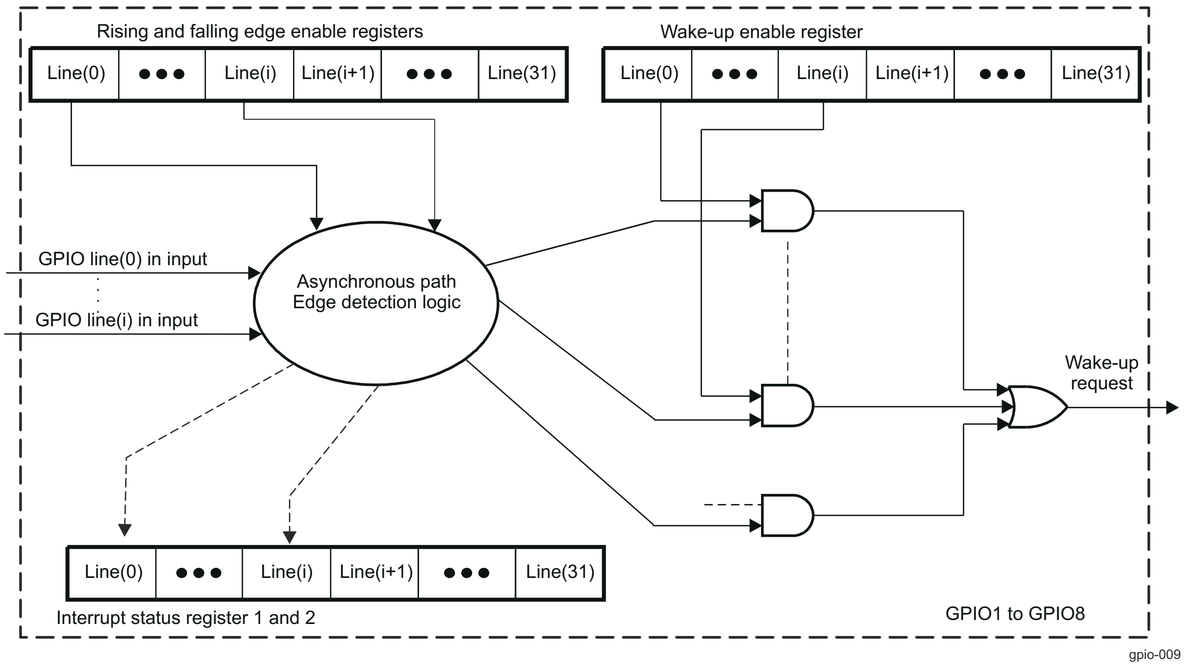

Figure 27-11. Wake-Up Request Generation

27.4.2.3 Wake-Up Event Conditions During Transition To/From IDLE State

In phase A, only the synchronous path is enabled. A synchronous interrupt request (see Section 27.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s) and prevents the GPIO from transitioning into IDLE state until the interrupt is cleared.

In phase B, the asynchronous path and synchronous path are enabled during the first five functional clock cycles of SLEEPTRANS state. During this period a synchronous interrupt request (see Section 27.4.2.1, *Synchronous Path: Interrupt Request Generation*) prevents the GPIO from transitioning into IDLE state. A shorter pulse puts the module into IDLE state but triggers a wakeup once in IDLE.

In phase C, only the asynchronous path is enabled. A wake-up request (see Section 27.4.2.2, *Asynchronous Path: Wake-Up Request Generation*) triggers a wake-up request from the GPIO and when the module is awakened an interrupt is generated. If debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request.

In phase D, eight open-core protocol (OCP) clock cycles occur until the module is in FUNCT state, the synchronous path is enabled, and an event that fulfills the pulse width requirements (see Section 27.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s).

In phase E, only the synchronous path is enabled. A synchronous interrupt request (see Section 27.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s).

Figure 27-12 shows the wake-up event conditions.

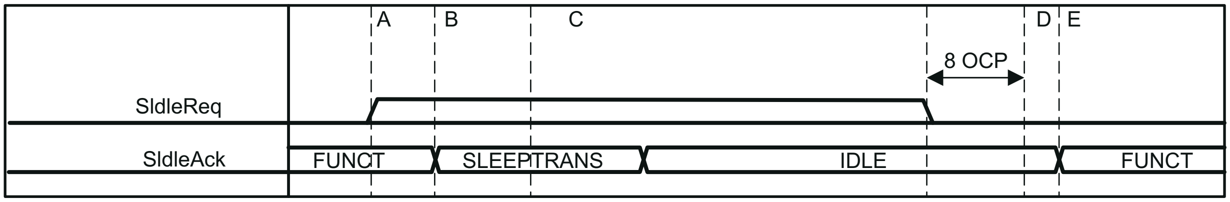

Figure 27-12. Wake-Up Event Conditions

27.4.2.4 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or DSP subsystem in the device) receives an interrupt request issued by the GPIO module, it reads the corresponding interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the software resets the status bit and releases the interrupt line by setting the corresponding bit of the interrupt status register to 1. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

Note

The status bit must be reset to re-enter idle mode.

27.4.3 General-Purpose Interface Clock Configuration

27.4.3.1 Clocking

Each GPIO module uses two clocks:

- Debounce clock: The 32-kHz debounce clock, GPIOi_DBCLK (where i = 1 to 8 with one debounce clock per module), comes from the PRCM module and is used to debounce the submodule logic (without the corresponding configuration registers). This module can sample the input line and filter the input level using a programmed delay.

  The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. Because the value is global for all the ports of one GPIO module, up to eight different debouncing values are possible. The debounce cell runs with the debounce clock (32 kHz). This register represents the number of clock cycle(s) to be used.

  The following formula describes the required input stable time to be propagated to the debounced output:

  Required input line stable = (the value of the GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME bit field + 1) × 31,

  where the value of the GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME bit field is from 0 to 255.

  For more information, see *CD_L4_PER1 Clock Domain*, and *CD_WKUPAON Clock Domain*, in *Power, Reset, and Clock Management*.
- Interface clock: The interface clock, GPIOi_ICLK (where i = 1 to 8), comes from the PRCM module and is used throughout the GPIO module (except within the debounce cell logic). GPIOi_ICLK clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

  For more information, see *CD_L4_PER1_Clock Domain*, and *CD_WKUPAON Clock Domain*, in *Power, Reset, and Clock Management*.

Table 27-3 describes the clocks in the GPIO modules.

Table 27-5 summarizes the functional clock configuration.

Table 27-5. Functional Clock Configuration

Interface Clock	GPIO_CTRL[2:1]GATINGRATIO	Functional Clock
GPIOi_ICLK (where i = 1 to 8)	00	GPIOi_ICLK /1
GPIOi_ICLK (where i = 1 to 8)	01	GPIOi_ICLK /2
GPIOi_ICLK (where i = 1 to 8)	10	GPIOi_ICLK /4
GPIOi_ICLK (where i = 1 to 8)	11	GPIOi_ICLK /8

27.4.4 General-Purpose Interface Hardware and Software Reset

The GPIO can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- Hardware reset: The GPIO2 to GPIO8 modules are attached to the L4PER_RET_RST reset domain. GPIO1 is attached to the WKUPAON_RST reset domain.

  The hardware reset has a global reset action on the GPIO modules of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO module, the GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit monitors the internal reset status; it is set when the reset completes. For more information, see *Reset Domains*, in *Power, Reset, and Clock Management*.
- Software reset: Each GPIO module has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit. The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules.

Setting the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit to 1 resets the module. A bit value of 1 remains until the reset completes. When the software reset completes, the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as a hardware reset. The GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit is cleared during a software reset. RESETDONE is set to 1 when the software reset completes.

27.4.5 General-Purpose Interface Power Management

27.4.5.1 Power Domain

GPIO1 is attached to the PD_WKUPAON power domain (see *Power Management*, in *Power, Reset, and Clock Management*). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUPAON power domain is continuously active. The GPIO2 to GPIO8 modules are attached to the PD_L4PER power domain (see *Power Management*, in *Power, Reset, and Clock Management*). The PD_L4PER power domain is not active continuously.

27.4.5.2 Power Management

27.4.5.2.1 Idle Scheme

To reduce dynamic consumption, an efficient idle scheme is based on the following:

- Efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_WAKEUP) are sideband signals between the PRCM module and the general-purpose interface (see Section 27.4.6.2, *Wake-Up Requests Generation*).

27.4.5.2.2 Operating Modes

Three operating modes are defined for the module:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

  If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

Idle mode is configured within the module and activated on request by the host processor through sideband signals (see Section 27.4.5.2.3, *System Power Management and Wakeup*).

The disabled mode is set by software through a dedicated configuration bit, GPIOi.GPIO_CTRL[0] DISABLEMODULE (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the system interface. When setting the GPIO_CTRL[0] DISABLEMODULE bit (enabling or disabling the GPIO module), it is important to switch the debouncing clock on or off in the following order:

- The GPIO optional debouncing clock must be enabled before the GPIO module is set (GPIO_CTRL[0]DISABLEMODULE = 0x0).
- The GPIO optional debouncing clock must be disabled after the GPIO module is disabled (GPIO_CTRL[0]DISABLEMODULE = 0x1).

27.4.5.2.3 System Power Management and Wakeup

The PRCM module can require the GPIO modules to be idled for power-saving purposes.

The general-purpose interface has eight identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see Section 27.4.6.2, *Wake-Up Requests Generation*): one per GPIO module. The general-purpose interface allows the GPIO modules to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field.

Idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode

  When the GPIO module is configured in smart-idle mode, it checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared), and there is no write access to the GPIO.GPIO_DEBOUNCINGTIME register, which is waiting to be synchronized.

  Idle acknowledge is then asserted and the module enters into idle mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

  In idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs.
- Smart-idle wake-up mode

  If the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field selects smart-idle or smart-idle wake-up mode, the GPIO module evaluates its internal capability to have the interface clock switched off. Once all internal activity ceases (the DATA INPUT REGISTER completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to the GPIO_DEBOUNCINGTIME register pending to be synchronized), the idle acknowledge is asserted and the GPIO enters into Idle mode, ready to issue a wake-up request when the expected transition occurs on an enabled GPIO input pin. This wake-up request is effectively sent only if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit of the system configuration register enables the GPIO wake-up capability (see GPIO_SYSCONFIG). When the system is awake, the IDLE request goes inactive, the idle acknowledge and wake-up request (if the GPIO triggered the wake-up in the system) signals are immediately deasserted, and the asynchronous wake-up request (if it exists) is reflected into the synchronous interrupt status registers.
- Force-idle mode

  When the GPIO module is configured in force-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 0x0) and receives an IDLE request from the PRCM module, the GPIO module waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

  When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.
- No-idle mode

  When the GPIO module is configured in no-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 0x1) and receives an IDLE request from the PRCM module, the GPIO module does not go into idle mode and the idle acknowledge is never sent.

Note

For more information about the idle modes, see *Power Management*, in *Power, Reset, and Clock Management*.

27.4.5.2.4 Module Power Saving

The GPIO module has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the system interface logic can be gated when the module is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in the GPIOi.GPIO_DATAIN register is not accessed.
- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for the logic in the synchronous event detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no detection, the corresponding clock is gated off.

  All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO_CTRL[2:1] GATINGRATIO bit field and can take the values 1, 2, 4, and 8. The interface clock is enabled for this logic one cycle every N cycles. When N is 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic runs at the equivalent frequency of interface clock frequency divided by N.
- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. Setting this bit to 1 forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled with the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

Table 27-6 describes the power-management features available for the general-purpose interface module.

Note

For information about source clock gating and sleep/wake-up transitions, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

Table 27-6. Local Power-Management Features

Feature	Register Bits/Bit Fields	Description
Clock autogating	GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE	It sets the clock-gating strategy for the OCP interface block.
Slave-idle modes	GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Force-idle, no-idle, and smart-idle wake-up-capable modes are available.
Clock activity	GPIOi.GPIO_CTRL[0] DISABLEMODULE	Enable and disable the module.
Debouncing enable	GPIOi.GPIO_DEBOUNCENABLE[31:0] DEBOUNCEENABLE	Debouncing mode is available.
Global wake-up enable	GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE	This register enables or disables a specific IRQ request source to generate a wake-up signal.

Table 27-7 describes the clock activity settings.

Table 27-7. Clock Activity Settings

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
00	Force-idle	The GPIO module goes into inactive mode independently of the internal module state, and the IDLE acknowledge is never sent.	No
01	No-idle	The GPIO module does not go into Idle mode and the IDLE acknowledge is never sent.	No

Table 27-7. Clock Activity Settings (continued)

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
10	Smart-idle	The GPIO module evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the IDLE acknowledge is asserted and the GPIO enters idle mode.	No
11	Smart-idle wake-up	The GPIO module evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the IDLE acknowledge is asserted and the GPIO enters idle mode.	Yes

27.4.6 General-Purpose Interface Interrupt and Wake-Up Requests

27.4.6.1 Interrupt Requests Generation

All interrupt sources (the 32 GPIO input channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 16 interrupt lines (two interrupt lines per GPIO module instance).

- Synchronous interrupt request line 1 is default mapped on the MPU,DSP and IPU INTC subsystem.
- Synchronous interrupt request line 2 is mapped on the CROSSBAR.

Table 27-8 lists the event flags, and their mask, that can cause module interrupts.

Table 27-8. Events

Event Flag	Event Mask	Synchronous	Sensitivity	Description
GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLINE	Yes	Edge/level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE	Yes	Edge/level	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLINE	Yes	Edge/level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE	Yes	Edge/level	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_0[31:0] INTLINE	Yes	Edge/level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_1[31:0] INTLINE	Yes	Edge/level	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE	No	Edge/level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE	No	Edge/level	Corresponding to the second line of interrupt

Note

For more information about interrupt mapping, see Table 27-4, *GPIO Hardware Request*.

Synchronous interrupt request line 1 and line 2 are active depending on their respective interrupt-enable1 and interrupt-enable 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

- interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1)

  The interrupt enable1 (or interrupt enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line 1 (or line 2). The interrupt-enable registers are programmed synchronously with the interface clock.

These registers can be accessed with direct read/write operations or by using the alternate set-and-clear protocol feature for register update. This feature allows setting or clearing explicit bits of these registers with a single write access (see Section 27.4.9, *General-Purpose Interface Set-and-Clear Protocol*).

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1)

  The interrupt status 1 (or interrupt status 2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line 2) request (or the wake-up line).

  When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wakeup). To reset a bit in this register, set the appropriate bit to 1. However, an interrupt cannot be generated by writing 1 to the interrupt status 1 (or interrupt status 2) register.

  If 0 is written to a bit in this register, the value in the corresponding bit in the interrupt status 1 and remains unchanged. The interrupt status 1 (or interrupt status 2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and interrupt status 2 registers are set when the GPIO module is awaken.

CAUTION

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset and the interrupt line released (by setting the corresponding bit of the interrupt status register to 1).

Before enabling an interrupt for the GPIO channel in the interrupt-enable register (GPIOi.GPIO_IRQSTATUS_SET_0 or GPIOi.GPIO_IRQSTATUS_SET_1) the corresponding status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

27.4.6.2 Wake-Up Requests Generation

The GPIO1 module of the general-purpose interface is attached to the WKUPAON power domain (see *Power Management*, in *Power, Reset, and Clock Management*, and can wake up the system.

Note

The GPIO2 to GPIO8 modules belong to the PD_L4PER power domain and thus their wake-up capabilities are operational only when the PD_L4PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

Note

Only gpio1_[3:0] can be used to generate a direct wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_IRQWAKEN_0 and GPIO_IRQWAKEN_1 wake-up-enable registers (where i = 1 to 8).

The wake-up-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

This register can be accessed with direct read/write operations.

Note

There must be a correlation between the wake-up enable and interrupt-enable registers. If a GPIO pin has a wake-up configured on it, it must also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the IDLE state, no interrupt is generated; thus, the corresponding bit from the interrupt status register is not cleared, and the module does not acknowledge a future IDLE request.

Table 27-9 lists the mapping of the wake-up signals.

Table 27-9. Wake-Up Signals

Name	Mapping	Comments
GPIOi_WAKE	GPIOi_SWAKEUP	Where i = 1 to 8. The destination is the PRCM module.

27.4.7 General-Purpose Interface Channels Description

Table 27-10 describes the GPIO channels.

Table 27-10. GPIO Channels Description

Channel Number	Type(1)	Mapping	Wake-Up Feature	Comments
GPIO1				
[3:0]	I	gpio1_[3:0]	Yes	GPIO. Wake-up path. Inputs only.
[31:4]	I/O	gpio1_[31:4]	Yes	GPIO. Wake-up path.
GPIO2				
[31:0]	I/O	gpio2_[31:0]	Yes	GPIO
GPIO3				
[31:0]	I/O	gpio3_[31:0]	Yes	GPIO
GPIO4				
[31:0]	I/O	gpio4_[31:0]	Yes	GPIO
GPIO5				
[31:0]	I/O	gpio5_[31:0]	Yes	GPIO
GPIO6				
[3:0]	—	Reserved	Reserved	Not pinned out.
[31:4]	I/O	gpio6_[31:4]	Yes	GPIO
GPIO7				
[19:0]	I/O	gpio7_[19:0]	Yes	GPIO
[21:20]	—	Reserved	Reserved	Not pinned out.
[31:22]	I/O	gpio7_[31:22]	Yes	GPIO
GPIO8				
[23:0]	I/O	gpio8_[23:0]	Yes	GPIO
[24]	I	CHGDETECT1	Yes	Charge-detect interrupt from USB2PHY1.
[25]	I	CHGDETECT2	Yes	Charge-detect interrupt from USB2PHY2.
[26]	—	Reserved	Reserved	Not pinned out.
[27]	I	gpio8_27	Yes	GPIO. Input only.
[31:28]	I/O	gpio8_in[31:28]	Yes	GPIO

(1) I = Input; O = Output; I/O = bidirectional

Note

Channels 24 and 25 of GPIO8 are internally connected inside the device to the charger detection (CHGDETECT) output, respectively, to USB2PHY1 and USB2PHY2. This allows interrupt generation on the corresponding GPIO channel, if either of the mentioned events occurs.

Note

For more information about pin configuration, see *Pad Configuration Registers*, in *Control Module*.

Note

GPIO pins can directly snoop device pads even if those are configured in the other modes. For GPIO output user needs to set pad mux.

27.4.8 General-Purpose Interface Data Input/Output Capabilities

The output-enable register (GPIOi.GPIO_OE) controls the I/O capability of each pin. At reset, all the GPIO-related pins are configured as inputs, and their output capabilities are disabled. This register is not used within the module. Its only function is to carry the pad configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data-output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set-and-clear protocol register update feature. This feature gives the possibility to set or clear specific bits of this register with a single write access to the set output data register (GPIOi.GPIO_SETDATAOUT) or to the clear output data register (GPIOi.GPIO_CLEARDATAOUT) address (see Section 27.4.9, *General-Purpose Interface Set-and-Clear Protocol*). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable (GPIOi.GPIO_ WAKEUPENABLE) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1) registers.

When configured as an input (the desired bit is set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and write data). If the application uses a pin as an input, the application must properly configure the wake-up enable (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_0) registers to the interrupt and wake-up feature as needed. For using the alternate set-and-clear protocol, see Section 27.4.9, *General-Purpose Interface Set-and-Clear Protocol.*

27.4.9 General-Purpose Interface Set-and-Clear Protocol

27.4.9.1 Description

The GPIO module implements the set-and-clear protocol register update for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQSTATUS_CLR_0
- GPIOi.GPIO_IRQSTATUS_CLR_1
- GPIOi.GPIO_IRQSTATUS_SET_0
- GPIOi.GPIO_IRQSTATUS_SET_1

This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear: Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

27.4.9.2 Clear Instruction

27.4.9.2.1 Clear Register Addresses

- Clear interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_CLR_0 and GPIOi.GPIO_IRQSTATUS_CLR_1).

  A write operation in the GPIO_IRQSTATUS_CLR_0 (or GPIO_IRQSTATUS_CLR_1) register clears the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

  A read of the clear interrupt enable0 (or enable1) register returns the value of the GPIO_IRQSTATUS_CLR_0 (or GPIO_IRQSTATUS_CLR_1) register.
- Clear data-output register (GPIOi.GPIO_CLEARDATAOUT).

  A write operation in the clear data-output register clears the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

  A read of the clear data-output register returns the value of the data-output register.

27.4.9.2.2 Clear Instruction Example

Assume the data-output register (or one of the interrupt or wake-up-enable registers) contains the binary value 0b0000 0001 0000 0001 and bit 0 is to be cleared.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data-output register (or at the address of the clear interrupt or wake-up-enable register). After this write operation, a reading of the data-output register (or the interrupt or wake-up-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

Note

Although the general-purpose interface registers are 32 bits wide, only the 16 least-significant bits (LSBs) are represented in this example.

Figure 27-13 is an example of a clear instruction.

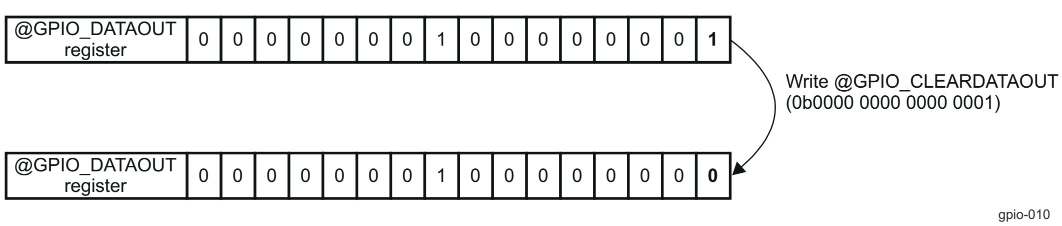

Figure 27-13. GPIO_CLEARDATAOUT Register Example

27.4.9.3 Set Instruction

27.4.9.3.1 Set Register Addresses

- Set interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1).

  A write operation in the GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register sets the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

  A read of the set interrupt-enable 0 (or enable1) register returns the value of the interrupt GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register.
- Set data-output register (GPIOi.GPIO_SETDATAOUT).

A write operation in the set data-output register sets the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data-output register returns the value of the data-output register.

27.4.9.3.2 Set Instruction Example

Assume the interrupt enable1 (or enable2) register (or the data-output register) contains the binary value 0b0000 0001 0000 0000 and bits 15, 3, 2, and 1 are to be set.

With the set instruction feature, the user has only to write 0b1000 0000 0000 1110 at the address of the GPIO_SETDATAOUT register. After this write operation, a reading of the GPIO_SETDATAOUT register returns 0b1000 0001 0000 1110: bits 15, 3, 2, and 1 have been set.

Note

Although the general-purpose interface registers are 32 bits wide, only the 16 LSBs are represented in this example.

Figure 27-14 is an example of a set instruction.

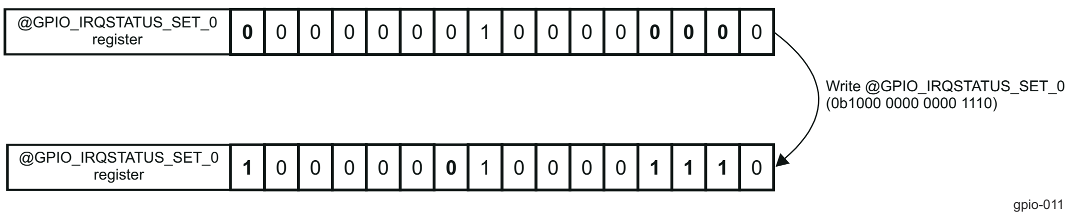

Figure 27-14. Write in GPIO_IRQSTATUS_SET_0 Register Example

The set wake-up-enable register offers the same feature with the wake-up-enable register.

27.5 General-Purpose Interface Programming Guide

27.5.1 General-Purpose Interface Low-Level Programming Models

27.5.1.1 Global Initialization

27.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the general-purpose interface. For more information, see Section 27.2, *General-Purpose Interface Environment*, and Section 27.3, *General-Purpose Interface Integration*.

Table 27-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information about the module configuration, see *Clock Management*, in *Power, Reset, and Clock Management*.
Control module	Module specific pad muxing must be set in the control module. For more information about the module configuration, see *Pad Configuration Registers*, in *Control Module*.
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see *Interrupt Controllers*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

27.5.1.1.2 General-Purpose Interface Module Global Initialization

This procedure initializes the general-purpose Interface module after a power-on reset (POR) or software reset.

Table 27-12. General-Purpose Interface Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	GPIO_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset completed?	GPIO_SYSSTATUS[0] RESETDONE	= 0x1
Configure idle mode.	GPIO_SYSCONFIG[4:3] IDLEMODE	0x-
Configure interface clock gating.	GPIO_SYSCONFIG[0] AUTOIDLE	0x-
Set clock-gating ratio.	GPIO_CTRL [2:1] GATINGRATIO	0x-
Configure GPIO channels as input or output.	GPIO_OE[31:0] OUTPUTEN	0x-
Set debounce time value.	GPIO_DEBOUNCINGTIME[7:0] DEBOUNCINGTIME	0x-
Enable/disable debouncing for desired input line. (For example, when used with a push-button)	GPIO_DEBOUNCENABLE[31:0] DEBOUNCENABLE	0x-
Interrupt and wake-up requests configuration		
(Optional) Enable/disable wake-up for desired input lines.	GPIO_IRQWAKEN_0[31:0] INTLINE and/or GPIO_IRQWAKEN_1[31:0] INTLINE	0x-
(Optional) Enable wake-up generation.	GPIO_SYSCONFIG[2] ENAWAKEUP	0x1
Configure detection events. **Note** NOTE: Simultaneous enabling of high-level and low-level detection for one given pin creates a constant-interrupt generator.	GPIO_LEVELDETECT0[31:0] LEVELDETECT0 and/or GPIO_LEVELDETECT1[31:0] LEVELDETECT1 and/or GPIO_RISINGDETECT[31:0] RISINGDETECT and/or GPIO_FALLINGDETECT[31:0] FALLINGDETECT	0x-
Clear interrupt status	GPIO_IRQSTATUS_0[31:0] INTLINE and/or GPIO_IRQSTATUS_1[31:0] INTLINE	0xFFFF FFFF

Table 27-12. General-Purpose Interface Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Enable interrupts for desired input lines. If wakeup is enabled, it is mandatory to enable the corresponding interrupt.	GPIO_IRQSTATUS_SET_0[31:0] INTLINE and/or GPIO_IRQSTATUS_SET_1[31:0] INTLINE	0x-

Note

Detection of events requires a functional clock running for every group of 8 bits. If detection of events is enabled only within one octet (for example, 0x0012 0000), power saving can be achieved. Else (for example, 0x0102 0000), using two octets requires one more clock to be run by the module.

27.5.1.2 General-Purpose Interface Operational Modes Configuration

27.5.1.2.1 General-Purpose Interface Read Input Register

Table 27-13. General-Purpose Interface Read Input Register

Step	Register/Bit Field/Programming Model	Value
Read interrupt status	GPIO_IRQSTATUS_0[31:0] INTLINE and/or GPIO_IRQSTATUS_1[31:0] INTLINE	0x-
Read input register value.	GPIO_DATAIN[31:0] DATAIN	0x-
Clear interrupt status	GPIO_IRQSTATUS_0[31:0] INTLINE and/or GPIO_IRQSTATUS_1[31:0] INTLINE	0xFFFF FFFF

27.5.1.2.2 General-Purpose Interface Set Bit Function

Table 27-14. General-Purpose Interface Set Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 0x1 to set desired bit(s) in DATAOUT register.	GPIO_SETDATAOUT [31:0] INTLINE	0x-

27.5.1.2.3 General-Purpose Interface Clear Bit Function

Table 27-15. General-Purpose Interface Clear Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 0x1 to clear desired bit(s) in DATAOUT register.	GPIO_CLEARDATAOUT [31:0] INTLINE	0x-

27.6 General-Purpose Interface Register Manual

27.6.1 General-Purpose Interface Instance Summary

Table 27-16 summarizes the general-purpose interface instance.

Table 27-16. Instance Summary

Module Name	Module Base Address	Size
GPIO7	0x4805 1000	408 Bytes
GPIO8	0x4805 3000	408 Bytes
GPIO2	0x4805 5000	408 Bytes
GPIO3	0x4805 7000	408 Bytes
GPIO4	0x4805 9000	408 Bytes
GPIO5	0x4805 B000	408 Bytes
GPIO6	0x4805 D000	408 Bytes
GPIO1	0x4AE1 0000	408 Bytes

27.6.2 General-Purpose Interface Registers

27.6.2.1 General-Purpose Interface Register Summary

Table 27-17 summarizes the general-purpose interface GPIO2, GPIO7 and GPIO8 registers.

Table 27-17. General-Purpose Interface GPIO2, GPIO7 and GPIO8 Registers Summary

Chapter 28

Keyboard Controller

This chapter describes the keyboard module (KBD) of the device.

28.1 Keyboard Controller Overview 6661
28.2 Keyboard Controller Environment 6663
28.3 Keyboard Controller Integration 6666
28.4 Keyboard Controller Functional Description 6668
28.5 Keyboard Controller Programming Guide 6677
28.6 Keyboard Controller Register Manual 6681

28.1 Keyboard Controller Overview

The keyboard controller implements a built-in scanning algorithm for hardware-based key-press decoding and reduces overhead in the microprocessor unit (MPU) software.

The keyboard controller includes a debouncing feature to ensure that only one key combination can be registered in the programmed time.

The keyboard controller can handle up to 9 × 9 keys, works on a 32-kHz clock, and can generate wake-up events when the chip is in sleep mode.

Figure 28-1 shows the keyboard controller.

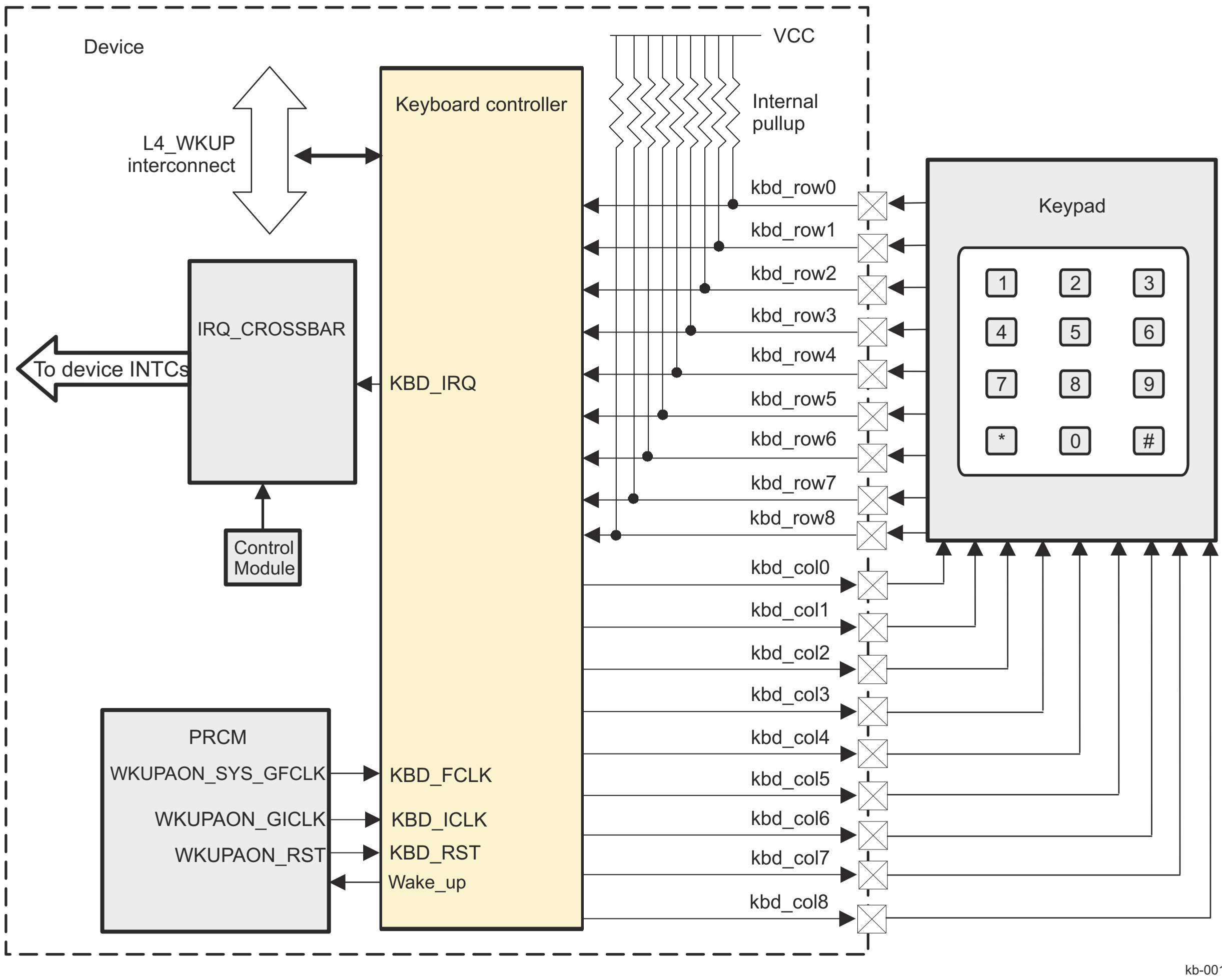

Figure 28-1. Keyboard Controller Overview

The keyboard controller includes the following main features:

- Support of multiconfiguration keyboards up to 9 rows × 9 columns
- Each key coded on 1 bit in two 32-bit registers
- Long-key value or repeat timing reconfigurable on the fly
- Event detection on key press and key release
- Multikey-press detection and decoding
- Long-key detection on prolonged key press
- Integrated timer with four programmable comparison values
- Programmable time-out on permanent key press or after keyboard release
- Programmable interrupt generation on key events

- Software reset capability
- Read/write-posted register access modes
- 8-/16-/32-bit access supported on the level 4 (L4) interface
- 32-bit data bus
- 7-bit address bus
- An over run generation if a master reads a register to late

28.2 Keyboard Controller Environment

The keyboard controller external interface pins map on the device pads when the device IO cells are configured and multiplexed for the keypad function by the control module. For more information, see *Pad Configuration Registers*, and Section 27.2.1, *General-Purpose Interface as a Keyboard interface*.

The external keypad typically connects directly to the keyboard controller of the device (see Figure 28-2).

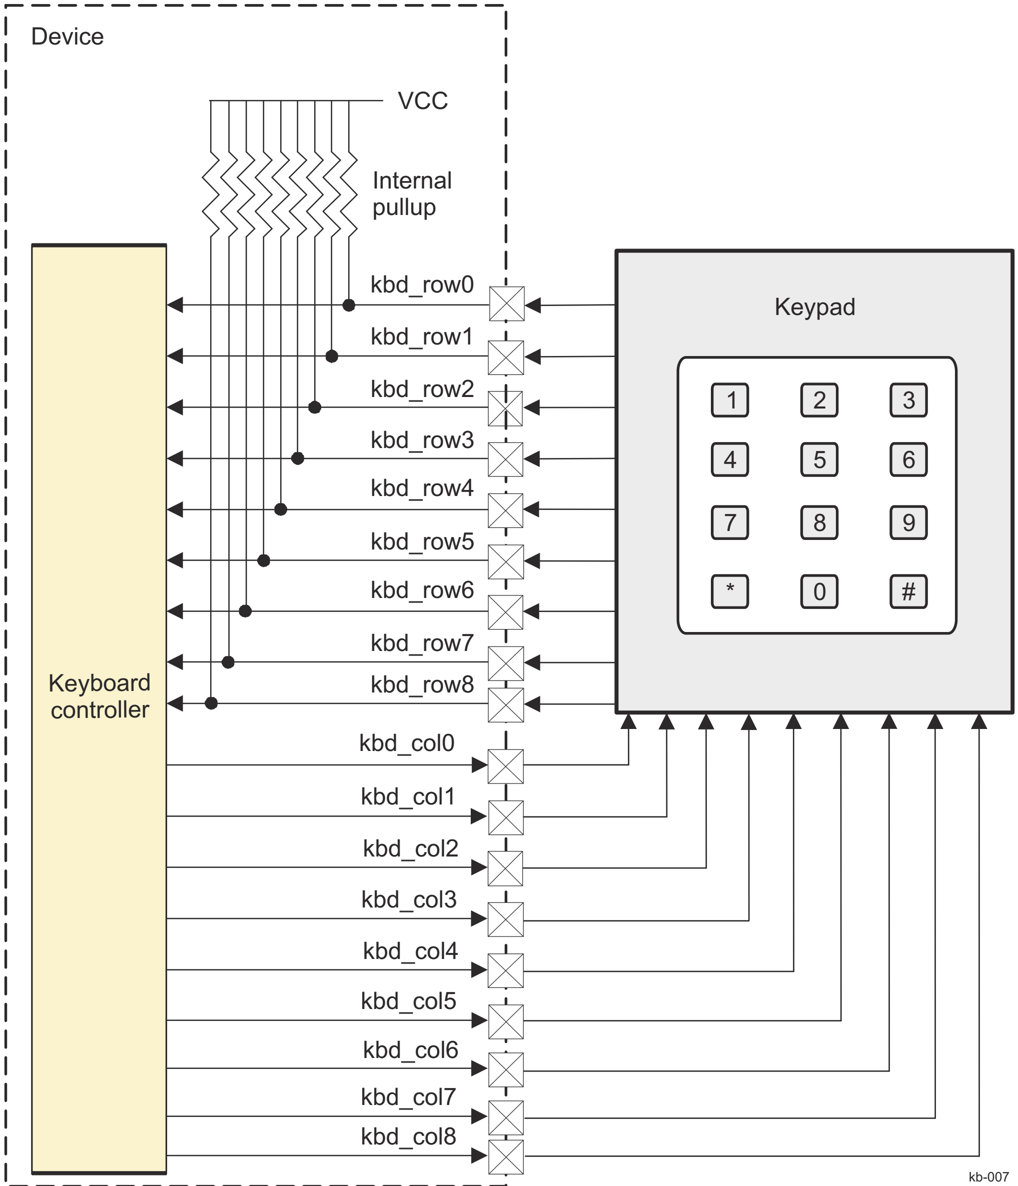

Figure 28-2. Typical Keyboard Environment

Note

To acheive the configuration shown in Figure 28-2 software needs to reconfigure the internal pulls on the kbd_* pads appropriately. The settings of those pads default to pull down resistors selected, software must reconfigure to pull ups on rows and to disable the pulls on columns.

28.2.1 Keyboard Controller Functions/Modes

The keyboard controller executes two functions:

- Keypad scanning and decoding for input of the external key presses. For more information, see Section 28.4.5, *Keyboard Controller Software Mode*, and Section 28.4.6, *Keyboard Controller Hardware Decoding Modes*.
- Device wakeup by interrupt request to the processor when a key is pressed and the device is in idle or sleep mode. For more information, see Section 28.4.6.4, *Keyboard Controller Interrupt Generation*.

28.2.2 Keyboard Controller Signals

Table 28-1 describes the module signals and specifies their links to functions.

Table 28-1. I/O External Keyboard Signals

Signal	I/O[1]	Description	Reset Value	Function	Wake-Up Capability
kbd_row0	I	Keypad row 0 feed	HiZ (pulled up)	Key reading	Yes
kbd_row1	I	Keypad row 1 feed	HiZ (pulled up)	Key reading	Yes
kbd_row2	I	Keypad row 2 feed	HiZ (pulled up)	Key reading	Yes
kbd_row3	I	Keypad row 3 feed	HiZ (pulled up)	Key reading	Yes
kbd_row4	I	Keypad row 4 feed	HiZ (pulled up)	Key reading	Yes
kbd_row5	I	Keypad row 5 feed	HiZ (pulled up)	Key reading	Yes
kbd_row6	I	Keypad row 6 feed	HiZ (pulled up)	Key reading	Yes
kbd_row7	I	Keypad row 7 feed	HiZ (pulled up)	Key reading	Yes
kbd_row8	I	Keypad row 8 feed	HiZ (pulled up)	Key reading	Yes
kbd_col0	O	Keypad column 0 feed, active low	HiZ	Key reading	No
kbd_col1	O	Keypad column 1 feed, active low	HiZ	Key reading	No
kbd_col2	O	Keypad column 2 feed, active low	HiZ	Key reading	No
kbd_col3	O	Keypad column 3 feed, active low	HiZ	Key reading	No
kbd_col4	O	Keypad column 4 feed, active low	HiZ	Key reading	No
kbd_col5	O	Keypad column 5 feed, active low	HiZ	Key reading	No
kbd_col6	O	Keypad column 6 feed, active low	HiZ	Key reading	No
kbd_col7	O	Keypad column 7 feed, active low	HiZ	Key reading	No
kbd_col8	O	Keypad column 8 feed, active low	HiZ	Key reading	No

(1) I = Input; O = Output

28.2.3 Protocols and Data Formats

The keyboard controller detects and decodes multikey combinations using the following rules:

- Any 2-key combination is valid and can be decoded.
- Combinations using more than two keys are valid only if the rows and columns used do not cross over on another key to be detected. This is caused by equipotent propagation on a row/column (multikey limitations).

Figure 28-3 shows an example of multikey limitation.

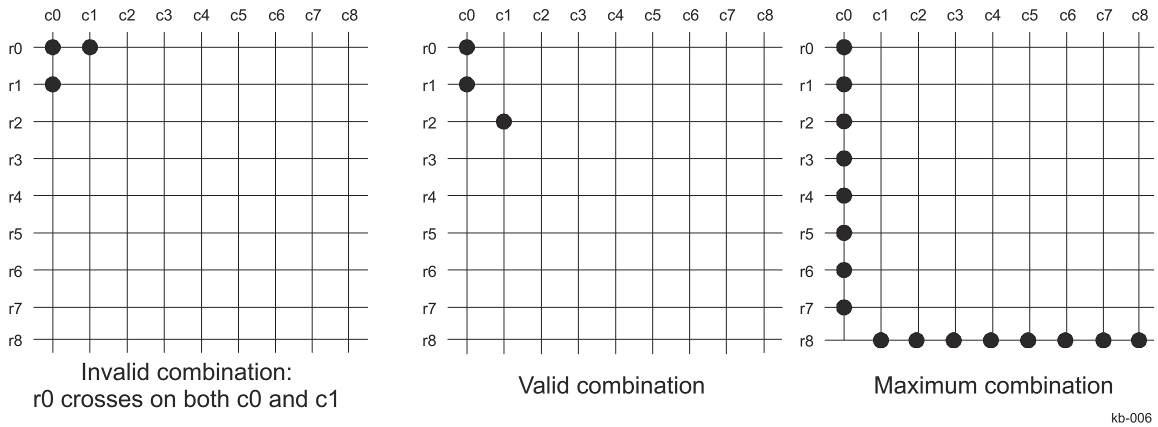

Figure 28-3. Multikey Limitation Example

Note

When using the keyboard controller with a smaller keypad (for example, 5 × 5), unused rows must be tied high to prevent disturbing the scanning process. Normally, all rows must be pulled up internally at the I/O cells of the device.

28.3 Keyboard Controller Integration

Figure 28-4 shows keyboard controller integration.

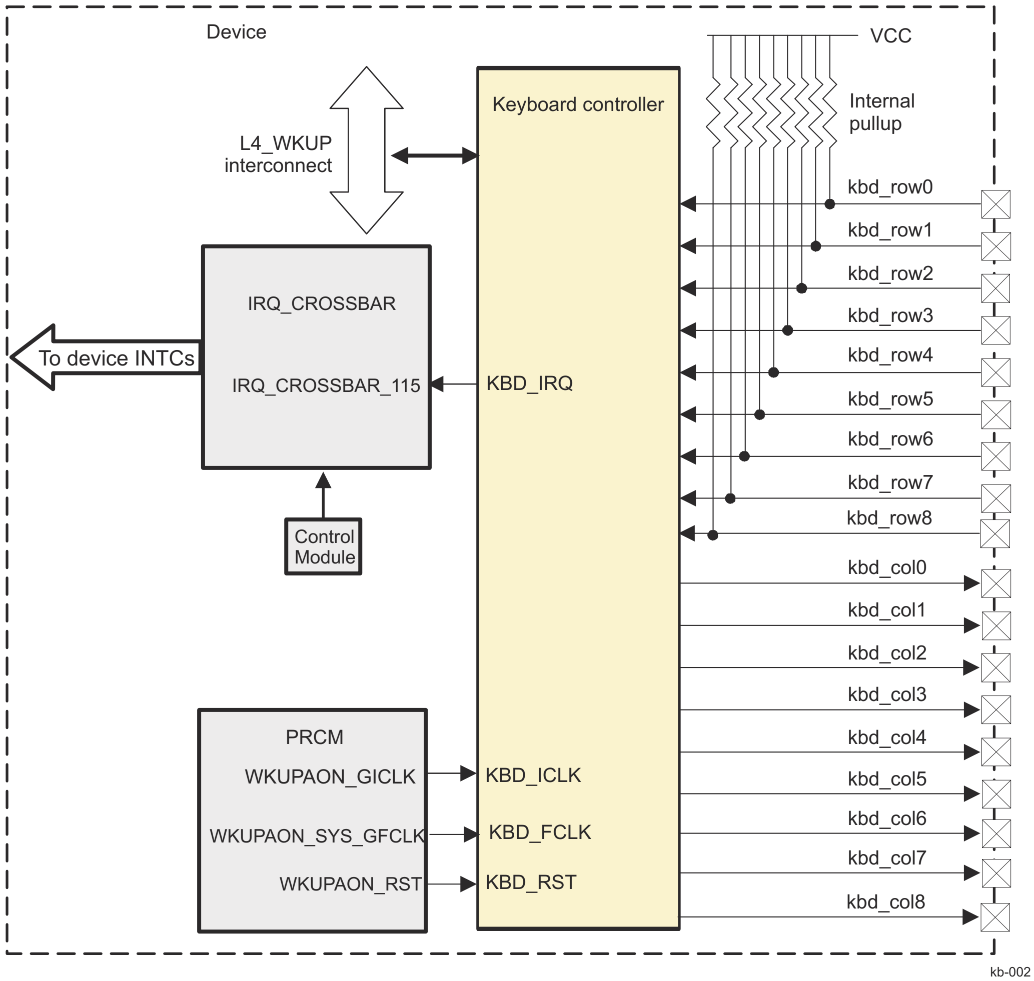

Figure 28-4. Keyboard Controller Integration

The control module must enable the internal pullups of the GPIO cells for all keypad rows (for more information about the configuration, see *Control Module*).

Table 28-2 through Table 28-4 summarize the integration of the module in the device.

Table 28-2. Keyboard Controller Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
KBD	PD_WKUPAON	Yes	L4_WKUP

Table 28-3. Keyboard Controller Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
KBD	KBD_FCLK	WKUPAON_SYS_GFCLK	PRCM	32-kHz functional clock. For information about PRCM clock gating and management, see *Clock Domain-Level Clock Management*, in *Power, Reset, and Clock Management*.

Table 28-3. Keyboard Controller Clocks and Resets (continued)

KBD	KBD_ICLK	WKUPAON_GICLK	PRCM	L4-interconnect interface clock. For information about PRCM clock gating and management, see *Clock Domain-Level Clock Management*, in *Power, Reset, and Clock Management*.
		Resets		
KBD	KBD_RST	WKUPAON_RST	PRCM	Reset signal for the Keyboard controller.

Table 28-4. Keyboard Controller Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
KBD	KBD_IRQ	IRQ_CROSSBAR_115	MPU_IRQ_120	Keyboard Controller interrupt request

Note

The “**Default Mapping**” column in Table 28-4 *Keyboard Controller Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For the description of the interrupt source, see Section 28.4.4, *Interrupt Requests*.

28.4 Keyboard Controller Functional Description

28.4.1 Keyboard Controller Block Diagram

Figure 28-5 shows the functional specification block diagram of the keyboard controller.

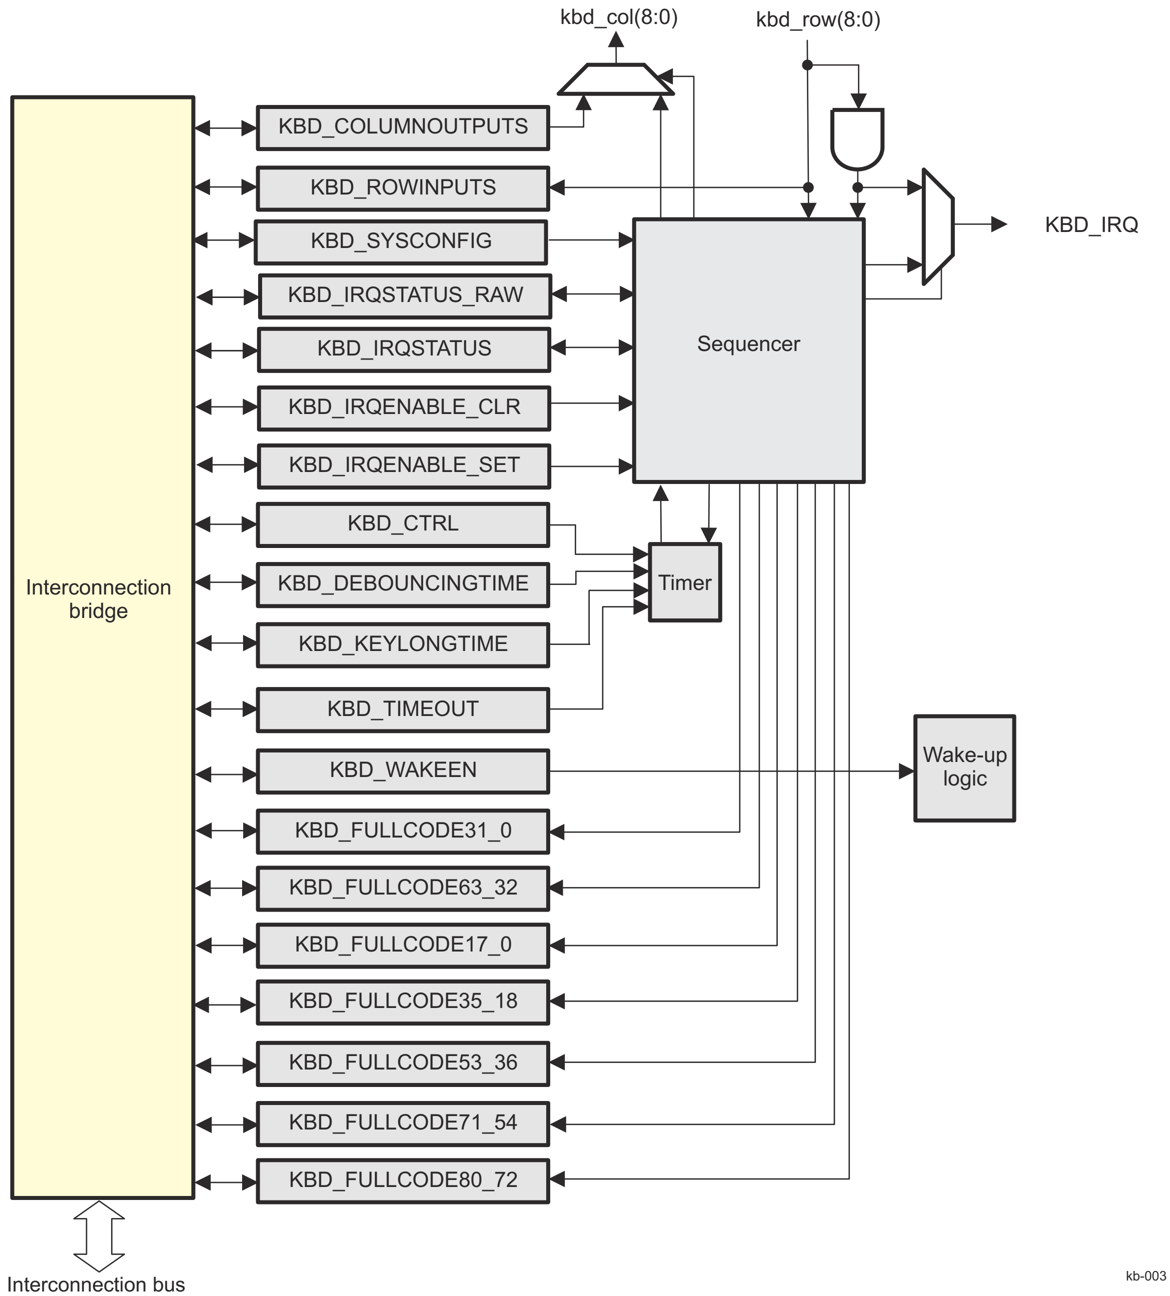

Figure 28-5. Keyboard Controller Block Diagram

The keyboard controller detects events issued on any key of the connected keyboard and generates an interrupt to alert the host processor. The built-in hardware-scan algorithm decodes the pressed keys, including multikey combinations.

To reduce MPU software overhead, the hardware performs detecting and decoding in the keyboard controller state-machine. However, hardware decoding can be deactivated so that software handles the scanning algorithm.

The value of the columns output is determined in the KBD_COLUMNOUTPUTS[8:0] KBC_REG bit field. To activate a keypad row-column connection, the corresponding bit must be 0b0.

The following sections describe subfunctions and subfunction interactions (control and data paths).

28.4.2 Keyboard Controller Software Reset

To perform a software reset, set the KBD_SYSCONFIG[1] SOFTRESET bit to 1. When the software reset completes, the KBD_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing mailbox operations.

28.4.3 Keyboard Controller Power Management

Table 28-5 describes the power-management features available for the keyboard controller.

Note

For information about source clock gating and a description of the sleep/wake-up transitions, see *Clock Domain-Level Clock Management*, in *Power, Reset, and Clock Management*.

Table 28-5. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	KBD_SYSCONFIG[4:3] IDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Master standby modes	N/A	N/A
Wake-up sources enable	KBD_IRQWAKEEN	This register holds one active-high enable bit per event source able to generate a wake-up signal.

28.4.4 Keyboard Controller Interrupt Requests

Table 28-6 lists the event flags, and their mask, that can cause module interrupts.

Table 28-6. Events

Event Flag	Event Mask	Description
KBD_IRQSTATUS[3] MISS_EVENT	–	A miss event occurs.
KBD_IRQSTATUS[2] IT_TIMEOUT	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR [2] IT_TIMEOUT_EN	A time-out event is detected.
KBD_IRQSTATUS[1] IT_LONG_KEY	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR [1] IT_LONG_KEY_EN	A long-key event is detected.
KBD_IRQSTATUS[0] IT_EVENT	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR [0] IT_EVENT_EN	An event is detected.

28.4.5 Keyboard Controller Software Mode

The KBD_CTRL[1] NSOFTWARE_MODE bit selects software mode when it is set to 0.

In software mode, the keyboard controller internal sequencer, which performs automatic scanning and decoding, is disabled. Consequently, software must manually perform the scanning algorithm.

The scanning sequence is managed using the keyboard controller column outputs register (KBD_COLUMNOUTPUTS) and the keyboard controller row inputs register (KBD_ROWINPUTS). In this configuration, the keyboard interrupt is a logical ANDing of all bits of the KBD_ROWINPUTS register.

For more information about the software scan, see Section 28.5.1, *Keyboard Controller Low-Level Programming Model*.

28.4.6 Keyboard Controller Hardware Decoding Modes

28.4.6.1 Functional Modes

When running in hardware (default) decoding mode (the KBD_CTRL[1] NSOFTWARE_ MODE bit is set to 1), the keyboard controller offers several functional modes; these modes are summarized in Table 28-7.

The keyboard interrupt depends on the configuration in the keyboard controller interrupt-enable register (KBD_IRQENABLE_SET). If the event is enabled (bit 0 is set to 1), an interrupt is generated when the sequencer detects an event. Even if this interrupt is disabled, the flag status of the keyboard controller interrupt-status register (KBD_IRQSTATUS) is updated.

Table 28-7. Keyboard Controller Functional Modes

Functional Mode	Associated Interrupt	Associated Timer Value	Description	Control
Keyboard event	Event interrupt	Debouncing value	Occurs when a key is pressed or released Always enabled	KBD_CTRL[8:5] bits must be set to 0 to disable all the other features.
Long key	Long-key interrupt	Long-key value	Used to detect a key that is pressed for a long time Should be associated with the long-key time-out function or repeat mode	KBD_CTRL[5] LONG_KEY
Repeat key	Long-key interrupt	Long-key value	Generates an interrupt every long-key delay No time-out can be associated.	KBD_CTRL[8] REPEAT_MODE
Empty time-out	Time-out interrupt	Empty time-out value	Interrupt generated if no key is pressed during an empty time-out period.	KBD_CTRL[6] TIMEOUT_EMPTY
Long-key time-out	Time-out interrupt	Long-key time-out value	Associated with the long-key function Generated after a long-key interrupt if no event occurs during a long-key time-out period	KBD_CTRL[7] TIMEOUT_LONG_KEY

Each mode can be activated/deactivated by setting the corresponding bits (5, 6, 7, and 8) in the KBD_CTRL register with the appropriate values (for more information, see Section 28.6, *Keyboard Controller Register Manual*).

28.4.6.2 Keyboard Controller Timer

As described in the previous section, each functional mode is associated with a timer value. Depending on the selected mode, the keyboard controller timer is loaded with the corresponding value as set in the related registers:

- KBD_DEBOUNCINGTIME
- KBD_KEYLONGTIME
- KBD_TIMEOUT

Table 28-8 summarizes the values of the keyboard controller timer.

Table 28-8. Keyboard Controller Timer Values

Timer Value	Associated Register Field	Description
Debouncing time	KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE	To remove the effects of glitches when an event occurs on the keyboard, the controller waits for a debouncing period before taking a snapshot of the current state on the keyboard matrix. The timer is loaded with the debouncing time value after each detected event on the keyboard matrix. An event interrupt is generated after this delay.
Long-key time	KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE	This is the delay before generating a long-key interrupt after an event interrupt. If the long-key mode is selected, the timer is loaded with the long-key time value after an event interrupt is generated. In repeat mode, the timer is reloaded with the same value after a long-key interrupt, and starts to count down again.
Long-key time-out	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	The timer is loaded with the time-out value and then a long-key interrupt is generated and starts to count down. When it reaches 0, a time-out interrupt is generated and the keyboard controller returns to its IDLE state. This long-key time-out does not work in repeat mode.
Empty key time-out	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	The time-out interrupt occurs if no key is pressed during this delay. The keyboard controller then returns to IDLE state.

The timer countdown period depends on three factors:

- The loaded value as set in:
  - KBD_DEBOUNCINGTIME
  - KBD_KEYLONGTIME
  - KBD_TIMEOUT
- The value of the prescale clock timer as set in the KBD_CTRL[4:2] PTV bit field. This programmable clock divider allows the reduction of the clock frequency used by the timer.
- The frequency of the keyboard controller functional clock (32 kHz). This clock is actually either 32K oscillator, or it is the SYSCLK1/610, depending on sysboot[9:8] state at power-on. For more information about sysboot states see *Initialization*.

The period is calculated as follows:

$T_{period} = (T_{value} + 1) \times 2^{PTV + 1} \times T_{clk}$

Where:

T_{value} is the value stored in the KBD_DEBOUNCINGTIME, KBD_KEYLONGTIME, or KBD_TIMEOUT register.

PTV is the value of the KBD_CTRL[4:2] PTV bit field.

T_{clk} is the period of the 32-kHz functional clock; that is, 31.25 μs or other (depending wheather the 32K oscillator or the SYSCLK1/610 clock is selected as source).

The KBD_CTRL[4:2] PTV bit field determines the division factor of the timer clock. Table 28-9 lists the divider rates.

Table 28-9. Timer Prescale Values

KBD_CTRL[4:2] PTV Value	Divisor
0	2
1	4
2	8
3	16
4	32
5	64
6	128
7	256

Note

The timer minimum period is 62.5 μs; its maximum period is 524.288 seconds.

CAUTION

To prevent undefined results, the KBD_CTRL[4:2] PTV bit field must not be changed when the timer is running.

The timer value registers (KBD_DEBOUNCINGTIME, KBD_KEYLONGTIME, and KBD_TIMEOUT) can be updated at any time, whether or not the timer is running. Nevertheless, the timer is updated only on the fly for the long-key time value. The new debouncing and time-out values are loaded only on the next load. Depending on the updated register, two cases can occur:

- The KBD_KEYLONGTIME register is updated; the new value stored in the KBD_KEYLONGTIME register is loaded into the timer when the register is written. If the timer is already counting down when KBD_KEYLONGTIME is updated, it counts down from the new value loaded in KBD_KEYLONGTIME.
- The KBD_DEBOUNCINGTIME or KBD_TIMEOUT register is updated; the new value is considered only when the next timer loads. If the timer is counting down when the registers are updated, the timer continues counting down from the previous value and is loaded with the new one on the next load.

Regardless of the timer state (stopped, counting down any of the values previously described, etc.), when a new event occurs on the keyboard, the timer is stopped and loaded with the debouncing time value. It then starts counting down.

28.4.6.3 State-Machine Status

To facilitate debugging, each state of the state-machine is coded in a register that indicates the current state of the machine. Table 28-10 lists the corresponding codes.

Table 28-10. State-Machine Values

KBD_STATEMACHINE[3:0] Value	Description
0x0	Idle
0x1	Scanning
0x2	Load timer debouncing
0x3	Test timer debouncing
0x4	Generated interrupt event
0x6	Load timer long key
0x7	Test timer long key
0x8	Generated interrupt long key
0x9	Load timer time-out
0xA	Test timer time-out
0xB	Generated interrupt time-out
0xF	Other

28.4.6.4 Keyboard Controller Interrupt Generation

28.4.6.4.1 Interrupt-Generation Scheme

The keyboard controller generates the KBD_IRQ interrupt signal connected to the IRQ_CROSSBAR_115 input. Each functional mode generates dedicated interrupt events (logged in the KBD_IRQSTATUS register) that can be masked using the KBD_IRQENABLE_CLR register or unmasked using the KBD_IRQENABLE_SET register.

The KBD_IRQSTATUS register is updated when the selected functional mode generates an interrupt event. However, the KBD_IRQ signal is asserted on the related event only if the corresponding bit is set to 0x1 in the KBD_IRQENABLE_SET register.

Note

To reset the interrupt status bit, 1 must be written to the appropriate bit of the KBD_IRQSTATUS read/write register.

Figure 28-6 shows the different interrupt events generated in each keyboard controller functional mode and details the relationships between them.

Note

Depending on the selected mode, some interrupt events cannot be generated.

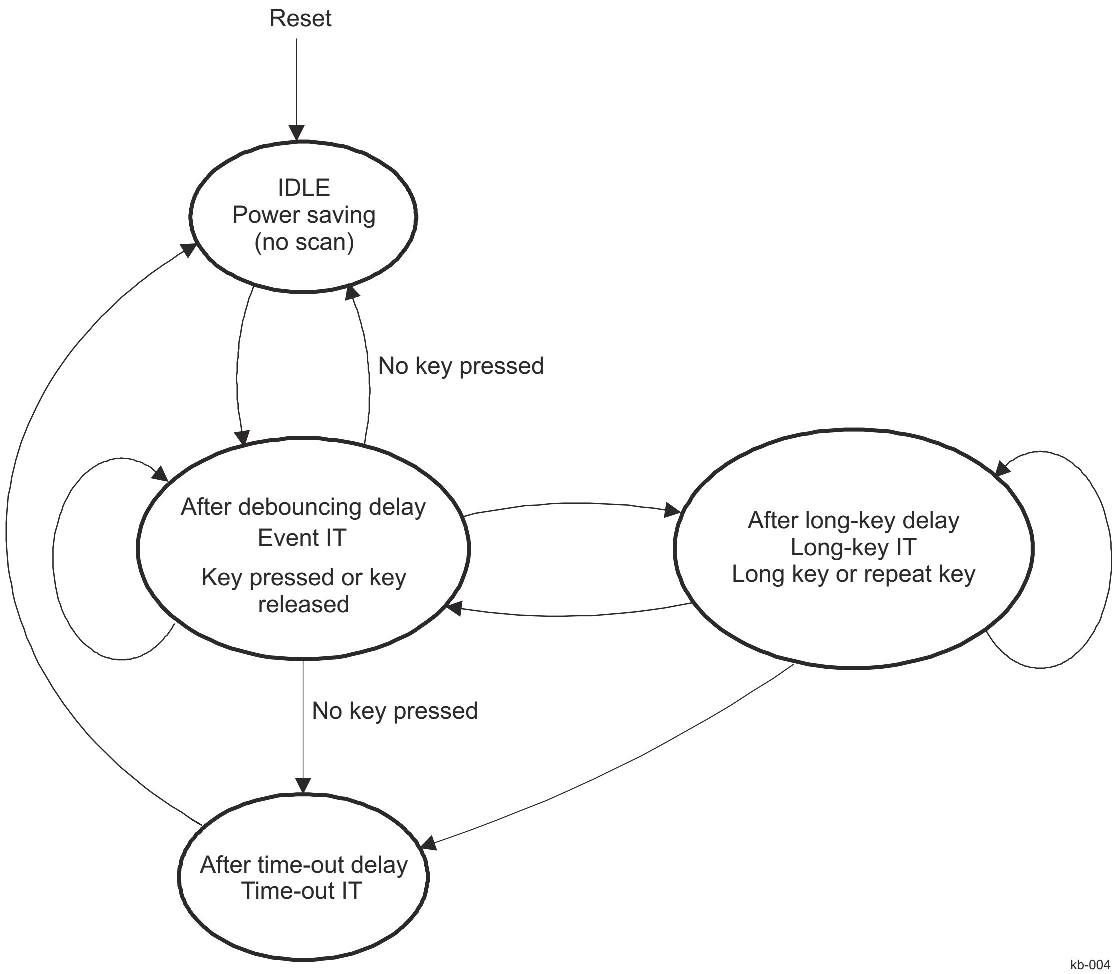

Figure 28-6. Functional Modes and Related Interrupt Events

While running in hardware-decoding mode, the keyboard controller performs automatic scans when not in IDLE state. When a key-press event occurs on the keyboard matrix, the keyboard controller leaves IDLE state and an interrupt event (the KBD_IRQSTATUS[0] IT_EVENT bit) is set after the timer counts down the debouncing delay. An IT_EVENT is generated when a key is pressed or released.

Note

An IT_EVENT is generated regardless of the selected functional mode. If no time-out is set and no more keys are pressed, the keyboard controller returns to IDLE state.

If long-key detection mode is set when the timer counts down the long-key delay, an interrupt long key (the KBD_IRQSTATUS[1] IT_LONG_KEY bit) is generated. If the repeat mode is set, the IT_LONG_KEY interrupt is generated periodically every long-key delay.

A time-out can also be set in event detection or long-key detection mode. In this case, a time-out interrupt (the KBD_IRQSTATUS[2] IT_TIMEOUT bit) is generated after the time-out delay timer expires. After such an interrupt, the keyboard controller always returns to IDLE state.

Note

No time-out can be set in repeat mode. Only a keyboard event can stop the periodic interrupt generation.

28.4.6.4.2 Keyboard Buffer and Missed Events (Overrun Feature)

The keyboard controller has an overrun feature: A dedicated buffer allows the keyboard controller to memorize two successive events. If two successive events occur before a read is performed, the second event is stored and a second interrupt is generated when the first interrupt is cleared, allowing two consecutive key events to be received.

If a third event occurs before the first event is treated, a missed event interrupt (the KBD_IRQSTATUS[3] MISS_EVENT bit) is generated to report the lost event.

Note

The MISS_EVENT interrupt is not routed to the KBD_IRQ signal; software must check the KBD_IRQSTATUS[3] MISS_EVENT bit to detect any missed events.

28.4.7 Keyboard Controller Key Coding Registers

The keyboard controller matrix pressed keys state (indicating which columns/rows are connected) is reflected in the KBD_FULLCODE17_0 to KBD_FULLCODE80_72 registers, as shown in Figure 28-7. These registers are updated only when interrupt event status is inactive to prevent a lost event.

Note

The KBD_FULLCODE31_0 and KBD_FULLCODE63_32 registers, which are limited to supporting keyboards of a maximum 8 × 8 array size, can be used for back-to-back software compatibility.

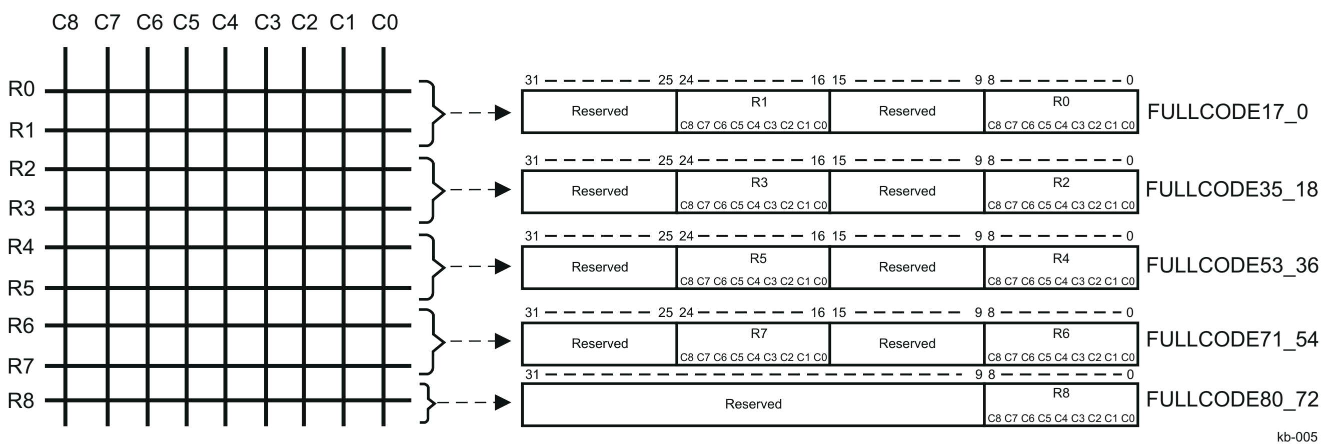

Figure 28-7. Key Coding Registers

Each of the 9 × 9 keyboard size supporting registers (KBD_FULLCODE17_0 to KBD_FULLCODE71_54) stores the state of two keyboard rows. The KBD_FULLCODE80_72 register stores the state of the last row, R8:

- The KBD_FULLCODE17_0 register code rows 0, 1 (row 0 is coded between bits 0 and 8, row 1 is coded between bits 16 and 24)
- The KBD_FULLCODE35_18 register code rows 2, 3 (row 2 is coded between bits 0 and 8, row 3 is coded between bits 16 and 24)
- The KBD_FULLCODE53_36 register code rows 4, 5 (row 4 is coded between bits 0 and 8, row 5 is coded between bits 16 and 24)
- The KBD_FULLCODE71_54 register code rows 6, 7 (row 6 is coded between bits 0 and 8, row 7 is coded between bits 16 and 24)
- The KBD_FULLCODE80_72 register code row 8 (row 8 is coded between bits 0 and 8)

In each of these registers (excluding KBD_FULLCODE80_72):

- Bit 0 corresponds to column(0) – row (i) key, … , bit 8 corresponds to column(8) – row (i) key.

- Bits from 9 to 15 are reserved.
- Bit 16 corresponds to column(0) – row (i + 1) key, … , bit 24 corresponds to column (8) – row (i + 1) key.
- Bits 31 to 25 are reserved, where i = 0, 2, 4, 6.

In the KBD_FULLCODE80_72 register, bit 0 corresponds to column (0) – row (8) key, …, the bit 8 corresponds to column (8) – row (8) key, and the remaining bits (from 9 to 31) are reserved.

Each of the 8 × 8-keyboard size supporting registers (KBD_FULLCODE31_0 and KBD_FULLCODE63_32) stores the state of four keyboard rows:

- The KBD_FULLCODE31_0 register code rows 0, 1, 2, and 3 (row 0 is coded between bits 0 and 7, row 1 is coded between bits 8 and 15, row 2 is coded between bits 16 and 23, and row 3 is coded between bits 24 and 31)
- The KBD_FULLCODE63_32 register code rows 4, 5, 6, and 7 (row 4 is coded between bits 0 and 7, row 5 is coded between bits 8 and 15, row 6 is coded between bits 16 and 23, and row 7 is coded between bits 24 and 31)

In these registers:

- KBD_FULLCODE31_0[0] corresponds to column (0) – row (0) key,…, KBD_FULLCODE31_0[7] corresponds to column (7) – row (0).
- KBD_FULLCODE31_0[8] corresponds to column (0) – row (1) key,..., KBD_FULLCODE31_0[15] corresponds to column (7) – row (1).
- KBD_FULLCODE31_0[16] corresponds to column (0) – row (2) key,..., KBD_FULLCODE31_0[23] corresponds to column (7) – row (2).
- KBD_FULLCODE31_0[24] corresponds to column (0) – row (3) key,..., KBD_FULLCODE31_0[31] corresponds to column (7) – row (3).
- KBD_FULLCODE63_32[0] corresponds to column (0) – row (4) key,..., KBD_FULLCODE63_32[7] corresponds to column (7) – row (4).
- KBD_FULLCODE63_32[8] corresponds to column (0) – row (5) key,..., KBD_FULLCODE63_32[15] corresponds to column (7) – row (5).
- KBD_FULLCODE63_32[16] corresponds to column (0) – row (6) key,..., KBD_FULLCODE63_32[23] corresponds to column (7) – row (6).
- KBD_FULLCODE63_32[24] corresponds to column (0) – row (7) key,..., KBD_FULLCODE63_32[31] corresponds to column (7) – row (7).

Note

The keyboard fullcode registers are not updated in software mode.

Note

When using a smaller keyboard (for example, 5 × 5 or 4 × 4), the bits of the unused columns/rows are not used.

28.4.8 Keyboard Controller Register Access

28.4.8.1 Write Registers Access

The keyboard module uses a posted-write scheme to update any internal registers. This means the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later due to a resynchronization in the functional clock domain. This has the advantage of not stalling the interconnect system or the CPU that requested the write transaction. For each functional register, a pending bit is provided that is set if there is a pending write access to this register. The pending bits are accessible in the keyboard pending write register (KBD_PENDING).

In this mode, it is mandatory that the CPU checks the pending bits before any write access in the functional registers. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can also lead to unexpected results).

A register read following a posted write (on the same register) may not read the previous write value if the write posted process is not complete. Software synchronization must be used to avoid noncoherent read.

This posted period is defined as the interval between the posted write access request and the reset of the pending bit in the KBD_PENDING register, and can be quantified:

T (reset posted bit maximum) = 3 × Ticlk + 3 × Tfuncclk

The time it takes to accomplish the writing is:

T (write accomplish maximum) = 1 × Ticlk + 3 × Tfuncclk

where:

Ticlk is the L4 interface clock period, and Tfuncclk is the functional clock period.

28.4.8.2 Read Registers Access

The keyboard module uses a posted-read scheme for reading any internal register. The read transaction is immediately acknowledged on the L4 interface. The value of the functional register to be read must be previously synchronized. This has the advantage of not stalling the interconnect system or the CPU that requested the read transaction.

The posted-read scheme can be used only if Freq(KBD_FCLK) < Freq(KBD_ICLK)/4.

28.5 Keyboard Controller Programming Guide

28.5.1 Keyboard Controller Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

28.5.1.1 Global Initialization

28.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the keyboard module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the keyboard. For more information, see Section 28.2, *Keyboard Controller Environment,* and Section 28.3, *Keyboard Controller Integration*.

Table 28-11 describes the global initialization of surrounding modules.

Table 28-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See *Power, Reset, and Clock Management*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow the keyboard controller IRQ to be mapped to certain device INTC line. For more information see Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description, in *Control Module*.
Interrupt controllers	Device INTCs must be configured to enable the interrupt request generation. For more information about enabling interrupts, see Chapter 17, Interrupt Controllers.
Control module	The pad configuration registers must be configured to map the keyboard interface signals to the device pads, to determine the signal directions and for all keyboard rows to enable the internal pull-ups of the associated IO cells . For more information about this configuration, see *Pad Configuration Registers.*

28.5.1.1.2 Keyboard Controller Global Initialization

28.5.1.1.2.1 Main Sequence – Keyboard Controller Global Initialization

This procedure initializes the keyboard controller after a POR or software reset (see Table 28-12).

Table 28-12. Keyboard Controller Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the debouncing time of filtering the glitches on pressing or releasing key.	KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value).	KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	0x–
Define the logical value of the column outputs (KEYPAD configuration) (logical 0 bit = active column-row).	KBD_COLUMNOUTPUTS[8:0] KBC_REG	0x–
Perform the functional configuration of the keyboard module and the prescale clock timer value.	KBD_CTRL	0x00000–
Clear the interrupt-status register.	KBD_IRQSTATUS	0x0000000F
Enable (0b1)/disable (0b0) certain keyboard events for generating an interrupt request.	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR [2:0] IT_..._EN	0x–
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	KBD_IRQWAKEEN[2:0] WUP_..._ENA	0x–

28.5.1.2 Operational Modes Configuration

28.5.1.2.1 Keyboard Controller in Hardware Decoding Mode (Default Mode)

28.5.1.2.1.1 Main Sequence – Keyboard Controller Hardware Mode

After reset, all available functional modes are disabled, except detect-event mode, which is always active. Table 28-13 describes the keyboard controller hardware mode.

Table 28-13. Keyboard Controller Hardware Mode

Step	Register/Bit Field/Programming Model	Value
Activate the internal keyboard controller sequencer by setting the bit.	KBD_CTRL[1] NSOFTWARE_MODE	0b1
Select the functional mode by setting its corresponding bit to 1.	KBD_CTRL[8:5]	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value).	KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	0x–
Configure the debouncing time of filtering the glitches on pressing or releasing key.	KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE	0x–
Clear the interrupt-status register.	KBD_IRQSTATUS	0x0000000F
Enable (by writing 1)/disable (by writing 0) certain keyboard event for generating an interrupt request	KBD_IRQENABLE_SET or KBD_IRQENABLE_CLR[2:0] IT_..._EN	0x–
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	KBD_IRQWAKEEN[2:0] WUP_..._ENA	0x–
Wait for the KBD_IRQ interrupt signal assertion.		
Read the interrupt-status register to determine which event caused the interrupt.	KBD_IRQSTATUS	
Read the KBD_FULLCODE17_0 to KBD_FULLCODE80_72 registers (or 8 × 8 keyboard-size-supporting KBD_FULLCODE31_0 and KBD_FULLCODE63_32 registers) to determine which key matrix combination was pressed.	KBD_FULLCODE17_0 [ROWi bits] (where i = 0 or 1) up to KBD_FULLCODE71_54 [ROWi bits] (where i = 6 or 7); KBD_FULLCODE80_72 [ROWi bits] (where i = 8); (or KBD_FULLCODE31_0[j] FULL_CODE_31_0 and KBD_FULLCODE63_32[k] FULL_CODE_63_32 bits (where j = 0 to 31, k = 32 to 63)	
Clear the corresponding bit(s) in the interrupt-status register by writing logical 1.	KBD_IRQSTATUS	0x1

Note

The long-key detection mode and the repeat mode cannot be used simultaneously, because they share the same interrupt status bit and are mutually exclusive. Software must ensure that only one of these modes at a time is selected.

Note

All interrupts are disabled on reset.

Note

When two events occur successively before the first event is read, the second interrupt is generated when the first interrupt is cleared. When more than two events in a row occur, the KBD_IRQSTATUS[3] MISS_EVENT bit is set. Software must check this bit, which is not reflected on the KBD_IRQ line.

Note

The keyboard controller uses a posted-write scheme to update any internal register. Software must read the pending write status bits to ensure that the next write access is not discarded because of ongoing write synchronization. For more information, see Section 28.4.8.1, *Write Registers Access*.

28.5.1.2.2 Keyboard Controller Software Scanning Mode

28.5.1.2.2.1 Main Sequence – Keyboard Controller Software Mode

Table 28-14 describes the keyboard controller software mode.

Table 28-14. Keyboard Controller Software Mode

Step	Register/Bit Field/Programming Model	Value D
Deactivate the internal keyboard controller sequencer by clearing the bit.	KBD_CTRL[1] NSOFTWARE_MODE	0b0
Enable the interrupt event by setting the bit.	KBD_IRQENABLE_SET[0] IT_EVENT_EN	0b1
Wait for the KBD_IRQ interrupt signal assertion. Begin the software scan when the interrupt signal is asserted:		
1) Disable all columns to drive a logical 0 on the kbd_col[8:0] output by writing 0xFF. (logical 1 bit = inactive column-row)	KBD_COLUMNOUTPUTS[8:0] KBC_REG	0xFF
2) Drive kbd_col(i) output, (where i = 0 to 8), to 0 to capture a pressed-key-event, at the corresponding row input.	KBD_COLUMNOUTPUTS[i] KBC_REG (where i = 0 to 8)	0b0
3) Read the KBR_LATCH bit field of the KBD_ROWINPUTS register to determine which is the pressed key. IF: KBR_LATCH k-bit = 0 , where k = 0 to 8 Then, the corresponding k-row is connected to the column being enabled.	KBD_ROWINPUTS[8:0] KBR_LATCH	
END IF		
Repeat step 2) and step 3) for all existing columns.	KBD_IRQWAKEEN[2:0] WUP_..._ENA	0x–

Note

In software mode, during the manual keyboard scan, an interrupt is generated when a pressed key is detected.

28.5.1.2.3 Using the Timer

For information about programming the keyboard controller timer, see Section 28.4.6.2, *Keyboard Controller Timer*.

28.5.1.2.4 State-Machine Status Register

To see the state of the state-machine, see Section 28.4.6.3, *State-Machine Status*.

28.5.1.3 Keyboard Controller Events Servicing

Table 28-15 lists the keyboard controller event servicing.

Table 28-15. Keyboard Controller Event Servicing

Step	Register/Bit Field/Programming Model	Value
Clear all eventual previous indications of treated interrupts; write the IRQSTATUS register:	KBD_IRQSTATUS	0x0000000F
Enable the desired sources of interrupt by writing in:	KBD_IRQENABLE	0x0000000–

Table 28-15. Keyboard Controller Event Servicing (continued)

Step	Register/Bit Field/Programming Model	Value
Unmask (enable) the desired sources of interrupt by writing logical 1 in the desired bit fields.	KBD_IRQWAKEEN	0x0000000–
When event occurs:		
Read the status register.	KBD_IRQSTATUS	
IF: KBD_IRQSTATUS[3] MISS_EVENT = 1	Start the interrupt handler for missed event.	
ELSIF: KBD_IRQSTATUS[2] IT_TIMEOUT = 1	Start the interrupt handler for timeout event.	
ELSIF: KBD_IRQSTATUS[1] IT_LONG_KEY = 1	Start the interrupt handler for long key pressed event.	
ELSIF: KBD_IRQSTATUS[0] IT_EVENT = 1	Start the interrupt handler for pressed key event.	
ENDIF		
Wait for the execution of the corresponding interrupt handler.	Interrupt controller of the MPU	
Clear the corresponding IRQ status register bits by writing 1 there.	KBD_IRQSTATUS	0x0000000–
Disable the corresponding sources of interrupt if needed by writing 0 at the corresponding bit fields.	KBD_IRQENABLE or KBD_IRQWAKEEN	0x0000000-
Read the status register.	KBD_IRQSTATUS	
IF :	KBD_IRQSTATUS[2] IT_TIMEOUT	=1
Handle the timeout event.		
Clear the corresponding status flag.	KBD_IRQSTATUS[2] IT_TIMEOUT	0x1
ELSE IF:	KBD_IRQSTATUS[1] IT_LONG_KEY	=1
Handle the long pressed key event.		
Clear the corresponding status flag.	KBD_IRQSTATUS[1] IT_LONG_KEY	0x1
ELSE IF:	KBD_IRQSTATUS[0] IT_EVENT	=1
Handle the pressed key event.		
Clear the corresponding status flag.	KBD_IRQSTATUS[0] IT_EVENT	0x1
ENDIF		
Disable the interrupts if needed.	KBD_IRQENABLE_CLR[2:0]	0x1

28.6 Keyboard Controller Register Manual

Chapter 29

Pulse-Width Modulation Subsystem

This chapter describes the Pulse-Width Modulation (PWM) subsystem in the device.

29.1 PWM Subsystem Resources 6693
29.2 Enhanced PWM (ePWM) Module 6708
29.3 Enhanced Capture (eCAP) Module 6802
29.4 Enhanced Quadrature Encoder Pulse (eQEP) Module 6824

29.1 PWM Subsystem Resources

29.1.1 PWMSS Overview

The device has three embedded Pulse Width Modulation Subsystems (PWMSS1, PWMSS2 and PWMSS3). Each PWMSS includes one instance of :

- Enhanced High Resolution Pulse Width Modulator (eHRPWM)
- Enhanced Capture (eCAP)
- Enhanced Quadrature Encoded Pulse (eQEP)

Figure 29-1 shows an overview of each of the 3 available on the device PWM-subsystems.

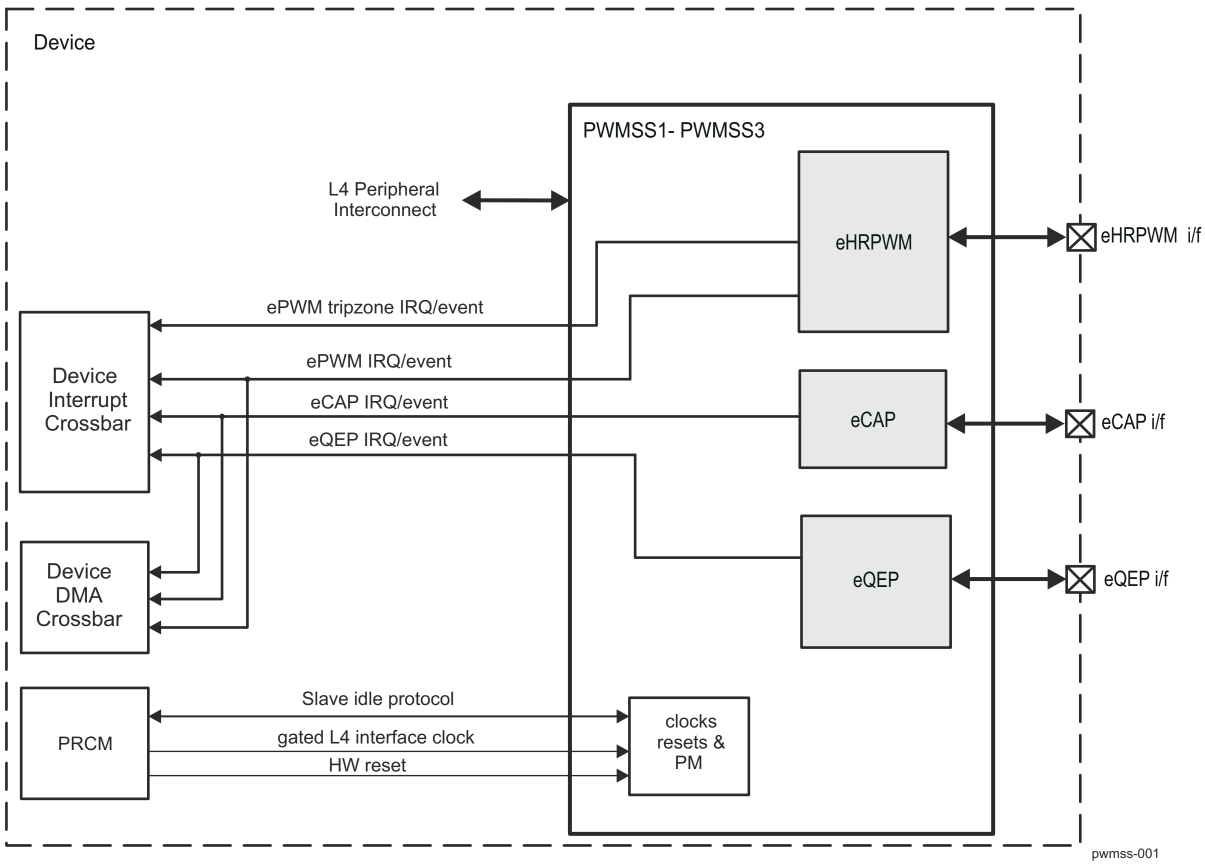

Figure 29-1. PWMSS Block Diagram

29.1.1.1 PWMSS Key Features

The supported features by the device PWMSS-s are:

eHRPWM

- Dedicated 16 bit time-base with Period/Frequency control
- Can support 2 independent PWM outputs with Single edge operation
- Can support 2 independent PWM outputs with Dual edge symmetric operation
- Can support 1 independent PWM output with Dual edge asymmetric operation
- Supports Dead-band generation with independent Rising and Falling edge delay control
- Provides asynchronous over-ride control of PWM signals during fault conditions
- Supports “trip zone” allocation of both latched and un-latched fault conditions
- Allows events to trigger both CPU interrupts and start of ADC conversions
- Support PWM chopping by high frequency carrier signal, used for pulse transformer gate drives.
- High-resolution module with programmable delay line:

- – Programmable on a per PWM period basis
- – Can be inserted either on the rising edge or falling edge of the PWM pulse or both or not at all

eCAP

- Dedicated input Capture pin
- 32 bit Time Base (counter)
- 4 x 32 bit Time-stamp Capture registers (PWMSS_ECAP_CAP1 - PWMSS_ECAP_CAP4)
- 4 stage sequencer (Mod4 counter) which is synchronized to external events (ECAPx pin edges)
- Independent Edge polarity (Rising/Falling edge) selection for all 4 events
- Input Capture signal pre-scaling (from 1 to 16)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 Time-stamp events
- Control for continuous Time-stamp captures using a 4 deep circular buffer (PWMSS_ECAP_CAP1 - PWMSS_ECAP_CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

eQEP

- Input Synchronization
- Three Stage/Six Stage Digital Noise Filter
- Quadrature Decoder Unit
- Position Counter and Control unit for position measurement
- Quadrature Edge Capture unit for low speed measurement
- Unit Time base for speed/frequency measurement
- Watchdog Timer for detecting stalls

At a PWMSS system level :

- each of the three PWMSS generates 2x eHRPWM, 1x eCAP and 1x eQEP event mapped to both the device IRQ crossbar.
- Three of the interrupt events (excluding ePWM tripzone event) are also mapped as DMA requests to the device DMA crossbar.
- The different PWMSS - ePWM/eHRPWM and eCAP modules have their synchronization input /output signals coupled in a daisy chain implemented between PWMSS1, PWMSS2 and PWMSS3 within the device.

29.1.1.2 PWMSS Unsupported Fetaures

The PWMSS limitations in the device are :

- No ePWM inputs are pinned-out (available at the off-chip boundary)
- Only one ePWM tripzone input is pinned-out
- No ePWM digital comparator inputs are pinned-out
- Only input signals of QEP are pinned-out.

Table 29-1. PWMSS Unsupported Features

Feature	Reason
ePWM inputs	Not pinned out
ePWM tripzone 1-5 inputs	Only Tripzone0 is pinned out
ePWM digital comparators	Inputs not connected
eQEP quadrature outputs	Only input signals are connected

29.1.2 PWMSS Environment

29.1.2.1 PWMSS I/O Interface

Table 29-2 shows the device integrated PWMSS subsystems interface signals to external devices.

Table 29-2. PWM Subsystems I/O Signals

PWMSS Modules Level Signal Name	Device Level Signal Name	I/O Type[(1)]	Description	Module Pin Reset Value
		PWMSS1		
EPWM1A	ehrpwm1A	O	PWM1 output A	0
EPWM1B	ehrpwm1B	O	PWM1 output B	0
EPWM1SYNCI	ehrpwm1_synci	I	PWM1 Sync input	HiZ

$\overline{\text{EPWM2\_TRIP\_TZ[0]}}$	ehrpwm2_tripzone_input	I	PWM2 TripZone input	HiZ
ECAP2_CAPIN_APWMOUT	eCAP2_in_PWM2_out	I/O	eCAP2 Capture input/PWM2 output	HiZ
EQEP2_A	eQEP2A_in	I	eQEP2 Quadrature input	HiZ
EQEP2_B	eQEP2B_in	I	eQEP2 Quadrature input	HiZ
EQEP2_INDEX	eQEP2_index	I/O	eQEP2 Index input/output	HiZ
EQEP2_STROBE	eQEP2_strobe	I/O	eQEP2 Strobe input/output	HiZ
		PWMSS3		
EPWM3A	ehrpwm3A	O	PWM3 output A	0
EPWM3B	ehrpwm3B	O	PWM3 output B	0
$\overline{\text{EPWM3\_TRIP\_TZ[0]}}$	ehrpwm3_tripzone_input	I	PWM3 TripZone input	HiZ
ECAP3_CAPIN_APWMOUT	eCAP3_in_PWM3_out	I/O	eCAP3 Capture input/PWM3 output	HiZ
EQEP3_A	eQEP3A_in	I	eQEP3 Quadrature input	HiZ
EQEP3_B	eQEP3B_in	I	eQEP3 Quadrature input	HiZ
EQEP3_INDEX	eQEP3_index	I/O	eQEP3 Index input/output	HiZ
EQEP3_STROBE	eQEP3_strobe	I/O	eQEP3 Strobe input/output	HiZ

(1) I = Input; O = Output

Note

The PWMSSn (where n=1 to 3 synchronization I/O signals which are NOT available at chip pad level are as follows:

- ePWM2SYNCI/SYNCO, ePWM3SYNCI/SYNCO
- eCAP1SYNCI/SYNCO, eCAP2SYNCI/SYNCO, eCAP3SYNCI/SYNCO

These signals are interconnected via a daisy chain implemented within the device. See also Section 29.1.3.1.2.

For more details on synchronization daisy-chain which exist between the PWMSS1, PWMSS2 and PWMSS3, refer to the Section 29.1.3.1.2 .

Figure 29-2 shows the external interface I/Os for the integrated modules in PWMSSn (where n=1 to 3) .

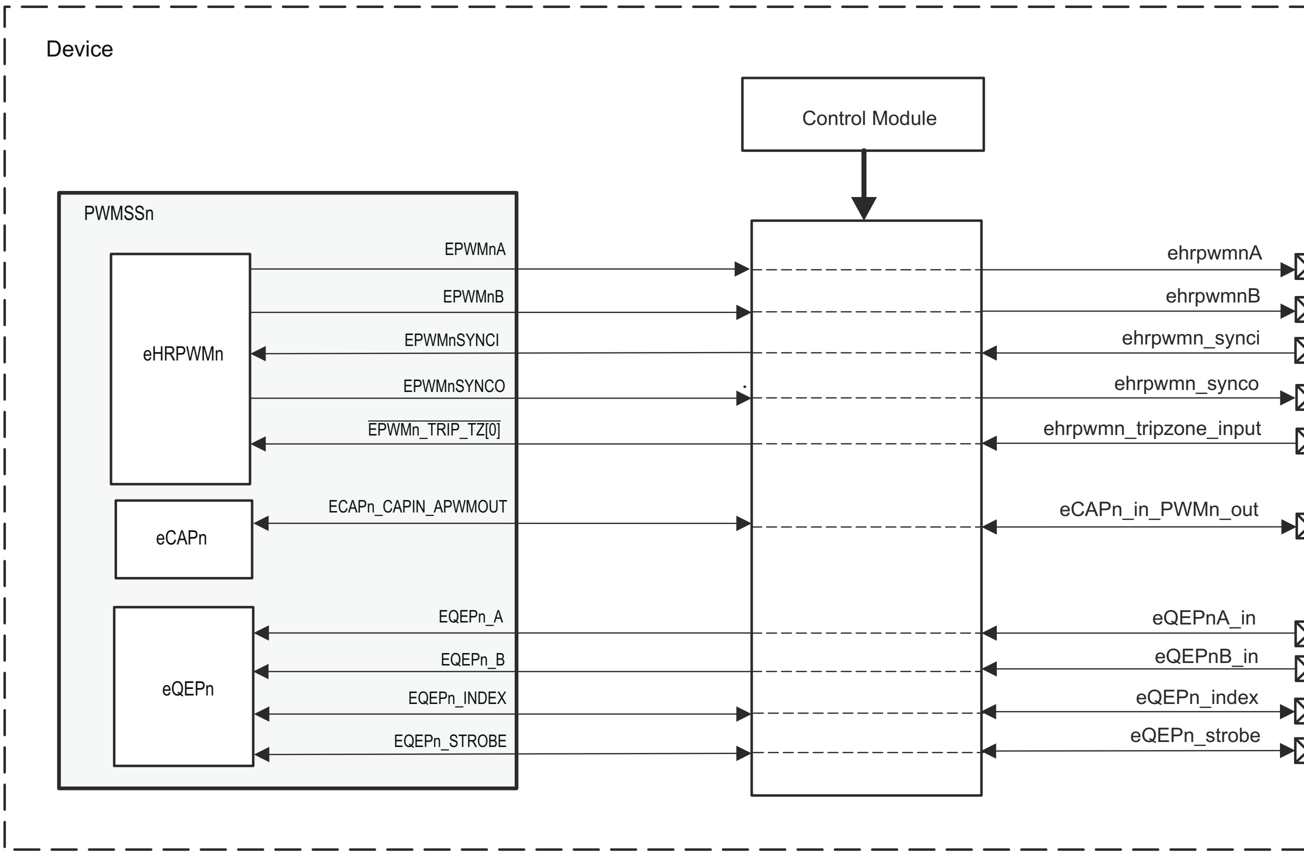

Figure 29-2. PWMSS External Interface I/Os

Note

The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the *Pad Configuration Registers*, in the chapter, *Control Module*.

29.1.3 PWMSS Integration

There are three instances of the PWMSS integrated in the device. Each of the the Pulse Width Modulation Subsystems (PWMSS) includes a single instance of one pulse width modulator (ePWM) including an Enhanced High Resolution Modulator (eHRPWM), one Enhanced Capture (eCAP), and one Enhanced Quadrature Encoded Pulse (eQEP) modules.

Note

Let's assume that the letter "x" is used to denote the number of a PWMSS submodule (ePWM/eCAP and eQEP) within the device, and NOT within the PWMSSn itself. Because there is only one ePWM/ eCAP and eQEP per device PWMSS, device point of view, the index - "x" of a module matches the PWMSS index "n". Therefore the ePWM1/eHRPWM1, eCAP1 and eQEP1 correspond to PWMSS1; ePWM2/eHRPWM2/eCAP2 and eQEP2 correspond to PWMSS2; ePWM3/eHRPWM3/eCAP3 and eQEP3 correspond to PWMSS3, i.e. x=n.

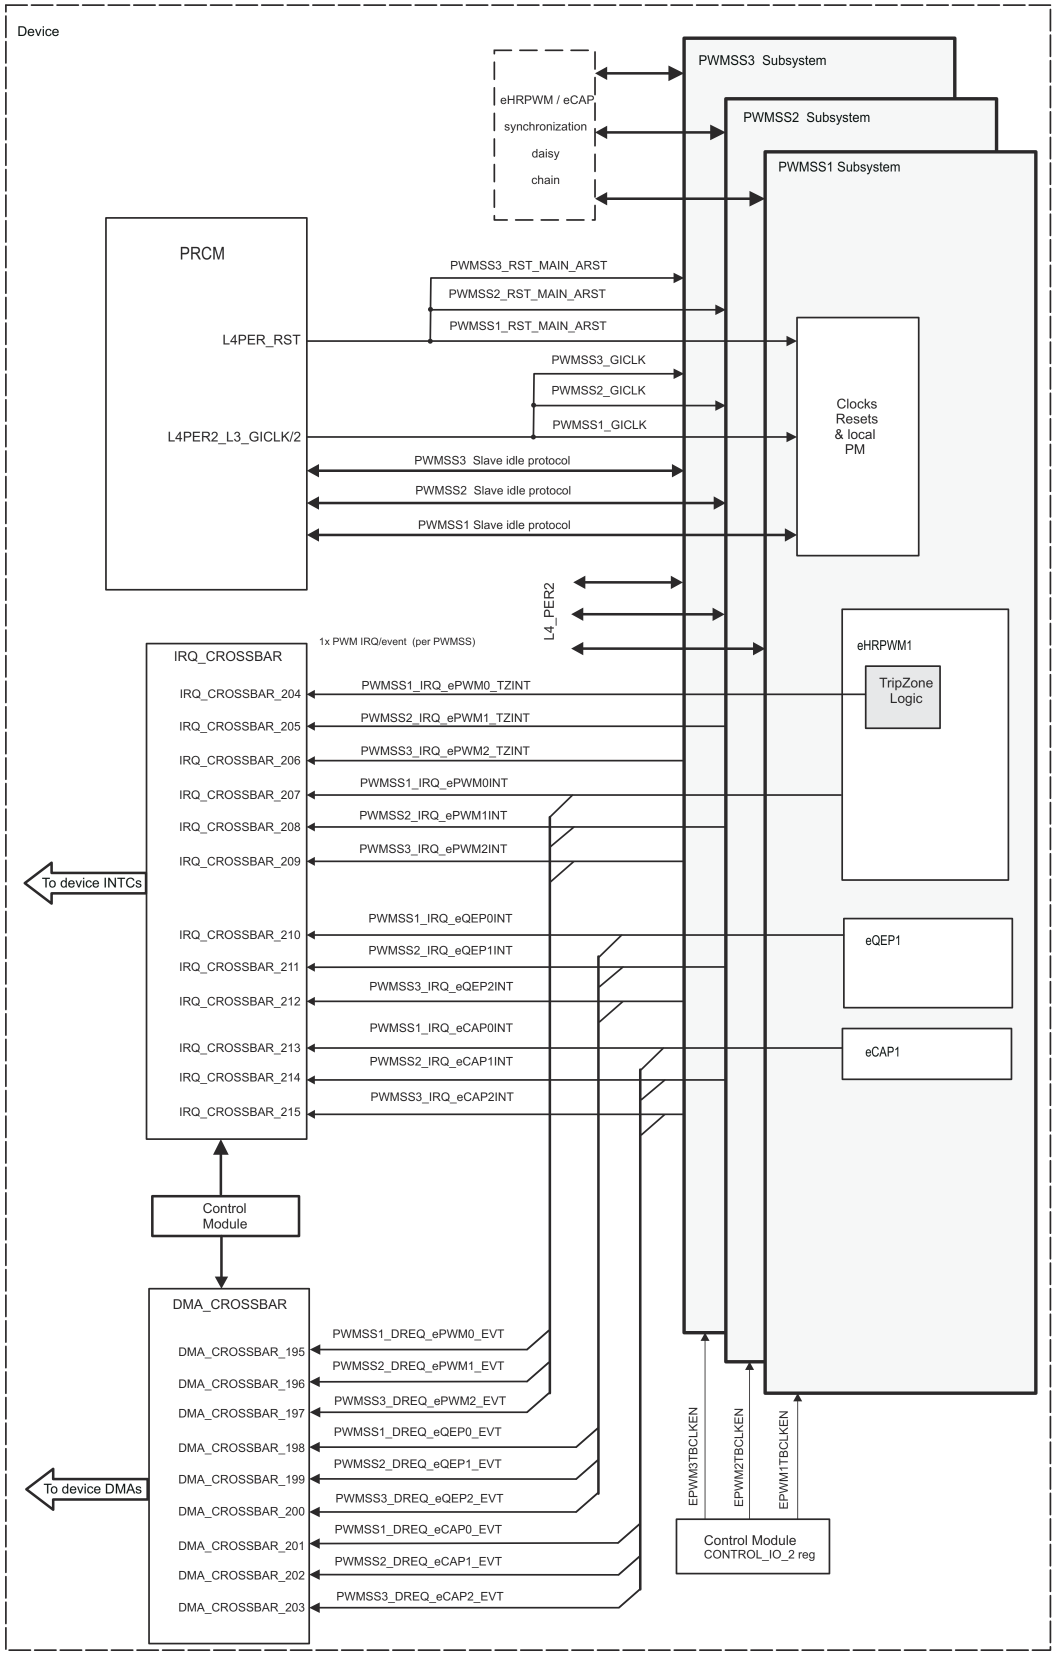

Figure 29-3. PWMSS Integration

At system level the PWMSS1 through PWMSS3 integration features:

- A 32-bit slave configuration port on the L4_PER2 interconnect.
- A single gateable interface and functional clock from PRCM shared between the 3 PWMSS.
- A slave idle protocol with the device PRCM
- A "non-wakeup capable Smart Idle" mode supported

Note

For more information about the slave idle protocol, see *Module Level Clock Management* in *Power, Reset, and Clock Management*.

- A non-retention hardware reset from PRCM to all 3 PWMSS simultaneously
- A PWMSS global level software reset which imapcts all registers of a PWMSS at the same time
- 4 hardware events per PWMSS, i.e. a total of 12 events. From these events each PWMSS :
  – generates 4 interrupts to the device IRQ_CROSSBAR
  – generates 3 DMA requests, mapped to the device DMA_CROSSBAR
- A synchronization input/output daisy chain-like connection exists between the PWMSS1,PWMSS2 and PWMSS3. For more details, refer to Section 29.1.3.1.2.

Table 29-3 through Table 29-5 summarize the integration of the module in the device.

Table 29-3. PWMSS Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
PWMSS1	PD_COREAON	L4_PER2

	PWMSS3_IRQ_ePWM2INT	IRQ_CROSSBAR_209	-	eHRPWM3 event/interrupt.
	PWMSS3_IRQ_eQEP2INT	IRQ_CROSSBAR_212	-	eQEP3 event/interrupt.
	PWMSS3_IRQ_eCAP2INT	IRQ_CROSSBAR_215	-	eCAP3 event/interrupt.
		DMA Requests		
Module Instance	**Source Signal Name**	**Destination DMA_CROSSBAR Input**	**Default Mapping**	**Description**
PWMSS1	PWMSS1_DREQ_ePWM0_EVT	DMA_CROSSBAR_195	-	eHRPWM1 event DMA request.
	PWMSS1_DREQ_eQEP0_EVT	DMA_CROSSBAR_198	-	eQEP1 event DMA request.
	PWMSS1_DREQ_eCAP0_EVT	DMA_CROSSBAR_201	-	eCAP1 event DMA request.
PWMSS2	PWMSS2_DREQ_ePWM1_EVT	DMA_CROSSBAR_196	-	eHRPWM2 event DMA request.
	PWMSS2_DREQ_eQEP1_EVT	DMA_CROSSBAR_199	-	eQEP2 event DMA request.
	PWMSS2_DREQ_eCAP1_EVT	DMA_CROSSBAR_202	-	eCAP2 event DMA request.
PWMSS3	PWMSS3_DREQ_ePWM2_EVT	DMA_CROSSBAR_197	-	eHRPWM3 event DMA request.
	PWMSS3_DREQ_eQEP2_EVT	DMA_CROSSBAR_200	-	eQEP3 event DMA request.
	PWMSS3_DREQ_eCAP2_EVT	DMA_CROSSBAR_203	-	eCAP3 event DMA request.

Note

The “Default Mapping” column inTable 29-5,*PWMSS Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

For more information about the device DMA_SYSTEM module, see Section 16.1, *System DMA*.

For more information about the device EDMA module, see Section 16.2, *Enhanced DMA*.

29.1.3.1 PWMSS Module Interfaces Implementation

This section describes how the different PWMSSn (where n=1 to 3 for the device) submodules - ePWM/ eHRPWM, eQEP and eCAP can be used in terms of their functional interfaces considering PWMSS **device specific integration**.

29.1.3.1.1 Device Specific PWMSS Features

A High-Resolution PWM (HRPWM) modulator is added to the ePWM module in each of the device PWMSS subsystems, hence the device ePWMs are signified as eHRPWMs.

Note

The HR PWM option applies only to the ePWMxA output channel of the PWMSSn (ehre n=1 to 3 for the device). The PWMSSn ePWMxB channel has conventional capabilities. For more details on HRPWM features of ePWM modules refer to the Section 29.2.45 .

While the eCAP functionalities are fully implemented in the device, the eHRPWM and eQEP module interface have some restrictions in functionality. The eHRPWM and eQEP restrictions which are common between the PWMSS1, PWMSS2 and PWMSS3 subsystems are, as follows:

- For ePWM comparators - only the outputs (ehrpwmxA and ehrpwmxB) are available at chip level
- Only one tripzone input pin - EPWMx_TRIP_TZ[0] of ePWM/eHRPWM is available to user at chip level
- Only QEP inputs (A/ B/INDEX and STROBE) are available to user at chip level

The eHRPWM and eQEP functional interface signals which are NOT available to user for the PWMSS1, PWMSS2 and PWMSS3 are summarized in Table 29-6.

Table 29-6. Device Limitations for the eHRPWM and eQEP Functional Interfaces of PWMSSn

Module Interface	Signal	Description	Comment
PWMSSn eHRPWM (where n= 1 to 3)	EPWM_COMP_EPWMDCMAH	ePWM Comparator A input (HIGH)	Not available at chip boundary (can not be used)
	EPWM_COMP_EPWMDCMAL	ePWM Comparator A input (LOW)	
	EPWM_COMP_EPWMDCMBH	ePWM Comparator B input (HIGH)	
	EPWM_COMP_EPWMDCMBL	ePWM Comparator B input (LOW)	
	EPWM_EPWMA_i	ePWM A input	
	EPWM_EPWMB_i	ePWM B input	
	EPWM_TRIP_TZ[5:1]	ePWM Tripzone inputs [5:1]	
	EPWM_ADC_SOCA	ePWM Start of ADC conversion A output	
	EPWM_ADC_SOCB	ePWM Start of ADC conversion B output	
	EPWM_TRIP_TZ_O[5:0]	ePWM Tripzone outputs	
PWMSSn eQEP (where n= 1 to 3)	EQEP_ERR_PHASE_ERR	eQEP phase error output	Not available at chip boundary (can not be used)
	EQEP_EQEPA_O	eQEP quadrature A output	
	EQEP_EQEPB_O	eQEP quadrature B output	

Note

Only for the device eHRPWM1 module, the SYNCI input and SYNCO output signals are available at chip-level – these are the signals ehrpwm1_synci and ehrpwm1_synco, respectively. The eHRPWM2 and eHRPWM3 SYNCi and SYNCO signals are not available on device pads. For more information, see section, PWMSS Environment.

29.1.3.1.2 Daisy-Chain Connectivity between PWMSS Modules

The PWM (eHRPWM) and capture (eCAP) components of the PWMSSn (where n= 1 through 3 for the device) provide synchronization signals to allow them to be synchronized to other modules or events. In the device, these signals are connected in a daisy-chain fashion as shown in Figure 29-4. Only the PWMSS1 eHRPWM input synchronization signal is terminated at a device pad (ehrpwm1_synci signal), such that device external sync events can be directly applied only to the PWMSS1 eHRPWM (eHRPWM1) submodule. A synchronization output from device PWMSS is available only from the eHRPWM1 on the ehrpwm1_synco output pin . The PWMSS2 and PWMSS3 rely on synchronization signals from its neighbour PWM subsystem within device ,as shown in Figure 29-4.

Note

The PWMSS1.EPWM1SYNCI signal (device ehrpwm1_synci input signal) triggers the event of the eHRPWM1 Phase Register being loaded into the Counter register (TBCNT -> TBPHS). This event is synchronous to the PWMSS1 eHRPWM **time-base clock** (TBCLK).

The PWMSS1 EPWM1SYNCO (device ehrpwm1_synco output signal) is implicitly synchronous to the time-base clock, as this signal has a programmable source of event (in EPWM_TBCTL[5:4] SYNCOSEL) triggered synchronously to the eHRPWM1 TBCLK.

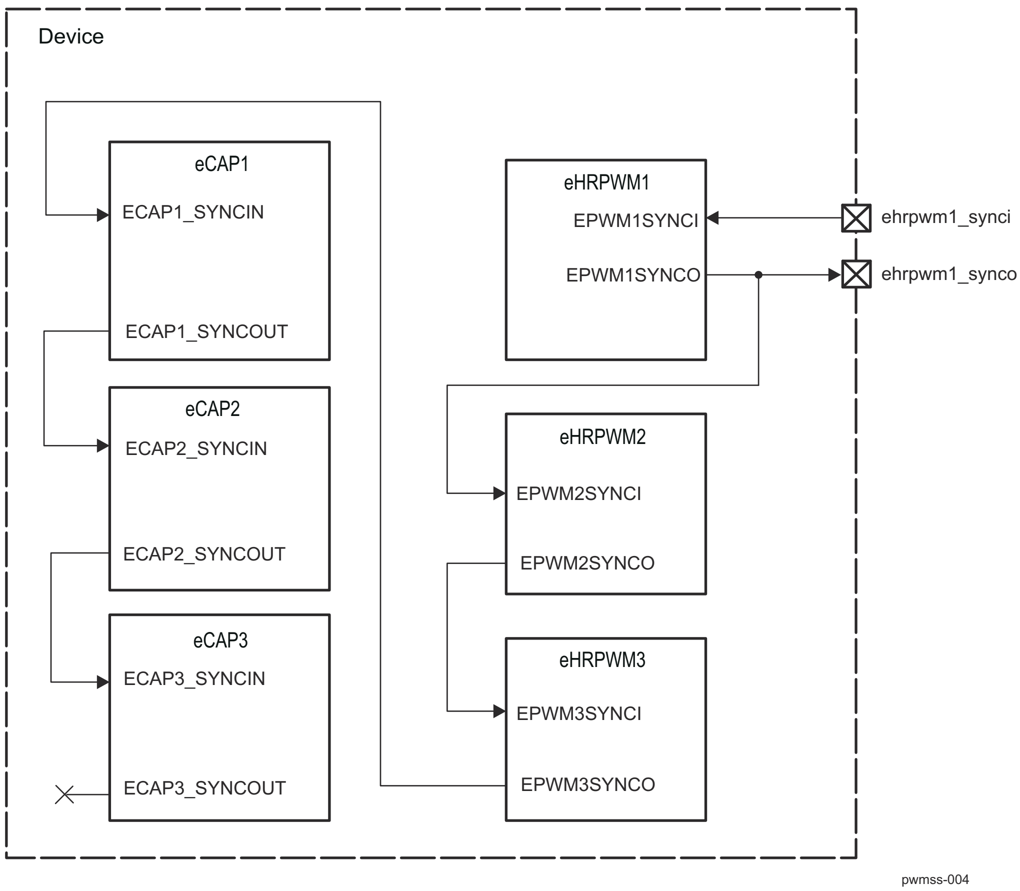

Figure 29-4. Synchronization between PWMSS1, PWMSS2 and PWMSS3

29.1.3.1.3 eHRPWM Modules Time Base Clock Gating

Each PWMSSn ePWM/eHRPWM module has an EPWMTBCLKEN module input used to individually enable/disable its ePWM time-base clock. For each PWMSSn (where n=1 to 3), the ePWM/eHRPWM time-base clock enable input comes from the device core control module register - CTRL_CORE_CONTROL_IO_2, as follows:

- PWMSS1 ePWM -> CTRL_CORE_CONTROL_IO_2[22] PWMSS3_TBCLKEN bit
- PWMSS2 ePWM -> CTRL_CORE_CONTROL_IO_2[21] PWMSS2_TBCLKEN bit
- PWMSS3 ePWM -> CTRL_CORE_CONTROL_IO_2[20] PWMSS1_TBCLKEN bit

This individual TBCLKEN control can be used to align the ePWM time base clock between the three device PWMSS subsystems. PWMSSn_TBCLKEN bit set to 0b0, holds the TBCLK generation counter in its reset state. When PWMSSn_TBCLKEN is set to 0b1, then the TBCLK generation counter is allowed to count.

For more details on the CTRL_CORE_CONTROL_IO_2, refer to the *Control Module Register Manual*, in the chapter *Control Module*.

29.1.4 PWMSS Subsystem Power, Reset and Clock Configuration

29.1.4.1 PWMSS Local Clock Management

The system configuration register - PWMSS_SYSCONFIG is used to configure the local clock management of a PWMSSn slave configuration port on the device L4_PER2 interconnect. Note that this register impacts the behaviour of the root interface and functional clock PWMSSn_GICLK inside PWMSSn (n=1 to 3) shared between the ePWM/eHRPWM, eQEP and eCAP modules within a subsystem. An idle handashake protocol is supported between PWMSSn and the device PRCM.

Note

For more information about the slave idle protocol, see *Module Level Clock Management* in *Power, Reset, and Clock Management*.

Table 29-7. Local IDLE Clock Management Features

Feature	Register bitfield	Description
Slave idle mode	PWMSS_SYSCONFIG[3:2] IDLEMODE	The available modes are: Force-idle, no-idle, and smart-idle (non-wakeup capable) modes.

Note

The device PWM subsystems are part of the CD_L4_PER2 clock domain. For more details on the PWM subsystems top level clock-management modes and control, refer to the *Clock Domain Module Attributes*, in the *Power, Reset, and Clock Management*.

29.1.4.2 PWMSS Modules Local Clock Gating

Note

PWMSS Modules Local Clock Gating feature is not supported in this family of devices.

In addition to PWMSS level IDLE clock management, described above, a clock configuration register - PWMSS_CLKCONFIG is used to individually gate (stop) or enable interface and functional clock to the ePWM/eHRPWM, eCAP and eQEP modules. By default, the interface/functional clocks are enabled to all modules.

The clock status register - PWMSS_CLKSTATUS is used in the PWMSS submodule to indicated acknowledgement of a clock stop or clock enable request.

The PWMSS_CLKCONFIG and PWMSS_CLKSTATUS role is described in Table 29-8.

Table 29-8. Local Module Clock Control and Status Features

Clock Control/Status Feature	PWMSSn Module	Register bit
Request "stop interface and functional clock" to module	ePWM/eHRPWM	PWMSS_CLKCONFIG[9] EPWM_CLKSTOP_REQ
	eQEP	PWMSS_CLKCONFIG[5] EQEP_CLKSTOP_REQ
	eCAP	PWMSS_CLKCONFIG[1] ECAP_CLKSTOP_REQ
"Stop module interface and functional clock" acknowledged status	ePWM/eHRPWM	PWMSS_CLKSTATUS[9] EPWM_CLKSTOP_ACK
	eQEP	PWMSS_CLKSTATUS[5] EQEP_CLKSTOP_ACK

"Enable module Interface and functional clock" acknowledged status	ePWM/eHRPWM	PWMSS_CLKSTATUS[8] EPWM_CLK_EN_ACK
	eQEP	PWMSS_CLKSTATUS[4] EQEP_CLK_EN_ACK
	eCAP	PWMSS_CLKSTATUS[0] ECAP_CLK_EN_ACK

Note

In order for PWMSSn to enter "Idle state", all PWMSSn submodules must have acknowledged a stop clock request, i.e. the PWMSS_CLKSTATUS bits EPWM_CLKSTOP_ACK, ECAP_CLKSTOP_ACK and EQEP_CLKSTOP_ACK must be raised 'HIGH'.

29.1.4.3 PWMSS Software Reset

The PWMSS_SYSCONFIG[0] SOFTRESET bit can be used to exert a "PWMSS" software reset impacting ePWM/eHRPWM, eCAP and eQEP modules of PWMSSn at the same time. The software has to poll the same bit until it is deasserted by HW, to insure software reset of all modules is completed.

29.1.5 PWMSS_CFG Register Manual

This section provides description of the PWM subsystem (top) level functional registers.

29.1.5.1 PWMSS_CFG Instance Summary

Table 29-9. PWMSS_CFG Instance Summary

Module Name	Module Base Address L4_PER2 Interconnect	Size (Bytes)
PWMSS1_CFG	0x4843 E000	48 Bytes
PWMSS2_CFG	0x4844 0000	48 Bytes
PWMSS3_CFG	0x4844 2000	48 Bytes

29.2 Enhanced PWM (ePWM) Module

29.2.1 ePWM Overview

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

As already described in Section 29.1.3, the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1, EPWM2A and EPWM2B belong to ePWM2, etc.

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. A given ePWM module functionality can be extended with the so called **High-Resolution Pulse Width modulator**. Refer to the Section 29.1.3, to determine which ePWM instances include the HRPWM feature. The HRPWM functionalities are described in Section 29.2.45 . Each ePWM module is indicated by a numerical value starting with 1. For example ePWM1 is the first instance, the ePWM2 is the second instance in the device, etc. The ePWMx indicates any instance.

As also described in Section 29.1.3.1.2, the ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, the PWMSSn integration allows this synchronization scheme to be extended to the capture peripheral modules (eCAP). The number of modules is device-dependent and based on target application needs. Modules can also operate stand-alone.

Each ePWM module supports the following features:

- **Dedicated 16-bit time-base counter with period and frequency control**
- **Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:**
  – Two independent PWM outputs with single-edge operation
  – Two independent PWM outputs with dual-edge symmetric operation
  – One independent PWM output with dual-edge asymmetric operation
- **Asynchronous override control of PWM signals through software.**
- **Programmable phase-control support for lag or lead operation relative to other ePWM modules.**
- **Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.**
- **Dead-band generation with independent rising and falling edge delay control.**
- **Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.**
- **A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.**
- **Programmable event prescaling minimizes CPU overhead on interrupts.**
- **PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.**

Each ePWM module is connected to the input/output signals shown in Figure 29-5. The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected may differ from what is shown in Figure 29-5. See Section 29.1.3.1.2 for the actual synchronization scheme implemented in the device. Each ePWM module consists of seven submodules and is connected within a system via the signals shown in Figure 29-6.

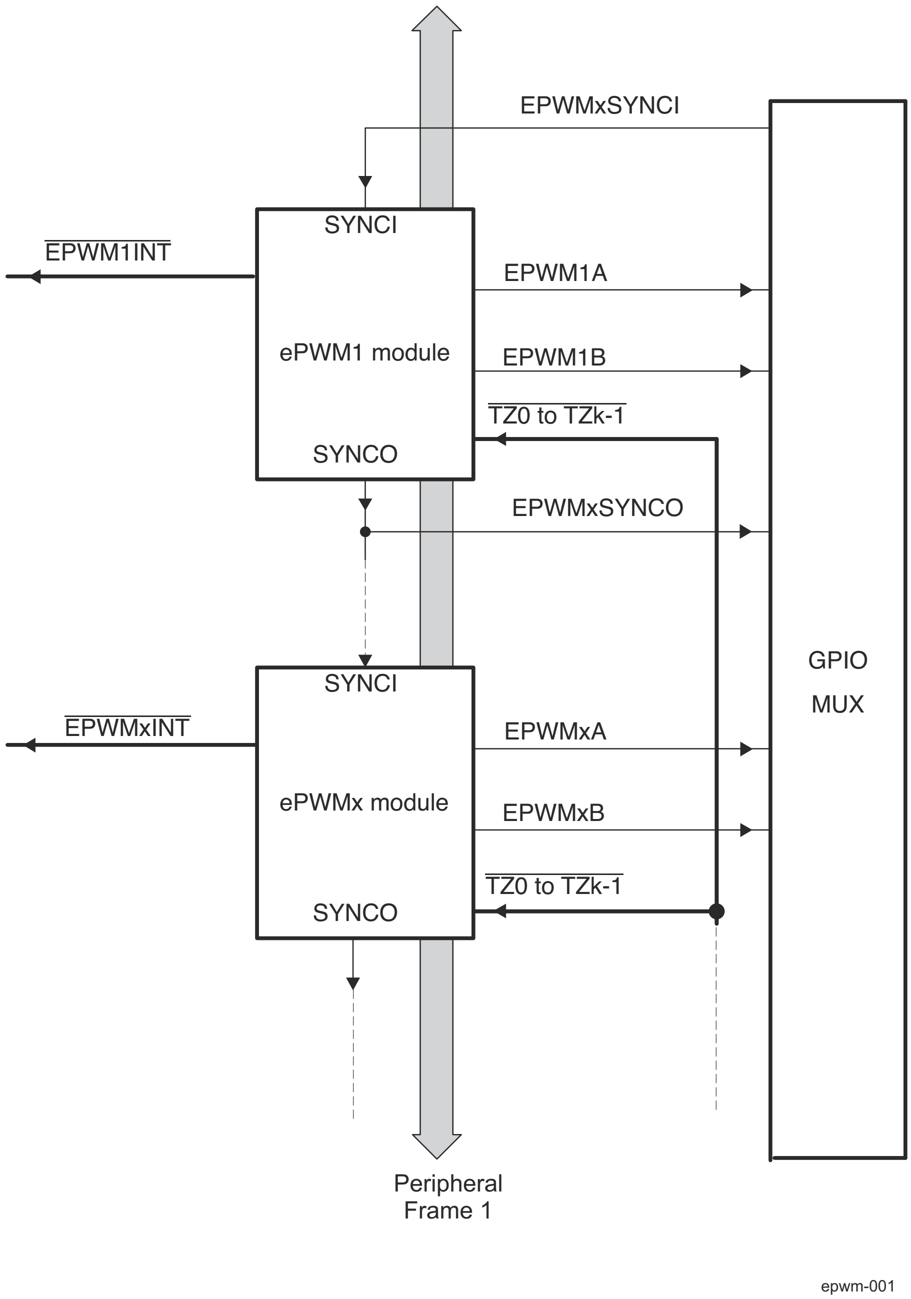

Figure 29-5. Multiple ePWM Modules

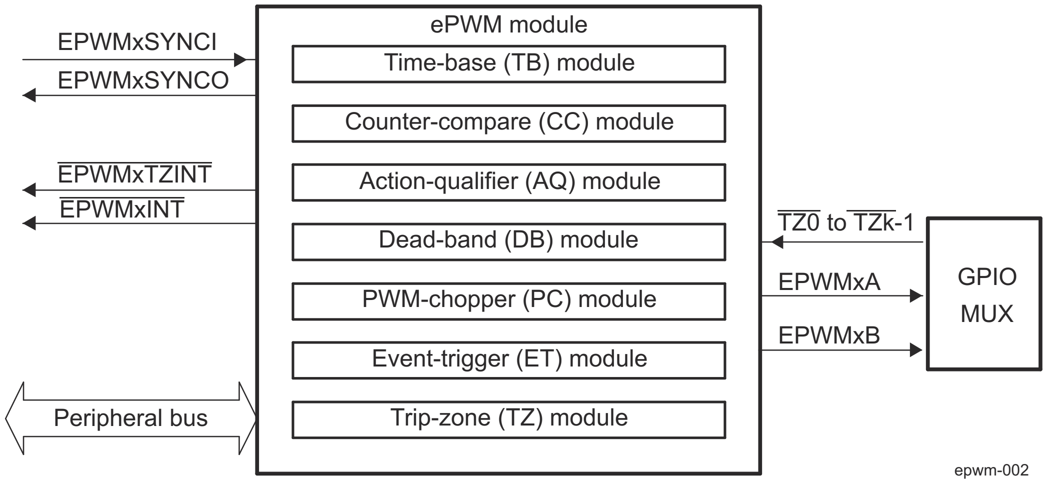

Figure 29-6. Submodules and Signal Connections for an ePWM Module

Figure 29-7 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for your device.
- **Trip-zone signals ($\overline{TZ0}$ to $\overline{TZk\text{-}1}$).** These **k** input signals alert the ePWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral.

Note

According to the device ePWMx (where x= 1to 3) trip zone i/f implementation, the number of input signals implemented is k=1, which means **ONLY the ePWMx $\overline{TZ0}$ input is available at chip level**. Refer to the Section 29.1.3, for details on trip zone input implementation.

- **Time-base synchronization input (EPWMxSYNCI) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). **The synchronization output for ePWM3 (EPWM3SYNCO) is also connected to the eCAP1SYNCI of the first enhanced capture module (eCAP1).**
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

Figure 29-7 also shows the key internal submodule interconnect signals. Each submodule is described in Section 29.2.2 .

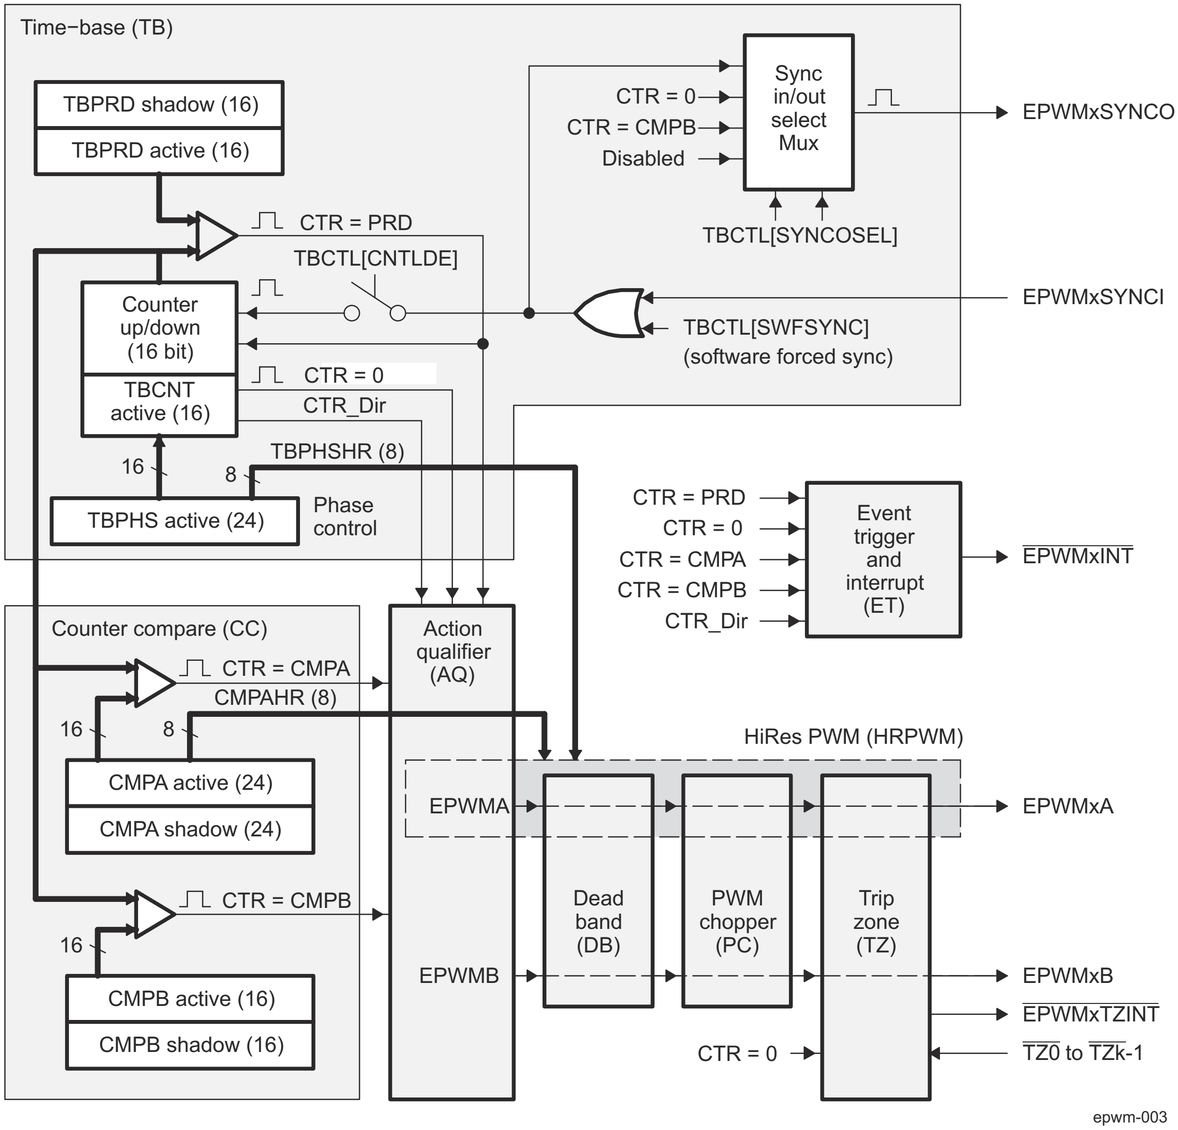

Figure 29-7. ePWM Submodules and Critical Internal Signal Interconnects

29.2.2 ePWM Functional Description

Seven submodules are included in each ePWM peripheral. There are some instances that include a high-resolution submodule that allows more precise control of the PWM outputs. Each of these submodules performs specific tasks that can be configured by software.

29.2.3 ePWM Submodule Features

Table 29-15 lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in Section 29.2.14 for relevant details.

Table 29-15. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	• Scale the time-base clock (TBCLK) relative to the system clock (SYSCLKOUT). • Configure the PWM time-base counter (TBCNT) frequency or period. • Set the mode for the time-base counter: – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Configure how the time-base counter will behave when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module: – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated.
Counter-compare (CC)	• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output
Action-qualifier (AQ)	• Specify the type of action taken when a time-base or counter-compare submodule event occurs: – No action taken – Output EPWMxA and/or EPWMxB switched high – Output EPWMxA and/or EPWMxB switched low – Output EPWMxA and/or EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead-band through software
Dead-band (DB)	• Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification.
PWM-chopper (PC)	• Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.

Table 29-15. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	• Configure the ePWM module to react to one, all, or none of the trip-zone pins. • Specify the tripping action taken when a fault occurs: – Force EPWMxA and/or EPWMxB high – Force EPWMxA and/or EPWMxB low – Force EPWMxA and/or EPWMxB to a high-impedance state – Configure EPWMxA and/or EPWMxB to ignore any trip condition. • Configure how often the ePWM will react to the trip-zone pin: – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely.
Event-trigger (ET)	• Enable the ePWM events that will trigger an interrupt. • Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) • Poll, set, or clear event flags
High-Resolution PWM (HRPWM)	• Enable extended time resolution capabilities • Configure finer time granularity control or edge positioning

Note

The system clock - SYSCLKOUT is the ePWM functional clock derived from the PWMSSn gateable interface and functional clock PWMSSn_GICLK, described in the Section 29.1.3.

Code examples are provided in the remainder of this chapter that show how to implement various ePWM module configurations. These examples use the constant definitions shown in Section 29.2.4 .

29.2.5 Proper ePWM Interrupt Initialization Procedure

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Initialize peripheral registers
4. Clear any spurious ePWM flags
5. Enable ePWM interrupts
6. Enable global interrupts

29.2.6 ePWM Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules (ePWMx) to work together as a single system. Figure 29-8 illustrates the time-base module's place within the ePWM.

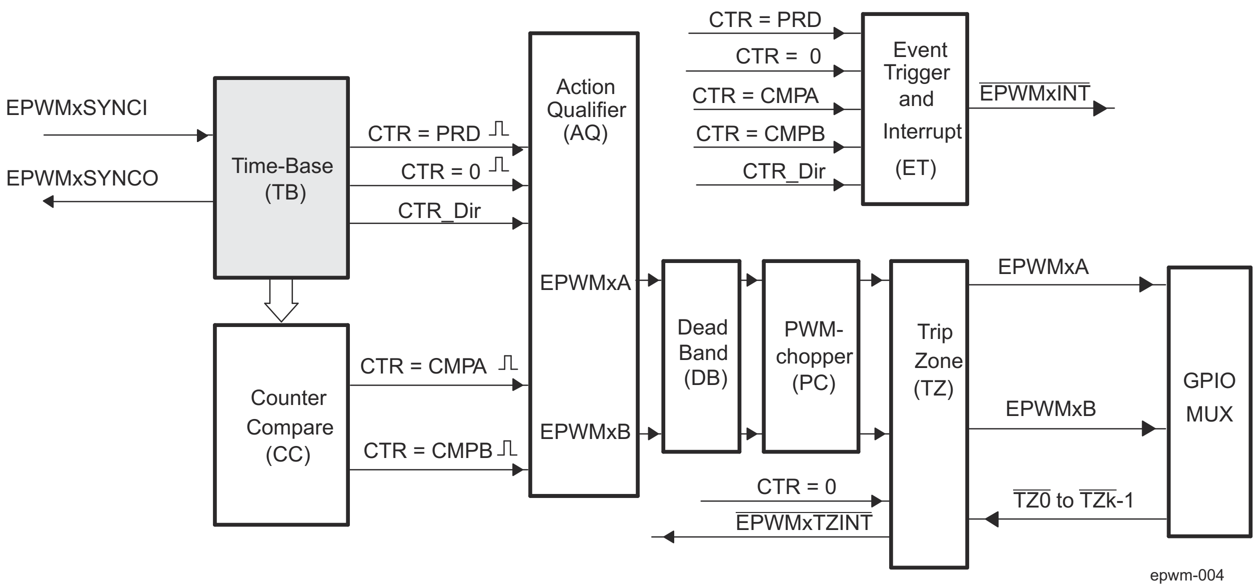

Figure 29-8. ePWM Time-Base Submodule Block Diagram

29.2.7 Purpose of the ePWM Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWMx time-base counter (TBCNT) frequency or period in the EPWM_TBCNT register to control how often events occur.
- Manage time-base synchronization with other ePWMx modules.
- Maintain a phase relationship with other ePWMx modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - TBCNT = PRD: Time-base counter (EPWM_TBCNT register) equal to the specified period in EPWM_TBPRD register (i.e. TBCNT = TBPRD) .
  - TBCNT = 0: Time-base counter equal to zero (TBCNT = 0000h).
- Configure the rate of the time-base clock; a prescaled version of the CPU system clock (SYSCLKOUT). This allows the time-base counter to increment/decrement at a slower rate.

29.2.8 Controlling and Monitoring the ePWM Time-Base Submodule

Table 29-16 lists the registers used to control and monitor the time-base submodule.

Table 29-16. ePWM Time-Base Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCTL	Time-Base Control Register	0h	No
EPWM_TBSTS	Time-Base Status Register	2h	No
HRPWM_TBPHSHR	HRPWM extension Phase Register (1)	4h	No
EPWM_TBPHS	Time-Base Phase Register	6h	No
EPWM_TBCNT	Time-Base Counter Register	8h	No
EPWM_TBPRD	Time-Base Period Register	Ah	Yes

(1) This register is available only on ePWM instances that include the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. See Section 29.1.3 to determine which ePWM instances include this feature.

Figure 29-9 shows the critical signals and registers of the time-base submodule. Table 29-17 provides descriptions of the key signals associated with the time-base submodule.

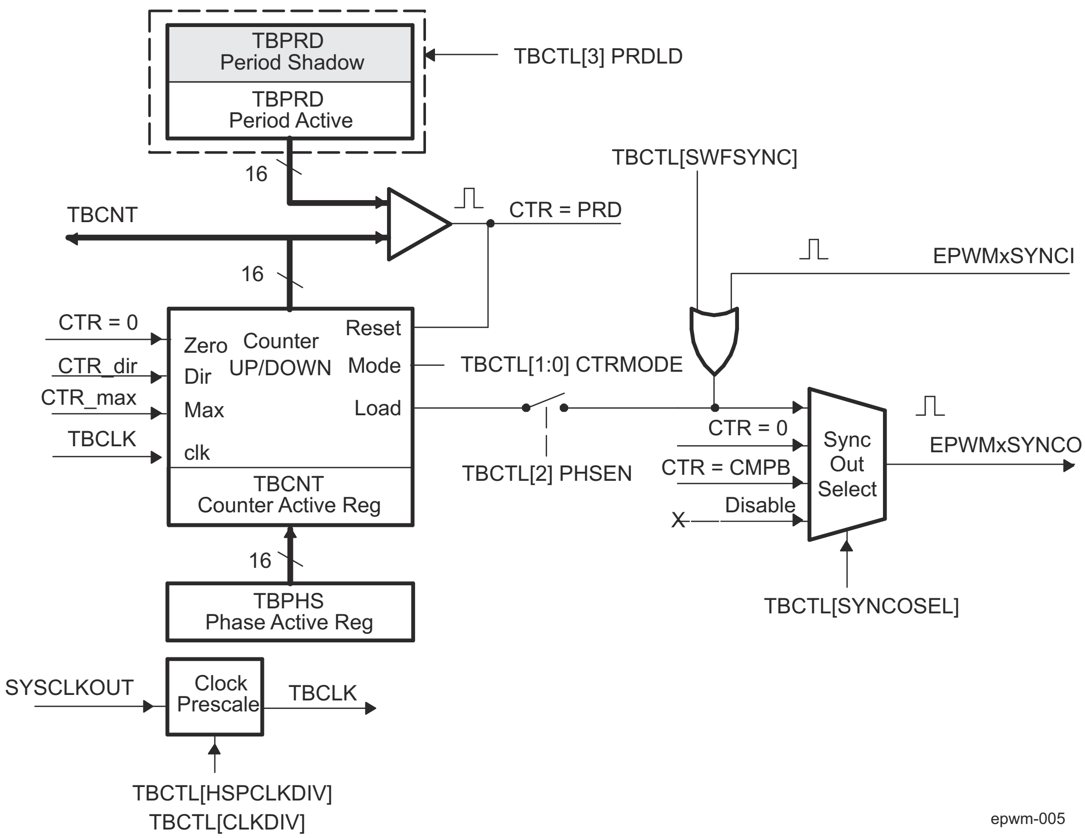

Figure 29-9. ePWM Time-Base Submodule Signals and Registers

Table 29-17. ePWM Key Time-Base Signals

Signal	Description
EPWMxSYNCI	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1) this signal comes from a device pin . For subsequent ePWM modules this signal is passed from another ePWM peripheral. For example, EPWM2SYNCI is generated by the ePWM1 peripheral and the EPWM3SYNCI is generated by ePWM2. See Section 29.2.11 for information on the synchronization order of a particular device.

Table 29-17. ePWM Key Time-Base Signals (continued)

Signal	Description
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: 1. EPWMxSYNCI (Synchronization input pulse) 2. TBCNT = 0: The time-base counter (register EPWM_TBCNT) equal to zero (TBCNT = 0000h). 3. TBCNT = CMPB: The time-base counter (register EPWM_TBCNT) equal to the counter-compare B register - EPWM_CMPB (i.e. bitfield TBCNT = bitfield CMPB) .
TBCNT = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.
TBCNT = 0	Time-base counter equal to zero. This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.
TBCNT = CMPB	Time-base counter equal to active counter-compare B register (TBCNT = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic.
CTR_dir	Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CTR_max	Time-base counter equal max value. (TBCNT = FFFFh) Generated event when the EPWM_TBCNT value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock. This is a prescaled version of the system clock - SYSCLKOUT(1) and is used by all submodules within the ePWMn. This clock determines the rate at which time-base counter increments or decrements.

(1) The system clock - SYSCLKOUT is the ePWM functional clock derived from the PWMSSn gateable interface and functional clock PWMSSn_GICLK, described in Section 29.1.3.

29.2.9 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (EPWM_TBPRD) register and the mode of the time-base counter. Figure 29-10 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when when the period is set to 4 (EPWM_TBPRD register bitfield TBPRD = 0x4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (SYSCLKOUT).

The time-base counter has three modes of operation selected by the time-base control register (EPWM_TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

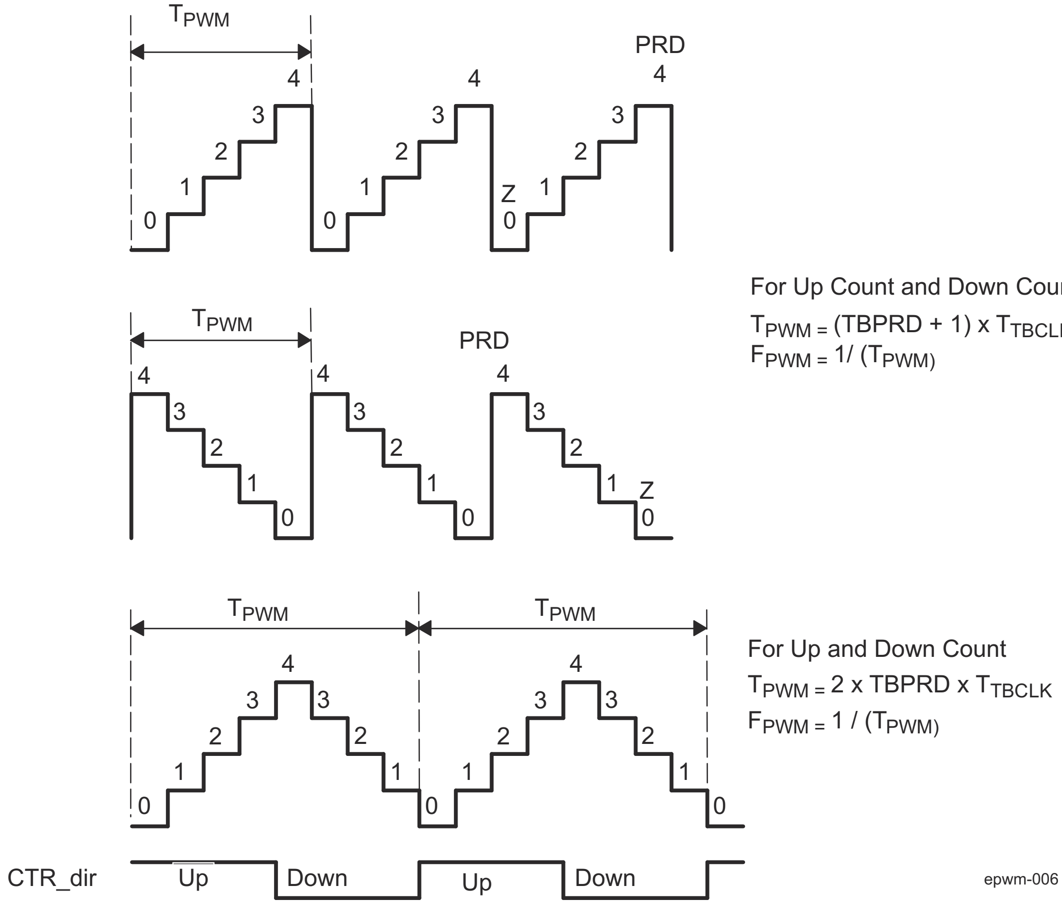

Figure 29-10. ePWM Time-Base Frequency and Period

29.2.10 ePWM Time-Base Period Shadow Register

The time-base period register (EPWM_TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the EPWM_TBCTL[3] PRDLD bit. This bit enables and disables the EPWM_TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The EPWM_TBPRD shadow register is enabled when EPWM_TBCTL[3] PRDLD = 0. Reads from and writes to the EPWM_TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (EPWM_TBPRD (Active) ← EPWM_TBPRD (shadow)) when the time-base counter (register (EPWM_TBCNT) equals zero (TBCNT = 0000h). By default the EPWM_TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (EPWM_TBCTL[3] PRDLD = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

29.2.11 ePWM Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCI) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin . For the device ePWM environment sync pin details refer to the Section 29.1.2. The possible synchronization connections for the remaining ePWM modules is shown in Figure 29-11.

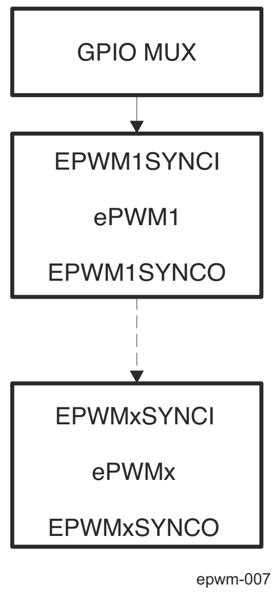

Figure 29-11. ePWM Time-Base Counter Synchronization Scheme 1

Each ePWM module can be configured to use or ignore the synchronization input. If the EPWM_TBCTL[2] PHSEN bit is set, then the time-base counter (TBCNT) of the ePWM module (register EPWM_TBCNT) will be automatically loaded with the phase register (EPWM_TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (EPWM_TBPHS → EPWM_TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1 to the EPWM_TBCTL[6] SWFSYNC control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the EPWM_TBCTL[13] PHSDIR bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See Figure 29-12 through Figure 29-15 for examples.

Clearing the EPWM_TBCTL[2] PHSEN bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

29.2.12 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

As already described in the Section 29.1.3.1.3, PWMSS1_TBCLKEN through PWMSS3_TBCLKEN bits in the CTRL_CORE_CONTROL_IO_2 register of the device Core Control Module can be used to individually control or globally synchronize the time-base clocks of all enabled ePWM modules on a device. When all PWMSSN_TBCLKEN (where n = 1 to 3) bits are set to 0b0, the time-base clocks of all ePWMx (where x = 1 to 3) modules are stopped (default). When all PWMSSn_TBCLKEN bits are simultaneously set in SW to 0b1, all ePWMx modules (x = 1 to 3) time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the EPWM_TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable the ePWM module clocks.
2. Set PWMSSn_TBCLKEN = 0. This will stop the time-base clock within any enabled ePWMx module.
3. Configure the prescaler values and desired ePWM modes per each involved ePWMx.
4. Simultaneously set bits PWMSSn_TBCLKEN to 0b1 (where n = 1 to 3) 1.

29.2.13 ePWM Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, Figure 29-12 to Figure 29-15 show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

29.2.14 ePWM Counter-Compare (CC) Submodule

Figure 29-16 illustrates the counter-compare submodule within the ePWM. Figure 29-17 shows the basic structure of the counter-compare submodule.

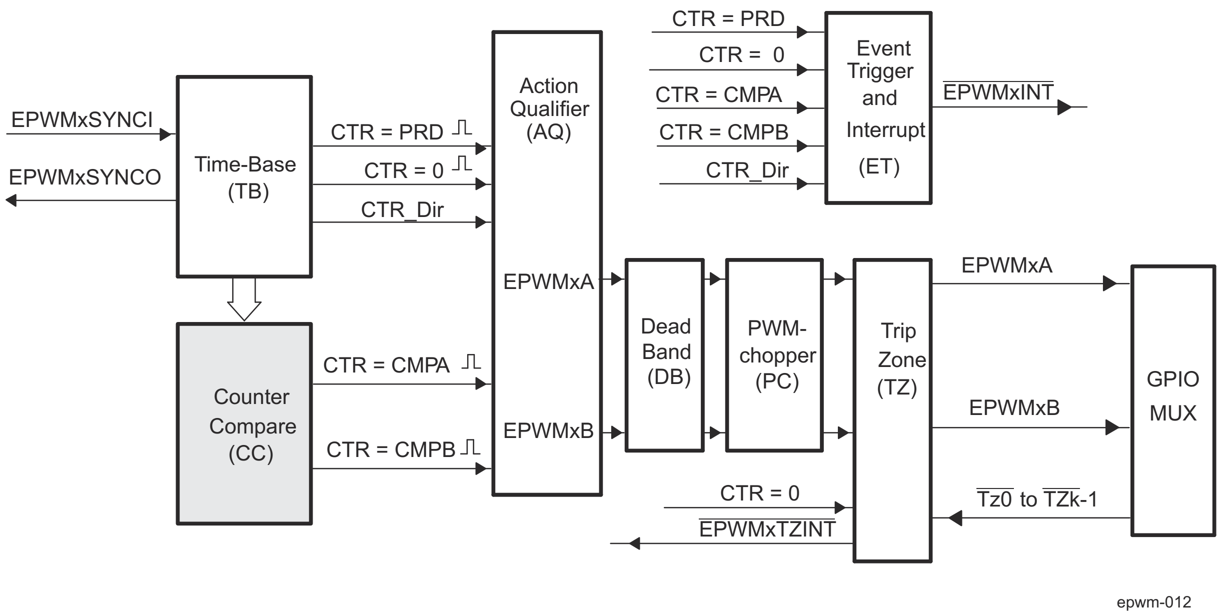

Figure 29-16. ePWM Counter-Compare Submodule

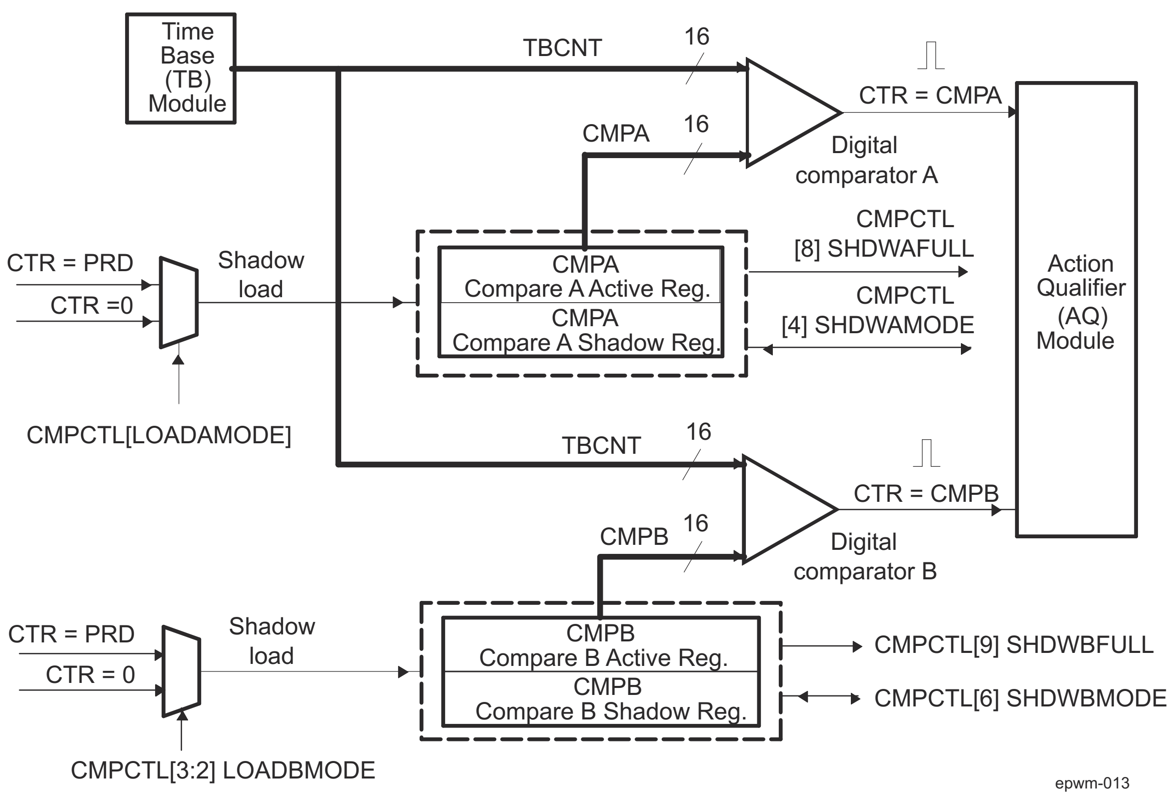

Figure 29-17. ePWM Counter-Compare Submodule Signals and Registers

29.2.15 Purpose of the ePWM Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (EPWM_CMPA) and counter-compare B (EPWM_CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare submodule:

- Generates events based on programmable time stamps using the EPWM_CMPA and EPWM_CMPB registers
  – TBCNT = CMPA: Time-base counter equals counter-compare A register (TBCNT = CMPA).
  – TBCNT = CMPB: Time-base counter equals counter-compare B register (TBCNT = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

29.2.16 Controlling and Monitoring the ePWM Counter-Compare Submodule

Table 29-18 lists the registers used to control and monitor the counter-compare submodule. Table 29-19 lists the key signals associated with the counter-compare submodule.

Table 29-18. ePWM Counter-Compare Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_CMPCTL	Counter-Compare Control Register.	Eh	No
HRPWM_CMPAHR	HRPWM Counter-Compare A Extension Register [(1)]	10h	Yes
EPWM_CMPA	Counter-Compare A Register	12h	Yes
EPWM_CMPB	Counter-Compare B Register	14h	Yes

(1) This register is available only on ePWM modules with the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. See Section 29.1.3 to determine which ePWM instances include this feature.

Table 29-19. ePWM Counter-Compare Submodule Key Signals

Signal	Description of Event	Register Bitfields Compared
TBCNT = CMPA	Time-base counter equal to the active counter-compare A value	TBCNT = CMPA
TBCNT = CMPB	Time-base counter equal to the active counter-compare B value	TBCNT = CMPB
TBCNT = PRD	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCNT = TBPRD
TBCNT = 0	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCNT = 0000h

29.2.17 Operational Highlights for the ePWM Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. TBCNT = CMPA: Time-base counter equal to counter-compare A register (EPWM_TBCNT = EPWM_CMPA).
2. TBCNT = CMPB: Time-base counter equal to counter-compare B register (TBCNT = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to Section 29.2.20 for more details.

The counter-compare registers EPWM_CMPA and EPWM_CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the EPWM_CMPCTL[4] SHDWAMODE and EPWM_CMPCTL[6] SHDWBMODE bits. These bits enable and disable the EPWM_CMPA shadow register and EPWM_CMPB shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Mode:** The shadow mode for the EPWM_CMPA is enabled by clearing the EPWM_CMPCTL[4] SHDWAMODE bit and the shadow register for CMPB is enabled by clearing the EPWM_CMPCTL[6] SHDWBMODE bit. Shadow mode is enabled by default for both EPWM_CMPA and EPWM_CMPB.

  If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:
  – TBCNT = PRD: Time-base counter equal to the period (TBCNT = TBPRD).
  – TBCNT = 0: Time-base counter equal to zero (TBCNT = 0000h)
  – Both TBCNT = PRD and TBCNT = 0

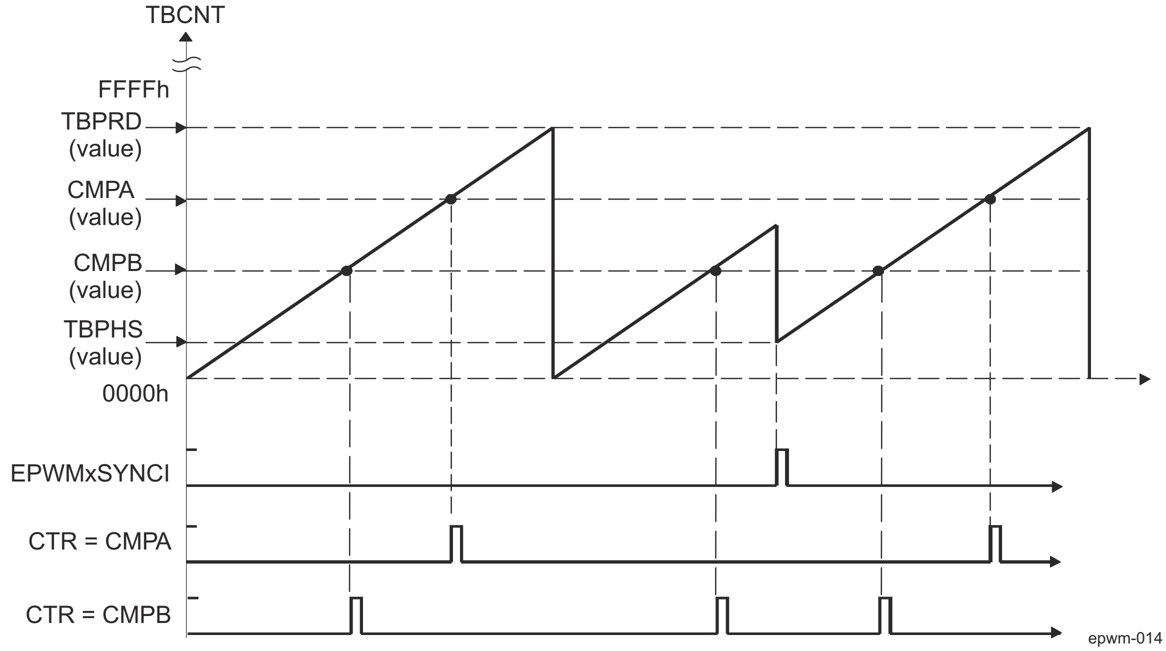
  Which of these three events is specified by the EPWM_CMPCTL[1:0] LOADAMODE and EPWM_CMPCTL[3:2] LOADBMODE register bits. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.
- **Immediate Load Mode:** If immediate load mode is selected (EPWM_TBCTL[4] SHDWAMODE = 1 or EPWM_TBCTL[6] SHDWBMODE = 1), then a read from or a write to the register will go directly to the active register.

29.2.18 ePWM Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in Figure 29-18 to Figure 29-21 show when events are generated and how the EPWMxSYNCI signal interacts.



An EPWMxSYNCI external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

Figure 29-18. ePWM Counter-Compare Event Waveforms in Up-Count Mode

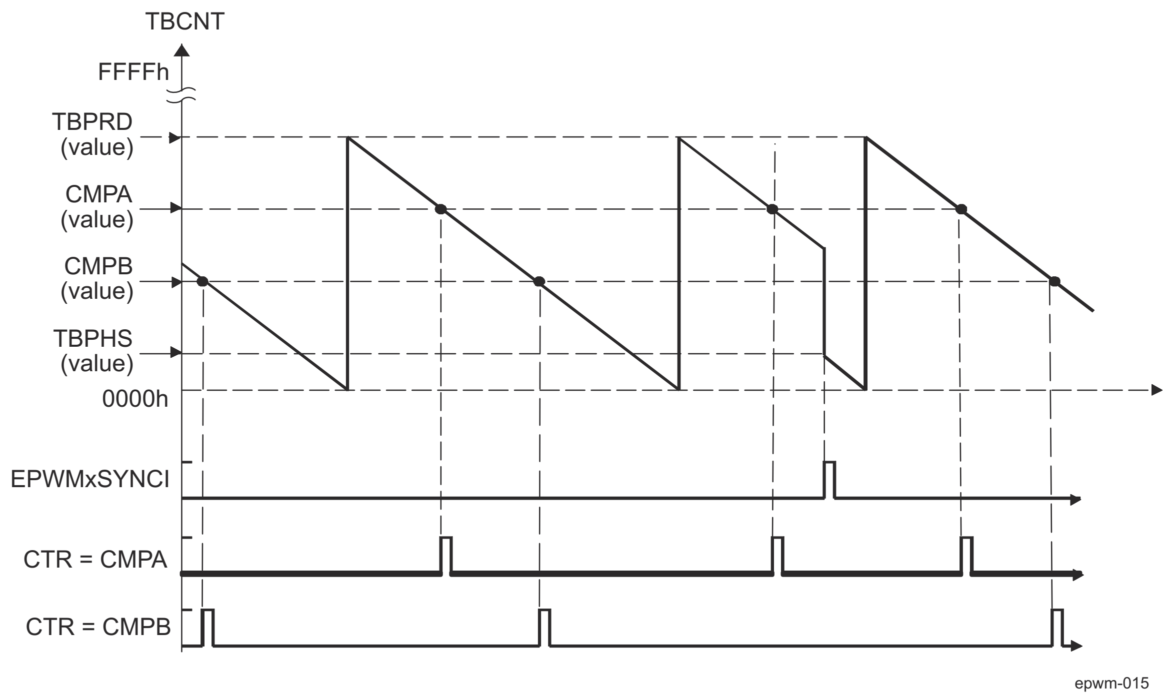


Figure 29-19. ePWM Counter-Compare Events in Down-Count Mode

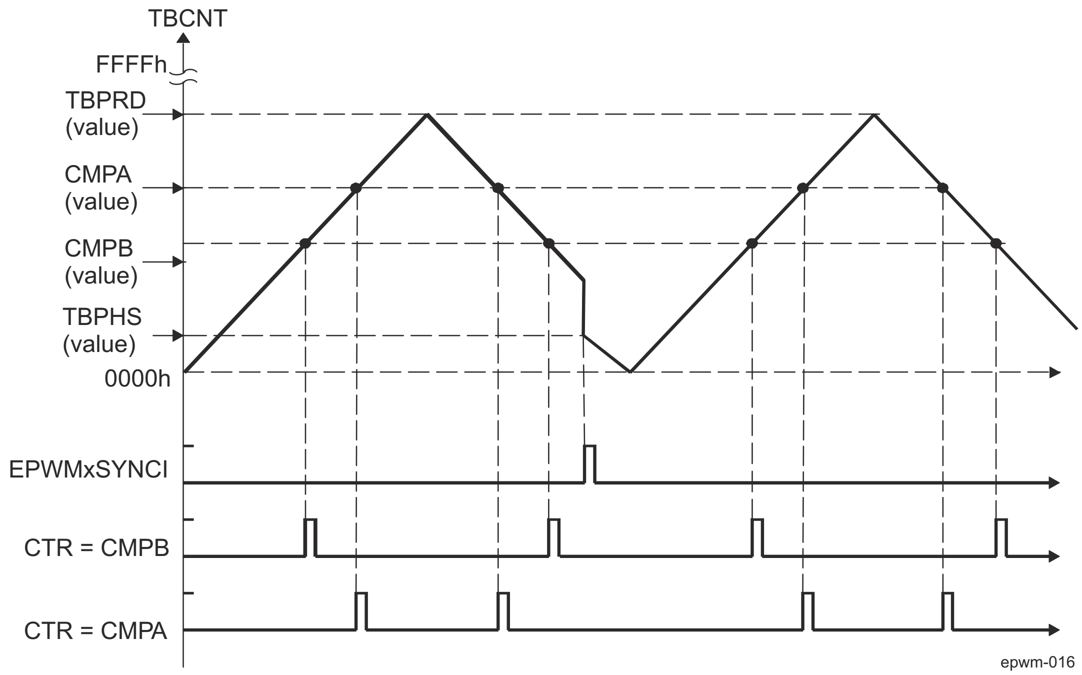

Figure 29-20. ePWM Counter-Compare Events in Up-Down-Count Mode, EPWM_TBCTL[13] PHSDIR = 0 Count Down on Synchronization Event

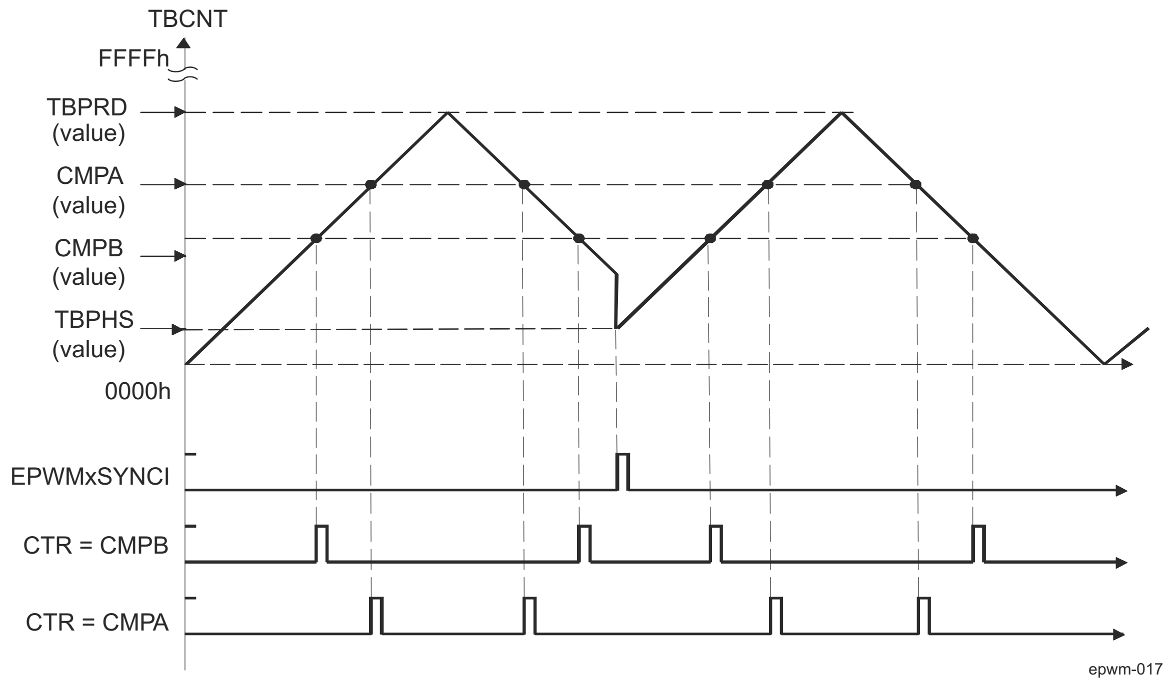

Figure 29-21. ePWM Counter-Compare Events in Up-Down-Count Mode, EPWM_TBCTL[13] PHSDIR = 1 Count Up on Synchronization Event

29.2.19 ePWM Action-Qualifier (AQ) Submodule

Figure 29-22 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system. The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

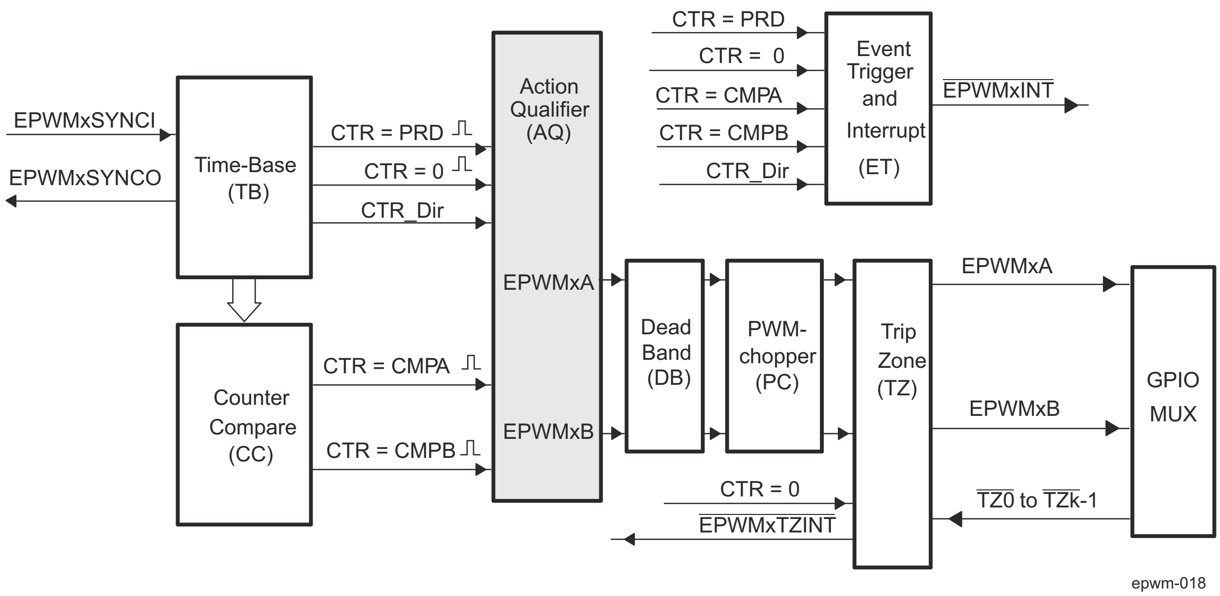

Figure 29-22. ePWM Action-Qualifier Submodule

29.2.20 Purpose of the ePWM Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  – TBCNT = PRD: Time-base counter equal to the period (TBCNT = TBPRD)
  – TBCNT = 0: Time-base counter equal to zero (TBCNT = 0000h)
  – TBCNT = CMPA: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
  – TBCNT = CMPB: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing.

29.2.21 Controlling and Monitoring the ePWM Action-Qualifier Submodule

Table 29-20 lists the registers used to control and monitor the action-qualifier submodule.

Table 29-20. Action-Qualifier Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_AQCTLA	Action-Qualifier Control Register For Output A (EPWMxA)	16h	No
EPWM_AQCTLB	Action-Qualifier Control Register For Output B (EPWMxB)	18h	No
EPWM_AQSFRC	Action-Qualifier Software Force Register	1Ah	No
EPWM_AQCSFRC	Action-Qualifier Continuous Software Force	1Ch	Yes

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in Figure 29-23. The possible input events are summarized again in Table 29-21.

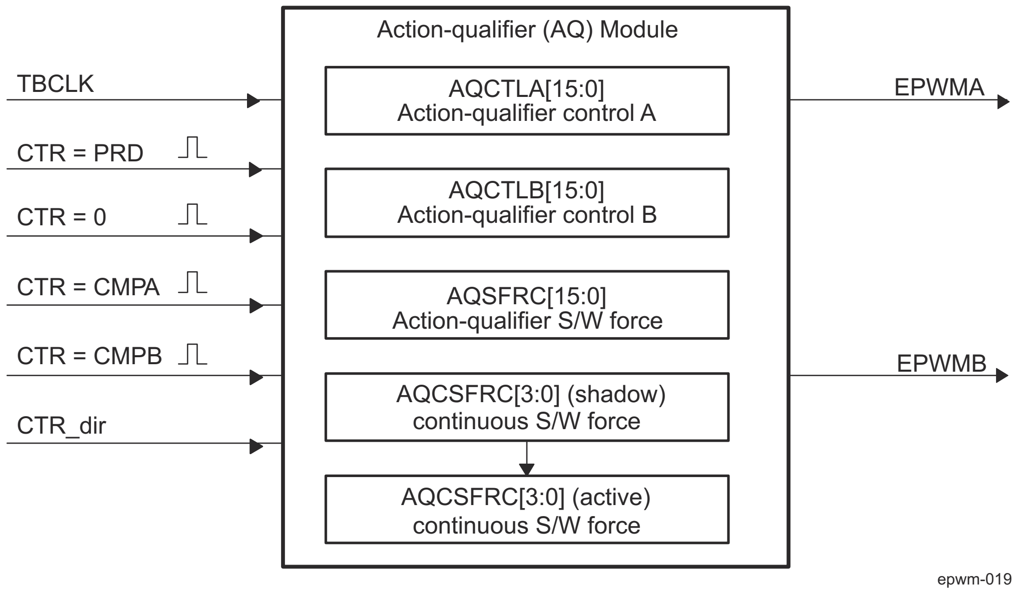

Figure 29-23. ePWM Action-Qualifier Submodule Inputs and Outputs

Table 29-21. ePWM Action-Qualifier Submodule Possible Input Events

Signal	Description	Register Bitfield Compared
TBCNT = PRD	Time-base counter equal to the period value	TBCNT = TBPRD
TBCNT = 0	Time-base counter equal to zero	TBCNT = 0000h
TBCNT = CMPA	Time-base counter equal to the counter-compare A	TBCNT = CMPA
TBCNT = CMPB	Time-base counter equal to the counter-compare B	TBCNT = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by registers EPWM_AQSFRC and EPWM_AQCSFRC.

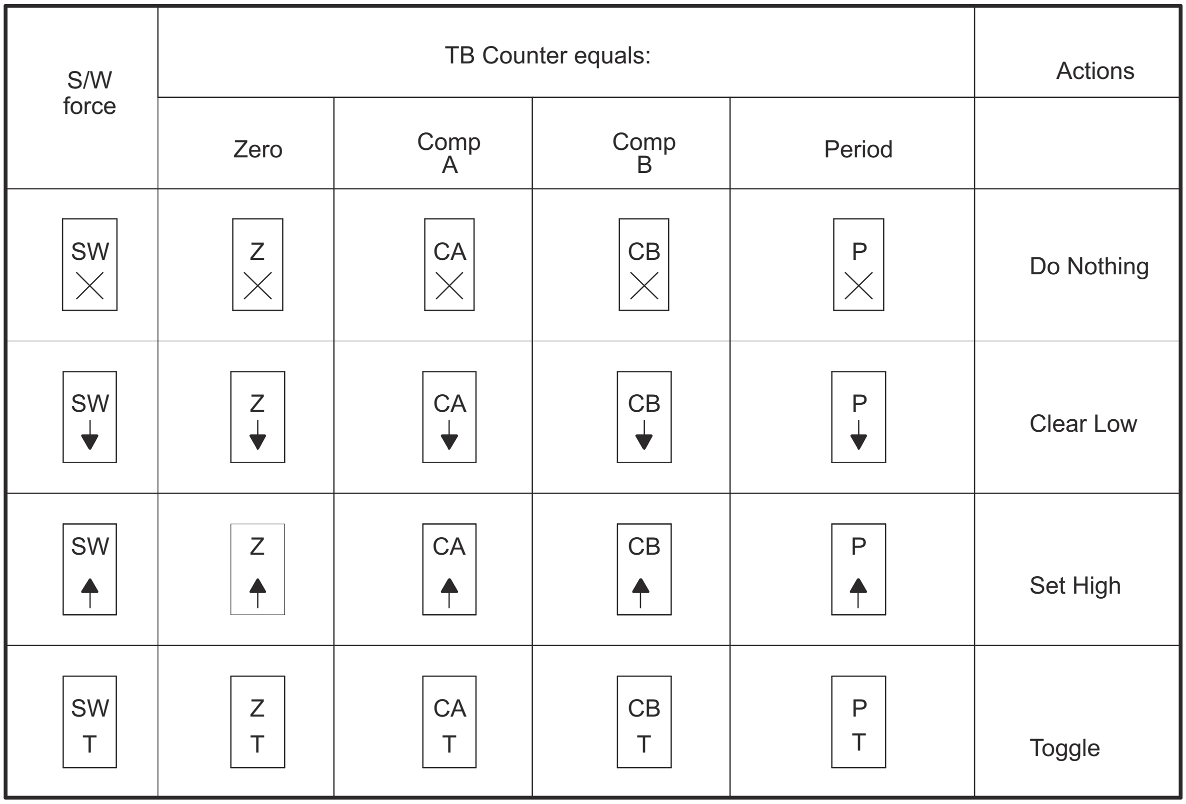
The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts. See the event-trigger submodule description in Section 29.2.41 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both TBCNT = CMPA and TBCNT = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in Figure 29-24. Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.



epwm-020

Figure 29-24. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

29.2.22 ePWM Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in Table 29-22. A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

Table 29-22. ePWM Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event if TBCNT is Incrementing TBCNT = 0 up to TBCNT = TBPRD	Event if TBCNT is Decrementing TBCNT = TBPRD down to TBCNT = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD in EPWM_TBPRD active register)
5	Counter equals CMPB on down-count (CBD) [(1)]	Counter equals CMPB on up-count (CBU) [(1)]
6 (Lowest)	Counter equals CMPA on down-count (CAD) [(1)]	Counter equals CMPA on up-count (CBU) [(1)]

(1) To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

Table 29-23 shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 29-23. ePWM Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

Table 29-24 shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 29-24. ePWM Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in Table 29-25.

Table 29-25. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAU/CBU
Up-Count Mode	If CMPA/CMPB ≤ TBPRD period, then the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB > TBPRD, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If CMPA/CMPB < TBPRD, the event will occur on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event will occur on a period match (TBCNT = TBPRD).
Up-Down-Count Mode	If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB is ≥ TBPRD, the event will occur on a period match (TBCNT = TBPRD).	If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCNT = TBPRD).

29.2.23 Waveforms for Common ePWM Configurations

Note

The waveforms in this chapter show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (EPWM_CMPA and EPWM_CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If you load EPWM_CMPA/EPWM_CMPB on zero, then use EPWM_CMPA/EPWM_CMPB values greater than or equal to 1.
- If you load EPWM_CMPA/EPWM_CMPB on period, then use EPWM_CMPA/EPWM_CMPB values less than or equal to TBPRD - 1.

  This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load EPWM_CMPA/ EPWM_CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load EPWM_CMPA/ EPWM_CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

Figure 29-25 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When EPWM_CMPA = EPWM_TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

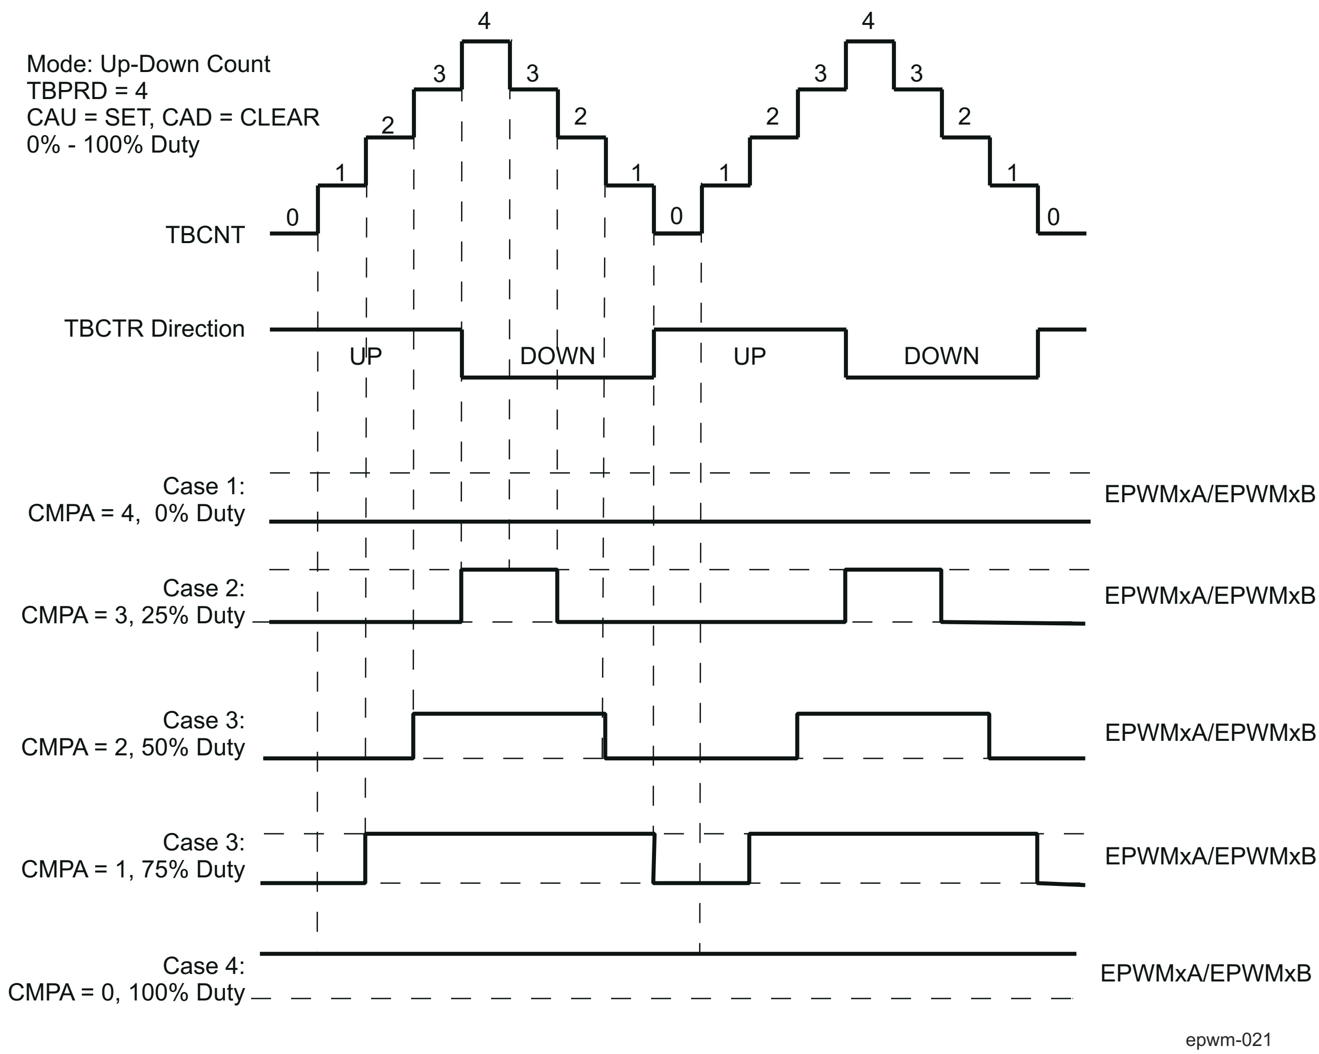


Figure 29-25. ePWM Up-Down-Count Mode Symmetrical Waveform

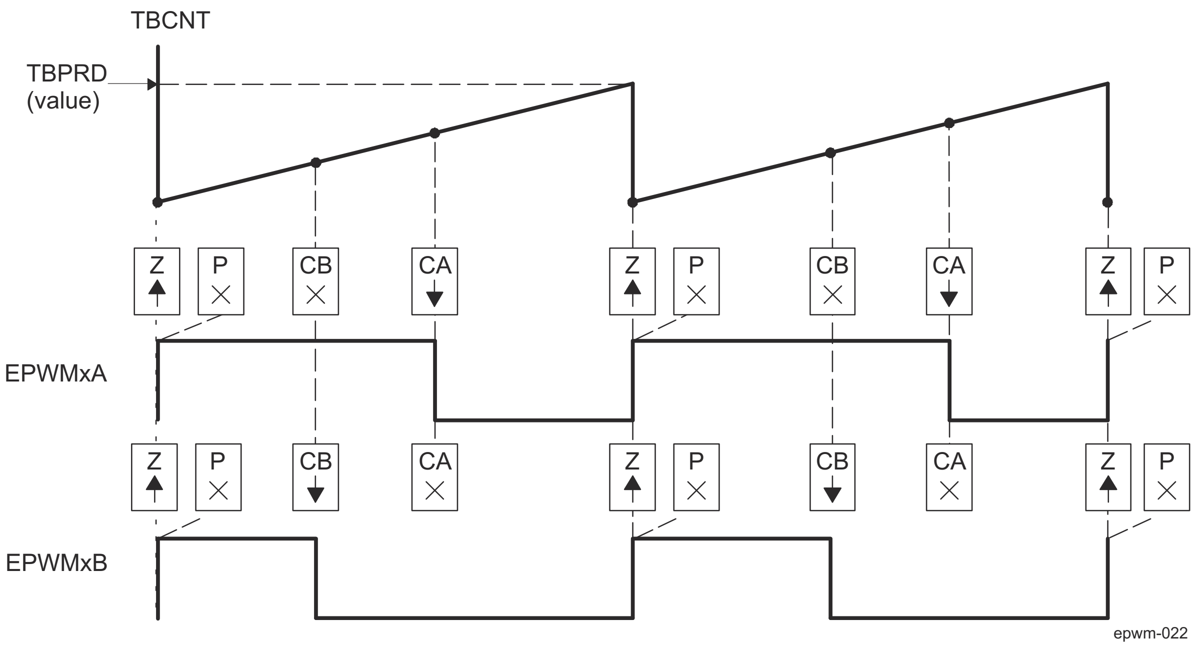
The PWM waveforms in Figure 29-26 through Figure 29-31 show some common action-qualifier configurations. Some conventions used in the figures are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers (EPWM_TBPRD, EPWM_CMPA, and EPWM_CMPB). The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

Table 29-26 and Table 29-27 contains initialization and runtime register configurations for the waveforms in Figure 29-26.



A. PWM period = (TBPRD + 1) × T_{TBCLK}

B. Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).

C. Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).

D. The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.

E. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

29.2.24 ePWM Dead-Band Generator (DB) Submodule

Figure 29-32 illustrates the dead-band generator submodule within the ePWM module.

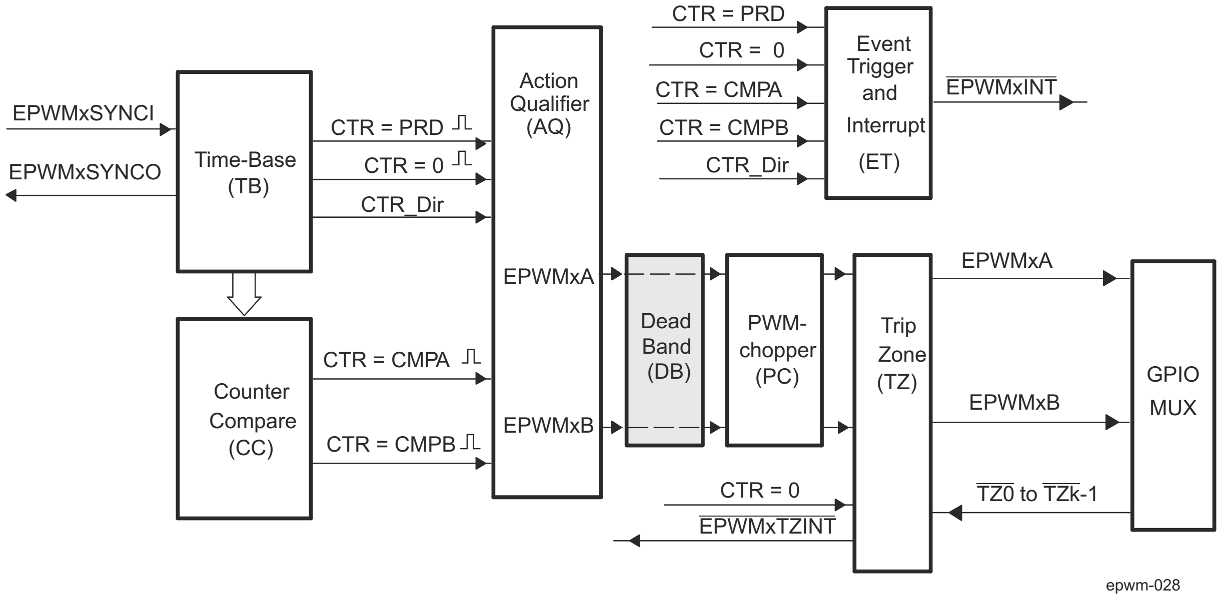

Figure 29-32. Dead-Band Generator Submodule

29.2.25 Purpose of the ePWM Dead-Band Submodule

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  – Active high (AH)
  – Active low (AL)
  – Active high complementary (AHC)
  – Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

29.2.26 Controlling and Monitoring the ePWM Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

Table 29-38. Dead-Band Generator Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_DBCTL	Dead-Band Control Register	1Eh	No
EPWM_DBRED	Dead-Band Rising Edge Delay Count Register	20h	No
EPWM_DBFED	Dead-Band Falling Edge Delay Count Register	22h	No

29.2.27 Operational Highlights for the ePWM Dead-Band Generator Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in Figure 29-33.

- **Input Source Selection:** The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the EPWM_DBCTL[5:4] IN_MODE control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
  - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  - EPWMxB In is the source for both falling-edge and rising-edge delay.
- **Output Mode Control:** The output mode is configured by way of the EPWM_DBCTL[1:0] OUT_MODE bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- **Polarity Control:** The polarity control (EPWM_DBCTL[3:2] POLSEL) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

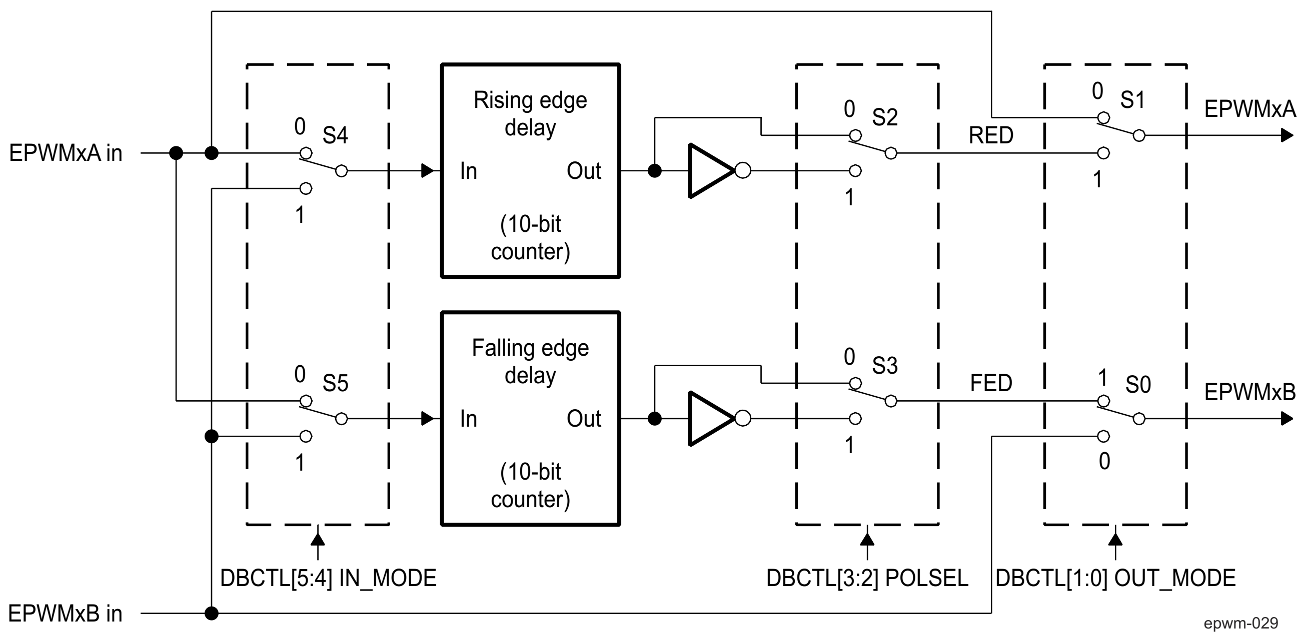

Figure 29-33. Configuration Options for the ePWM Dead-Band Generator Submodule

Although all combinations are supported, not all are typical usage modes. Table 29-39 lists some classical dead-band configurations. These modes assume that the EPWM_DBCTL[5:4] IN_MODE is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 29-39 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 29-34. Note that to generate equivalent waveforms to Figure 29-34, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in Table 29-39 show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

Table 29-39. Classical Dead-Band Operating Modes

		EPWM_DBCTL[3:2] POLSEL		EPWM_DBCTL[1:0] OUT_MODE	
Mode	**Mode Description** (1)	**S3**	**S2**	**S1**	**S0**
1	EPWMxA and EPWMxB Passed Through (No Delay)	x	x	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

(1) These are classical dead-band modes and assume that EPWM_DBCTL[5:4] IN_MODE = 0b00. That is, EPWMxA in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the IN_MODE configuration.

Figure 29-34 shows waveforms for typical cases where 0% < duty < 100%.

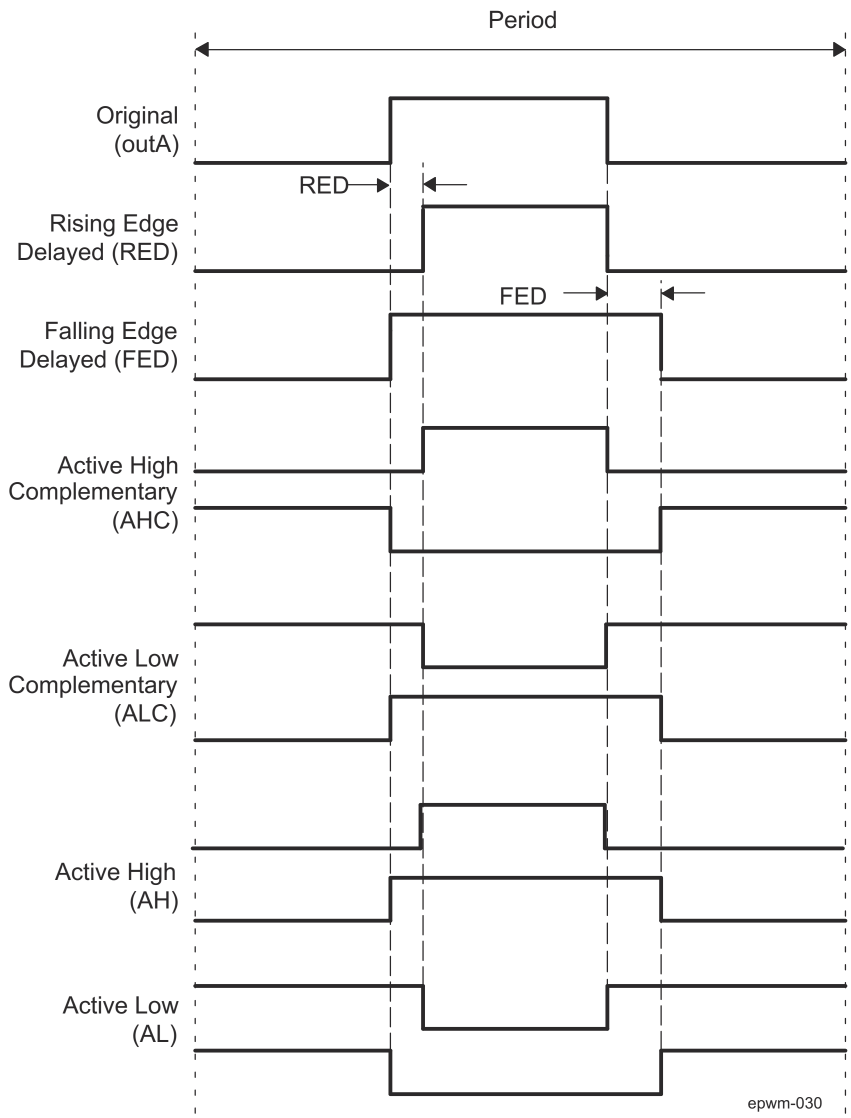

Figure 29-34. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the EPWM_DBRED and EPWM_DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

FED = EPWM_DBFED × T_{TBCLK}

RED = EPWM_DBRED × T_{TBCLK}

Where T_{TBCLK} is the period of TBCLK, the prescaled version of SYSCLKOUT.

29.2.28 PWM-Chopper (PC) Submodule

Figure 29-35 illustrates the PWM-chopper (PC) submodule within the ePWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

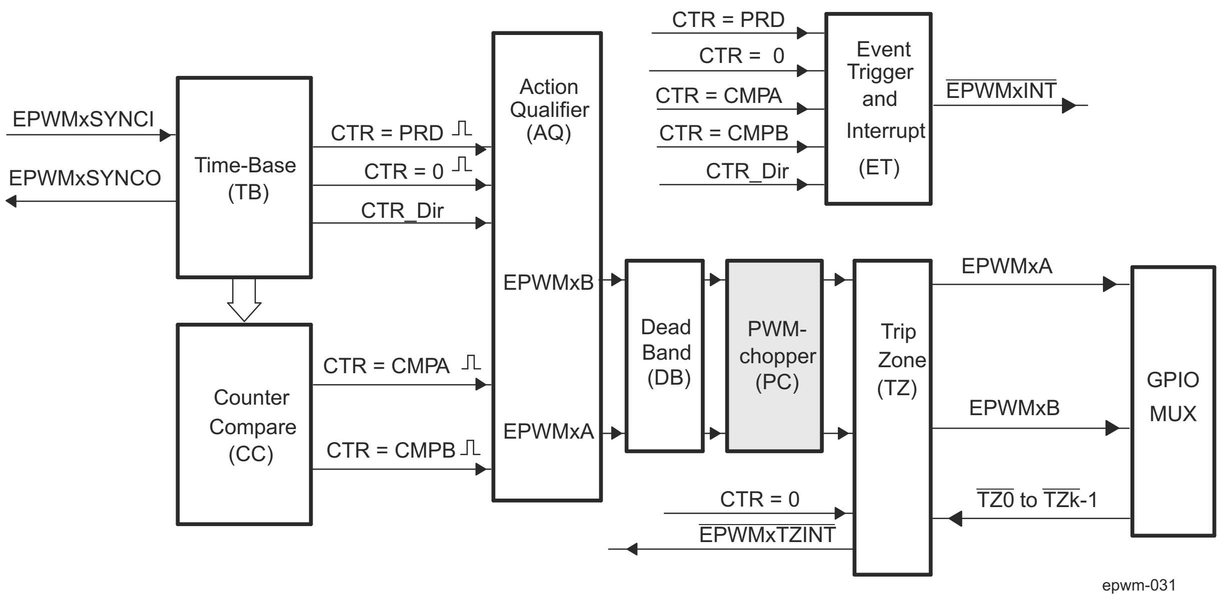

Figure 29-35. PWM-Chopper Submodule

29.2.29 Purpose of the PWM-Chopper Submodule

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

29.2.30 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the register in Table 29-40.

Table 29-40. PWM-Chopper Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_PCCTL	PWM-chopper Control Register	3Ch	No

29.2.31 Operational Highlights for the PWM-Chopper Submodule

Figure 29-36 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from SYSCLKOUT. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the EPWM_PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

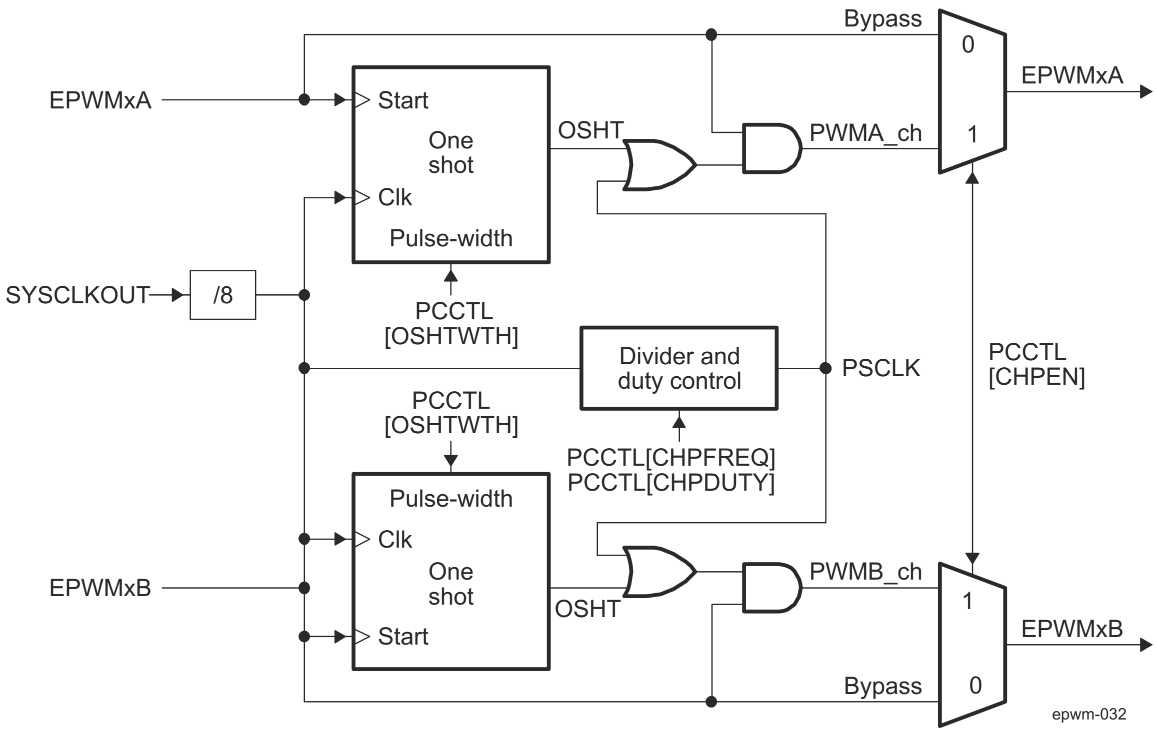

Figure 29-36. PWM-Chopper Submodule Signals and Registers

29.2.32 PWM Chopper Waveforms

Figure 29-37 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

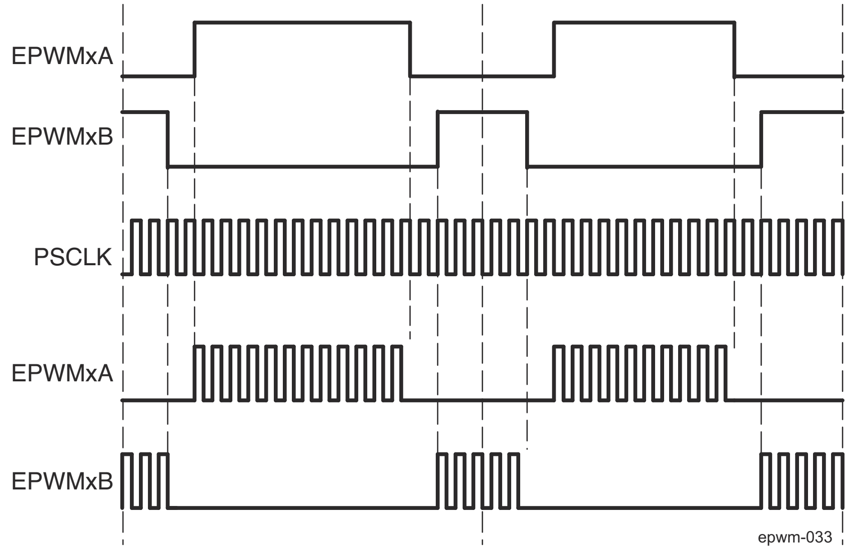

Figure 29-37. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only

29.2.33 PWM-Chopper One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$T_{1stpulse} = T_{SYSCLKOUT} \times 8 \times OSHTWTH$

Where $T_{SYSCLKOUT}$ is the period of the system clock (SYSCLKOUT) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 29-38 shows the first and subsequent sustaining pulses.

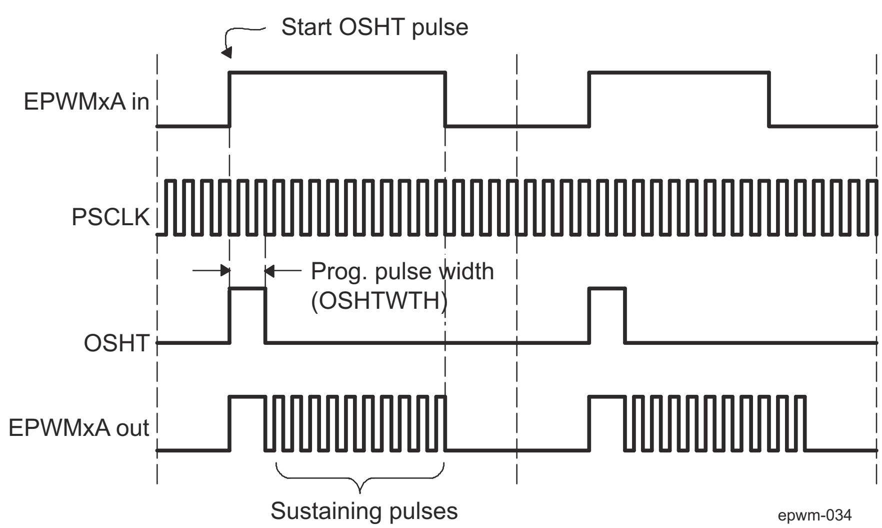

Figure 29-38. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

29.2.34 PWM-Chopper Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 29-39 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

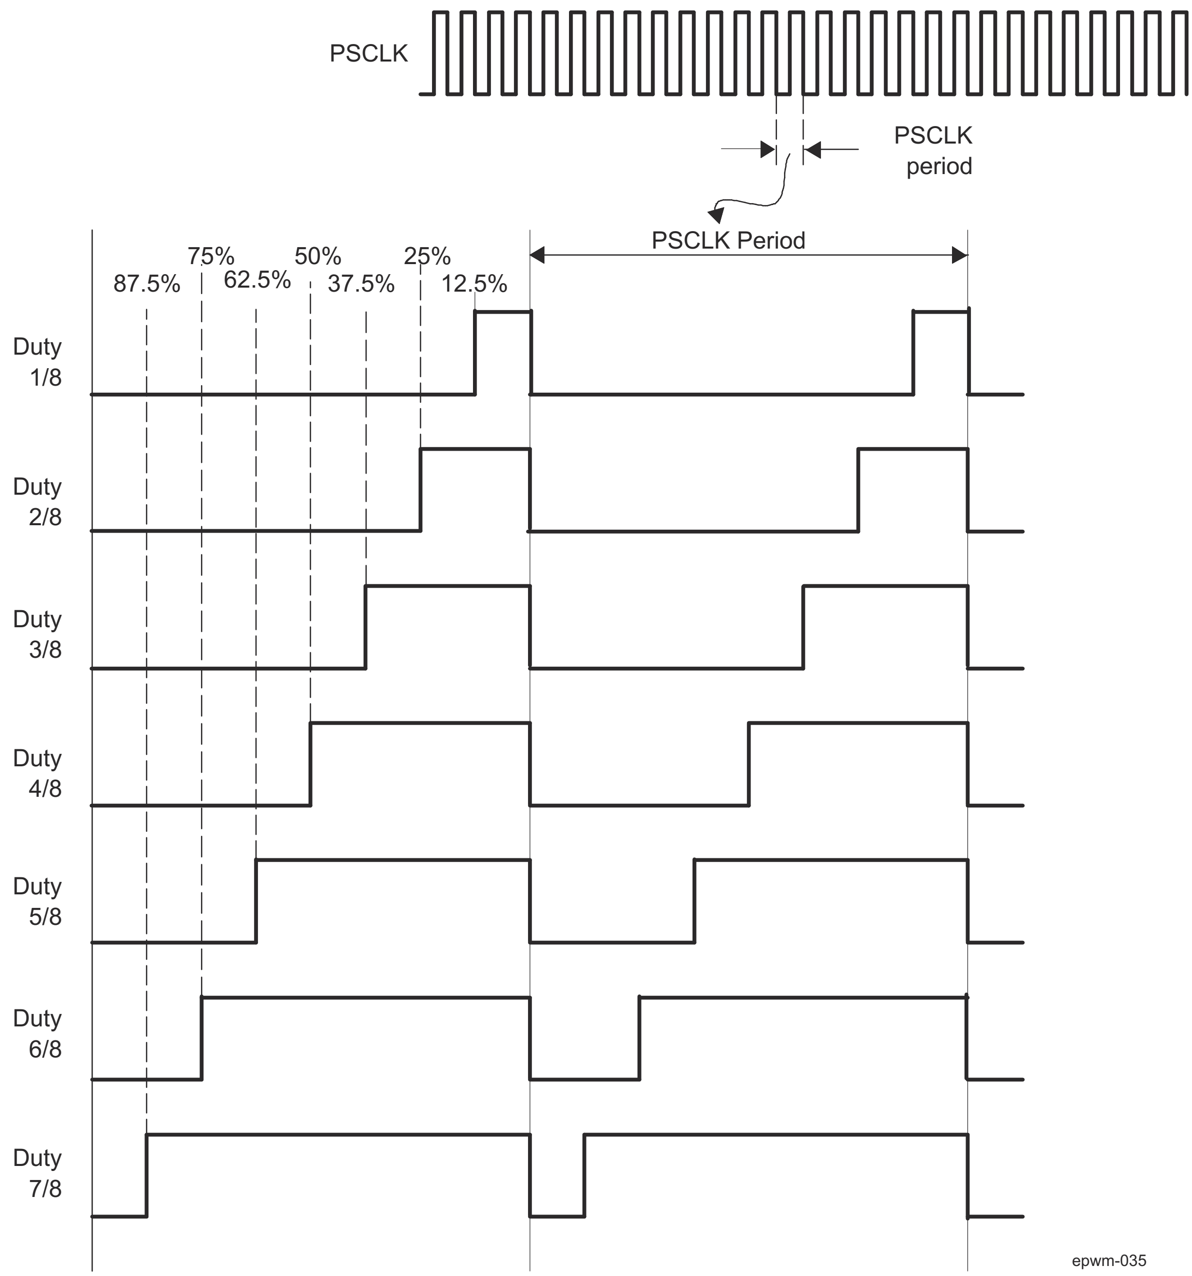

Figure 29-39. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

29.2.35 ePWM Trip-Zone (TZ) Submodule

Figure 29-40 shows how the trip-zone (TZ) submodule fits within the ePWM module. Each ePWM module is connected to every $\overline{TZ}$ signal that are sourced from the GPIO MUX. These signals indicates external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur. See Section 29.1.3 to determine the number of trip-zone pins available for the device.

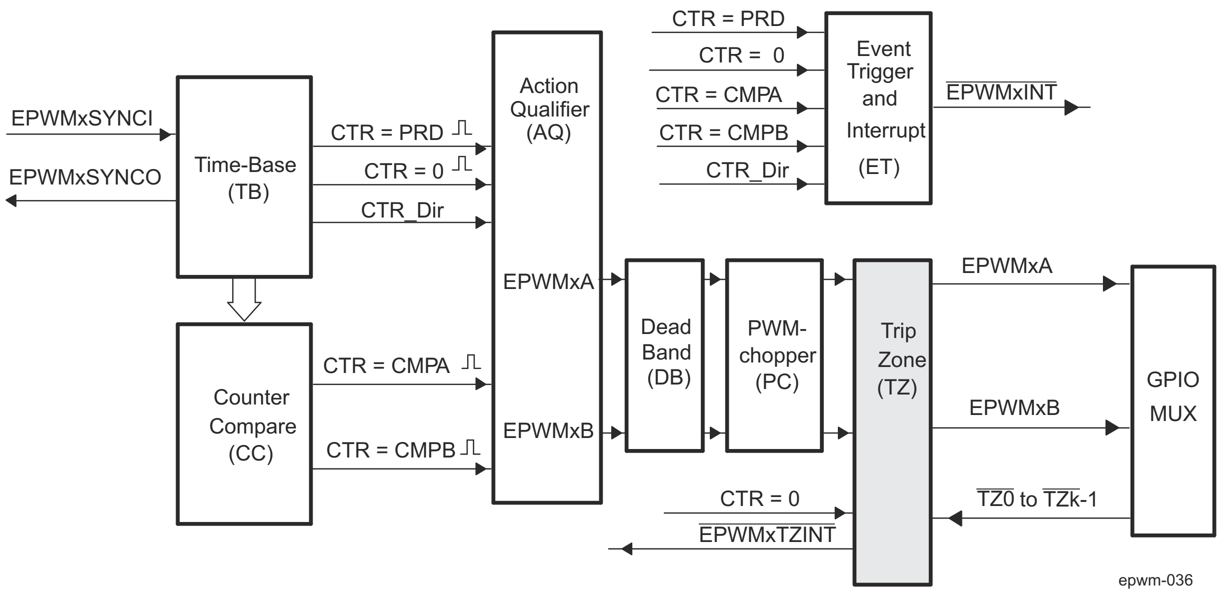

Figure 29-40. ePWM Trip-Zone Submodule

29.2.36 Purpose of the ePWM Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs $\overline{TZ0}$ to $\overline{TZk-1}$ can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

Note

For each ePWMx, from the tripzone inputs $\overline{\text{EPWM\_TRIP\_TZ[5:0]}}$, ONLY the $\overline{\text{EPWM\_TRIP\_TZ[0]}}$ input of ePWM tripzone is chip accessible and usable, i.e. k=1.

29.2.37 Controlling and Monitoring the ePWM Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 29-41. ePWM Trip-Zone Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TZSEL	Trip-Zone Select Register	24h	No
EPWM_TZCTL	Trip-Zone Control Register	28h	No
EPWM_TZEINT	Trip-Zone Enable Interrupt Register	2Ah	No
EPWM_TZFLG	Trip-Zone Flag Register	2Ch	No
EPWM_TZCLR	Trip-Zone Clear Register	2Eh	No
EPWM_TZFRC	Trip-Zone Force Register	30h	No

29.2.38 Operational Highlights for the ePWM Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals at pin $\overline{\text{TZ0}}$ to $\overline{\text{TZk-1}}$ is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used by a particular ePWM module is determined by the EPWM_TZSEL register for that specific ePWM module. The trip-zone signal may or may not be synchronized to the system clock (SYSCLKOUT). A minimum of 1 SYSCLKOUT low pulse on the $\overline{\text{TZ}}$ $\overline{\text{n}}$ inputs is sufficient to trigger a fault condition in the ePWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the $\overline{\text{TZk}}$ inputs.

Note

Only the TZ[0] input is accessible at chip level (i.e. k=1).

The $\overline{\text{TZk}}$ input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a ePWM module. The configuration is determined by the EPWM_TZSEL[7:0] CBCk and EPWM_TZSEL[15:8] OSHTk bits (where k corresponds to the trip pin) respectively.

- **Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the EPWM_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. Table 29-42 lists the possible actions. In addition, the cycle-by-cycle trip event flag (EPWM_TZFLG[1] CBC) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM_TZEINT register.

  The specified condition on the pins is automatically cleared when the ePWM time-base counter reaches zero (EPWM_TBCNT bitfield TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The EPWM_TZFLG[1] CBC flag bit will remain set until it is manually cleared by writing to the EPWM_TZCLR[1] CBC bit. If the cycle-by-cycle trip event is still present when the EPWM_TZFLG[1] CBC bit is cleared, then it will again be immediately set.
- **One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the EPWM_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. Table 29-42 lists the possible actions. In addition, the one-shot trip event flag (EPWM_TZFLG[2] OST) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM_TZEINT register. The one-shot trip condition must be cleared manually by writing to the EPWM_TZCLR[2] OST bit.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the EPWM_TZCTL[1:0] TZA and EPWM_TZCTL[3:2] TZB register bits. One of four possible actions, shown in Table 29-42, can be taken on a trip event.

Table 29-42. Possible Actions On an ePWM Trip Event

EPWM_TZCTL[1:0] TZA and/or EPWM_TZCTL[3:2] TZB	EPWMxA and/or EPWMxB	Comment
0	High-Impedance	Tripped
1h	Force to High State	Tripped
2h	Force to Low State	Tripped
3h	No Change	Do Nothing. No change is made to the output.

29.2.39 ePWM Trip-Zone Configurations

Scenario A:

A one-shot trip event on $\overline{TZ0}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - EPWM_TZSEL[8] OSHT1 = 1: enables $\overline{TZ}$ as a one-shot event source for ePWM1
  - EPWM_TZCTL[1:0] TZA = 2: EPWM1A will be forced low on a trip event.
  - EPWM_TZCTL[3:2] TZB = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - EPWM_TZSEL[8] OSHT1 = 1: enables $\overline{TZ}$ as a one-shot event source for ePWM2
  - EPWM_TZCTL[1:0] TZA = 1: EPWM2A will be forced high on a trip event.
  - EPWM_TZCTL[3:2] TZB = 1: EPWM2B will be forced high on a trip event.

29.2.40 Generating ePWM Trip Event Interrupts

Figure 29-41 and Figure 29-42 illustrate the trip-zone submodule control and interrupt logic, respectively.

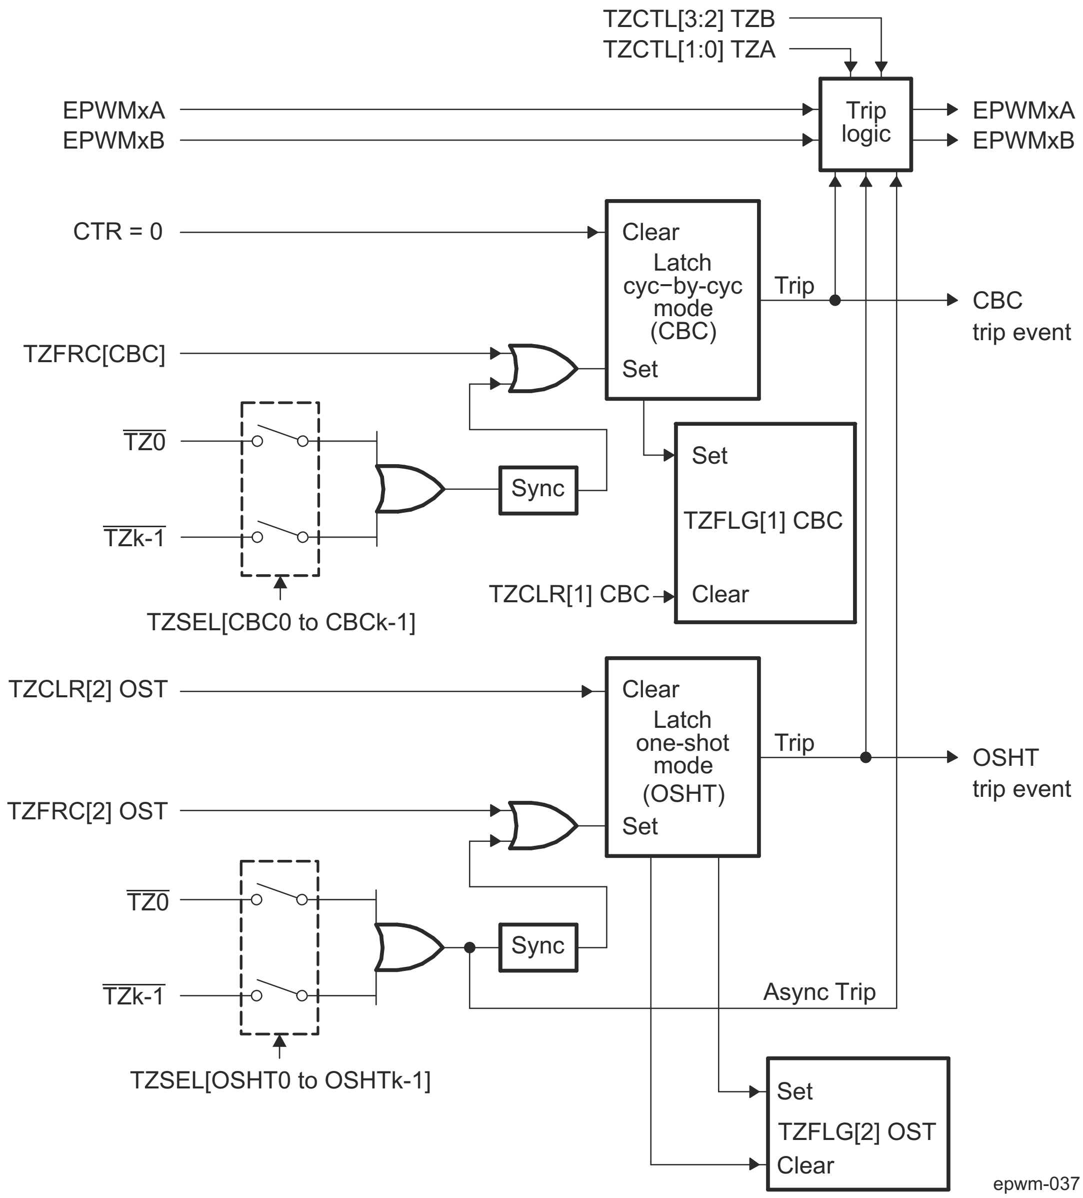

Figure 29-41. ePWM Trip-Zone Submodule Mode Control Logic

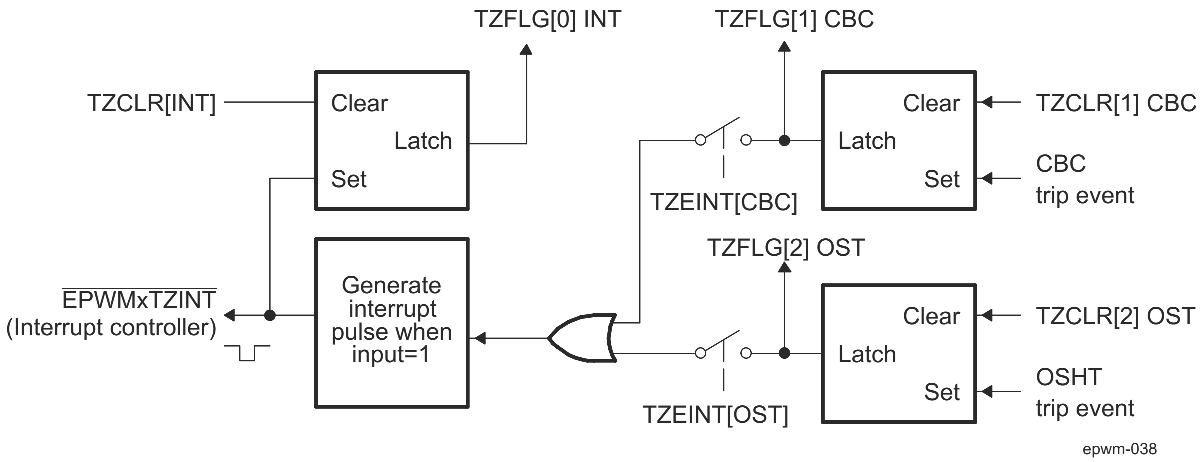

Figure 29-42. ePWM Trip-Zone Submodule Interrupt Logic

29.2.41 ePWM Event-Trigger (ET) Submodule

Figure 29-43 shows the event-trigger (ET) submodule in the ePWM system. The event-trigger submodule manages the events generated by the time-base submodule and the counter-compare submodule to generate an aggregated interrupt request.

Note

The ePWMx ET interrupt request output is further routed via the device IRQ_CROSSBAR, to different device host interrupt controllers, located outside PWMSSn. For more details on interrupt event routing outside the ePWM, refer to the Section 29.1.3.

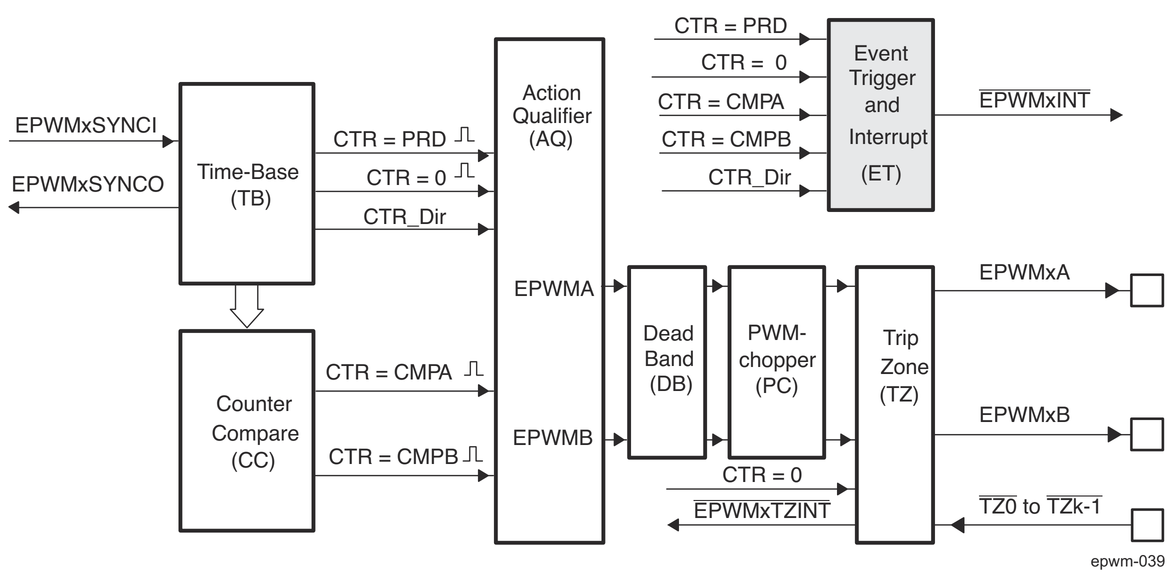

Figure 29-43. ePWM Event-Trigger Submodule

29.2.42 Purpose of the ePWM Event-Trigger Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base and counter-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests at:

  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags

29.2.43 Controlling and Monitoring the ePWM Event-Trigger Submodule

The key registers used to configure the event-trigger submodule are shown in Table 29-43:

Table 29-43. Event-Trigger Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_ETSEL	Event-Trigger Selection Register	32h	No
EPWM_ETPS	Event-Trigger Prescale Register	34h	No
EPWM_ETFLG	Event-Trigger Flag Register	36h	No
EPWM_ETCLR	Event-Trigger Clear Register	38h	No
EPWM_ETFRC	Event-Trigger Force Register	3Ah	No

29.2.44 Operational Overview of the ePWM Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line as shown in Figure 29-44. Mapping interrupt lines to device host interrupt controllers is device specific and is covered in the Section 29.1.3.

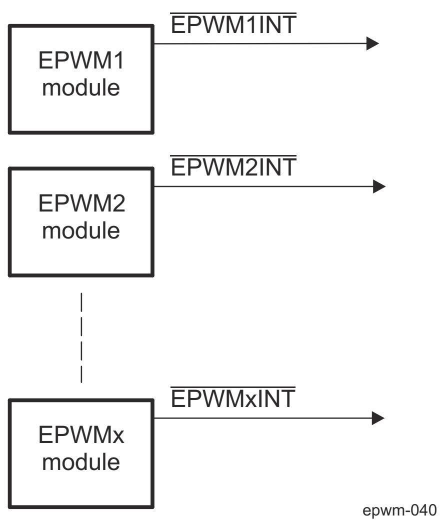

Figure 29-44. ePWM Event-Trigger Submodule Inter-Connectivity to Interrupt Controller

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 29-45) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

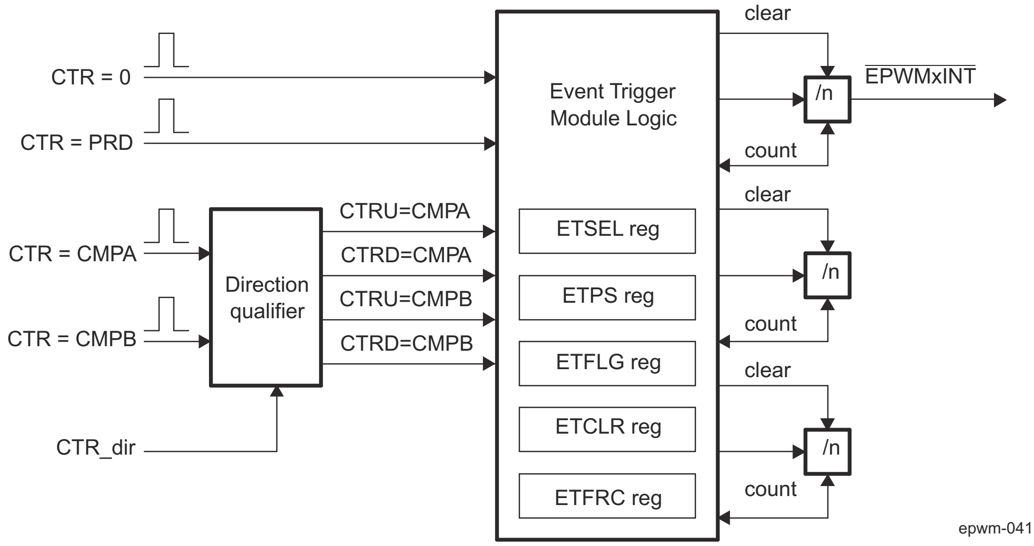

Figure 29-45. ePWM Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

- ETSEL—This selects which of the possible events will trigger an interrupt.
- ETPS—This programs the event prescaling options previously mentioned.
- ETFLG—These are flag bits indicating status of the selected and prescaled events.
- ETCLR—These bits allow you to clear the flag bits in the EPWM_ETFLG register via software.
- ETFRC—These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in Figure 29-46.

Figure 29-46 shows the event-trigger's interrupt generation logic. The interrupt-period (EPWM_ETPS[1:0] INTPRD) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (EPWM_ETSEL[2:0] INTSEL) bits. The event can be one of the following:

- Time-base counter equal to zero (EPWM_TBCNT bitfield TBCNT = 0000h).
- Time-base counter equal to period (EPWM_TBCNT bitfield TBCNT = TBPRD value in EPWM_TBPRD active register).
- Time-base counter equal to the compare A register (EPWM_CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (EPWM_CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (EPWM_CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (EPWM_CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (EPWM_ETPS[3:2] INTCNT) register bits. That is, when the specified event occurs the EPWM_ETPS[3:2] INTCNT bits are incremented until they reach the value specified by EPWM_ETPS[1:0] INTPRD. When EPWM_ETPS[3:2] INTCNT = EPWM_ETPS[1:0] INTPRD the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When EPWM_ETPS[3:2] INTCNT reaches EPWM_ETPS[1:0] INTPRD, one of the following behaviors will occur:

- If interrupts are enabled, EPWM_ETSEL[3] INTEN = 1 and the interrupt flag is clear, EPWM_ETFLG[0] INT = 0, then an interrupt pulse is generated and the interrupt flag is set, EPWM_ETFLG[0] INT = 1, and the event counter is cleared EPWM_ETPS[3:2] INTCNT = 0. The counter will begin counting events again.
- If interrupts are disabled, EPWM_ETSEL[3] INTEN = 0, or the interrupt flag is set, EPWM_ETFLG[0] INT = 1, the counter stops counting events when it reaches the period value EPWM_ETPS[3:2] INTCNT = EPWM_ETPS[1:0] INTPRD.
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[0] INT flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the EPWM_ETFRC[0] INT bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the EPWM_ETFRC[0] INT bit is also ignored.

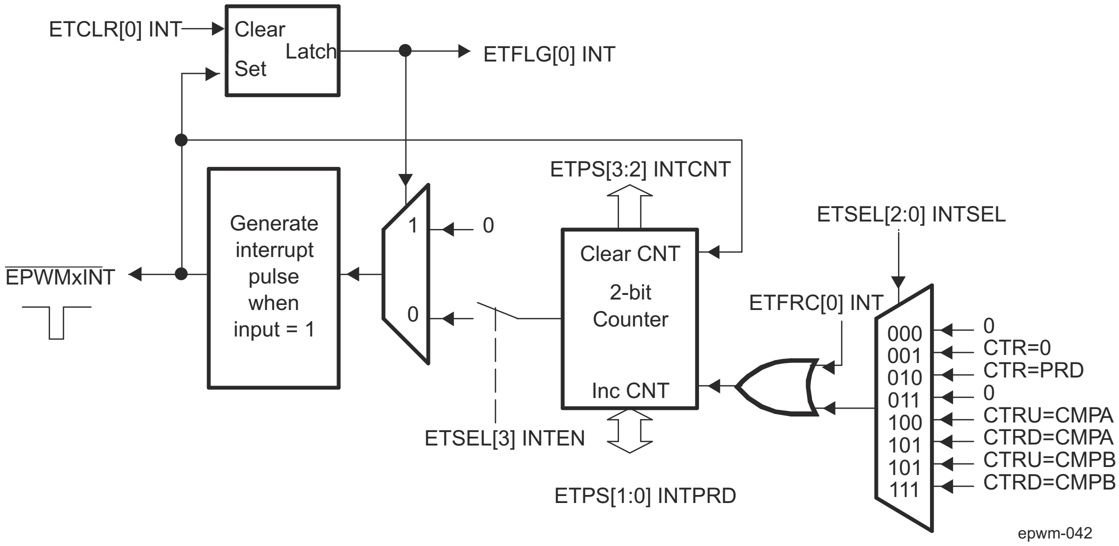

Figure 29-46. ePWM Event-Trigger Interrupt Generator

29.2.45 High-Resolution PWM (HRPWM) Submodule

Figure 29-47 shows the high-resolution PWM (HRPWM) submodule in the ePWM system. Some devices include the high-resolution PWM submodule, see Section 29.1.3 to determine which ePWM instances include this feature.

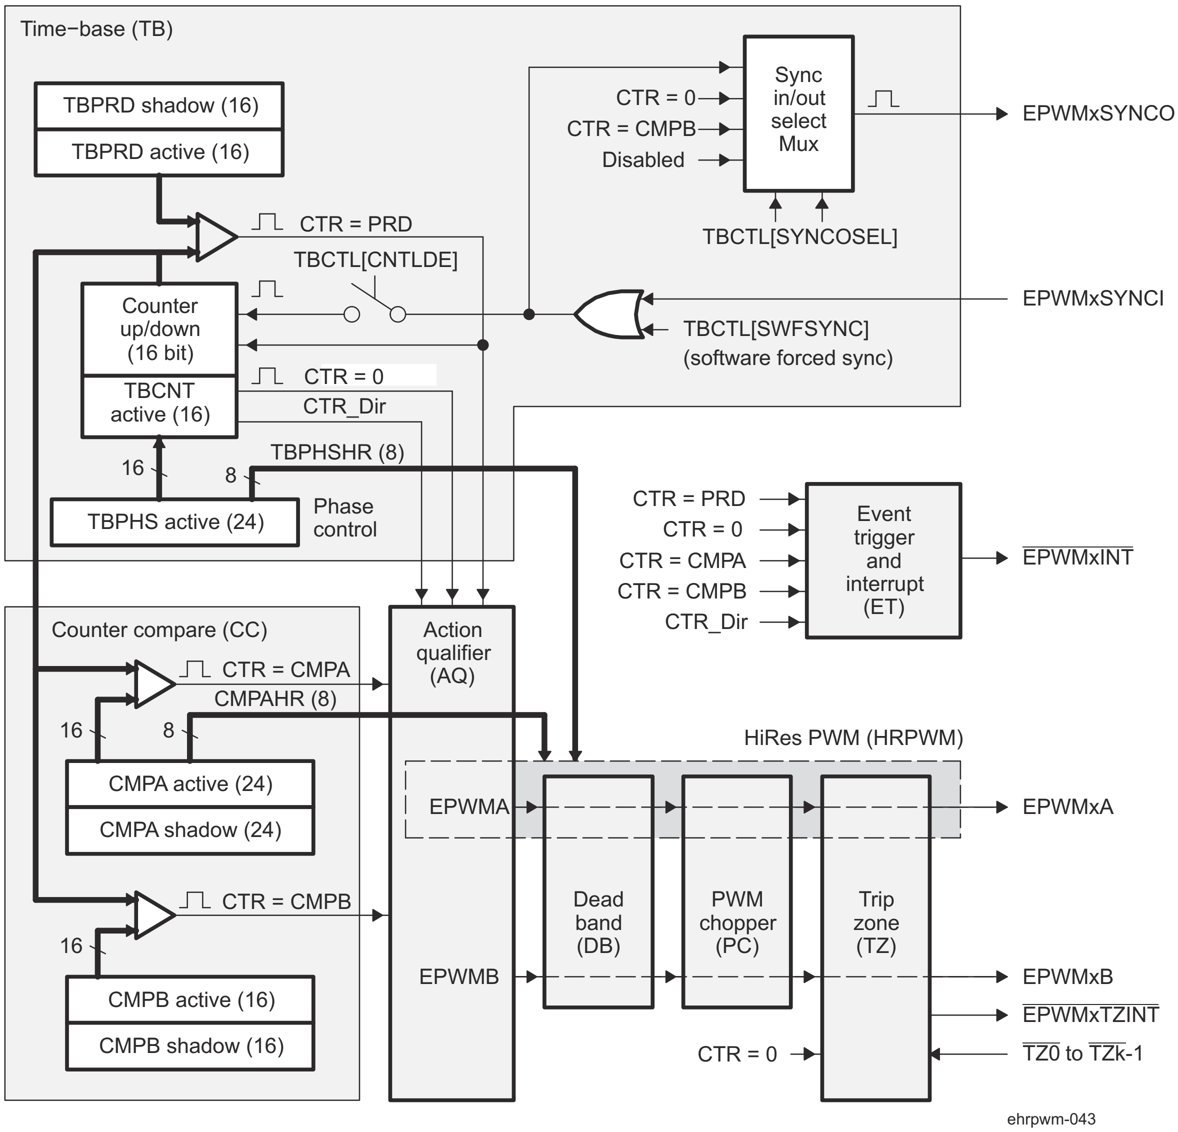

Figure 29-47. HRPWM System Interface

29.2.46 Purpose of the High-Resolution PWM Submodule

The enhanced high-resolution pulse-width modulator (eHRPWM) extends the time resolution capabilities of the conventionally derived digital pulse-width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
- Implemented using the A signal path of PWM, that is, on the EPWMxA output. **EPWMxB output has conventional PWM capabilities**

The ePWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 29-48, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

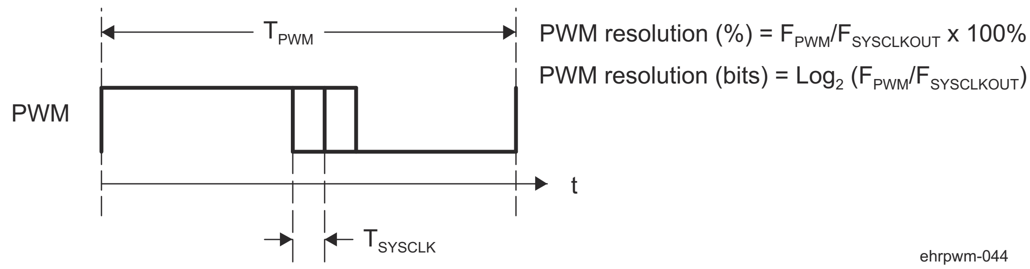

Figure 29-48. Resolution Calculations for Conventionally Generated PWM

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, you may want to consider HRPWM. As an example of improved performance offered by HRPWM, Table 29-44 shows resolution in bits for various PWM frequencies. Table 29-44 values assume a MEP step size of 180 ps. See your device-specific data manual for typical and maximum performance specifications for the MEP.

Table 29-44. Resolution for PWM and HRPWM

	Regular Resolution (PWM)		High Resolution (HRPWM)	
PWM Frequency (kHz)	Bits	%	Bits	%
20	12.3	0.0	18.1	0.000
50	11.0	0.0	16.8	0.001
100	10.0	0.1	15.8	0.002
150	9.4	0.2	15.2	0.003
200	9.0	0.2	14.8	0.004
250	8.6	0.3	14.4	0.005
500	7.6	0.5	13.8	0.007
1000	6.6	1.0	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2.0	11.4	0.036

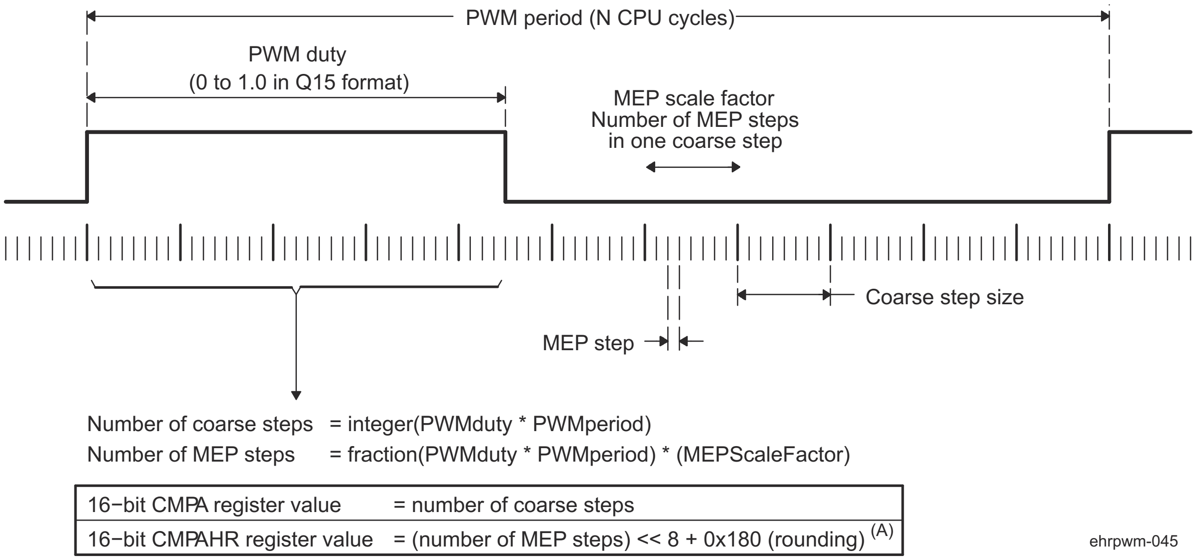
Although each application may differ, typical low-frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

29.2.47 Architecture of the High-Resolution PWM Submodule

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions.

Figure 29-49 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (HRPWM_CMPAHR).



A. For MEP range and rounding adjustment.

Figure 29-49. Operating Logic Using MEP

To generate an HRPWM waveform, configure the TBM, CCM, and AQM registers as you would to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical.

29.2.48 Controlling and Monitoring the High-Resolution PWM Submodule

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit EPWM_TBPHS and EPWM_CMPA registers used to control PWM operation.

- HRPWM_TBPHSHR - Time-Base Phase High-Resolution Register
- HRPWM_CMPAHR - Counter-Compare A High-Resolution Register

Table 29-45 lists the registers used to control and monitor the high-resolution PWM submodule.

Table 29-45. HRPWM Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
HRPWM_TBPHSHR	Extension Register for HRPWM Phase	4h	No
HRPWM_CMPAHR	Extension Register for HRPWM Duty	10h	Yes
HRPWM_HRCTL	HRPWM Configuration Register	1040h	No

29.2.49 Configuring the High-Resolution PWM Submodule

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRPWM_HRCTL register located at offset address 1040h. This register provides configuration options for the following key operating modes:

- **Edge Mode:** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE), or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge.
- **Control Mode:** The MEP is programmed to be controlled either from the HRPWM_CMPAHR register (duty cycle control) or the HRPWM_TBPHSHR register (phase control). RE or FE control mode should be used with HRPWM_CMPAHR register. BE control mode should be used with HRPWM_TBPHSHR register.
- **Shadow Mode:** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the HRPWM_CMPAHR register and should be chosen to be the same as the regular load option for the CMPA register. If HRPWM_TBPHSHR is used, then this option has no effect.

29.2.50 Operational Highlights for the High-Resolution PWM Submodule

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps, each of which has a time resolution on the order of 150 ps. The MEP works with the TBM and CCM registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. Table 29-46 shows the typical range of operating frequencies supported by the HRPWM.

Table 29-46. Relationship Between MEP Steps, PWM Frequency and Resolution

System (MHz)	MEP Steps Per SYSCLKOUT(1) (2) (3)	PWM Minimum (Hz)(4)	PWM Maximum (MHz)	Resolution at Maximum (Bits)(5)
50.0	111	763	2.50	11.1
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

(1) System frequency = SYSCLKOUT, that is, CPU clock. TBCLK = SYSCLKOUT
(2) Table data based on a MEP time resolution of 180 ps (this is an example value)
(3) MEP steps applied = $T_{SYSCLKOUT}$/180 ps in this example.
(4) PWM minimum frequency is based on a maximum period value, TBPRD = 65 535. PWM mode is asymmetrical up-count.
(5) Resolution in bits is given for the maximum PWM frequency stated.

29.2.51 HRPWM Edge Positioning

In a typical power control loop (switch modes, digital motor control (DMC), uninterruptible power supply (UPS)), a digital controller (PID, 2pole/2zero, lag/lead, etc.) issues a duty command, usually expressed in a per unit or percentage terms.

In the following example, assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on-time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. In Figure 29-50, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that you can attain. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 29-47.

By utilizing the MEP, you can achieve an edge position much closer to the desired point of 324 ns. Table 29-47 shows that in addition to the CMPA value, 22 steps of the MEP (HRPWM_CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ns.

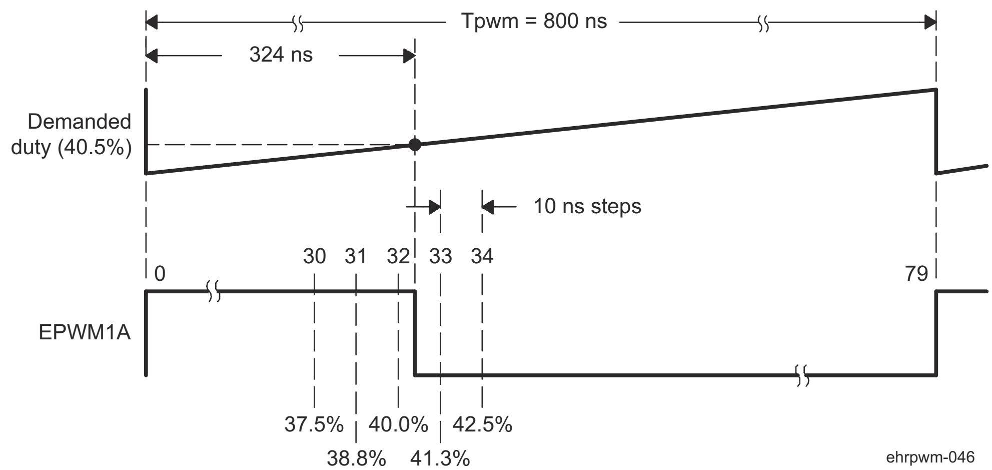


Figure 29-50. Required PWM Waveform for a Requested Duty = 40.5%

Table 29-47. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)

CMPA (count)(1) (2) (3)	DUTY (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

(1) System clock, SYSCLKOUT and TBCLK = 100 MHz, 10 ns
(2) For a PWM Period register value of 80 counts, PWM Period = 80 × 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz
(3) Assumed MEP step size for the above example = 180 ps

29.2.52 HRPWM Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard (EPWM_CMPA) and MEP (HRPWM_CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

System clock, SYSCLKOUT	=	10 ns (100 MHz)
PWM frequency	=	1.25 MHz (1/800 ns)
Required PWM duty cycle, **PWMDuty**	=	0.405 (40.5%)
PWM period in terms of coarse steps, **PWMperiod** (800 ns/10 ns)	=	80
Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), **MEP_SF**	=	55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	=	180h

Step 1: Percentage Integer Duty value conversion for EPWM_CMPA register

EPWM_CMPA register value	=	int(**PWMDuty** × **PWMperiod**); int means integer part
	=	int(0.405 × 80)
	=	int(32.4)
EPWM_CMPA register value	=	32 (20h)

Step 2: Fractional value conversion for HRPWM_CMPAHR register

HRPWM_CMPAHR register value	=	(frac(**PWMDuty** × **PWMperiod**) × **MEP_SF**) << 8) + 180h; frac means fractional part
	=	(frac(32.4) × 55 <<8) + 180h; Shift is to move the value as CMPAHR high byte
	=	((0.4 × 55) <<8) + 180h
	=	(22 <<8) + 180h
	=	22 × 256 + 180h ; Shifting left by 8 is the same multiplying by 256.
	=	5632 + 180h
	=	1600h + 180h
HRPWM_CMPAHR value	=	1780h; HRPWM_CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.

29.2.53 HRPWM Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational 3 SYSCLKOUT cycles after the period starts.

Duty cycle range limitations are illustrated in Figure 29-51. This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle.

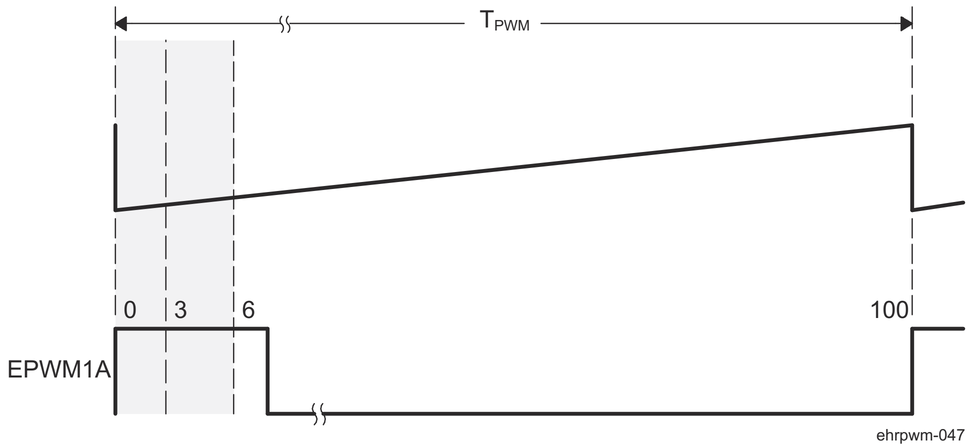

Figure 29-51. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz

If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in Figure 29-52. In this case low percent duty limitation is no longer an issue.

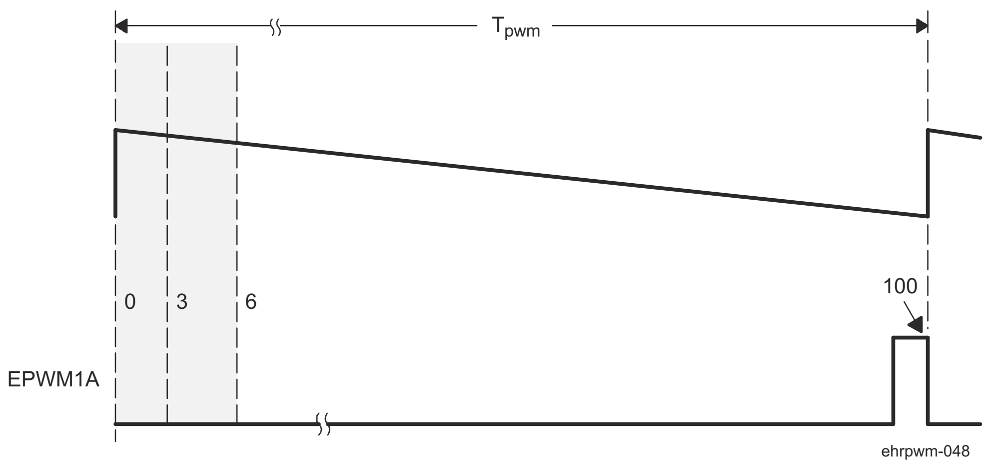

Figure 29-52. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz

29.2.54 eHRPWM Functional Register Groups

The Table 29-48 lists the groups of ePWM and the high-resolution PWM module registers according to their functionalities.

Table 29-48. ePWM/HRPWM Module Control and Status Registers Grouped by Submodule

Register Name	Offset	Size (×16)	Shadow	Register Description
Time-Base Submodule Registers				

Table 29-48. ePWM/HRPWM Module Control and Status Registers Grouped by Submodule (continued)

Register Name	Offset	Size (×16)	Shadow	Register Description
EPWM_TBCTL	0h	1	No	Time-Base Control Register
EPWM_TBSTS	2h	1	No	Time-Base Status Register
EPWM_TBPHS	6h	1	No	Time-Base Phase Register
EPWM_TBCNT	8h	1	No	Time-Base Counter Register
EPWM_TBPRD	Ah	1	Yes	Time-Base Period Register
Counter-Compare Submodule Registers				
EPWM_CMPCTL	Eh	1	No	Counter-Compare Control Register
EPWM_CMPA	12h	1	Yes	Counter-Compare A Register
EPWM_CMPB	14h	1	Yes	Counter-Compare B Register
Action-Qualifier Submodule Registers				
EPWM_AQCTLA	16h	1	No	Action-Qualifier Control Register for Output A (EPWMxA)
EPWM_AQCTLB	18h	1	No	Action-Qualifier Control Register for Output B (EPWMxB)
EPWM_AQSFRC	1Ah	1	No	Action-Qualifier Software Force Register
EPWM_AQCSFRC	1Ch	1	Yes	Action-Qualifier Continuous S/W Force Register Set
Dead-Band Generator Submodule Registers				
EPWM_DBCTL	1Eh	1	No	Dead-Band Generator Control Register
EPWM_DBRED	20h	1	No	Dead-Band Generator Rising Edge Delay Count Register
EPWM_DBFED	22h	1	No	Dead-Band Generator Falling Edge Delay Count Register
Trip-Zone Submodule Registers				
EPWM_TZSEL	24h	1	No	Trip-Zone Select Register
EPWM_TZCTL	28h	1	No	Trip-Zone Control Register
EPWM_TZEINT	2Ah	1	No	Trip-Zone Enable Interrupt Register
EPWM_TZFLG	2Ch	1	No	Trip-Zone Flag Register
EPWM_TZCLR	2Eh	1	No	Trip-Zone Clear Register
EPWM_TZFRC	30h	1	No	Trip-Zone Force Register
Event-Trigger Submodule Registers				
EPWM_ETSEL	32h	1	No	Event-Trigger Selection Register
EPWM_ETPS	34h	1	No	Event-Trigger Pre-Scale Register
EPWM_ETFLG	36h	1	No	Event-Trigger Flag Register
EPWM_ETCLR	38h	1	No	Event-Trigger Clear Register
EPWM_ETFRC	3Ah	1	No	Event-Trigger Force Register
PWM-Chopper Submodule Registers				
EPWM_PCCTL	3Ch	1	No	PWM-Chopper Control Register
High-Resolution PWM (HRPWM) Submodule Registers				
HRPWM_TBPHSHR	4h	1	No	Extension for HRPWM Phase Register
HRPWM_CMPAHR	10h	1	No	Extension for HRPWM Counter-Compare A Register
HRPWM_HRCTL	40h	1	No	HRPWM Control Register

29.2.55 PWMSS_EPWM Register Manual

This section provides description of the device PWMSS ePWM and High Resolution-PWM relevant functional registers.

29.2.56 PWMSS_EPWM Instance Summary

29.2.59 PWMSS_EPWM Register Description

Table 29-51. EPWM_TBCTL

Address Offset	0x0000 0000		
Physical Address	0x4843 E200 0x4844 0200 0x4844 2200	**Instance**	PWMSS1_EPWM PWMSS2_EPWM PWMSS3_EPWM
Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FREE_SOFT		PHSDIR	CLKDIV			HSPCLKDIV			SWFSYNC	SYNCOSEL		PRDLD	PHSEN	CTRMODE	

Bits	Field Name	Description	Type	Reset
15:14	FREE_SOFT	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events: 0x0 = Stop after the next time-base counter increment or decrement 0x1 = Stop when counter completes a whole cycle. (a) Up-count mode: stop when the time-base counter = period (EPWM_TBCNT bitfield TBCNT = TBPRD in EPWM_TBPRD active register). (b) Down-count mode: stop when the time-base counter = 0000 (EPWM_TBCNT bitfield TBCNT = 0000h). (c) Up-down-count mode: stop when the time-base counter = 0000 (EPWM_TBCNT bitfield TBCNT = 0000h). 0x2 = Free run 0x3 = Free run	RW	0x0
13	PHSDIR	Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (EPWM_TBCNT) will count after a synchronization event occurs and a new phase value is loaded from the phase (EPWM_TBPHS) register. This is irrespective of the direction of the counter before the synchronization event.. In the up-count and down-count modes this bit is ignored. 0x0 = Count down after the synchronization event. 0x1 = Count up after the synchronization event.	RW	0x0
12:10	CLKDIV	Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. TBCLK = SYSCLKOUT/(HSPCLKDIV x CLKDIV) 0x0 = /1 (default on reset) 0x1 = /2 0x2 = /4 0x3 = /8 0x4 = /16 0x5 = /32 0x6 = /64 0x7 = /128	RW	0x0

Bits	Field Name	Description	Type	Reset
9:7	HSPCLKDIV	High-Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. TBCLK = SYSCLKOUT/(HSPCLKDIV x CLKDIV). This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral. 0x0 = /1 0x1 = /2 (default on reset) 0x2 = /4 0x3 = /6 0x4 = /8 0x5 = /10 0x6 = /12 0x7 = /14	RW	0x0
6	SWFSYNC	Software Forced Synchronization Pulse. 0x0 = Writing a 0 has no effect and reads always return a 0. 0x1 = Writing a 1 forces a one-time synchronization pulse to be generated. This event is ORed with the EPWMxSYNCI input of the ePWM module. SWFSYNC is valid (operates) only when EPWMxSYNCI is selected by SYNCOSEL = 00.	RW	0x0
5:4	SYNCOSEL	Synchronization Output Select. These bits select the source of the EPWMxSYNCO signal. 0x0 = EPWMxSYNC: 0x1 = TBCNT = 0: Time-base counter equal to zero (EPWM_TBCNT bitfield TBCNT= 0000h) 0x2 = TBCNT = CMPB : Time-base counter equal to counter-compare B (EPWM_TBCNT bitfield TBCNT = CMPB bitfield in EPWM_CMPB) 0x3 = Disable EPWMxSYNCO signal	RW	0x0
3	PRDLD	Active Period Register Load From Shadow Register Select 0x0 = The period register (EPWM_TBPRD) is loaded from its shadow register when the time-base counter, TBCNT, is equal to zero. A write or read to the EPWM_TBPRD register accesses the shadow register. 0x1 = Load the EPWM_TBPRD register immediately without using a shadow register. A write or read to the EPWM_TBPRD register directly accesses the active register.	RW	0x0
2	PHSEN	Counter Register Load From Phase Register Enable 0x0 = Do not load the time-base counter (EPWM_TBCNT) from the time-base phase register (EPWM_TBPHS) 0x1 = Load the time-base counter with the phase register when an EPWMxSYNCI input signal occurs or when a software synchronization is forced by the SWFSYNC bit.	RW	0x0

Bits	Field Name	Description	Type	Reset
1:0	CTRMODE	Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 0x0 = Up-count mode 0x1 = Down-count mode 0x2 = Up-down-count mode 0x3 = Stop-freeze counter operation (default on reset)	RW	0x0

Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED													CTRMAX	SYNCI	CTRDIR

Bits	Field Name	Description	Type	Reset
15:3	RESERVED		R	0x0000
2	CTRMAX	Time-Base Counter Max Latched Status Bit. 0x0 = Reading a 0 indicates the time-base counter never reached its maximum value. Writing a 0 will have no effect. 0x1 = Reading a 1 on this bit indicates that the time-base counter reached the max value 0xFFFF. Writing a 1 to this bit will clear the latched event.	RW1C	0x0
1	SYNCI	Input Synchronization Latched Status Bit. 0x0 = Writing a 0 will have no effect. Reading a 0 indicates no external synchronization event has occurred. 0x1 = Reading a 1 on this bit indicates that an external synchronization event has occurred (EPWMxSYNCI). Writing a 1 to this bit will clear the latched event.	RW1C	0x0

Bits	Field Name	Description	Type	Reset
0	CTRDIR	Time-Base Counter Direction Status Bit. At reset, the counter is frozen, therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via EPWM_TBCTL[1:0] CTRMODE. 0x0 = Time-Base Counter is currently counting down. 0x1 = Time-Base Counter is currently counting up.	R	0x0

TBPHS															

Bits	Field Name	Description	Type	Reset
15:0	TBPHS	These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. (a) If EPWM_TBCTL[2] PHSEN = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase. (b) If EPWM_TBCTL[2] PHSEN = 1, then the time-base counter (TBCNT) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization.	RW	0x0

TBPRD															

Bits	Field Name	Description	Type	Reset
15:0	TBPRD	These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the EPWM_TBCTL[3] PRDLD bit. By default this register is shadowed. (a) If EPWM_TBCTL[3] PRDLD = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero. (b) If EPWM_TBCTL[3] PRDLD = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. (c) The active and shadow registers share the same memory map address.	RW	0x0

Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMPA															

Bits	Field Name	Description	Type	Reset
15:0	CMPA	The value in the active EPWM_CMPA register is continuously compared to the time-base counter (register EPWM_TBCNT). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the EPWM_AQCTLA and EPWM_AQCTLB registers. The actions that can be defined in the EPWM_AQCTLA and EPWM_AQCTLB registers include the following. (a) Do nothing the event is ignored. (b) Clear: Pull the EPWMxA and/or EPWMxB signal low. (c) Set: Pull the EPWMxA and/or EPWMxB signal high. (d) Toggle the EPWMxA and/or EPWMxB signal. Shadowing of this register is enabled and disabled by the EPWM_CMPCTL[4] SHDWAMODE bit. By default this register is shadowed. (a) If EPWM_CMPCTL[4] SHDWAMODE = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the EPWM_CMPCTL[1:0] LOADAMODE bit field determines which event will load the active register from the shadow register. (b) Before a write, the EPWM_CMPCTL[8] SHDWAFULL bit can be read to determine if the shadow register is currently full. (c) If EPWM_CMPCTL[4] SHDWAMODE = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. (d) In either mode, the active and shadow registers share the same memory map address.	RW	0x0

Address offset	0x1E		
Physical Address	0x4843 E21E 0x4844 021E 0x4844 221E	**Instance**	PWMSS1_EPWM PWMSS2_EPWM PWMSS3_EPWM
Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED										IN_MODE		POLSEL		OUT_MODE	

Bits	Field Name	Description	Type	Reset
15:6	RESERVED		R	0x0
5:4	IN_MODE	Dead Band Input Mode Control. Bit 5 controls the S5 switch and bit 4 controls the S4 switch. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms, the default is EPWMxA In is the source for both falling and rising-edge delays. 0x0 = EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 0x1 = EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 0x2 = EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 0x3 = EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.	RW	0x0

Bits	Field Name	Description	Type	Reset
3:2	POLSEL	Polarity Select Control. Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that EPWM_DBCTL[1:0] OUT_MODE = 0b11 and EPWM_DBCTL[5:4] IN_MODE = 0b00. Other enhanced modes are also possible, but not regarded as typical usage modes. 0x0 = Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 0x1 = Active low complementary (ALC) mode. EPWMxA is inverted. 0x2 = Active high complementary (AHC). EPWMxB is inverted. 0x3 = Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.	RW	0x0
1:0	OUT_MODE	Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch. This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay. 0x0 = Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect. 0x1 = Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by EPWM_DBCTL[5:4] IN_MODE. 0x2 = Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule. The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by EPWM_DBCTL[5:4] IN_MODE. 0x3 = Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by EPWM_DBCTL[5:4] IN_MODE.	RW	0x0

RESERVED												INTCNT		INTPRD	

Bits	Field Name	Description	Type	Reset
15:4	RESERVED		R	0x0
3:2	INTCNT	ePWM Interrupt Event (EPWMx_INT) Counter Register. These bits indicate how many selected EPWM_ETSEL[2:0] INTSEL events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, EPWM_ETSEL[0] INT = 0 or the interrupt flag is set, EPWM_ETFLG[0] INT = 1, the counter will stop counting events when it reaches the period value EPWM_ETPS[3:2] INTCNT = EPWM_ETPS[1:0] INTPRD. 0x0 = No events have occurred. 0x1 = 1 event has occurred. 0x2 = 2 events have occurred. 0x3 = 3 events have occurred.	R	0x0
1:0	INTPRD	ePWM Interrupt (EPWMx_INT) Period Select. These bits determine how many selected EPWM_ETSEL[2:0] INTSEL events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (EPWM_ETSEL[0] INT = 1). If the interrupt status flag is set from a previous interrupt (EPWM_ETFLG[0] INT = 1) then no interrupt will be generated until the flag is cleared via the EPWM_ETCLR[0] INT bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the EPWM_ETPS[3:2] INTCNT bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented. 0x0 = Disable the interrupt event counter. No interrupt will be generated and EPWM_ETFRC[0] INT is ignored. 0x1 = Generate an interrupt on the first event INTCNT = 01 (first event) 0x2 = Generate interrupt on EPWM_ETPS[3:2] INTCNT = 0b10 (second event) 0x3 = Generate interrupt on EPWM_ETPS[3:2] INTCNT = 0b11 (third event)	RW	0x0

29.3 Enhanced Capture (eCAP) Module

29.3.1 eCAP Overview

29.3.2 Purpose of the eCAP Peripheral

Uses for eCAP include:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

29.3.3 eCAP Features

The eCAP module includes the following features:

- 32-bit time base counter
- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

29.3.4 eCAP Functional Description

The eCAP module represents one complete capture channel that can be instantiated multiple times depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers (PWMSS_ECAP_CAP1-PWMSS_ECAP_CAP4)
- 4-stage sequencer (Modulo4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (PWMSS_ECAP_CAP1-PWMSS_ECAP_CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

Multiple identical eCAP modules can be contained in a system as shown in Figure 29-53. For actual number of eCAP modules integrated in the device, refer to the Section 29.1.3. As already described in Section 29.1.3, the letter x within a signal or module name is used to indicate a generic eCAP instance on a device. For example, output interrupt request, ECAP1INT belongs to eCAP1, ECAP2INT belongs to eCAP2, etc.

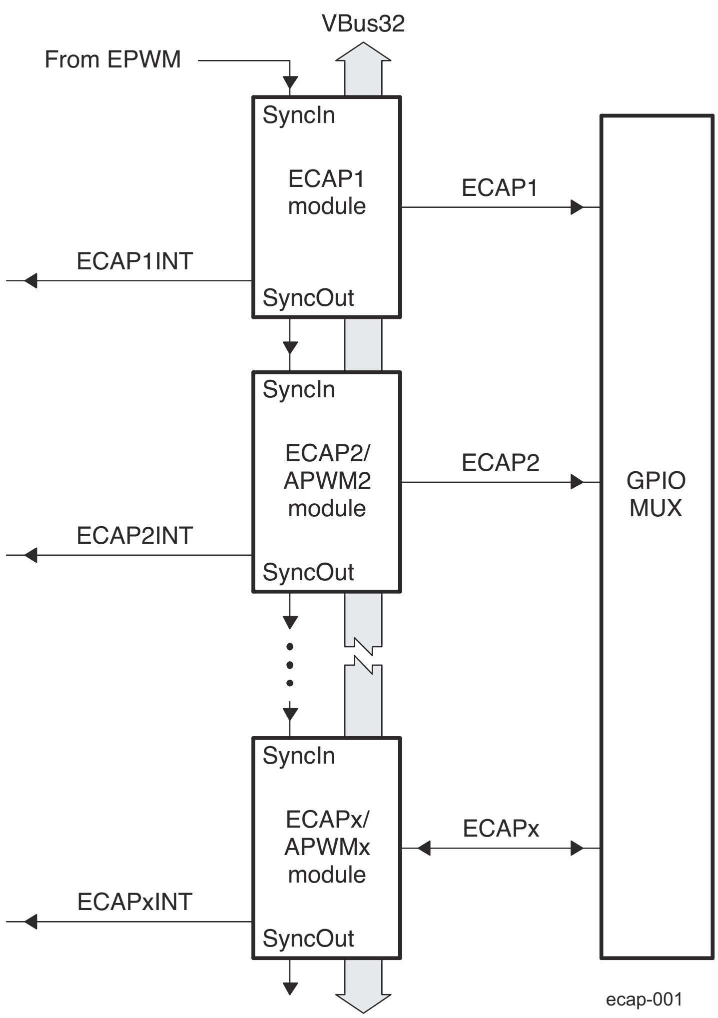

Figure 29-53. Multiple eCAP Modules

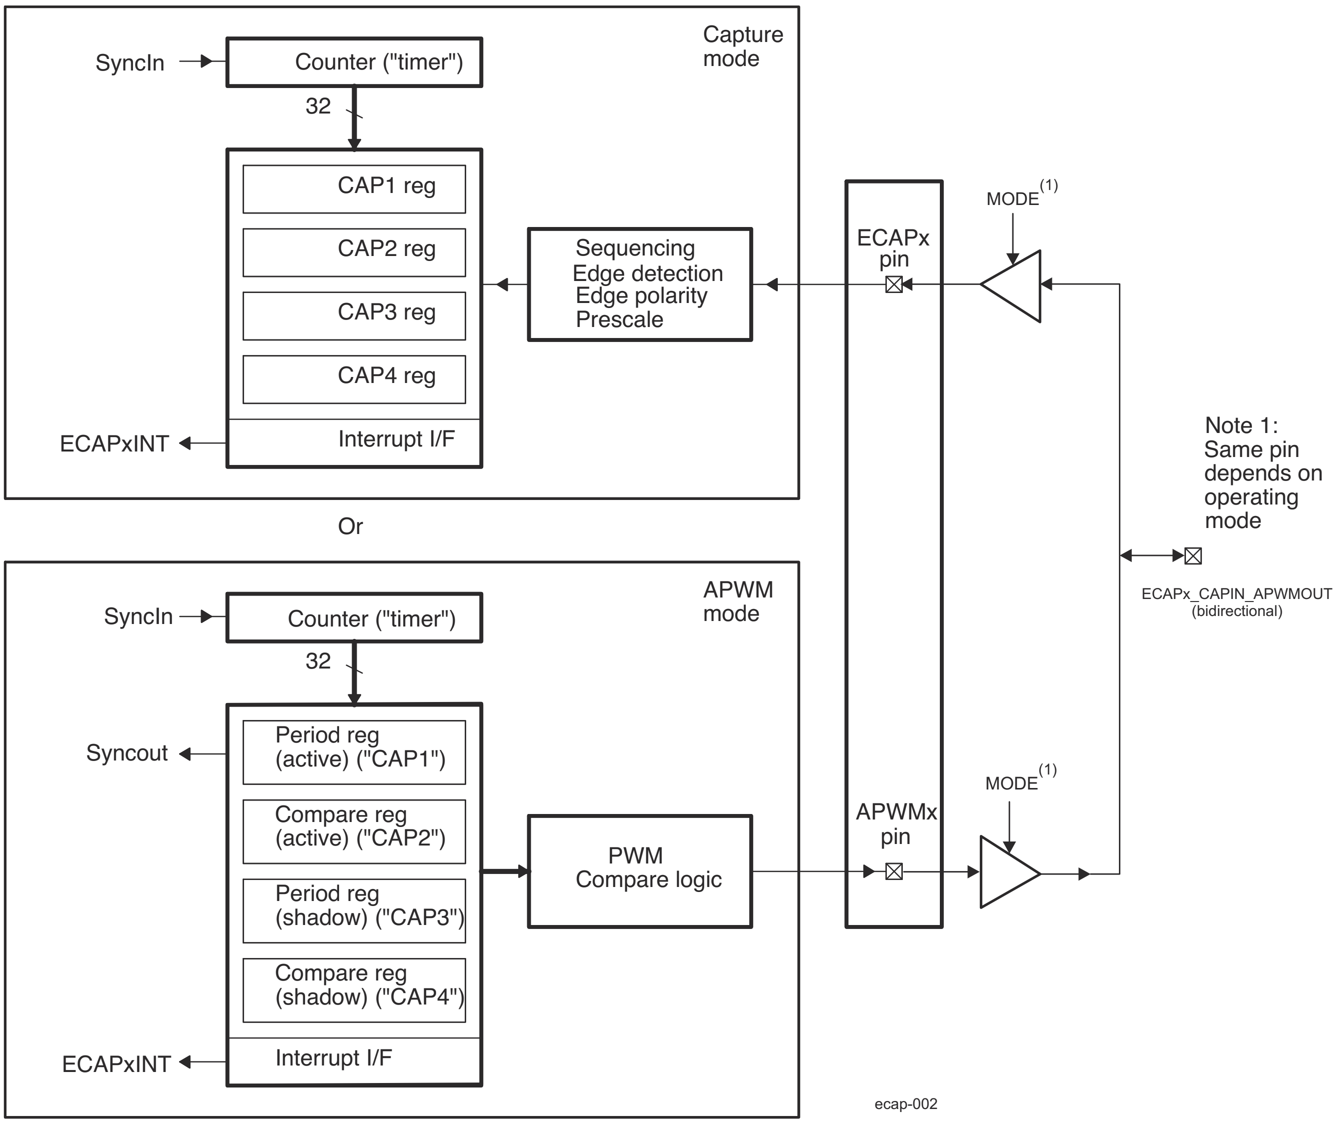
29.3.5 Capture and APWM Operating Mode

The eCAP module resources can be used to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 registers become the active period and compare registers, respectively, while PWMSS_ECAP_CAP3 and PWMSS_ECAP_CAP4 registers become the period and capture shadow registers, respectively. Figure 29-54 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.



A. A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.

B. In APWM mode, writing any value to PWMSS_ECAP_CAP1/PWMSS_ECAP_CAP2 active registers also writes the same value to the corresponding shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4. This emulates immediate mode. Writing to the shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4 invokes the shadow mode.

Figure 29-54. Capture and APWM Modes of Operation

29.3.6 eCAP Capture Mode Description

Figure 29-55 shows the various components that implement the capture function.

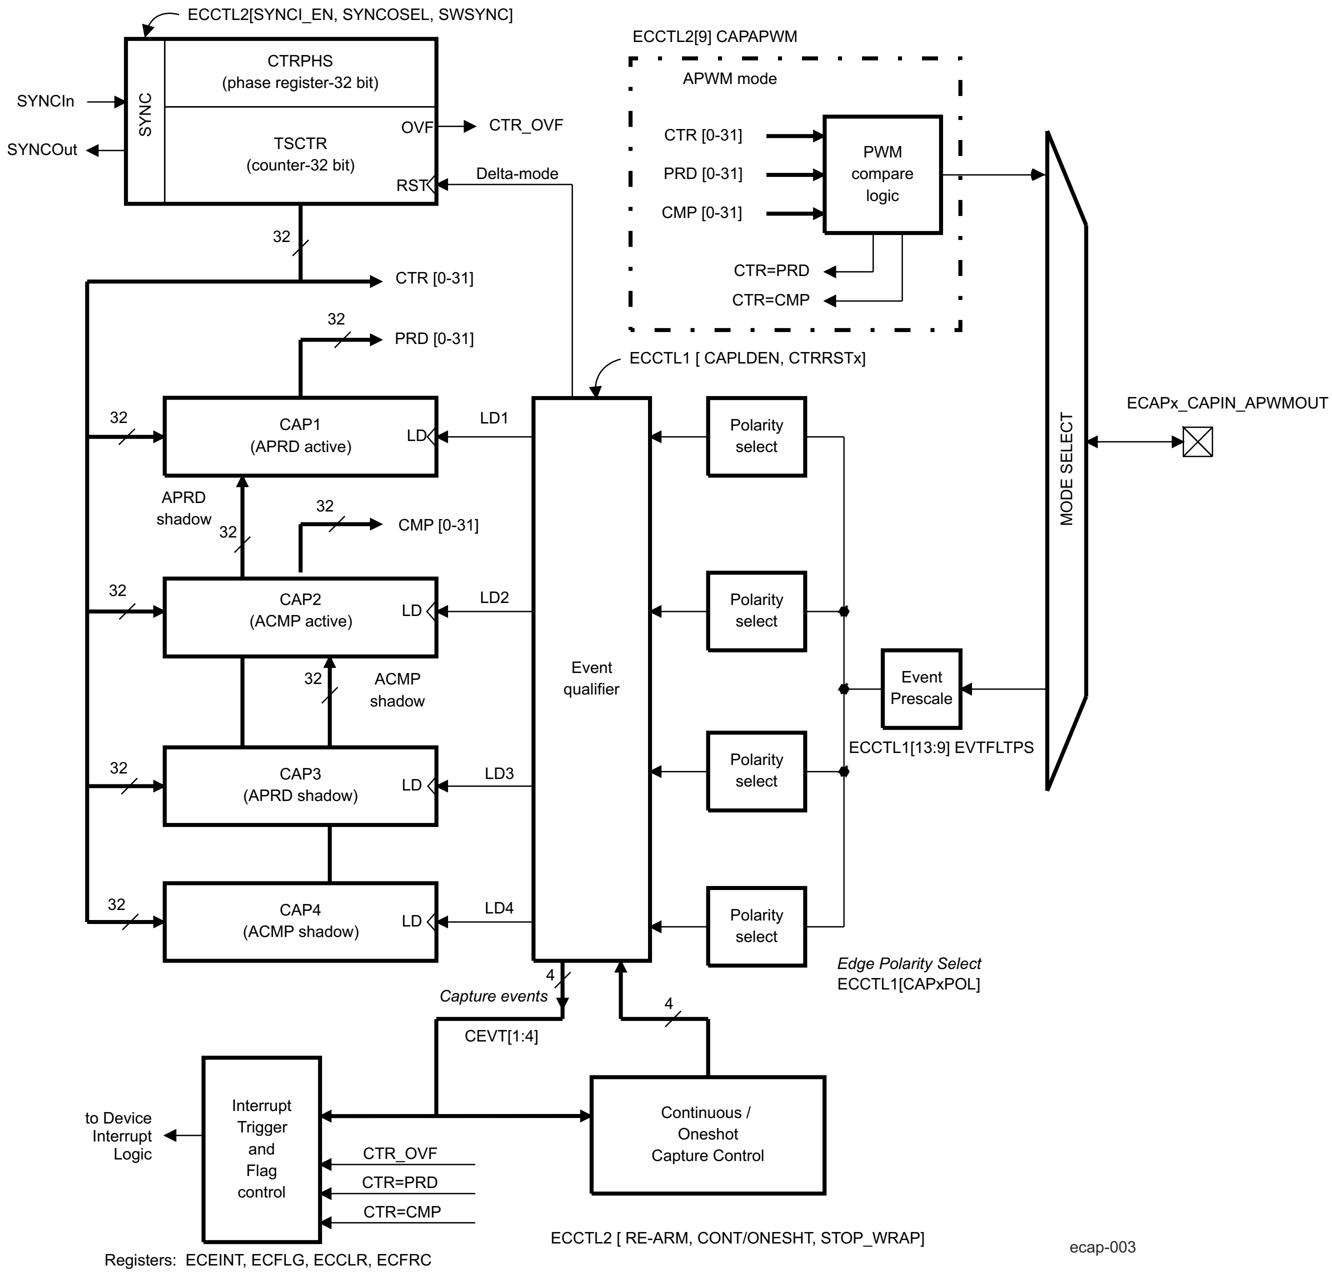


Figure 29-55. Capture Function Diagram

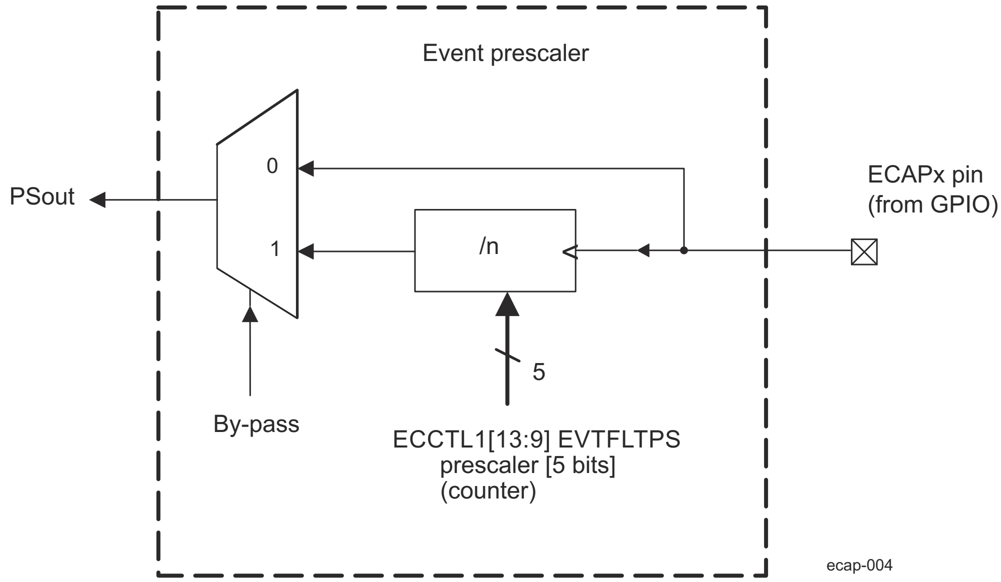
29.3.7 eCAP Event Prescaler

An input capture signal (pulse train) can be prescaled by N = 2-62 (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 29-56 shows a functional diagram and Figure 29-57 shows the operation of the prescale function.



A. When a prescale value of 1 is chosen (PWMSS_ECAP_ECCTL1[13:9] EVTFLTPS = 0b0000) the input capture signal by-passes the prescale logic completely.

Figure 29-56. Event Prescale Control

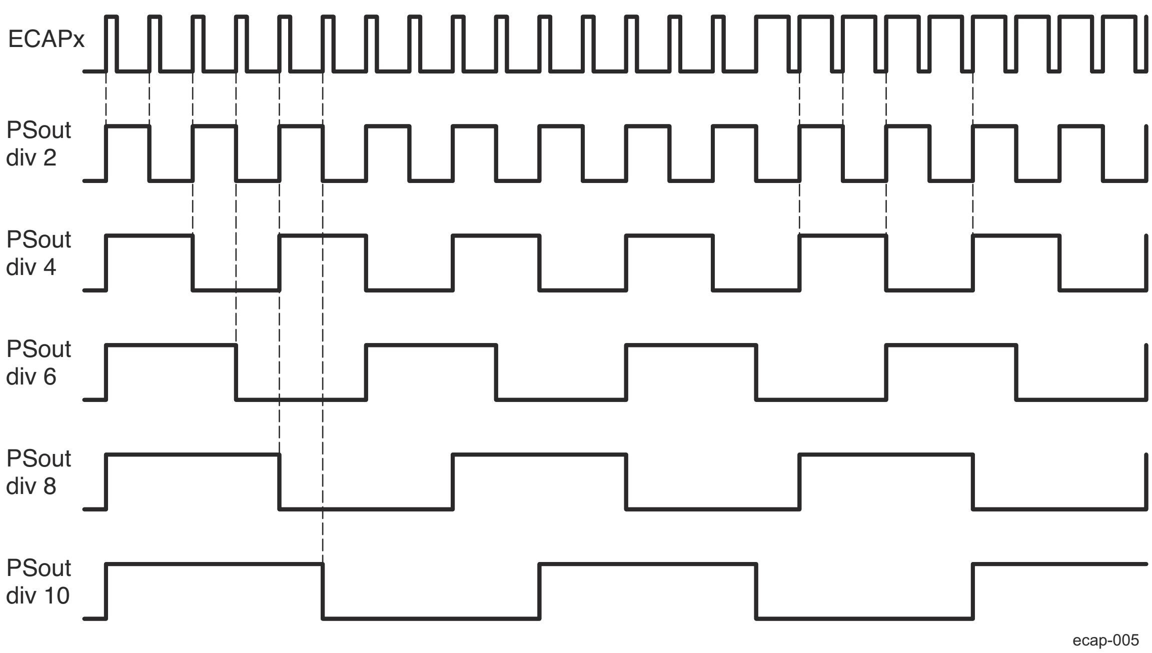


Figure 29-57. Prescale Function Waveforms

29.3.8 eCAP Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAP*n* register by the Mod4 counter. The CAP*n* register is loaded on the falling edge.

29.3.9 eCAP Continuous/One-Shot Control

- The Mod4 (2 bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal stops the Mod4 counter and inhibits further loads of the PWMSS_ECAP_CAP1-PWMSS_ECAP_CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block (Figure 29-58) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of PWMSS_ECAP_CAP1-4 registers (time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of PWMSS_ECAP_CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to PWMSS_ECAP_CAP1-4 in a circular buffer sequence.

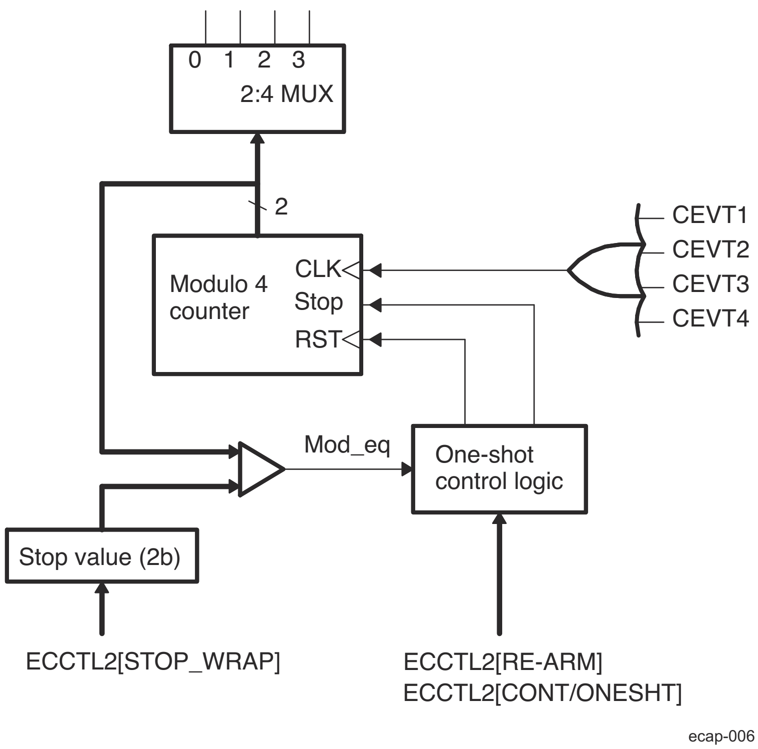

Figure 29-58. eCAP Continuous/One-shot Block Diagram

29.3.10 eCAP 32-Bit Counter and Phase Control

This counter (Figure 29-59) provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

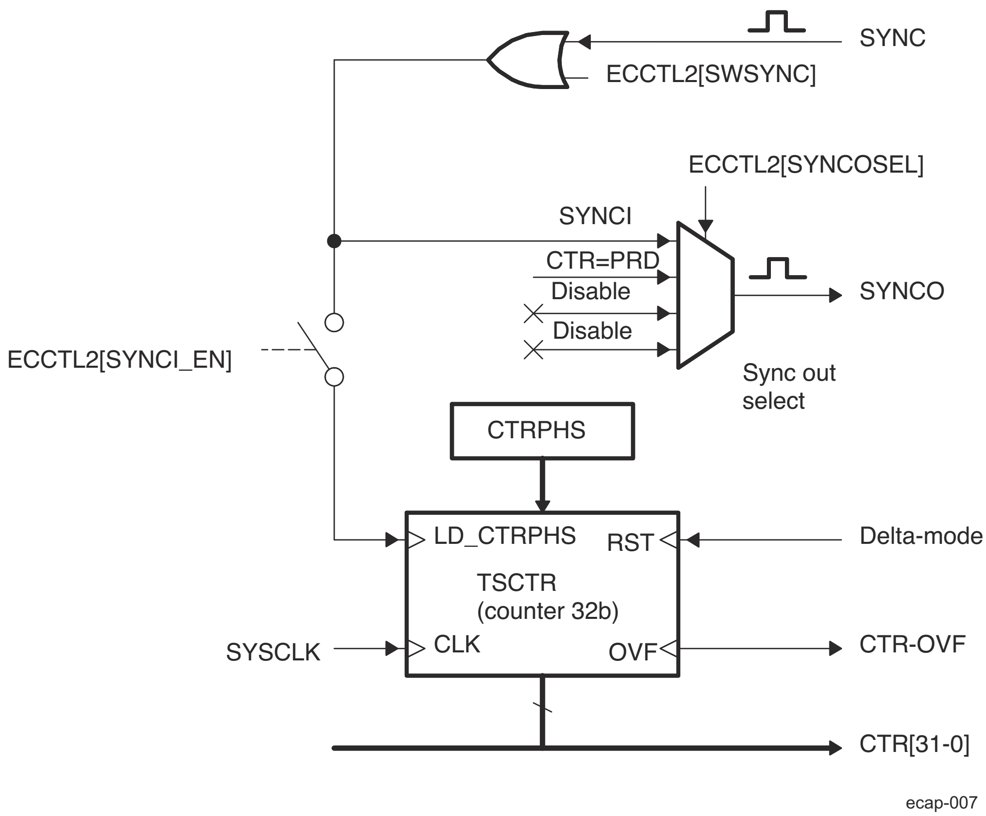

Figure 29-59. eCAP Counter and Synchronization Block Diagram

29.3.11 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 registers become the active period and compare registers, respectively, in APWM mode.

PWMSS_ECAP_CAP3 and PWMSS_ECAP_CAP4 registers become the respective shadow registers (APRD and ACMP) for PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 during APWM operation.

29.3.12 eCAP Interrupt Control

An Interrupt can be generated on capture events (CEVT1-CEVT4, CNTOVF) or APWM events (TSCNT = PRD, TSCNT = CMP). See Figure 29-60.

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CNTOVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the eCAP*n* module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, TSCNT = PRD, TSCNT = CMP) can be generated. The interrupt enable register (PWMSS_ECAP_ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (PWMSS_ECAP_ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (PWMSS_ECAP_ECCLR) before any other interrupt pulses are generated. You can force an interrupt event via the interrupt force register (PWMSS_ECAP_ECFRC). This is useful for test purposes.

29.3.13 eCAP Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of PWMSS_ECAP_CAP1 or PWMSS_ECAP_CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to PWMSS_ECAP_CAP1 or PWMSS_ECAP_CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0]

Note

The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (PWMSS_ECAP_ECCTL2[9] CAPAPWM == 0). The TSCNT = PRD, TSCNT = CMP flags are only valid in APWM mode (PWMSS_ECAP_ECCTL2[9] CAPAPWM == 1). CNTOVF flag is valid in both modes.

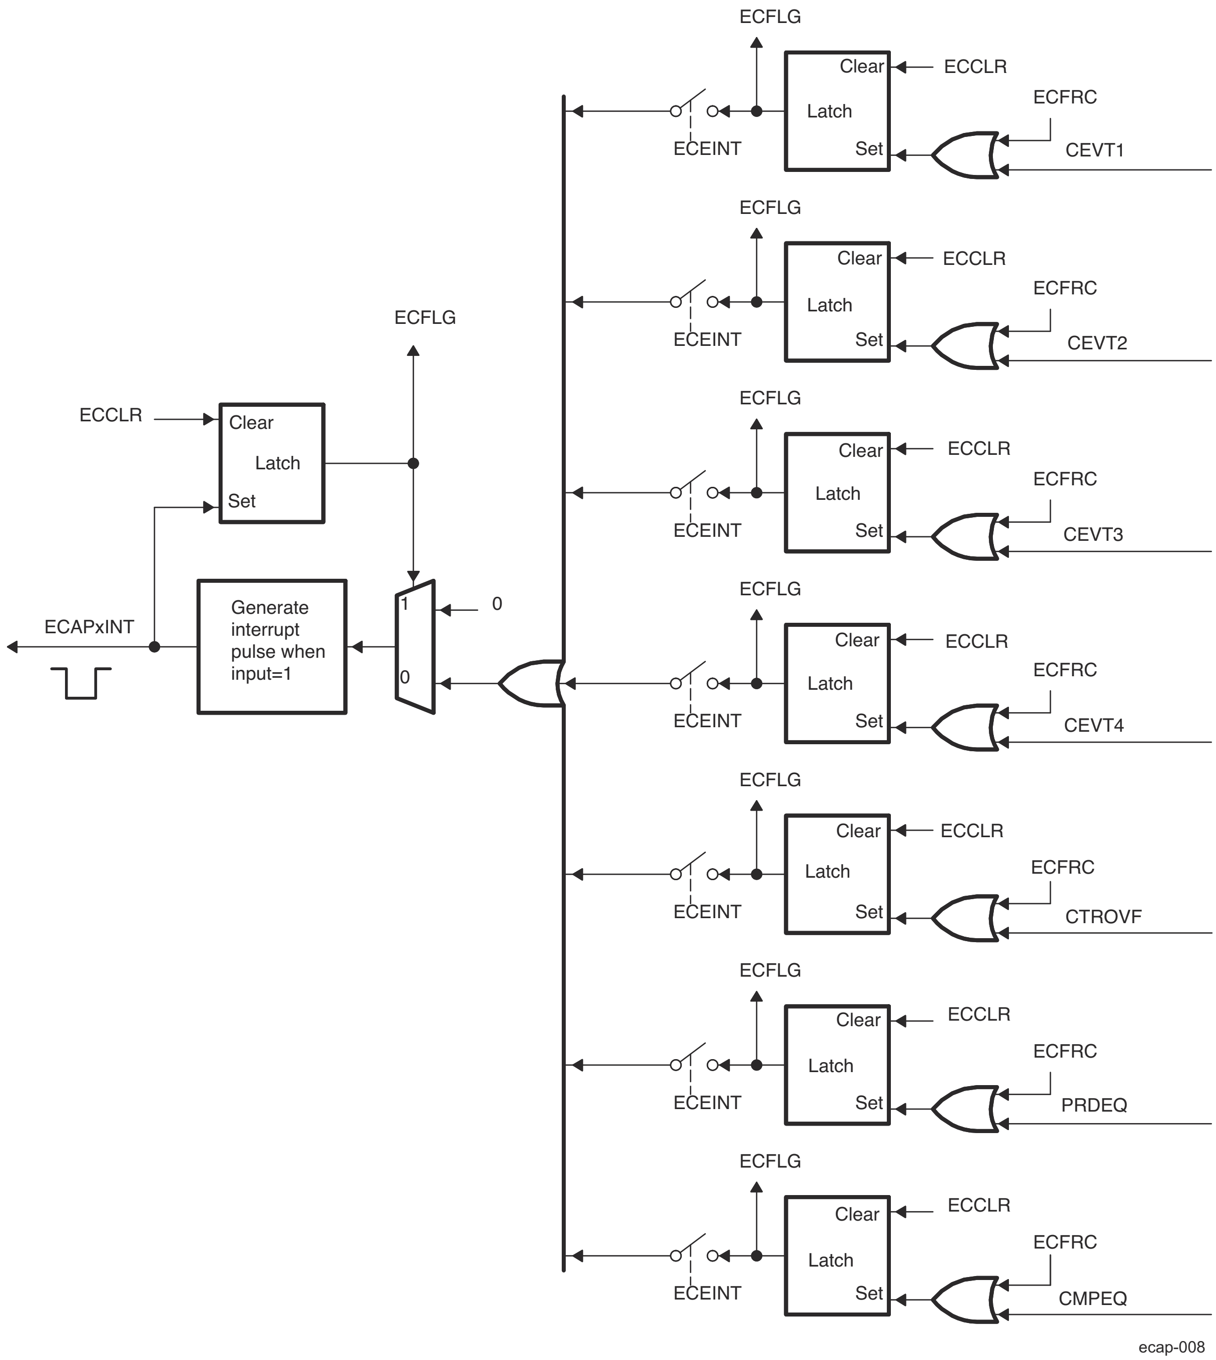

Figure 29-60. Interrupts in eCAP Module

29.3.14 eCAP Module APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When PWMSS_ECAP_CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (PWMSS_ECAP_CAP3/4). The shadow register contents are transferred over to PWMSS_ECAP_CAP1/2 registers either immediately upon a write, or on a TSCNT = PRD trigger.
- In APWM mode, writing to PWMSS_ECAP_CAP1/PWMSS_ECAP_CAP2 active registers will also write the same value to the corresponding shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4. This emulates immediate mode. Writing to the shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, you only need to use the shadow registers.

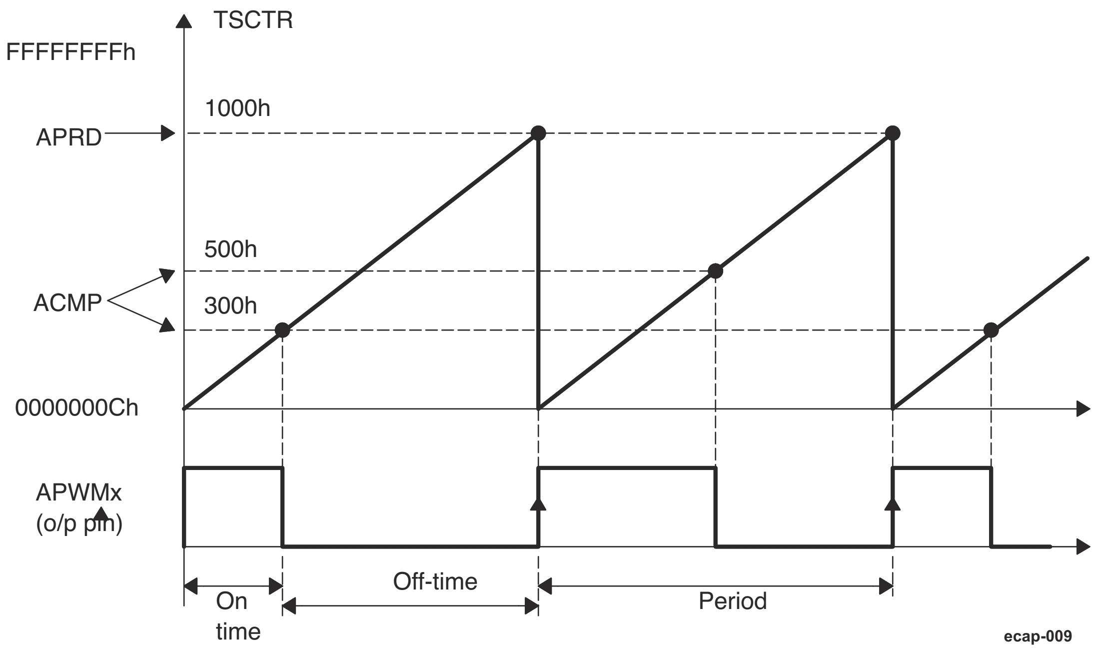

Figure 29-61. PWM Waveform Details Of eCAP APWM Mode Operation

The behavior of APWM active-high mode (APWMPOL == 0) is:

```
CMP = 0x00000000, output low for duration of period (0% duty)
```

```
CMP = 0x00000001, output high 1 cycle
```

```
CMP = 0x00000002, output high 2 cycles
```

```
CMP = PERIOD, output high except for 1 cycle (<100% duty)
```

```
CMP = PERIOD+1, output high for complete period (100% duty)
```

```
CMP > PERIOD+1, output high for complete period
```

The behavior of APWM active-low mode (APWMPOL == 1) is:

```
CMP = 0x00000000, output high for duration of period (0% duty)
```

```
CMP = 0x00000001, output low 1 cycle
```

```
CMP = 0x00000002, output low 2 cycles
```

```
CMP = PERIOD, output low except for 1 cycle (<100% duty)
```

```
CMP = PERIOD+1, output low for complete period (100% duty)
```

```
CMP > PERIOD+1, output low for complete period
```

29.3.15 Summary of eCAP Functional Registers

Table 29-111 shows the eCAP module control and status register set. All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode. The 16 least-significant bits of a 32-bit register are located on lowest address (even address).

Note

In APWM mode, writing to PWMSS_ECAP_CAP1/PWMSS_ECAP_CAP2 active registers also writes the same value to the corresponding shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4. This emulates immediate mode. Writing to the shadow registers PWMSS_ECAP_CAP3/PWMSS_ECAP_CAP4 invokes the shadow mode.

Table 29-111. eCAP Control and Status Functional Registers

Physical Address	0x4843 E104 0x4844 0104 0x4844 2104	**Instance**	PWMSS1_ECAP PWMSS2_ECAP PWMSS3_ECAP
Description	Counter Phase Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNTPHS																															

Bits	Field Name	Description	Type	Reset
31:0	CNTPHS	Counter phase value register that can be programmed for phase lag/lead. This register shadows TSCNT and is loaded into PWMSS_ECAP_TSCNT upon either a SYNCI event or S/W force via a control bit. Used to achieve phase control synchronization with respect to other eCAP and EPWM time-bases.	RW	0x0

Table 29-128. PWMSS_ECAP_ECCTL2

Address Offset	0x0000 002A		
Physical Address	0x4843 E12A 0x4844 012A 0x4844 212A	**Instance**	PWMSS1_ECAP PWMSS2_ECAP PWMSS3_ECAP
Description	ECAP Control Register 2		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED	APWM POL	CAPAP WM	SWSY NC	SYNCO_SEL	SYNCI _EN	TSCNT STP	REAR MRES ET	STOPVALUE	CONT ONES HT

Bits	Field Name	Description	Type	Reset
15:11	RESERVED		R	0x0
10	APWMPOL	APWM output polarity select. This is applicable only in APWM operating mode 0x0 = Output is active high (Compare value defines high time) 0x1 = Output is active low (Compare value defines low time)	RW	0x0
9	CAPAPWM	CAP/APWM operating mode select **0x0 = ECAP module operates in capture mode. This mode forces the following configuration.** (a) Inhibits TSCNT resets via TSCNT = PRD event. (b) Inhibits shadow loads on PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 registers. (c) Permits user to enable PWMSS_ECAP_CAP1-PWMSS_ECAP_CAP4 register load. (d) ECAP input/APWM output pin operates as a capture input. **0x1 = ECAP module operates in APWM mode. This mode forces the following configuration.** (a) Resets TSCNT on TSCNT = PRD event (period boundary). (b) Permits shadow loading on PWMSS_ECAP_CAP1 and PWMSS_ECAP_CAP2 registers. (c) Disables loading of time-stamps into PWMSS_ECAP_CAP1 - PWMSS_ECAP_CAP4 registers. (d) ECAP input/APWM ouput pin operates as a APWM output.	RW	0x0
8	SWSYNC	Software-forced Counter (TSCNT) Synchronizing. This provides a convenient software method to synchronize some or all ECAP time bases. In APWM mode, the synchronizing can also be done via the TSCNT = PRD event. Note: Selection TSCNT = PRD is meaningful only in APWM mode. However, you can choose it in CAP mode if you find doing so useful. 0x0 = Writing a zero has no effect. Reading always returns a zero 0x1 = Writing a one forces a TSCNT shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0b00. After writing a 1, this bit returns to a zero.	RW	0x0
7:6	SYNCO_SEL	Sync-Out Select 0x0 = Select sync-in event to be the sync-out signal (pass through) 0x1 = Select TSCNT = PRD event to be the sync-out signal 0x2 = Disable sync out signal 0x3 = Disable sync out signal	RW	0x0

Bits	Field Name	Description	Type	Reset
5	SYNCI_EN	Counter (TSCNT) Sync-In select mode 0x0 = Disable sync-in option 0x1 = Enable counter (TSCNT) to be loaded from PWMSS_ECAP_CNTPHS register upon either a SYNCI signal or a S/W force event.	RW	0x0
4	TSCNTSTP	Time Stamp (TSCNT) Counter Stop (freeze) Control 0x0 = TSCNT stopped 0x1 = TSCNT free-running	RW	0x0
3	REARMRESET	One-Shot Re-Arming Control, that is, wait for stop trigger. Note: The re-arm function is valid in one shot or continuous mode. 0x0 = Has no effect (reading always returns a 0) 0x1 = Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to zero. 2) Unfreezes the Mod4 counter. 3) Enables capture register loads.	RW	0x0
2:1	STOPVALUE	Stop value for one-shot mode. This is the number (between 1 and 4) of captures allowed to occur before the CAP (1 through 4) registers are frozen, that is, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1 and 4) of the capture register in which the circular buffer wraps around and starts again. Notes: STOPVALUE is compared to Mod4 counter and, when equal, the following two actions occur. (1) Mod4 counter is stopped (frozen). (2) Capture register loads are inhibited. In one-shot mode, further interrupt events are blocked until re-armed. 0x0 = Stop after Capture Event 1 in one-shot mode. Wrap after Capture Event 1 in continuous mode. 0x1 = Stop after Capture Event 2 in one-shot mode. Wrap after Capture Event 2 in continuous mode. 0x2 = Stop after Capture Event 3 in one-shot mode. Wrap after Capture Event 3 in continuous mode. 0x3 = Stop after Capture Event 4 in one-shot mode. Wrap after Capture Event 4 in continuous mode.	RW	0x3
0	CONTONESHT	Continuous or one-shot mode control (applicable only in capture mode) 0x0 = Operate in continuous mode 0x1 = Operate in one-shot mode	RW	0x0

29.4 Enhanced Quadrature Encoder Pulse (eQEP) Module

29.4.1 eQEP Overview

A single track of slots patterns the periphery of an incremental encoder disk, as shown in Figure 29-62. These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference.

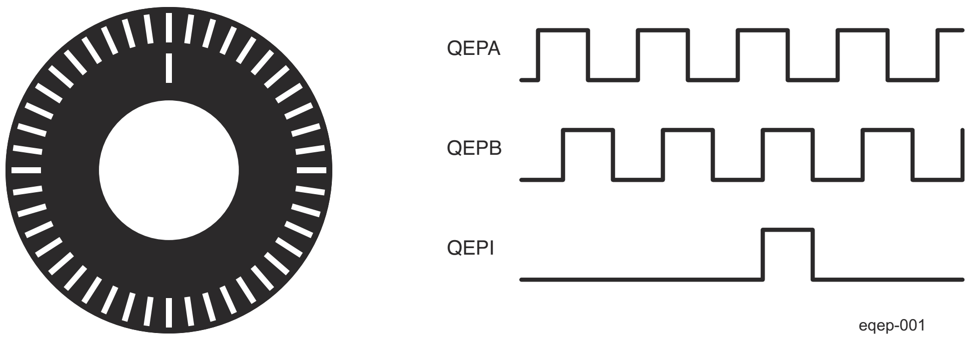

Figure 29-62. Optical Encoder Disk

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90 degrees out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vise versa as shown in Figure 29-63.

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 KHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

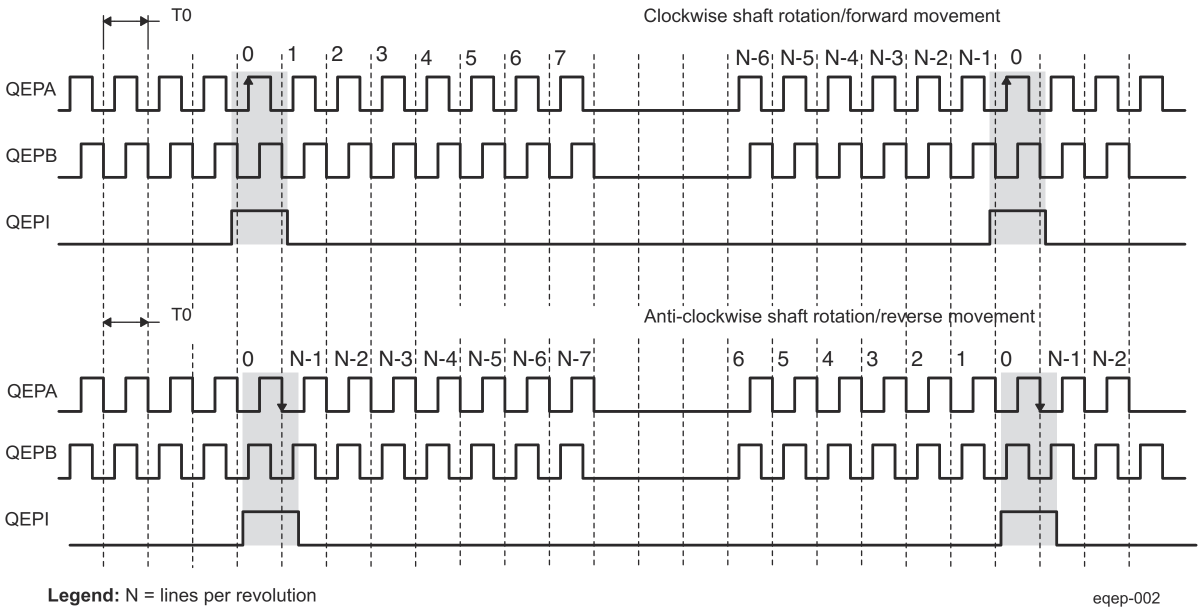

Figure 29-63. QEP Encoder Output Signal for Forward/Reverse Movement

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 29-64. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

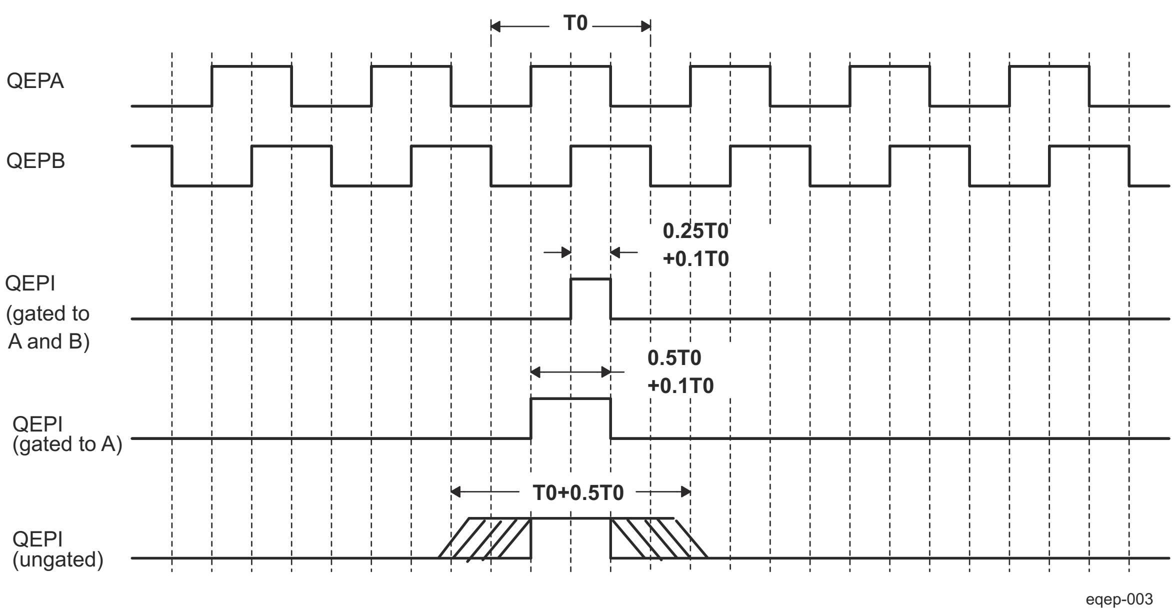

Figure 29-64. Index Pulse Example

Some typical applications of shaft encoders include robotics and even computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

General Issues: Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$V(k) \approx \frac{X(k) - X(k-1)}{T} = \frac{\Delta X}{T} \tag{8}$$

eqep-004

$$V(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \tag{9}$$

eqep-005

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

t(k): Time instant "k"

t(k-1): Time instant "k - 1"

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement.

Equation 8 is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity [x(k) - x(k-1)] is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant 1/T (where T is the constant time between unit time events and is known in advance).

Estimation based on Equation 8 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T. For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, Equation 9 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 9 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 8. A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 9 at low speed and have the software switch over to Equation 8 when the motor speed rises above some specified threshold.

29.4.2 eQEP Module Functional Description

This section provides the eQEP functional description and corrsponding functional details about EQEPx inputs .

Note

Multiple identical eQEP modules can be contained in a system. For actual number of eQEP modules integrated in the device, refer to the Section 29.1.3. The letter x within a signal or module name is used to indicate a generic eQEP instance on a device. For example, output interrupt request, EQEP1A belongs to eQEP1, EQEP2A belongs to eQEP2, etc.

The eQEP peripheral contains the following major functional units (as shown in Figure 29-65):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)

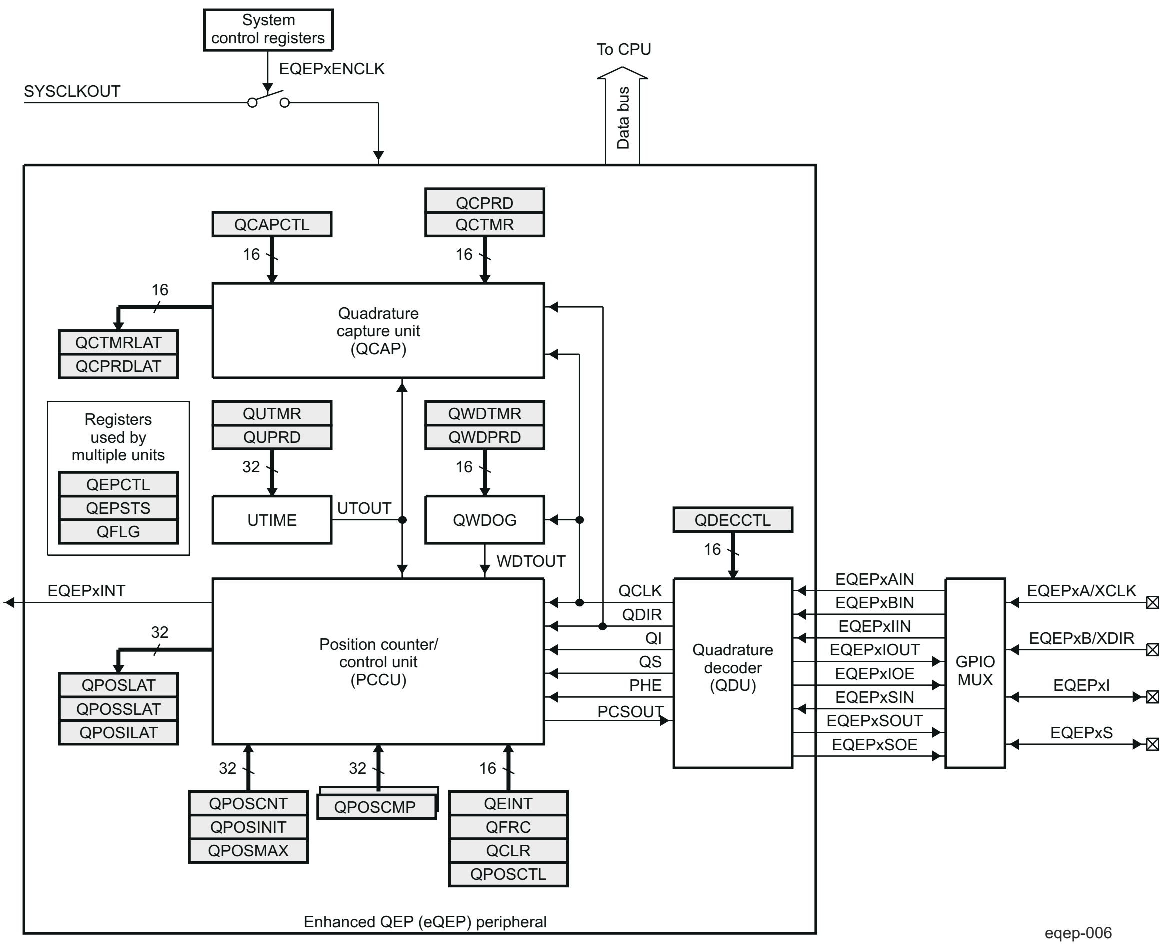

Figure 29-65. Functional Block Diagram of the eQEP Peripheral

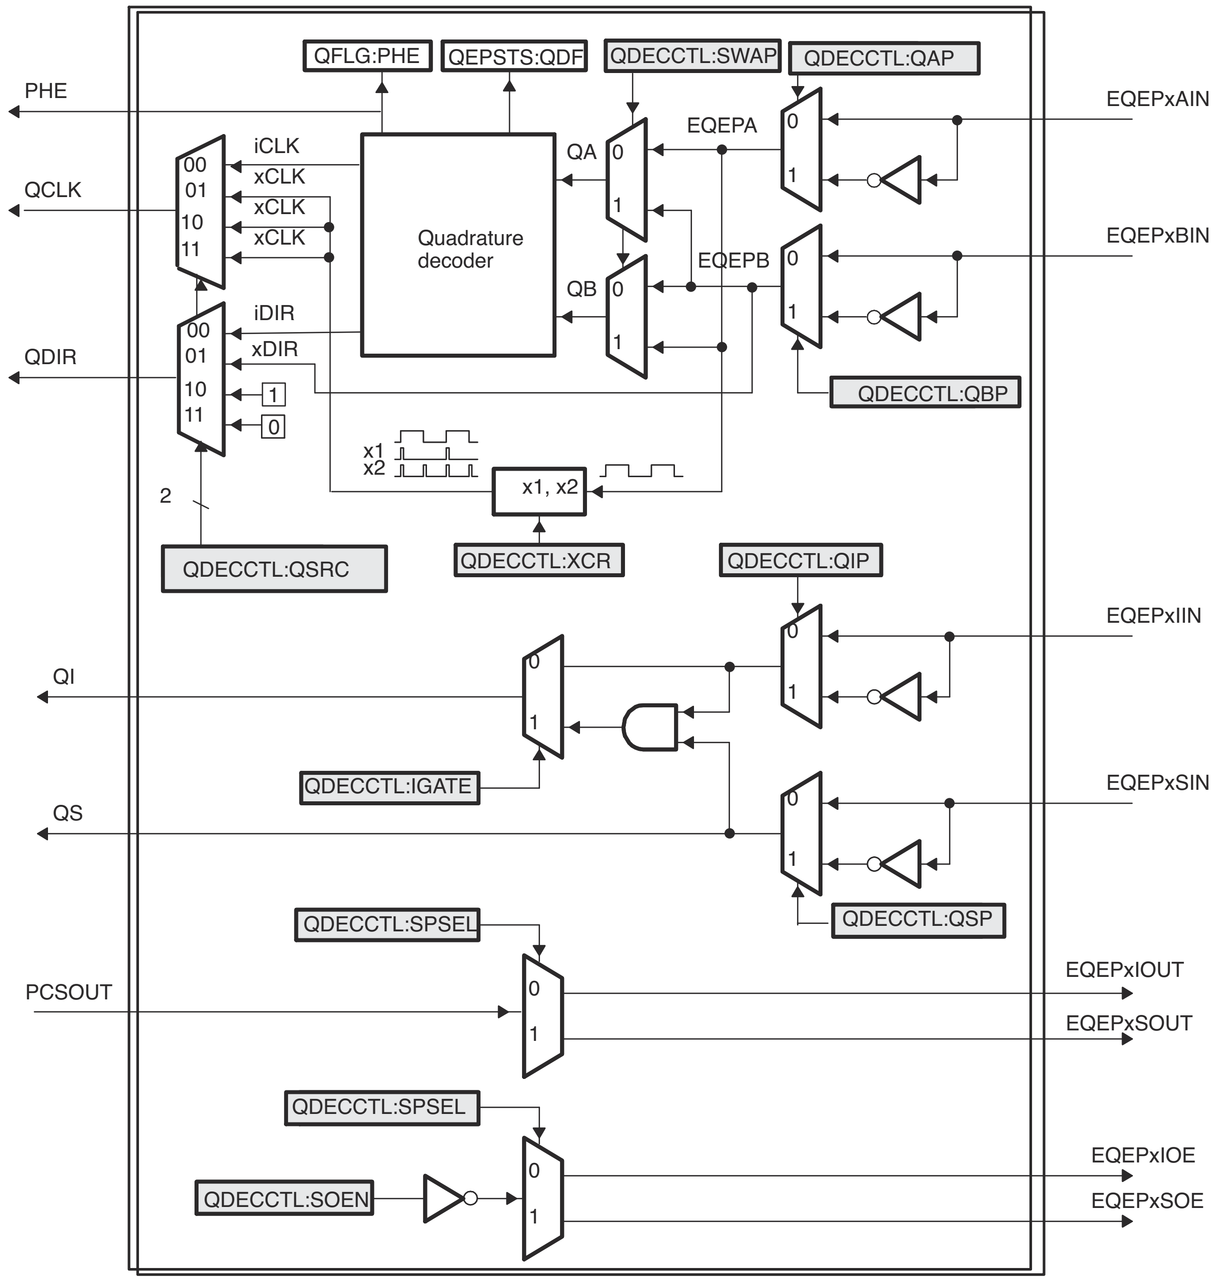
29.4.3 eQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- QEPA/XCLK and QEPB/XDIR: These two pins can be used in quadrature-clock mode or direction-count mode.
  - Quadrature-clock Mode: The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
  - Direction-count Mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.
- QEPI: Index or Zero Marker: The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- QEPS: Strobe Input: This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

29.4.4 eQEP Quadrature Decoder Unit (QDU)

Figure 29-66 shows a functional block diagram of the QDU.



eqep-007

Figure 29-66. Functional Block Diagram of Decoder Unit

29.4.5 eQEP Position Counter Input Modes

Clock and direction input to position counter is selected using the QSRC bit in the eQEP decoder control register (EQEP_QDECCTL), based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

29.4.6 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

Direction Decoding The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QDF bit in the eQEP status register (EQEP_QEPSTS). Table 29-140 and Figure 29-67 show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 29-68 shows the direction decoding and clock generation from the eQEP input signals.

Phase Error Flag In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the EQEP_QFLG register when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in Figure 29-67 are invalid transitions that generate a phase error.

Count Multiplication The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in Figure 29-68.

Reverse Count In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the eQEP decoder control register (EQEP_QDECCTL). This will swap the input to the quadrature decoder thereby reversing the counting direction.

Table 29-140. Quadrature Decoder Truth Table

	QA↑	UP	Decrement
	QB↑	TOGGLE	Increment or Decrement

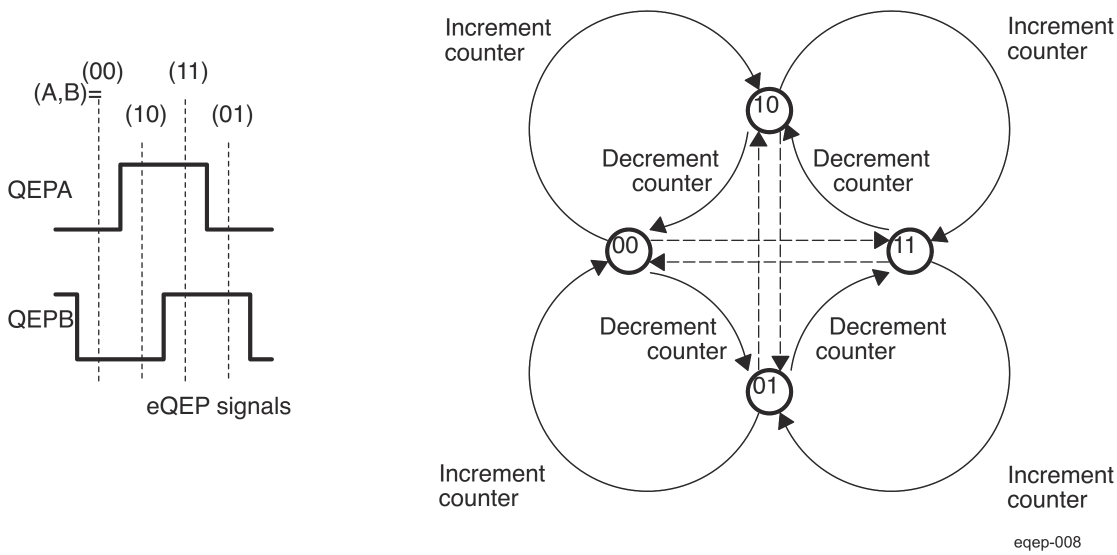

Figure 29-67. Quadrature Decoder State Machine

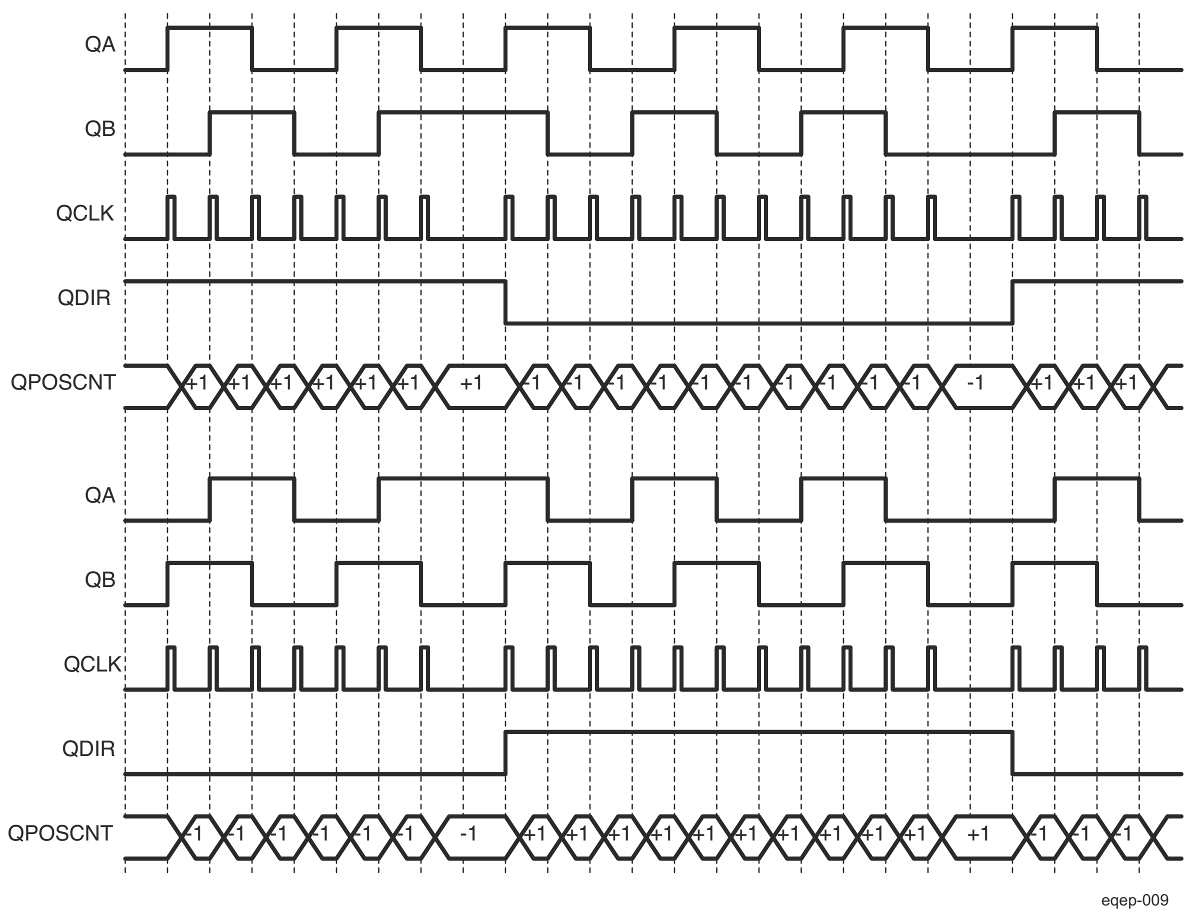

Figure 29-68. Quadrature-clock and Direction Decoding

29.4.7 eQEP Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high and decremented when the direction input is low.

29.4.8 eQEP Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the QEPA input. Setting of the XCR bit in the eQEP decoder control register (EQEP_QDECCTL) enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2× factor.

29.4.9 eQEP Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the QEPA input. Setting of the XCR bit in the eQEP decoder control register (EQEP_QDECCTL) enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by 2× factor.

29.4.10 eQEP Input Polarity Selection

Each eQEP input can be inverted using the in the eQEP decoder control register (EQEP_QDECCTL[8:5]) control bits. As an example, setting of the QIP bit in EQEP_QDECCTL inverts the index input.

29.4.11 eQEP Position-Compare Sync Output

The eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (EQEP_QPOSCNT) and the position-compare register (EQEP_QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the SOEN bit in the eQEP decoder control register (EQEP_QDECCTL) enables the position-compare sync output and the SPSEL bit in EQEP_QDECCTL selects either an eQEP index pin or an eQEP strobe pin.

29.4.12 eQEP Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (EQEP_QEPCTL and EQEP_QPOSCTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

29.4.13 eQEP Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, position counter is reset to 0 on overflow and to QPOSMAX bifield value in EQEP_QPOSMAX register on underflow. Overflow occurs when the position counter counts up after QPOSMAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/ underflow in EQEP_QFLG register.

29.4.14 eQEP Position Counter Reset on Index Event (EQEP_QEPCTL[31:12] PCRM] = 0b00)

If the index event occurs during the forward movement, then position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP_QPOSMAX register on the next eQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in EQEP_QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 29-69.

The position-counter value is latched to the EQEP_QPOSILAT register and direction information is recorded in the EQEP_QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (EQEP_QEPSTS[PCEF]) and error interrupt flag (EQEP_QFLG[PCE]) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (EQEP_QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (EQEP_QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration EQEP_QEPCTL[5:4] IEL bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

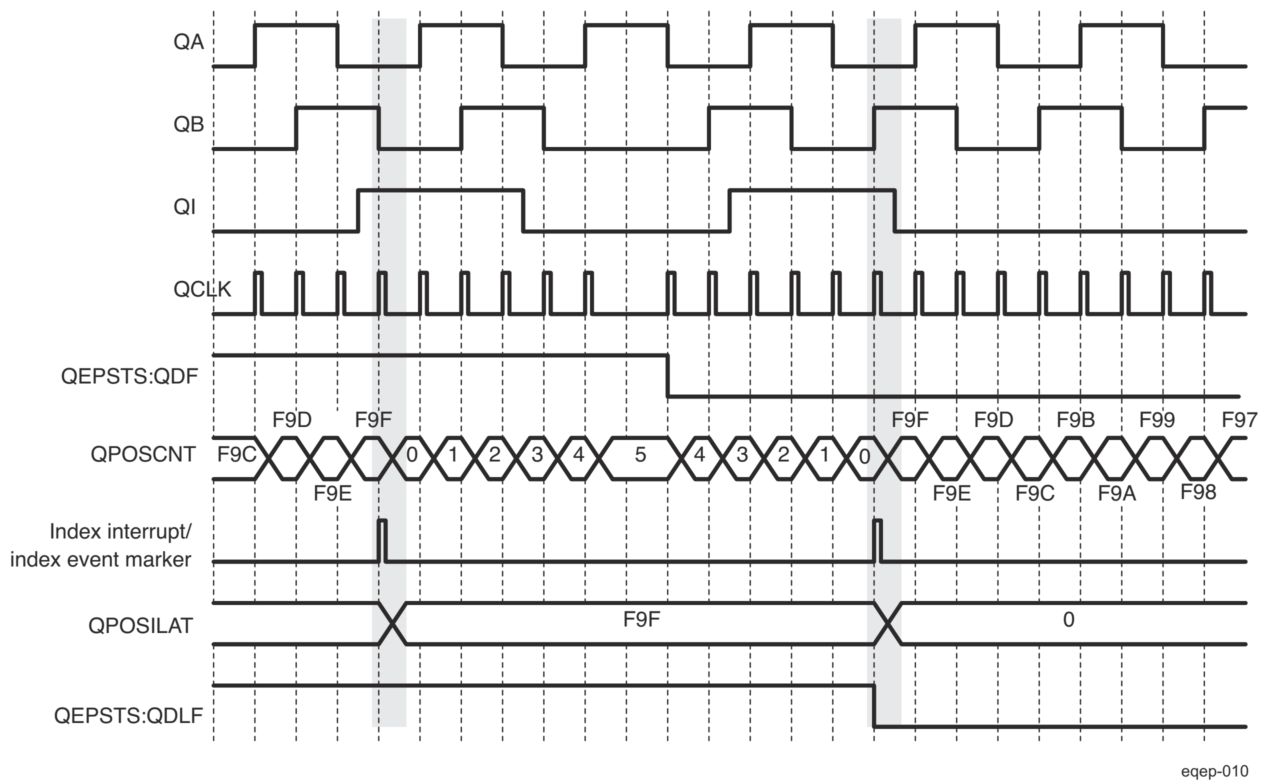

Figure 29-69. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or F9Fh)

29.4.15 eQEP Position Counter Reset on Maximum Position (EQEP_QEPCTL[13:12] PCRM=0b01)

If the position counter is equal to QPOSMAX (in EQEP_QPOSMAX register), then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 29-70 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in the EQEP_QEPSTS registers; it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (EQEP_QEPCTL[5:4] IEL=0b11).

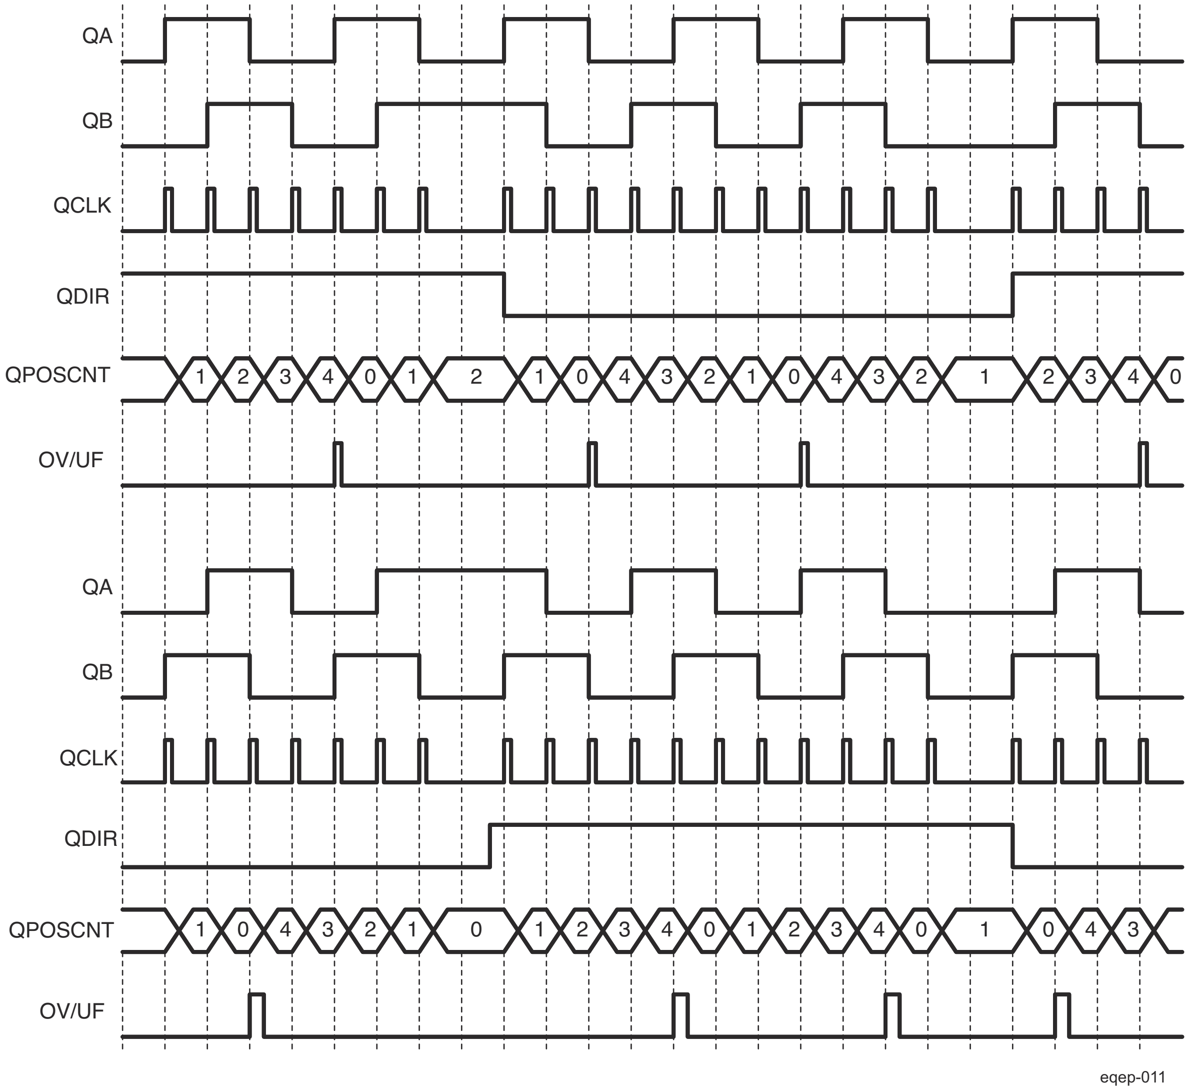

Figure 29-70. Position Counter Underflow/Overflow (QPOSMAX = 4)

29.4.16 Position Counter Reset on the First Index Event (EQEP_QEPCTL[13:12] PCRM = 0b10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP_QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in Section 29.4.15 .

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in EQEP_QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (EQEP_QEPCTL[5:4] IEL= 0b11).

29.4.17 Position Counter Reset on Unit Time out Event (EQEP_QEPCTL[13:12] PCRM = 0b11)

In this mode, the QPOSCNT value is latched to the EQEP_QPOSLAT register and then the QPOSCNT field is reset (to 0 or the QPOSMAX value in the EQEP_QPOSMAX register, depending on the direction mode selected by EQEP_QDECCTL[QSRC] bits on a unit time event). This is useful for frequency measurement.

29.4.18 eQEP Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter QPOSCNT (EQEP_QPOSCNT) into QPOSILAT (EQEP_QPOSILAT register) and QPOSSLAT (EQEP_QPOSSLAT register) bitfields, respectively, on occurrence of a definite event on these pins.

29.4.19 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (EQEP_QEPCTL[13:12] PCRM = 0b01 and EQEP_QEPCTL[13:12] PCRM = 0b10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the EQEP_QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (EQEP_QEPCTL[5:4] IEL = 0b01)
- Latch on Falling edge (EQEP_QEPCTL[5:4] IEL = 0b10)
- Latch on Index Event Marker (EQEP_QEPCTL[5:4] IEL = 0b11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (EQEP_QFLG[IEL]) is set when the position counter is latched to the EQEP_QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when EQEP_QEPCTL[13:12] PCRM = 0b00.

Latch on Rising Edge (EQEP_QEPCTL[5:4] IEL = 0b01)
The position counter value (QPOSCNT) is latched to the EQEP_QPOSILAT register on every rising edge of an index input.

Latch on Falling Edge (EQEP_QEPCTL[5:4] IEL = 0b10)
The position counter value (QPOSCNT) is latched to the EQEP_QPOSILAT register on every falling edge of index input.

Latch on Index Event Marker/Software Index Marker (EQEP_QEPCTL[5:4] IEL = 0b11)
The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (EQEP_QEPSTS[FIMF]) and direction on the first index event marker (EQEP_QEPSTS[FIDF]) in the EQEP_QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same

relative quadrature transition is used for latching the position counter (EQEP_QEPCTL[5:4] IEL = 0b11).

Figure 29-71 shows the position counter latch using an index event marker.

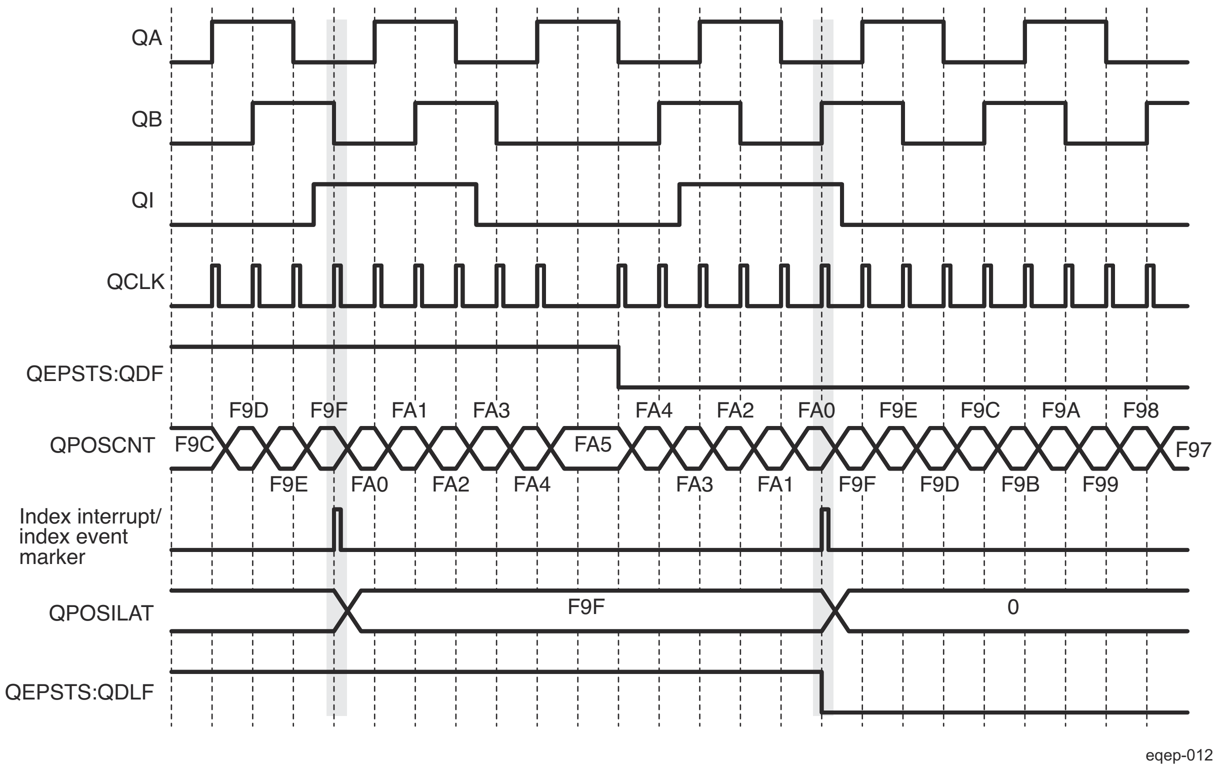

Figure 29-71. Software Index Marker for 1000-line Encoder (EQEP_QEPCTL[5:4] IEL = 0b01)

29.4.20 eQEP Strobe Event Latch

The position-counter value is latched to the EQEP_QPOSSLAT register on the rising edge of the strobe input by clearing the EQEP_QEPCTL[6] SEL bit.

If the EQEP_QEPCTL[6] SEL bit is set, then the position counter value is latched to the EQEP_QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in Figure 29-72.

The strobe event latch interrupt flag (EQEP_QFLG[SEL]) is set when the position counter is latched to the EQEP_QPOSSLAT register.

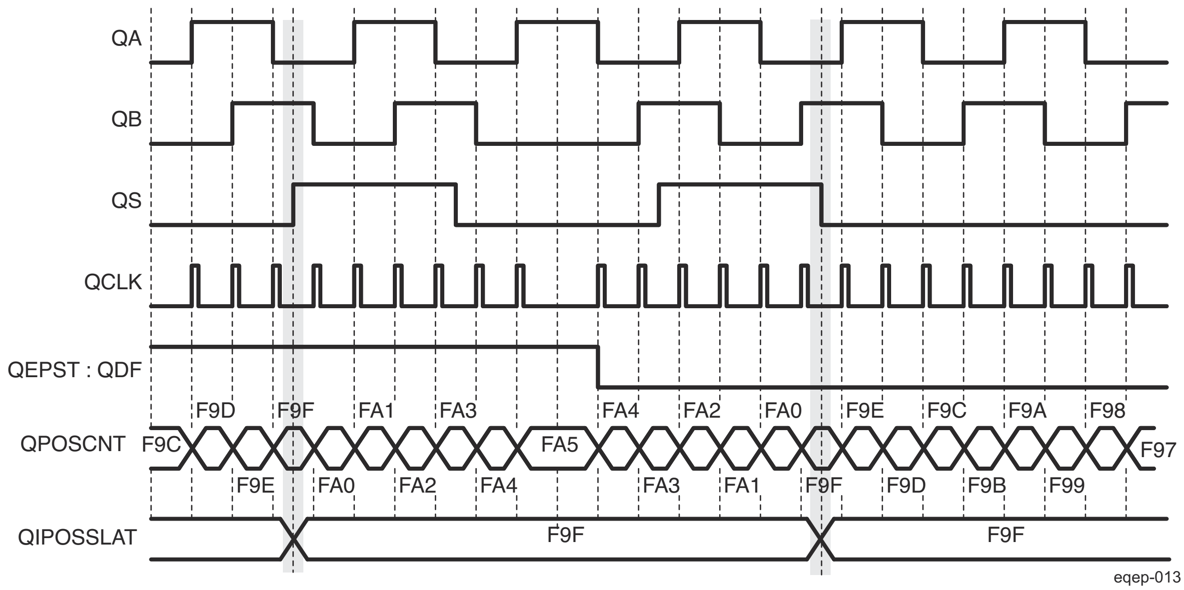

Figure 29-72. eQEP Strobe Event Latch (EQEP_QEPCTL[6] SEL = 0b1)

29.4.21 eQEP Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

Index Event Initialization (IEI)

The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input.

If the EQEP_QEPCTL[9:8] IEI bits are 0b10, then the position counter (EQEP_QPOSCNT) is initialized with a value in the EQEP_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The index event initialization interrupt flag (EQEP_QFLG[IEI]) is set when the position counter is initialized with a value in the EQEP_QPOSINIT register.

Strobe Event Initialization (SEI)

If the EQEP_QEPCTL[11:10] SEI bits are 0b10, then the position counter is initialized with a value in the EQEP_QPOSINIT register on the rising edge of strobe input.

If the EQEP_QEPCTL[11:10] SEI bits are 0b11, then the position counter (EQEP_QPOSCNT) is initialized with a value in the EQEP_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The strobe event initialization interrupt flag (EQEP_QFLG[SEI]) is set when the position counter is initialized with a value in the EQEP_QPOSINIT register.

Software Initialization (SWI)

The position counter can be initialized in software by writing a '1' to the EQEP_QEPCTL[7] SWI bit, which will automatically be cleared after initialization.

29.4.22 eQEP Position-Compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 29-73 shows a diagram. The position-compare (EQEP_QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the EQEP_QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

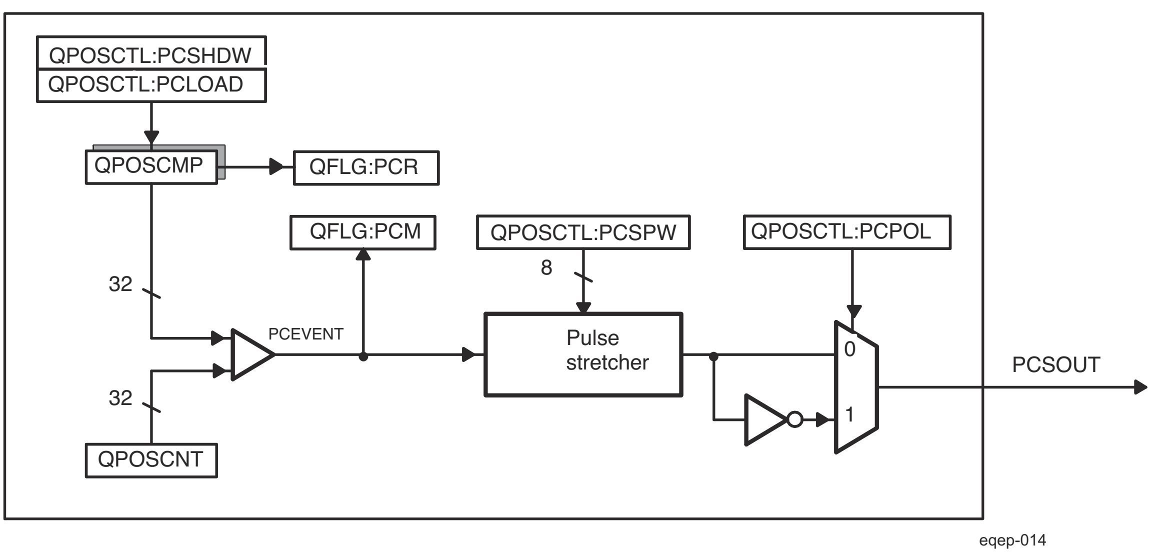

Figure 29-73. eQEP Position-compare Unit

In shadow mode, you can configure the position-compare unit (EQEP_QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events and to generate the position-compare ready (EQEP_QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

The position-compare match (EQEP_QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (EQEP_QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if EQEP_QPOSCMP bitfield QPOSCMP = 0x2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 29-74).

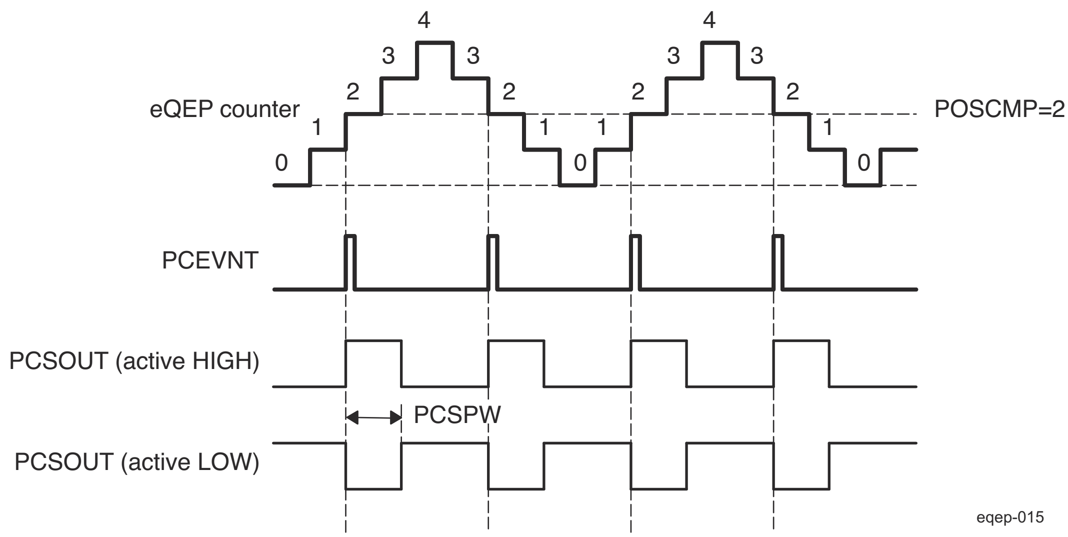

Figure 29-74. eQEP Position-compare Event Generation Points

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 29-75.

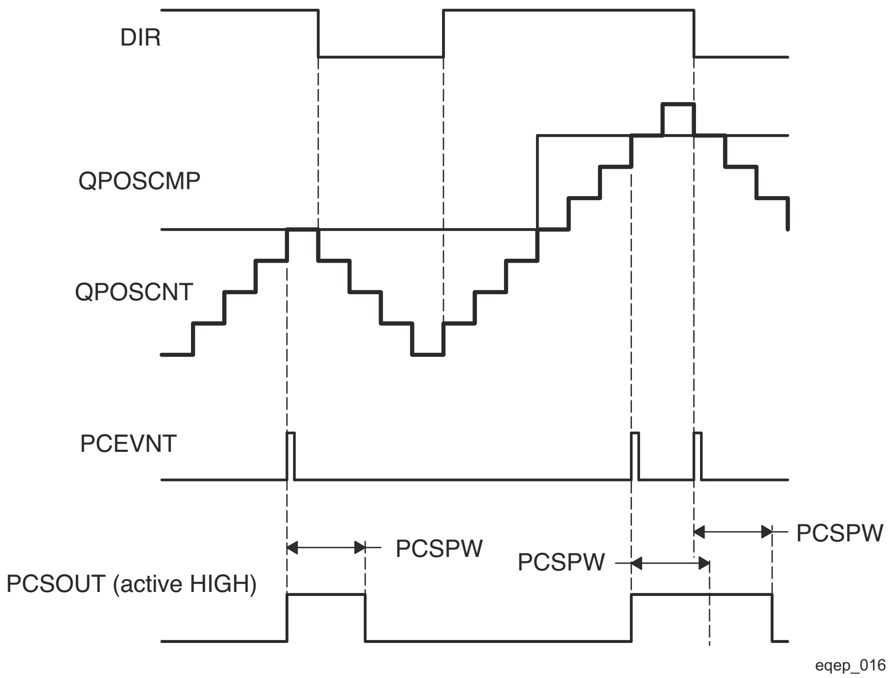

Figure 29-75. eQEP Position-compare Sync Output Pulse Stretcher

29.4.23 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in Figure 29-76. This feature is typically used for low speed measurement using the following equation:

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (10)$$

eqep-017

where,

- X - Unit position is defined by integer multiple of quadrature edges (see Figure 29-77)
- ΔT - Elapsed time between unit position events
- v(k) - Velocity at time instant "k"

The eQEP capture timer (QCTMR bitfield in EQEP_QCTMR register) runs from prescaled SYSCLKOUT and the prescaler is programmed by the EQEP_QCAPCTL[CCPS] bits. The capture timer QCTMR value is latched into the capture period register (EQEP_QCPRD) on every unit position event and then the capture timer is reset, a flag is set in EQEP_QEPSTS[UPEVNT] to indicate that new value is latched into the EQEP_QCPRD register. Software can check this status flag before reading the period register for low speed measurement and clear the flag by writing 1.

Note

The system clock - SYSCLKOUT is the eQEP functional clock derived from the PWMSSn gateable interface and functional clock PWMSSn_GICLK, described in Section 29.1.3.

Time measurement (ΔT) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag (EQEP_QEPSTS[COEF]) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (EQEP_QEPSTS[CDEF]).

Capture Timer (EQEP_QCTMR register) and Capture period register (EQEP_QCPRD) can be configured to latch on following events.

- CPU read of EQEP_QPOSCNT register
- Unit time-out event

If the EQEP_QEPCTL[2] QCLM bit is cleared, then the capture timer and capture period values are latched into the EQEP_QCTMRLAT and EQEP_QCPRDLAT registers, respectively, when the CPU reads the position counter in EQEP_QPOSCNT.

If the EQEP_QEPCTL[2] QCLM bit is set, then the position counter, capture timer, and capture period values are latched into the EQEP_QPOSLAT, EQEP_QCTMRLAT and EQEP_QCPRDLAT registers, respectively, on unit time out.

Figure 29-78 shows the capture unit operation along with the position counter.

Note

The EQEP_QCAPCTL register should not be modified dynamically (such as switching CAPCLK prescaling mode from QCLK/4 to QCLK/8). The capture unit must be disabled before changing the prescaler.

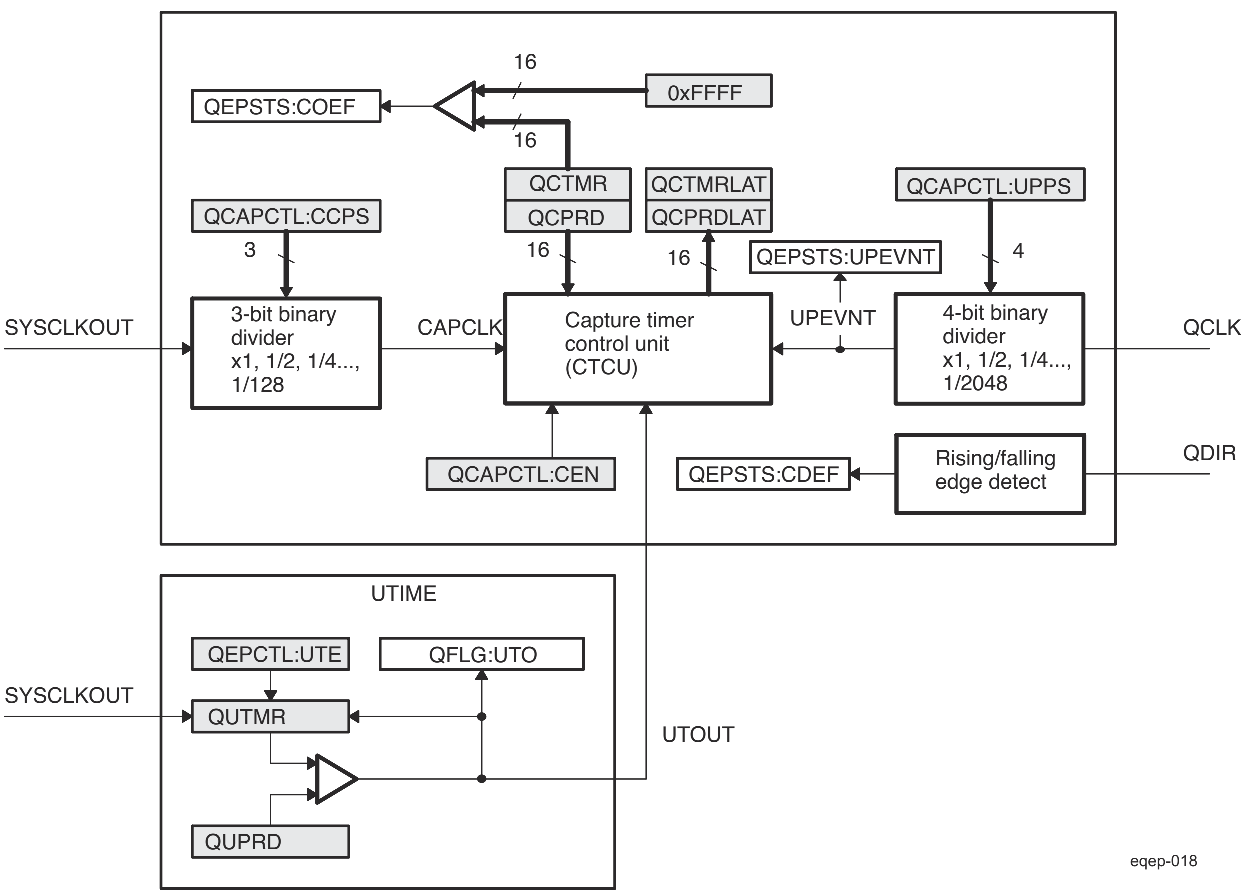

Figure 29-76. eQEP Edge Capture Unit

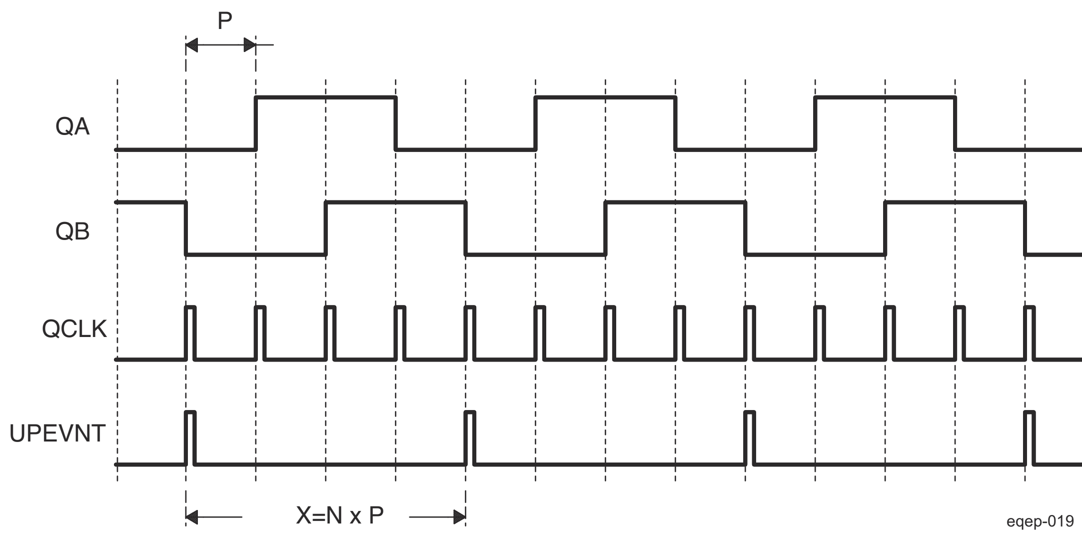

N - Number of quadrature periods selected using EQEP_QCAPCTL[UPPS] bits

Figure 29-77. Unit Position Event for Low Speed Measurement (EQEP_QCAPCTL[UPPS] = 0010)

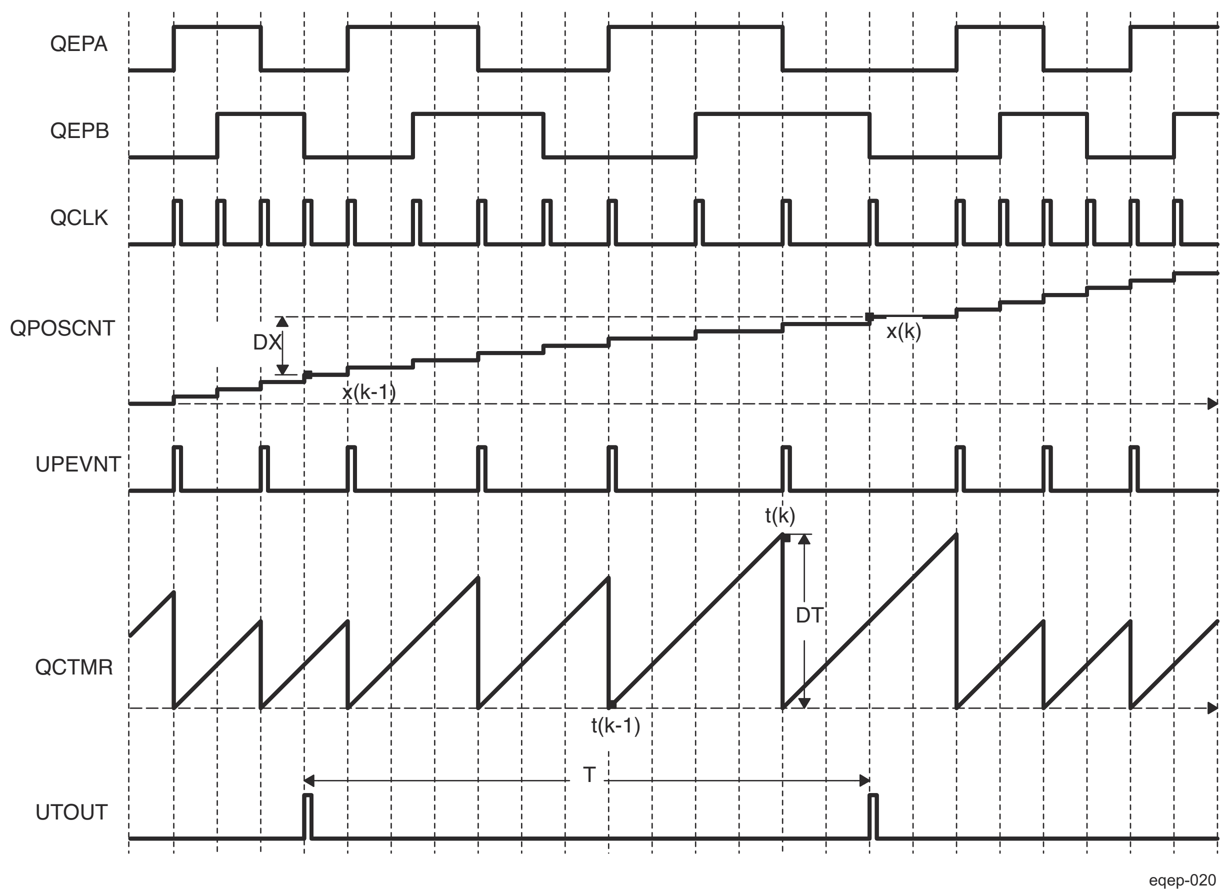

Figure 29-78. eQEP Edge Capture Unit - Timing Details

Velocity Calculation Equations:

$$V(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad o \tag{11}$$

eqep_021

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement

t(k): Time instant "k"

t(k-1): Time instant "k - 1"

Unit time (T) and unit period (X) are configured using the EQEP_QUPRD and EQEP_QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the EQEP_QPOSLAT and EQEP_QCPRDLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (EQEP_QUPRD)
ΔX	Incremental Position = QPOSLAT(k) - QPOSLAT(K - 1)
X	Fixed unit position defined by sensor resolution and ZCAPCTL[UPPS] bits
ΔT	Capture Period Latch (QCPRDLAT)

29.4.24 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrate clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer will time out and the watchdog interrupt flag will be set (EQEP_QFLG[WTO]). The time-out value is programmable through the watchdog period register (EQEP_QWDPRD).

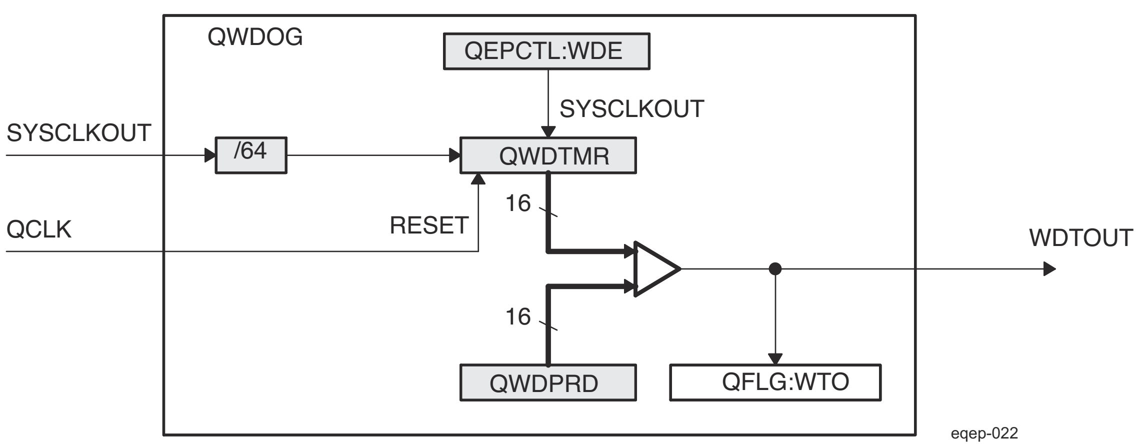

Figure 29-79. eQEP Watchdog Timer

29.4.25 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (EQEP_QFLG[UTO]) when the unit timer (QUTMR) matches the unit period register (EQEP_QUPRD).

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section 29.4.23 .

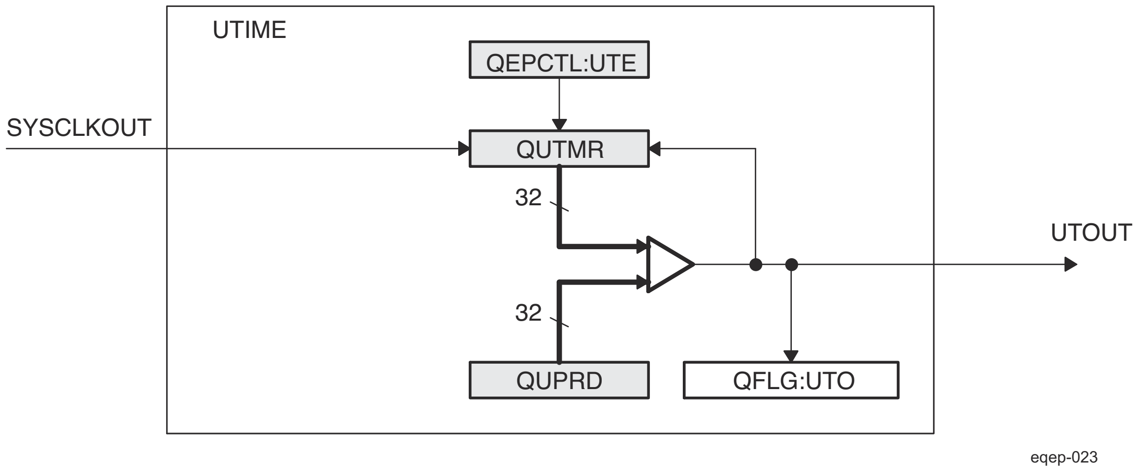

Figure 29-80. eQEP Unit Time Base

29.4.26 eQEP Interrupt Structure

Figure 29-81 shows how the interrupt mechanism works in the EQEP module.

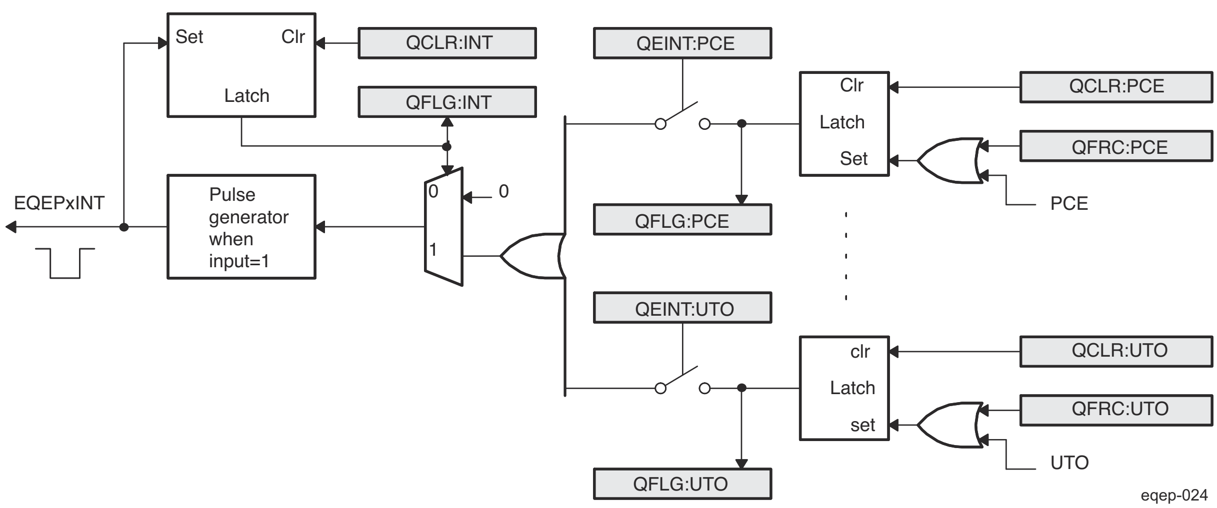

Figure 29-81. EQEP Interrupt Generation

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL, and UTO) can be generated. The interrupt control register (EQEP_QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (EQEP_QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated only to the interrupt controller if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (EQEP_QCLR), before any other interrupt pulses are generated. You can force an interrupt event by way of the interrupt force register (EQEP_QFRC), which is useful for test purposes.

29.4.27 Summary of PWMSS eQEP Functional Registers

Table 29-141 lists the registers with their memory locations, sizes, and reset values.

Table 29-141. eQEP Control and Status Functional Registers

Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FREE_SOFT		PCRM		SEI		IEI		SWI	SEL	IEL		PHEN	QCLM	UTE	WDE

Bits	Field Name	Description	Type	Reset
15:14	FREE_SOFT	Emulation Control Bits. In the values 0 through 3 listed below, x is different for the four following behaviors. EQEP_QPOSCNT behavior, x refers to the Position counter. QWDTMR behavior, x refers to the Watchdog counter. QUTMR behavior, x refers to the Unit timer. QCTMR behavior, x refers to the Capture timer. 0x0 = x stops immediately. For QPOSCNT behavior, the stop is on emulation suspend. 0x1 = x continues to count until the rollover. 0x2 = x is unaffected by emulation suspend. 0x3 = x is unaffected by emulation suspend.	RW	0x0
13:12	PCRM	Position counter reset mode 0x0 = Position counter reset on an index event 0x1 = Position counter reset on the maximum position 0x2 = Position counter reset on the first index event 0x3 = Position counter reset on a unit time event	RW	0x0
11:10	SEI	Strobe event initialization of position counter 0x0 = Does nothing (action disabled) 0x1 = Does nothing (action disabled) 0x2 = Initializes the position counter on rising edge of the QEPS signal 0x3 = Clockwise Direction: Initializes the position counter on the rising edge of QEPS strobe. Counter Clockwise Direction: Initializes the position counter on the falling edge of QEPS strobe	RW	0x0
9:8	IEI	Index event initialization of position counter 0x0 = Do nothing (action disabled) 0x1 = Do nothing (action disabled) 0x2 = Initializes the position counter on the rising edge of the QEPI signal (QPOSCNT = QPOSINIT) 0x3 = Initializes the position counter on the falling edge of QEPI signal (QPOSCNT = QPOSINIT)	RW	0x0
7	SWI	Software initialization of position counter 0x0 = Do nothing (action disabled) 0x1 = Initialize position counter, this bit is cleared automatically	RW	0x0
6	SEL	Strobe event latch of position counter 0x0 = The position counter is latched on the rising edge of QEPS strobe (QPOSSLAT = POSCCNT). Latching on the falling edge can be done by inverting the strobe input using the QSP bit in the EQEP_QDECCTL register. 0x1 = Clockwise Direction: Position counter is latched on rising edge of QEPS strobe. Counter Clockwise Direction: Position counter is latched on falling edge of QEPS strobe.	RW	0x0
5:4	IEL	Index event latch of position counter (software index marker) 0x0 = Reserved 0x1 = Latches position counter on rising edge of the index signal 0x2 = Latches position counter on falling edge of the index signal 0x3 = Software index marker. Latches the position counter and quadrature direction flag on index event marker. The position counter is latched to the EQEP_QPOSILAT register and the direction flag is latched in the EQEP_QEPSTS[QDLF] bit. This mode is useful for software index marking.	RW	0x0

Bits	Field Name	Description	Type	Reset
3	PHEN	Quadrature position counter enable/software reset 0x0 = Reset the eQEP peripheral internal operating flags/read-only registers. Control/configuration registers are not disturbed by a software reset. 0x1 = eQEP position counter is enabled	RW	0x0
2	QCLM	eQEP capture latch mode 0x0 = Latch on position counter read by CPU. Capture timer and capture period values are latched into EQEP_QCTMRLAT and EQEP_QCPRDLAT registers when CPU reads the EQEP_QPOSCNT register. 0x1 = Latch on unit time out. Position counter, capture timer and capture period values are latched into EQEP_QPOSLAT, EQEP_QCTMRLAT and EQEP_QCPRDLAT registers on unit time out.	RW	0x0
1	UTE	eQEP unit timer enable 0x0 = Disable eQEP unit timer 0x1 = Enable unit timer	RW	0x0
0	WDE	eQEP watchdog enable 0x0 = Disable the eQEP watchdog timer 0x1 = Enable the eQEP watchdog timer	RW	0x0

Chapter 30

Viterbi-Decoder Coprocessor

This chapter describes the Viterbi-Decoder Coprocessor (VCP) module.

30.1 VCP Overview........ 6867
30.2 VCP Integration........ 6869
30.3 VCP Functional Description........ 6871
30.4 VCP Modules Programming Guide........ 6890
30.5 VCP Register Manual........ 6897

30.1 VCP Overview

Channel decoding of voice and low bit-rate data channels found in cellular standards such as 2.5G, 3G and WiMAX require the decoding of convolutional encoded data. The Viterbi-decoder coprocessor 2 (VCP2) performs Viterbi-decoding for IS2000 and 3GPP wireless standards, and performs forward error correction for 2G and 3G wireless systems. The VCP can support 1941 12.2 Kbps class A 3G voice channels running at 333 MHz and offers a very cost effective and synergistic solution when combined with Texas Instruments (TI) DSPs. (for more information, see Section 30.1.1, *VCP Features*).

The device provides two instances of the VCP module respectively VCP1 and VCP2.

Figure 30-1 is an overview of the VCP in the device.

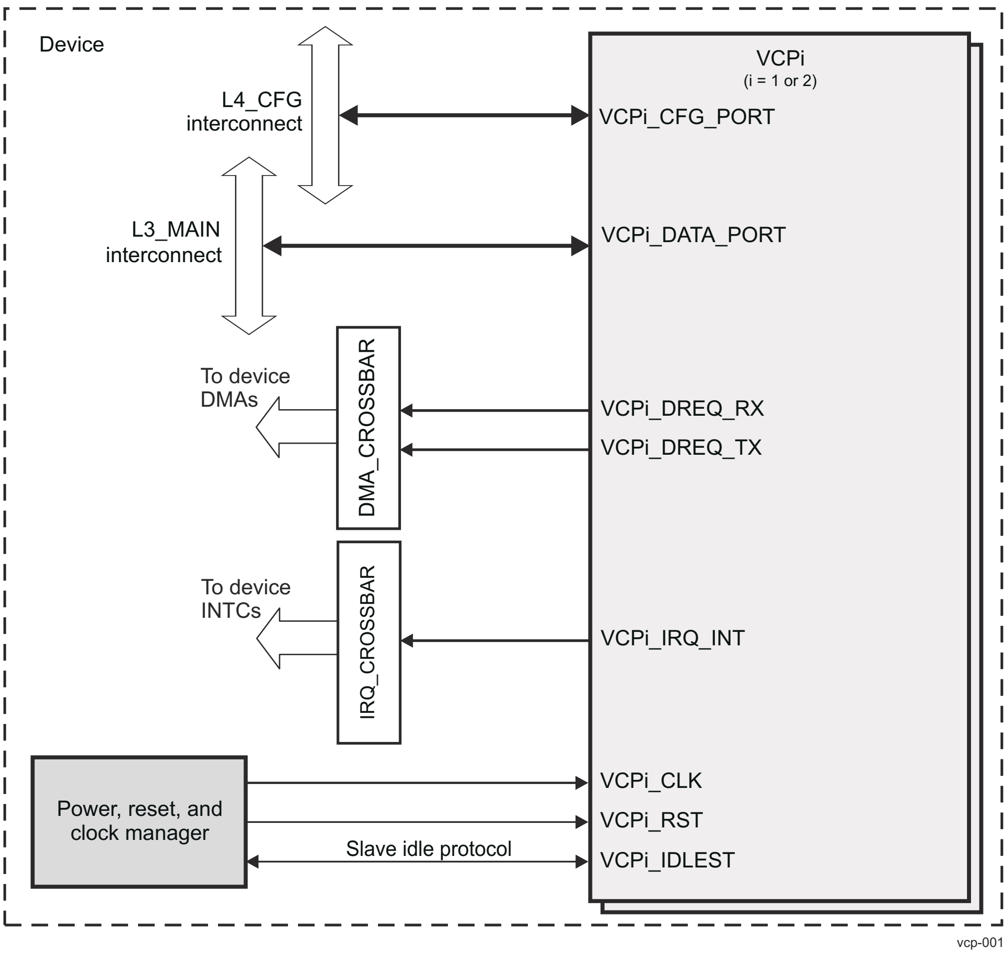

Figure 30-1. VCP Highlight

30.1.1 VCP Features

The main features of the VCP modules:

- L3 interconnect slave interface supports:
  - 64-bit data bus width
- L4 interconnect slave interface supports:
  - 32-bit access and configuration bus supported
  - Transmit and receive direct memory access (DMA) requests supported through DMA_CROSSBAR
  - Interrupt line for multiple interrupt source events to IRQ_CROSSBAR
  - Power management through IDLE power state

The VCP module provides:

- High flexibility
  - Variable constraint length, K = 5, 6, 7, 8, or 9
  - User-supplied code coefficients
  - Code rates (1/2, 1/3, or 1/4)
  - Configurable trace back settings (convergence distance, frame structure)
  - Branch metrics calculation and depuncturing done in software by the DSP
- System and development cost optimization
  - Releases DSP resources for other processing
  - Reduces board space and power consumption by performing decoding on-chip
  - Communicates between the DSP and the VCP1, VCP2 modules through the high performance EDMA engine
  - Uses its own optimized working memories
  - Provides debug capabilities during frame processing
  - Provides libraries for reduced development time

30.2 VCP Integration

This section describes the integration of the VCP1 and VCP2 modules in the device, including information about clocks, resets, and hardware requests.

Figure 30-2 shows the integration of the VCP modules in the device, including interrupt handlers, DMA requests, clock generators, and interconnections.

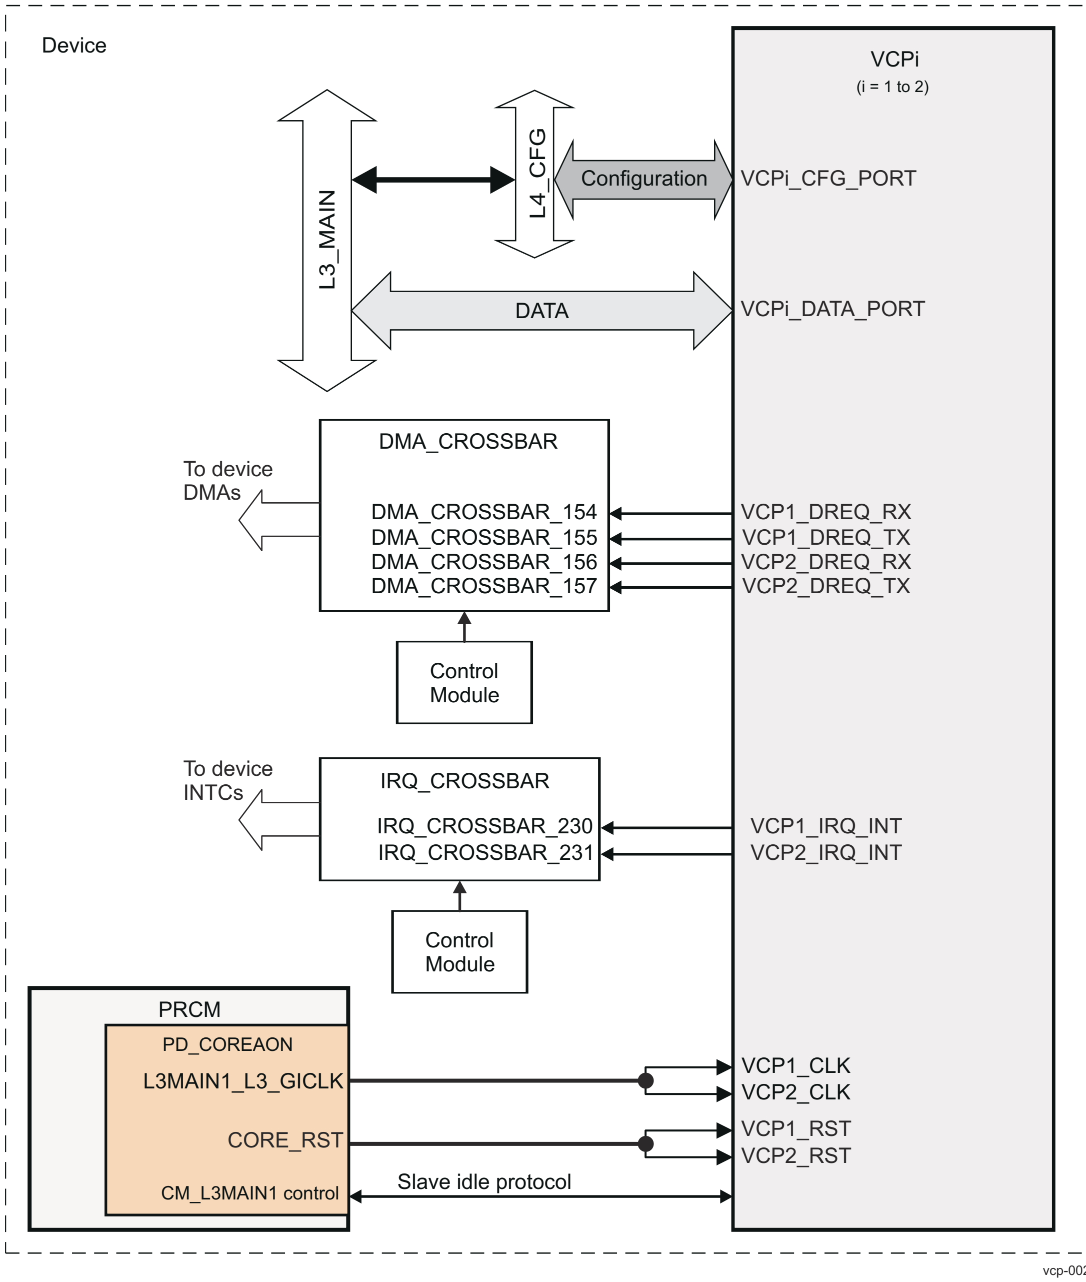

Figure 30-2. VCP1 and VCP2 Integration

Table 30-1 through Table 30-3 summarize the integration of the VCP modules in the device.

DMA Requests				
Module Instance	**Source Signal Name**	**DMA_CROSSBAR Input**	**Default Mapping**	**Description**
VCP1	VCP1_DREQ_RX	DMA_CROSSBAR_154	DMA_DSP1_DREQ_16 DMA_DSP2_DREQ_16	VCP1 RX Event
	VCP1_DREQ_TX	DMA_CROSSBAR_155	DMA_DSP1_DREQ_17 DMA_DSP2_DREQ_17	VCP1 TX Event
VCP2	VCP2_DREQ_RX	DMA_CROSSBAR_156	DMA_DSP1_DREQ_18 DMA_DSP2_DREQ_18	VCP2 RX Event
	VCP2_DREQ_TX	DMA_CROSSBAR_157	DMA_DSP1_DREQ_19 DMA_DSP2_DREQ_19	VCP2 TX Event

Note

The VCP1 and VCP2 interrupt request signals are not mapped by default.

The VCP1 and VCP2 DMA request signals are not mapped by default to DMA_SYSTEM.

For more information about the IRQ_CROSSBAR and DMA_CROSSBAR modules, see sections: Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description* and Section 18.4.6.5 , *DMA_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.

For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

Note

- For more information about the interrupt source, see Section 30.3.11.2, *Interrupt Requests*.
- For more information about the DMA source, see Section 30.3.12, *DMA Requests*.

30.3 VCP Functional Description

This section is a functional description of the VCP1 and VCP2 modules in the device.

30.3.1 VCP Block Diagram

Figure 30-3 shows the functional block diagram of the two instances of the VCP modules. It consists of four main blocks:

- VCP control, this block controls all the blocks within the VCP. It stores the Viterbi decoder parameters, analyzes commands from the DSP, and controls the global sequencing of events. The control unit also generates the two synchronization events to the DMA: a write event (VCPXEVT) and a read event (VCPREVT). The configuration bus loads the VCP with all the parameters and controls that affect the execution of the VCP. These parameters are memory mapped and accessed as 32-bit registers. These registers can be read and written by this bus.
- EDMA I/F unit, connected to L3 Interconnect, typically accessed by the EDMA. The EDMA is used to send the bulk of the input and output data. The data input to the VCP using the EDMA/L3 Interconnect bus are the branch metrics. The data output from the VCP using the EDMA/L3 Interconnect bus are either the hard decisions or soft decisions. The intended use of the EDMA bus is to transfer data that requires high bandwidths. This data includes the branch metrics and the decoded data. The intended use of the configuration bus is load data that requires low bandwidths. This includes the input parameters and output status registers.
- Memory block, contains all of the RAMs used by the Viterbi decoder
- Processing unit, of the VCP is realized by two main modules: the State Metrics Unit and the Trace Back Unit.

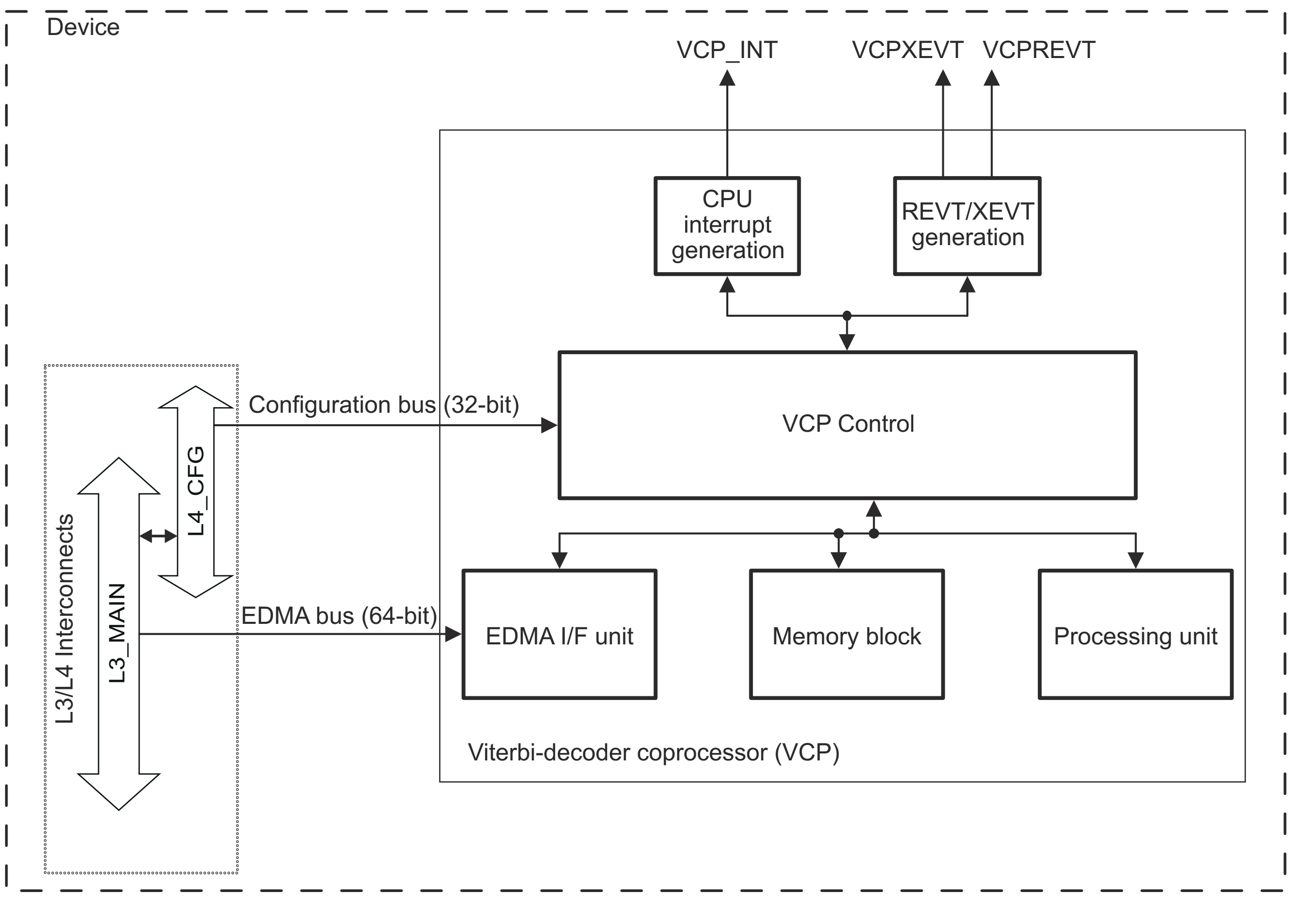

Figure 30-3. VCP Block Diagram

The DSP controls the operation of the VCP on Figure 30-3 using memory-mapped registers. The DSP typically sends and receives data using synchronized EDMA transfers through the 64-bit EDMA bus. The VCP sends two synchronization events to the EDMA:

- receive event (VCP1REVT and VCP2REVT)
- transmit event (VCP1XEVT and VCP2XEVT)

The VCP input data corresponds to the branch metrics and the output data to the hard decisions or soft decisions.

30.3.2 VCP Internal Interfaces

The interface signals can be grouped into the following four categories:

- The clock and reset signals (see Section 30.2, *VCP Integration* for signal mapping).
- The register interface that is used for the connection with the L4 interconnect for configuration and data transfer through L3_MAIN.
- The EDMA and interrupt interface used to request new context and packet data or to indicate available result data.
- Slave idle protocol to PRCM.

30.3.2.1 VCP Power Management

Two operating states are defined for all the VCP modules:

- ACTIVE state: The module is running synchronously on the interface and functional clocks. Interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc).
- IDLE state: As part of the system power management, the PRCM module can request the VCP modules to enter IDLE state. Depending on the configured acknowledgment mode, a VCP module effectively enters IDLE state or not. As soon as a VCP module enters IDLE state, its only activities are those unrelated to clock activity and its clocks are likely to be switched off at the PRCM level.

Note

IDLE request and IDLE acknowledge are only internal signals, with no means to observe or to control. The generation and control of the signals is purely hardware (managed automatically by the PRCM module and the VCP depending on the IDLEMODE settings).

Table 30-4 lists power-management features available for the VCP1 and VCP2 modules. For more information on global PRCM features, refer toChapter 3 *Power Reset and Clock Management*.

Table 30-4. Local Power-Management Features

Feature	Registers	Description
Clock Auto Gating	N/A	N/A
Slave Idle Modes	VCP_SYSCONFIG[3:2] IDLEMODE	• Idle request unconditionally acknowledged • Acknowledge always inactive • Idle request acknowledge pending internal conditions
Clock Activity	N/A	N/A
Master Standby Modes	N/A	N/A
Global Wake-up Enable	N/A	N/A
Wake-up Sources Enable	N/A	N/A

30.3.2.1.1 Idle Mode

Setting the VCP_SYSCONFIG[3:2] IDLEMODE bit-field to 0x2 activates the interface clock gating for power saving. In idle mode, the clock is active only when the registers are accessed or a VCP processing is ongoing.

When the IDLEMODE bit-field is set to 0x1- Acknowledge always inactive. When this bit-field is set to 0x0, Idle request unconditionally acknowledged and the clock is free-running.

30.3.2.2 VCP Clocks

The source of VCP1_CLK and VCP2_CLK is a interface clock signal L3MAIN1_L3_GICLK from CD_L3MAIN in PRCM.

The VCP1_CLK and VCP2_CLK run at the L3/L4 interconnect clock speeds. It is used to trigger access to the VCP modules - L3_MAIN to DATA port and L4_CFG to CFG port interfaces through the Cortex-A15 MPU/DSP shared bus.

Note

At the PRCM level, when all the conditions to shut off the L3MAIN1_L3_GICLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure VCP1 and VCP2 are ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the VCP modules.

At the PRCM level the status of VCP modules clock signals observe by registers: CM_L3MAIN1_VCP1_CLKCTRL and CM_L3MAIN1_VCP2_CLKCTRL.

For more information, refer to Chapter 3, *Power, Reset, and Clock Management*.

30.3.2.3 VCP Resets

Table 30-5 lists the resets used in the VCP1 and VCP2 modules.

Table 30-5. VCP1 and VCP2 Reset Description

Type	Name	Source	Description
Hardware	VCP1_RST VCP2_RST	PRCM	Global Reset
Software	VCP_SYSCONFIG[0] RESET_DONE	Internal	Reset from the idle command, reset is complete when its value is 1

This section covers the reset feature of the VCP1 and VCP2 modules.

The VCP_SYSCONFIG[0] RESET_DONE bit shows the status of the reset from the idle command. It indicates that the reset is complete when its value is 1. Software must ensure that the reset completes before doing VCP operations.

The behavior of software reset and hardware reset is the same, except that the software reset bit resets this module without affecting the whole device reset core domain.

30.3.2.4 Interrupt Requests

The VCP1 and VCP2 modules generates events shown in Table 30-6. An interrupt can be enable or disable by using the VCP_IRQENABLE_SET register.

Table 30-6. VCP1 and VCP2 Interrupts Description

Event Name	Description
VCP_IRQSTATUS[0] STATUS	Current active status of the interrupts after the enabling function.
VCP_IRQENABLE_SET[0] ENABLE_SET	User enables the VCP error interrupt
VCP_IRQENABLE_CLR[0] ENABLE_CLR	User disables the VCP error interrupt.

30.3.2.5 EDMA Requests

The VCP1 and VCP2 have EDMA request ports to request a new context, input data.

Each VCP has its own set of EDMA request signals, resulting in a set of four EDMA request signals (see Table 30-3).

The status of the EDMA requests observe by registers:

- VCP_DEBUG[0] DMA_R_REQ - Status of the VCP receive event (VCP1REVT and VCP2REVT)
- VCP_DEBUG[1] DMA_X_REQ - Status of the VCP tranmit event (VCP1XEVT and VCP2XEVT)

30.3.3 Functional Overview

The Viterbi Coprocessor performs the decoding of the following convolutional encoders:

- Linear shift register
- Outputs are combinations of previous inputs, defined by polynomial matrix.
- Constraint length K: number of delay elements + 1
- Code *rate r=1/n*: 1 input and n outputs, the number of outputs is issued from the number of polynomials, ie the number of rows in the matrix.

The Viterbi coprocessor (VCP) supports decoding of convolutional encoders with constraint length K from 5 to 9, and rates of 1/2, 1/3 or 1/4.

30.3.3.1 Theoretical Basics of the Convolutional Code.

A convolutional code is generated by passing the information sequence to be transmitted through a linear finite-state shift register. The VCP module is able to decode only a subset of those codes known as a single-shift register, nonrecursive convolutional code (see Figure 30-4). Important parameters for these types of codes are:

- The constraint length K (length of the delay line, the VCP2 supports K values from 5 to 9)
- The rate R given by R = k/n where k is the number of information bits needed to produce n output bits also known as codewords (the VCP2 supports 1/2, 1/3, and 1/4 codes with rates)
- The generator polynomials Gn describe how the outputs are generated from the inputs

30.3.3.2

Figure 30-4 shows the example block diagram of the Convolutional Encoder in VCP module.

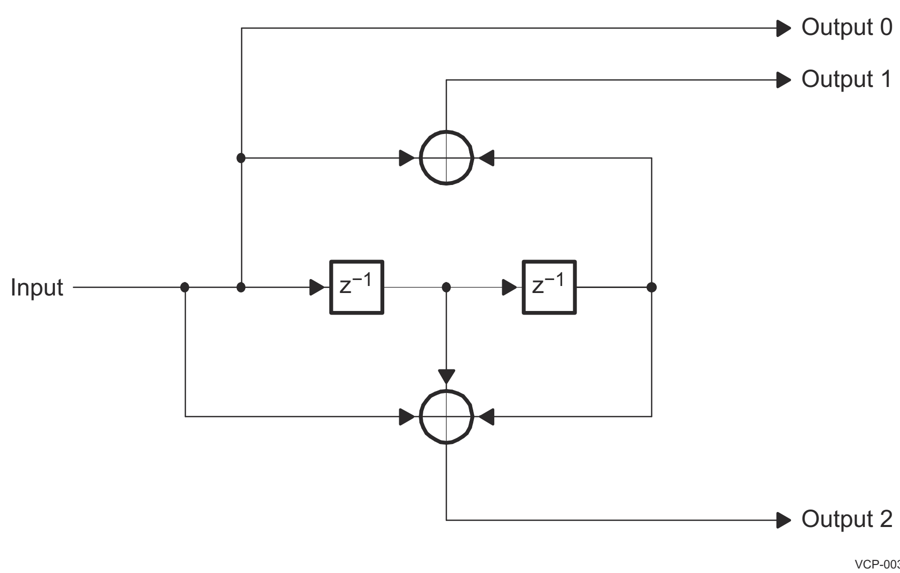

Figure 30-4. Convolutional Encoder Example Block Diagram

From the parameters, it can derive a trellis diagram that provides a useful representation of the code but whose complexity grows exponentially with the constraint length K. Figure 30-5 shows the trellis diagram of the code from Figure 30-4. The fact that there is a limited number of possible transitions from one state to another makes the code powerful and will be used in the decoding process.

As a maximum-likelihood sequence estimation (MLSE) decoder, the Viterbi decoder identifies the code sequence with the highest probability of matching the transmitted sequence based on the received sequence.

The Viterbi algorithm is composed of a metric update and a traceback routine. The metric update performs a forward recursion in the trellis over a finite number of symbol periods where probabilities are accumulated (the VCP accumulates on 13 bits) for each individual state, based on the current input symbol (branch metric information). The accumulated metric is known as path metrics or state metrics. Once a path through the trellis is identified, the traceback routine performs a backward recursion in the trellis and outputs hard decisions or soft decisions.

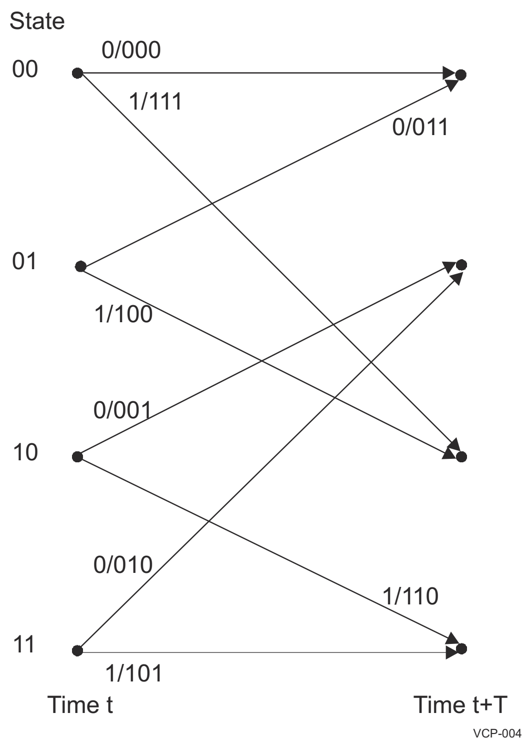

Figure 30-5. Trellis Diagram for Convolutional Encoder Example Block Diagram

30.3.4 VCP Architecture

A block diagram of the VCP processing unit is shown on Figure 30-6. The state metrics unit performs the Viterbi forward recursion using branch metrics as inputs, and updates the states metrics for all states (Add/Compare/Select or ACS operations) at every trellis stage. The state metrics memory is not accessible by the DSP. The traceback unit performs the Viterbi backward recursion and generates harddecisions or soft-decisions. The traceback memories are not directly accessible by the DSP.

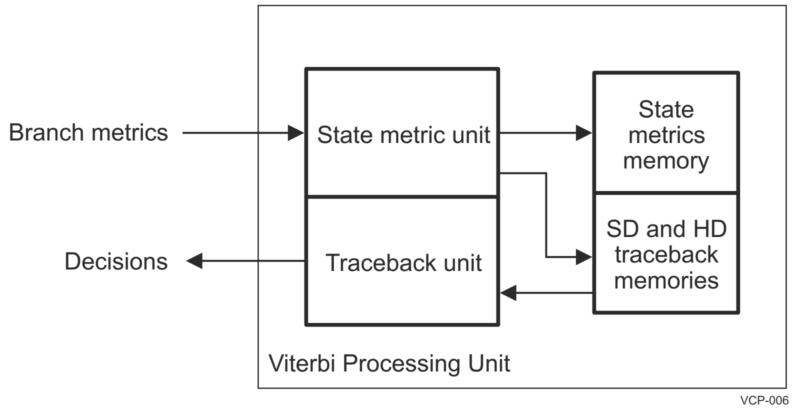

Figure 30-6. Viterbi Processing Unit

30.3.4.1 Sliding Windows Processing

The traceback hard decision memory can store up to 32768 traceback bits and there are $2^{(K-1)}$ bits stored at each trellis stage. Therefore, the traceback hard decision memory can store decisions of $32768/2^{(K-1)}$ symbols. The traceback soft decision memory can store up to 8192 traceback soft values and, therefore, contain up to 8192 soft decisions of $8192/2^{(K-1)}$ symbols. Assume a terminated frame of length F (excluding tail bits) and a constraint length K, F and K determine whether all decisions can be stored in the traceback memories.

If the decisions do not fit in the traceback HD/SD memory, then the convergent or mixed mode is used and the original frame is segmented into sliding windows (SW) otherwise, the traceback mode is set to tailed and no segmentation is required.

30.3.4.1.1 Tailed Traceback Mode

This mode is used when a full frame can reside within the coprocessor traceback memory. The state metrics are computed over $F + K - 1$ symbols, the traceback is initialized with the tails state and executed over $F + K - 1$ symbols. It should be noted that only F decisions are output. They are output in reverse order and in blocks of user-defined size.

Figure 30-7 shows Tailed Traceback Mode.

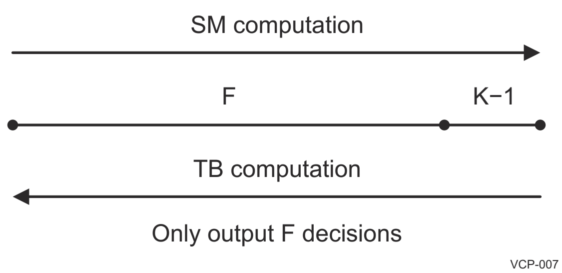

Figure 30-7. Tailed Traceback Mode

30.3.4.1.2 Mixed Traceback Mode

This mode is used when the full frame does not fit into the coprocessor traceback memory and the frame is terminated. The frame is split into sliding windows. The state metrics are computed over $F + K - 1$ symbols, the traceback is initialized with the tails state and executed over $F + K - 1$ symbols. It should be noted that only F decisions are output in blocks of user-defined size (see Section Figure 30-7). The state metrics computation of sliding window $i + 1$ is done in parallel with the traceback computation of sliding window i. Tailed traceback type is used on the last sliding window.

Figure 30-8 shows the sliding windows diagram for Mixed Traceback Mode.

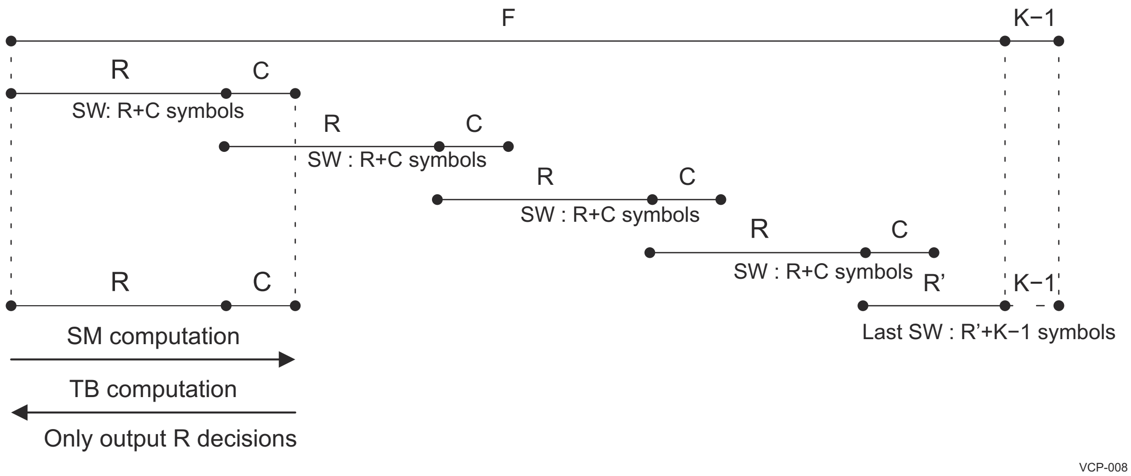

Figure 30-8. Mixed Traceback Mode - Example with Five Sliding Windows

30.3.4.1.3 Convergent Traceback Mode

This mode is used with nonterminated frames or when must decode a portion of the frame. When the frame does not fit into the coprocessor traceback memory, then the frame is split into sliding windows. The state metrics are computed over *F* + *C* symbols, the traceback is initialized with the tails state and executed over *F* + *C* symbols. It should be noted that only *F* decisions are output in blocks of user-defined size (see Section Figure 30-7). The state metrics computation of sliding window *i* + *1* is done in parallel with the traceback computation of sliding window *i*.

Figure 30-9 shows the sliding windows diagram for Convergent Traceback Mode.

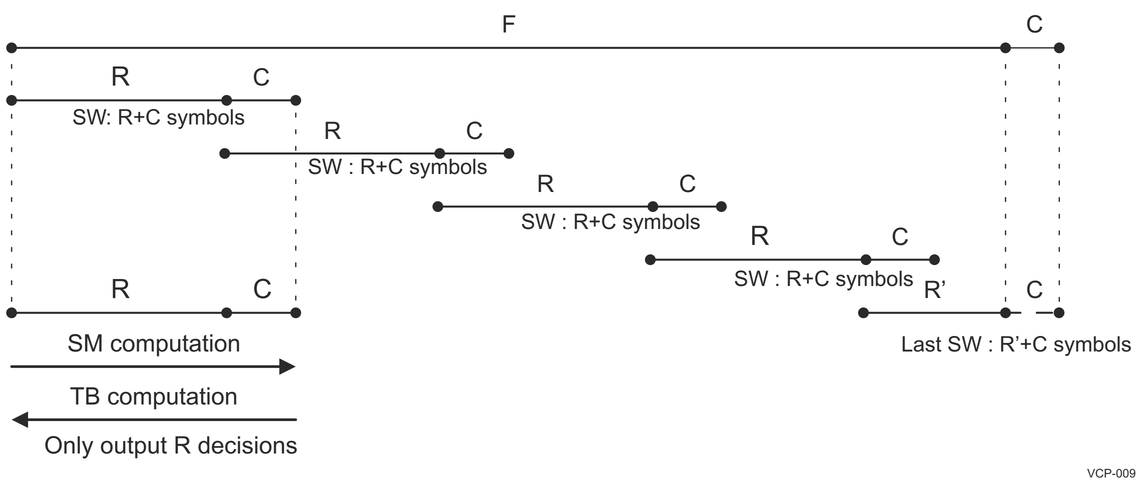

Figure 30-9. Convergent Traceback Mode - Example With Five Sliding Windows

30.3.4.1.4 F, R, and C Limitations

VCP modules have increased the traceback soft decision memory and output FIFO compared to the memory. The Traceback soft decision memory size has been increased from 1024 × 96 bits to 2048 × 64 bits. The output FIFO memory has been increased from 32 × 64 bits to 64 × 64 bits. In addition, the soft decision resolution is increased internally to 13 bits and is clipped to 8 bits when output from VCP module. These memory sizes have an effect on the *Fmax* parameter (i.e., the maximum frame size for tailed processing), and the *(R+C)* max parameter (i.e., the maximum sliding window length for mixed/convergent processing).

The VCP version 2 performance is as follows:

- Soft decisions:

- Allowed values for *C* are *C = N*(K-1)*, where *N* is a convergence multiplier. Table 30-7 and Table 30-8 show the possible values of N for each value of K for hard and soft decisions.
- *R* is constrained to be less than or equal to 248.
- *Fmax* and *(R+C)* max for VCP version 2 have been increased over VCP. This change reduces the number of sliding windows and, therefore, decreases the number of VCP version 2 cycles needed for traceback. Overall, there is no major improvement in the processing delay because a larger portion of cycles is spent in state metric accumulation, which is largely unaffected by the choice of *R* and *C*.

- Hard decisions:
  - (*R+C) max* for mixed/convergent processing for hard decisions has been increased from 605 to 635 for *K = 6*, and from 1020 to 2044 for *K = 5*. As with soft decisions, this change results in a small decrease in VCP version 2 cycle counts during traceback.

The procedure to calculate the reliability length is as follows. (The reliability length cannot be larger than *1920, or C ≤ 1920-(k-1)*).

1. Determine the convergence length
2. Determine the number of sliding windows: *Nsw = ceil(F/((R+ C)max - C)*
3. Determine the reliability length: *R = m x ceil(F/(Nsw × m))*
4. If *R > 248*, then increment number of sliding windows and repeat step 3
5. See Table 30-7 and Table 30-8 for hard decision and soft decision limits

Table 30-7. Traceback Soft Decision Sliding Window Limits

K	Maximum Frame Size	Fmax	(r + c)max	Multiple (m)	Convergent Multiplier (N)	Special Constraint
9	64	56	60	7	3, 6	
8	112	105	105	4	3, 6, 9, 12	
7	192	186	186	6	3, 6, 9, 12, 15, 18	
6	320	315	315	5	3, 6, 9, 12, 15, 18	r ≤ 248
5	1024	1020	320	4	3, 6, 9, 12, 15, 18	r ≤ 248

Table 30-8. Traceback Hard Decision Sliding Window Limits

K	Maximum Frame Size	Fmax	(r + c)max	Multiple (m)	Convergent Multiplier (N)
9	128	120	124	4	3, 6, 9, 12, 15
8	224	217	217	7	3, 6, 9, 12, 15, 18
7	384	378	378	6	3, 6, 9, 12, 15, 18
6	640	635	635	5	3, 6, 9, 12, 15, 18
5	2048	2044	2044	4	3, 6, 9, 12, 15, 18

30.3.4.1.5 Yamamoto Parameters

During the standard forward recursion, an entity called the Yamamoto bit is computed for each state and updated every symbol interval. The Yamamoto bit was proposed by Hirosuke Yamamoto (Hirosuke Yamamoto, "Viterbi Decoding Algorithm for Convolutional Codes with Repeat Request," IEEE Transactions on Information Theory, Vol. IT-26, No. 5, September 1980).

Basically, a bit (the Yamamoto bit) is associated with each state in the decoding process. Initially, all the Yamamoto bits are set (1). During the decoding process, the Yamamoto bit for a particular state comes from a couple of decisions made on the path metrics and the Yamamoto bit of previous states. The metrics of all paths leading to a particular state are compared. If the difference between any two metrics is less than a given threshold VCP_VCPIC1[27:16] YAMT bits, then the Yamamoto bit is cleared otherwise, the Yamamoto bit is inherited from the previous state of the path with the largest metric. The end result of this process (VCP_VCPOUT1[16] YAM) yields a zero (0) if anywhere along the decoding path there was a point where the decision between two paths was ambiguous. The VCP_VCPOUT1[16] YAM bit can therefore be used as a binary frame quality indicator.

The Yamamoto algorithm can be enabled or disabled by toggling the VCP_VCPIC1[28] YAMEN bit.

30.3.4.1.6 Input FIFO (Branch Metrics)

Figure 30-10 shows how the FIFO is used in either a double or quad buffering scheme. The VCP modules generate a VCPXEVT synchronization event each time the *nx1/4* of the buffer is empty, where (*n =1, 2, 3, 4*) or (*n = 2, 4*) depending on the value of VCP_VCPIC5[19:16] SYMX. The VCP_VCPIC5[19:16] SYMX bits define the buffer length as well as the VCPnXEVT event rate. The maximum allocatable size for the buffer in the input FIFO is 16 or 64-bit words. VCP_VCPIC5[19:16] SYMX defines the branch metric buffer length (minus one) to be transmitted to the VCP for each VCPnXEVT. Table 30-9 has the valid values for SYMX, along with the corresponding number of 64-bit transfers. If the number of 64 bit transfers is 16, then the double buffering scheme is used and VCPnXEVTs will be generated when half the FIFO is empty (either top or bottom half). If the number of 64-bit transfers is 8, then a quad buffering scheme is used and VCPnXEVTs will be generated as each quarter of the FIFO is emptied. The VCP version 2 only generates as many VCPXEVTs as needed to produce all the BMs required based on the SYMX value, Frame Length, and Rate. In other words, no potential excess VCPnXEVTs will be generated based on the FIFO being partially empty at the end of processing.

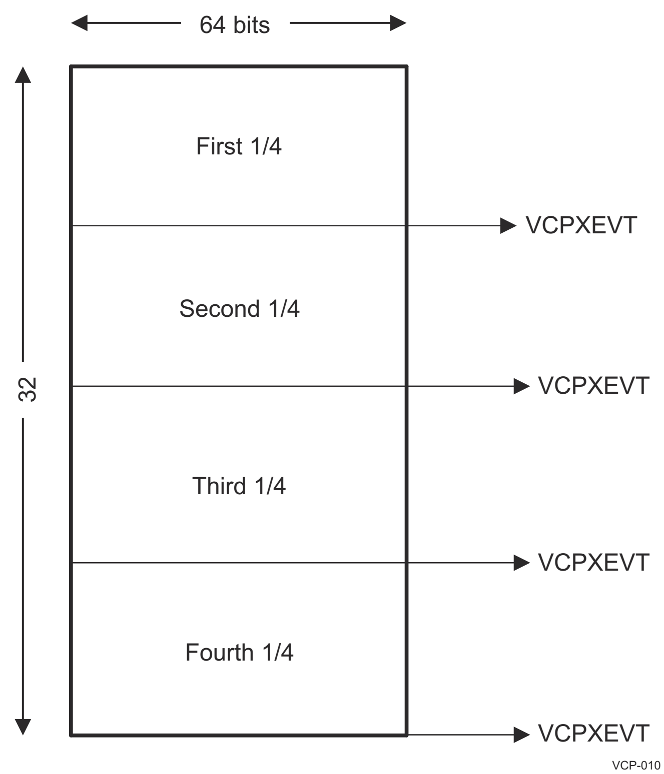

Figure 30-10. Input FIFO (Branch Metrics)

Table 30-9. Traceback Hard Decision Sliding Window Limits

Code Rate	SYMX	Number of 64-bit Transfer
1/4	3	16
1/4	1	8
1/3	7	16
1/3	3	8
1/2	15	16
1/2	7	8

30.3.4.1.7 Output FIFO (Decisions)

Figure 30-11 shows how the output FIFO is used in either a double or quad buffering scheme. The VCP modules generate a VCPREVT synchronization event each time the *nx1/4* of the buffer is empty, where (*n =1, 2, 3, 4*) or (*n = 2, 4*), depending on the value of SYMR. VCP_VCPIC5[24:20] SYMR bits define the buffer length, as well as the VCPnREVT event rate. The maximum size for buffer is 16 64-bit words.

- For hard-decisions:
  - If *F ≤ 2048*, then *SYMR = ceil F/64]-1*
  - If *F > 2048*, then *SYMR = 15 or 31*
- For soft-decisions:
  - If *F ≤ 256*, then *SYMR = ceil [F/8]-1*
  - If *F > 256*, then *SYMR = 15 or 31*

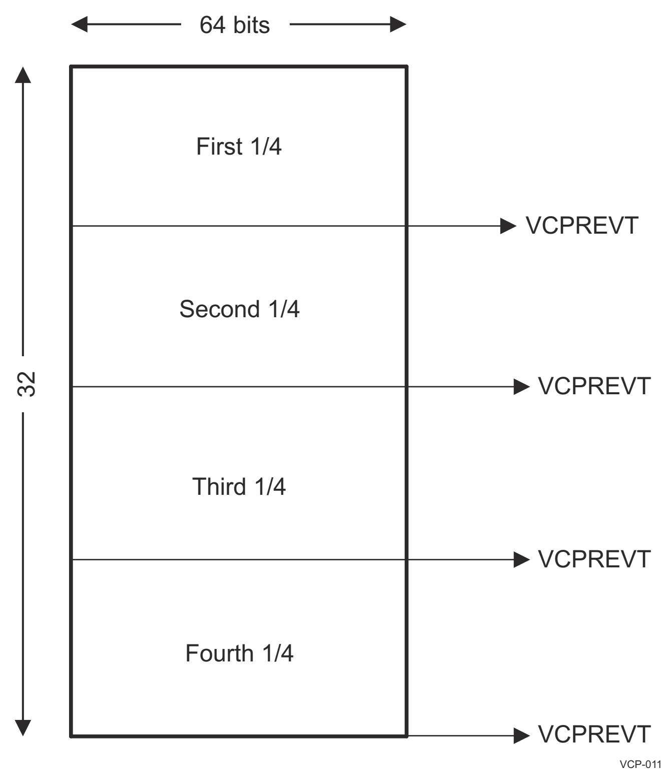

Figure 30-11. Output FIFO (Decisions Data)

If VCP_VCPIC5[23:20] SYMR = 31, double buffering is used and a VCPnREVT is generated when the first or second half of the buffer is filled. If SYMR = 15, then VCPnREVT is generated after each quarter of the buffer is filled. When *F ≤ 2048* for HD or *F ≤ 256* for SD outputs and SYMR is determined as described above, a single VCPnREVT is generated once all decisions have been written to the output FIFO.

30.3.5 VCP Input Data

30.3.5.1 Branch Metrics Calculations

The branch metrics (BM) are calculated by the DSP and stored in the DSP memory subsystem as 8-bit signed values. Per symbol interval T, for a rate *R = k/n* and a constraint length *K*, there are a total of $2^{(K-1+k)}$ branches in the trellis. For rate 1/n codes, only $2^{(n-1)}$ branch metrics need to be computed per symbol period and passed to the VCP module. Moreover, n symbols are required to calculate 1 branch metric.

Assuming BSPK modulated bits (0 → 1, 1→ -1), the branch metrics are calculated as follows:

- Rate 1/2: there are 2 branch metrics per symbol period

– $BM_0(t) = r_0(t) + r_1(t)$
– $BM_1(f) = r_0(t) - r_1(t)$

where r(t) is the received codeword at time t (2 symbols, $r_0(t)$ is the symbol corresponding to the encoder upper branch, see Figure 30-4).

- Rate 1/3: there are 4 branch metrics per symbol period
  – $BM_0(t) = r_0(t) + r_1(t) + r_2(t)$
  – $BM_1(t) = r_0(t) + r_1(t) - r_2(t)$
  – $BM_2(t) = r_0(t) - r_1(t) + r_2(t)$
  – $BM_3(t) = r_0(t) - r_1(t) - r_2(t)$

where r(t) is the received codeword (3 symbols, $r_0(t)$ is the symbol corresponding to the encoder upper branch; see Figure 30-4).

- Rate 1/4: there are 8 branch metrics per symbol period
  – $BM_0(t) = r_0(t) + r_1(t) + r_2(t) + r_3(t)$
  – $BM_1(t) = r_0(t) + r_1(t) + r_2(t) - r_3(t)$
  – $BM_2(t) = r_0(t) + r_1(t) - r_2(t) + r_3(t)$
  – $BM_3(t) = r_0(t) + r_1(t) - r_2(t) - r_3(t)$
  – $BM_4(t) = r_0(t) - r_1(t) + r_2(t) + r_3(t)$
  – $BM_5(t) = r_0(t) - r_1(t) + r_2(t) - r_3(t)$
  – $BM_6(t) = r_0(t) - r_1(t) - r_2(t) + r_3(t)$
  – $BM_7(t) = r_0(t) - r_1(t) - r_2(t) - r_3(t)$

where r(t) is the received codeword (4 symbols, $r_0(t)$ is the symbol corresponding to the encoder upper branch, see Figure 30-4).

The data must be sent to the VCP version 2 as described in Table 30-10, Table 30-11, and Table 30-12 for rates 1/2, 1/3, and 1/4, respectively (the base address must be double-word aligned).

The branch metrics can be saved in the DSP memory subsystem in either its native format or packed in words (user implementation). When working in big-endian mode, the VCP endian mode register (VCP_VCPEND) indicates if the data is 32-bit word packed or Native 8-bit format.

Table 30-10. Branch Metrics for Rate 1/2

Address (hex)	Data

Address (hex)	Data
Base + 10h	...

The state metric accumulation resolution is 13 bits on the VCP modules. Consequently, full 8-bit dynamic range is available for branch metrics on the VCP modules, for all constraint lengths and all code rates.

30.3.6 Soft Input Dynamic Ranges

The VCP implementation implies that the soft inputs need to be quantized so that the branch metrics satisfy the following bound B1 (branch metrics upper bound - absolute value):

$$2(C-1) -1 \geq (2\times(K-1) + 2) \times B1 \quad (12)$$

K is the constraint length and C determines the truncation of state metrics that can be performed without loss of decoding performance.

The VCP is designed with C = 13. The branch metrics can have a maximum dynamic range of 7+1 sign bits do [-128; +127]. This gives another branch metrics, upper bound B2 ≤ 128.

So for a given constraint length, min(B1, B2) will give the final branch metrics, maximum bound B.

To satisfy B in the branch metrics calculation, the soft input values, delivered as 8-bit-signed equalized values, are linearly scaled with the following formula where *1/n* is the rate.

$$Scaled = min(B1, B2)/n \times SoftValue/128 \quad (13)$$

Example

K=9, then B1 3 227.5 and the branch metrics range B2 is [-128; +127]. So the branch metrics need to be in [-128; +127] range.

If the rate is 1/3, then 128/3 ≈ 42, so the soft inputs need to be scaled by a factor 0.333333 and saturated within the range [-42; +42].

Table 30-13 summarizes the calculations for the different constraint length and rate:

Table 30-13. VCP Soft Inputs Quantization

1/Rate	K	Scaling Factor	Range
2	5, 6, 7, 8, 9	0.5	[-64; +63]
3	5, 6, 7, 8, 9	0.333333	[-42; +42]
4	5, 6, 7, 8, 9	0.25	[-31; +31]

30.3.7 VCP Memory Sleep Mode

All VCP memories can be put into a low leakage (sleep) state. Putting the banks into a sleep mode disables the memories. The VCP1/2 can put the banks into dynamic sleep mode if the input control bits VCP_VCPEND[8] SLPZVDD and VCP_VCPEND[9] SLPZVSS in the endianness register are set. Once the bits are set, VCP memories will be put in the sleep mode based on the following truth table Table 30-14:

Table 30-14. VCP Memory Sleep Mode Truth Table

RAM	Conditions
sd	If (sdhd = 0), bank is in sleep mode. Else, bank wake up.
sm	If (exc_cmd = 0), bank is in sleep mode. Else, bank wake up.

30.3.8 Decision Data

The VCPs can be configured to generate either hard decisions (one bit per decision), or soft decisions (8-bit value per decision). Ordering of the VCP decisions depends on the VCP_VCPIC3[28] OUT_ORDER bit-field and the VCP_VCPEND[1] SD bit, if the DSP is set to work in big-endian mode and the results or Soft Decisions (see the VCP version 2 endian mode register VCP_VCPEND). The decisions buffer start address must be double-word aligned and the buffer size must be a multiple of 8 bytes.

The soft decisions in the VCP are initially computed with the path metrics at 13-bit values. The results are then clipped to 8-bit signed integer values before being stored in the traceback soft decision memory.

30.3.9 Endianness

The VCP endian mode register VCP_VCPEND is intended to solve possible little-endian issues.

30.3.9.1 Branch Metrics

When the data are saved in their 8-bit native format (*BM = 1*), they must be organized in the DSP memory as described in Table 30-15. When the data are packed on 32-bit words (BM = 0), they must be organized in the DSP memory as described in Table 30-16.

Table 30-15. Branch Metrics

Little_big_endian	BM	Description (MSB to LSB)
0	0	3, 2, 1, 0, 7, 6, 5, 4 => 7, 6, 5, 4, 3, 2, 1, 0 (bytes)

30.3.9.1.1 Hard Decisions

The VCP modules hard decisions bit-ordering within the 32-bit hard decision word, is programmable via the VCP_VCPIC3[28] OUT_ORDER bit, such that the oldest bit can be either in the MSB or the LSB position.

Figure 30-16. Trellis Stage Ordering of Hard Decisions in 32-Bit Word (OUT_ORDER = 0)

63	62	...	32	31	...	1	0
Stage N	Stage N - 1	...	Stage N - 31	Stage N - 32	...	Stage N - 62	Stage N - 63

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

OUT_ORDER = 1 orders the hard decision data in the order in which it is calculated in the State Metric computation; from 31 to 0 in the 32-bit word output.

Figure 30-17. Trellis Stage Ordering of Hard Decisions in 32-Bit Word (OUT_ORDER = 1)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

30.3.9.1.2 Soft Decisions

The VCP soft decisions are 8-bit results, and output 64 bits at a time. The soft decisions will be organized as shown in Table 30-18, based on the CPU's endianness and whether SD is set for Native or 32-bit packed results.

Table 30-18. Soft Decision Organization

Little_big_endian	BM	Description (MSB to LSB)
0	0	7, 6, 5, 4, 3, 2, 1, 0 => 3, 2, 1, 0, 7, 6, 5, 4 (bytes)
0	1	7, 6, 5, 4, 3, 2, 1, 0 => 0, 1, 2, 3, 4, 5, 6, 7 (bytes)
1	0	Endianness manager has no effect 7, 6, 5, 4, 3, 2, 1, 0 => 7, 6, 5, 4, 3, 2, 1, 0 (bytes)
1	1	Endianness manager has no effect 7, 6, 5, 4, 3, 2, 1, 0 => 7, 6, 5, 4, 3, 2, 1, 0 (bytes)

30.3.10 VCP Output Parameters

The VCP_VCPOUT0[12:0] FMAXS and VCP_VCPOUT0[28:16] FMINS bits indicate the final maximum and minimum state metric values, respectively. The VCP_VCPOUT1[7:0] FMAXI bit indicates the state index for the state with the final maximum state metric.

The VCP_VCPOUT1[16] YAM is described in Section 30.3.4.1.5 *Yamamoto Parameters*.

30.3.11 Event Generation

30.3.11.1 VCPnXEVT Generation

A VCP modules transmit events (VCP1XEVT and VCP2XEVT) are generated when any of the following conditions appear:

- A START command write in VCP_VCPEXE[3:0] COMMAND.
- Top one-fourth and half or bottom one-fourth and half of the input FIFO buffer (see Table 30-9) is empty.
- After all decisions have been read and VCP_VCPIC5[30] OUTF is cleared, or if all decisions have been read and the output registers have been read and VCP_VCPIC5[30] OUTF is set.

Note

The extra XEVT pulls the next set of input configurations via EDMA. If EDMA controller is not set up to link in another set of input configurations, then a dummy transfer should be set up to avoid an SER Event Flag being set for the EDMA Parameter Entry. If the flag is set, it effectively locks the VCP modules, and must be cleared before any future events can be processed for that entry.

30.3.11.2 VCPnREVT Generation

The VCP modules receive event (VCP1REVT and VCP2REVT) are generated when any of the following conditions appear:

- The traceback unit has written top one fourth and half or bottom one-fourth and half of the output FIFO buffer (see Figure 30-11).
- After the traceback is completed (the whole frame has been decoded).
- VCP_VCPIC5[30] OUTF bit is set to 1 and all decisions have been read to read the output registers.

30.3.12 Operational Modes

The following list describes the VCP1 and VCP2 modules operational modes.

- 0: Value at reset or value written by the coprocessor when previous instruction is read and its execution is ongoing. DSP may test the status word in the output control memory to check if the instruction is being executed.
- 1: Start - CPU orders the coprocessor to start a processing block: The first action of the coprocessor is then to generate the first XEVT to trigger DMA transfer of the input control words.
- 2: Pause - CPU orders the coprocessor to pause a processing block at the beginning of traceback.
- 3: Unpause (single_traceback) - CPU orders the coprocessor to restart at the beginning of traceback and halt at next traceback.
- 4: Unpause (finish_traceback) - CPU orders the coprocessor to restart at the beginning of traceback and complete decode.
- 5: Stop - CPU orders the coprocessor to reset: the coprocessor resets all VCP modules registers.

30.3.12.1 Debugging Features

Visibility into the internal operation of the VCP version 2 (i.e., the state metric accumulation, traceback memory) is available to the CPU via a pause command. However, since the pause command is not synchronized with the internal VCP version 2 state machine but is rather sent from the CPU at a random moment in time, this feature is of limited use.

The pause command on the VCP version 2 is augmented to provide visibility into VCP modules operation on a sliding window basis. Instead of using the normal start command which tells the VCPs to perform a complete decode of one frame (including input/output transfers via EDMA controller), halt at beginning of traceback and resume until next traceback commands are used, and the internal VCP memories can be inspected at various points in the decoding process. The procedure for using this command is as follows:

- VCP modules configuration and branch metrics are prepared
- A halt at the beginning of the traceback command is sent
- The VCP modules generates necessary interrupts to the EDMA to transfer input configuration and to start transferring branch metrics. The VCP1 and VCP2 perform state metric accumulation as branch metrics become available. When it reaches the end of the first sliding window (i.e., the reliability portion and the convergence portion), the VCP halts.
- The CPU polls the VCP1 and VCP2 status registers until the VCP's states changes from running to paused. At that point, the state metrics memory can be inspected, as well as the traceback memory. To perform an inspection, halt the CPU via a software breakpoint set at an appropriate point in the code, for instance. Then, the memory can be inspected visually via the debugger GUI, or, alternatively, the CPU can copy the relevant internal VCP memories to another location for later analysis.
  - The CPU sends the resume until next traceback command to the VCP.

– The VCPs perform the traceback, generate a portion of hard or soft decisions, and continue with state metric accumulation until the end of the next sliding window (i.e., another number of R stages, where R is the reliability length).
– The process continues until the decoding is complete. Alternatively, the decoding process can be run to completion after any sliding window by sending the resume to completion command instead of the resume until next traceback command.

Emulation modes are achieved with the programmable SOFT and FREE bits in the VCP emulation control registers VCP_VCPEMU.

When the CPU is halted during emulation, VCPs can be halted based on the setting of the VCP_VCPEMU[1] SOFT and VCP_VCPEMU[0] FREE bits. The VCPs can be halted at the traceback processing or frames processing boundary.

30.3.13 Errors and Status

To handle errors, the IRQ status must be enabled. The IRQ status is enabled by writing a 1 to the VCP_IRQENABLE_SET[0] ENABLE_SET bit. When the coprocessor detects an error, the coprocessor sets the status and error words, then sends an interrupt to the CPU. Any coprocessor processing is paused and the DSP must reset or start the coprocessor. An error occurs if the VCP modules receive an invalid value in the input configuration parameters. If an error is detected, the VCP_VCPERR bit-fields are set accordingly, the VCP_VCPSTAT0[2] ERR bit is set, the VCP_INT interrupts are generated, and no processing are engaged. In order to restart the VCPs the following steps must be taken:

1. Read the VCP_IRQSTATUS register
2. Read the VCP_VCPERR register
3. Write to the VCP_IRQSTATUS register the previously read value to specify that this interrupt had been handled.
4. Send another START command by VCP_VCPEXE[3:0] COMMAND.

The status registers are provided for debugging purposes and are best used when either the processor is halted or the VCP modules are halted. If an error occurs, the VCPs are halted and a VCP_INT interrupts are generated that can be mapped to a CPU interrupt. There may be cases where the status registers must be viewed when the VCP modules are still running. One such case is when the VCPs seem to have taken a long time in processing the current frame. In such cases, a watchdog timer should be used and set according to the frame length and VCPs configuration, in addition to some overhead to allow for EDMA usage.

Table 30-19 through Table 30-21 summarize the cases, when no errors can occur in register VCP_VCPERR.

Table 30-19. E_SYMR 0 (No error for SMAR)

TB Mode	VCP_VCPIC5[24:20] SYMR	# of 64 BitTransfers	ConditionTransfer
Hard	0 to 31	1 to 32	F ≤ 2048
Hard	31	32	F > 2048
Hard	15	16	F ≥ 2048
Soft	0 to 31	1 to 32	F ≤ 256
Soft	31	32	F ≥ 256
Soft	15	16	F > 256

Table 30-20. E_SYMX 0 (No error for SMAX)

Code Rate	VCP_VCPIC5[19:16] SYMX	# of 64-Bit	# of BM per	# trellis per
1/4	3	16	128	16
1/4	1	8	64	8
1/3	7	16	128	32
1/3	3	8	64	16
1/2	15	16	128	64
1/2	7	8	64	32

Table 30-21. MAXIMINERR 0 (Error Check)

Sign Imaxas	Sign Imins	Check Equation(1)
0	0	0 ≤ IMAXS - IMINS < 2048
1	1	0 ≤ IMAXS - IMINS < 2048
0	1	0 ≤ IMAXS - IMINS < 2048
1	0	0 ≤ (2 x 4096 + IMAXS) - IMINS < 2048

(1) See the bit-fields in register VCP_VCPIC4[28:16] IMINS and VCP_VCPIC4[12:0] IMAXS.

30.4 VCP Modules Programming Guide

The VCP1 and VCP2 require setting up the following context per user channel:

- Three to four EDMA parameters (see Table 30-22)
- The input configurations parameters

Several user channels can be programmed prior to starting the VCPs. A suggested implementation is to use the EDMA interrupt generation capabilities (refer to Section 16.2.4.9 *EDMA Interrupts* in Section 16.2 *Enhanced DMA controller*) and program the EDMA to generate an interrupt after the user channel's last VCPnREVT synchronized EDMA transfer has completed.

Table 30-22. Required EDMA Links Per User Channel

Direction	Data	Usage	Required/Optional
Transmit	Input configuration parameters	Send the input configuration parameters	Required
Transmit	Branch metrics	Send branch metrics	Required
Receive	Decisions	Read decisions	Required
Receive	Output parameters	Read output parameters	Optional (OUTF bit)

30.4.1 EDMA Resources

30.4.1.1 VCP1 and VCP2 Dedicated EDMA Resources

Within the available EDMA channel event sources, four are assigned to the VCP1 and VCP2 modules: event 0 and event 1.

- Event 0 is associated to the VCP1 and VCP2 receive events (VCP1REVT and VCP2REVT) and are used as the synchronization events for EDMA transfers from the VCP1 and VCP2 to the DSP (receive).
- Event 1 is associated to the VCP1 and VCP2 transmit event (VCP1XEVT and VCP2XEVT) and are used as the synchronization events for EDMA transfers from the DSP to the VCP1 and VCP2 (transmit).

For the default configuration of the crossbar, the VCP events are event 0 and event 1. If the crossbar is reconfigured, event 0 and event 1 must be programmed to the VCP events.

30.4.1.2 Special VCP EDMA Programming Considerations

The EDMA parameters consist of eight words as shown in Figure 30-18. All EDMA transfers, in the context of the VCPs, must contain an even number of words, and have source and destination addresses double-word aligned.

All EDMA transfers must be double-word aligned and the transfer size for the VCP EDMA transfers must be a multiple of 8. Single-word transfers that are not double-word aligned cause errors in the TCP2/VCP1/VCP2 memory.

Transfers to the VCP FIFOs must be configured to NOT use the EDMA FIFO/Const mode. Instead, the transfers should be set with:

- ACNT=8;
- BCNT=transfer_byte_count/8;
- BIDX=0(via SBIDX or DBIDX);
- ABSync trigger mode (via SYNCDIM = 1);

For more information about EDMA, refer to Section 16.2 *Enchanced DMA controller*.

Figure 30-18. EDMA Parameters Structure

30.4.1.2.1 Input Configuration Parameters Transfer

Note

The procedures described in this chapter concern the configuration of EDMA module in the device. For more information about EDMA module refer to Section 16.2 *Enhanced DMA controller*.

The procedure for configuring the EDMA transfer to the input configuration parameters is a 6-word VCPXEVT frame synchronized transfer. The parameters should be set in several EDMA registers (refer to Section 16.2.7 *EDMA Register Manual*), as described in Table 30-23:

Table 30-23. EDMA Transfer Options Parameters

Step	Register/Bit Field/Programming Model	Value
Intermediate transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[23] ITCCHEN	0x0: Disable
Transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[22] TCCHEN	0x0: Disable
Intermediate transfer complete interrupt is disabled	EDMA.EDMA_TPCC_OPT_n[21] ITCINTEN	0x0: Disable
Backward compatibility mode	EDMA.EDMA_TPCC_OPT_n[19] WIMODE	0x0: Normal operation
Transfer complete interrupt is disabled	EDMA.EDMA_TPCC_OPT_n[20] TCINTEN	0x0: Disable
Transfer complete code	EDMA.EDMA_TPCC_OPT_n[17:12] TCC	1 to 63
Transfer complete code mode	EDMA.EDMA_TPCC_OPT_n[11] TCCMODE	0x0: Normal operation
FIFO width	EDMA.EDMA_TPCC_OPT_n[10:8] FWID	x
Static Entry	EDMA.EDMA_TPCC_OPT_n[3] STATIC	0x0: Entry is updated as normal
Transfer Synchronization Dimension	EDMA.EDMA_TPCC_OPT_n[2] SYNCDIM	0x0: A-sync transfer, each event triggers the transfer of ACNT elements.
Destination Address Mode	EDMA.EDMA_TPCC_OPT_n[1] DAM	0x0: Destination address within an array increments. Destination is not a FIFO.
Source Address Mode	EDMA.EDMA_TPCC_OPT_n[0] SAM	0x0: Source Address within an array increments. Source is not a FIFO.
Source Address	EDMA.EDMA_TPCC_SRC_n[31:0] SRC	xxxx: User input configuration parameters start address.
Number of bytes in an array	EDMA.EDMA_TPCC_ABCNT_n[15:0] ACNT	24 - Number of bytes in 1st Dimension.
Number of arrays in a frame	EDMA.EDMA_TPCC_ABCNT_n[15:0] BCNT	0x1: One array in the frame. Count for 2nd Dimension.

Table 30-23. EDMA Transfer Options Parameters (continued)

Step	Register/Bit Field/Programming Model	Value
Destination Address	EDMA.EDMA_TPCC_DST_n[31:0] DST	VCP_VCPIC0 - 32-bit destination address parameters.
Source 2nd Dimension Index	EDMA.EDMA_TPCC_BIDX_n[15:0] SBIDX	0x00

Source Frame Index	EDMA.EDMA_TPCC_CIDX_n[15:0] SCIDX	0x00
Destination Frame Index	EDMA.EDMA_TPCC_CIDX_n[31:16] DCIDX	0x00
C byte count. Count for 3rd Dimension	EDMA.EDMA_TPCC_CCNT_n[15:0] CCNT	0x1: One frame in the block

Upon completion, this EDMA transfer is linked to the EDMA for branch metrics transfer parameters.

30.4.1.2.2 Branch Metrics Transfer

Table 30-24 shows the sequence for configuring EDMA transfer to the branch metrics FIFO is a VCP1XEVT and VCP2XEVT frames synchronized transfer. The parameters should be set as:

Table 30-24. Configuration EDMA Transfer to the Branch Metrics FIFO

Step	Register/Bit Field/Programming Model	Value
Intermediate transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[23] ITCCHEN	0x0: Disable
Transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[22] TCCHEN	0x0: Disable
Intermediate transfer complete interrupt is disabled	EDMA.EDMA_TPCC_OPT_n[21] ITCINTEN	0x0: Disable
Transfer complete interrupt is enabled	EDMA.EDMA_TPCC_OPT_n[20] TCINTEN	0x1: Enabled
Backward compatibility mode	EDMA.EDMA_TPCC_OPT_n[19] WIMODE	0x0: Normal operation
Transfer complete code	EDMA.EDMA_TPCC_OPT_n[17:12] TCC	1 to 63
Transfer complete code mode	EDMA.EDMA_TPCC_OPT_n[11] TCCMODE	0x0: Normal completion
FIFO width	EDMA.EDMA_TPCC_OPT_n[10:8] FWID	x
Static Entry	EDMA.EDMA_TPCC_OPT_n[3] STATIC	0x0: Entry is updated as normal.
Transfer Synchronization Dimension	EDMA.EDMA_TPCC_OPT_n[2] SYNCDIM	0x1: AB-Sync, Each event triggers the transfer of BCNT arrays of ACNT elements.
Destination Address Mode	EDMA.EDMA_TPCC_OPT_n[1] DAM	0x0: INCR, Dst addressing within an array increments. Dst is not a FIFO.
Source Address Mode	EDMA.EDMA_TPCC_OPT_n[0] SAM	0x0: Source Address within an array increments. Source is not a FIFO.
Source Address	EDMA.EDMA_TPCC_SRC_n[31:0] SRC	xxxx: Branch Metrics Array start addressBranch Metrics Array start address.
Number of branch metrics bytes in an array	EDMA.EDMA_TPCC_ABCNT_n[15:0] ACNT	0x8, where $ACNT = 4 \times (SYMX+1) \times 2^{(r-1)}$ (14)

Table 30-24. Configuration EDMA Transfer to the Branch Metrics FIFO (continued)

Step	Register/Bit Field/Programming Model	Value
Number of arrays in a frame Where TNBM is Total Number of Branch Metrics in Bytes To calculate total number of branch metrics data in bytes: *Total number of Branch metrics = (F + K - 1) ×(2*$^{(r-1)}$*)* for mixed and tailed traceback mode In case of convergent mode, *Total number of Branch metrics = (F + C) ×(2*$^{(r-1)}$*)*	EDMA.EDMA_TPCC_ABCNT_n[15:0] BCNT	*BCNT = CEIL(TNBM/ ACNT)* (15)
Destination Address	EDMA.EDMA_TPCC_DST_n[31:0] DST	VCP_VCPWBM Branch Metrics FIFO Address - 32-bit destination address parameters.
Source 2nd Dimension Index	EDMA.EDMA_TPCC_BIDX_n[15:0] SBIDX	= ACNT (to create incrementing transfer)
Destination 2nd Dimension Index	EDMA.EDMA_TPCC_BIDX_n[31:16] DBIDX	0x00 (to access the FIFO)
Source Frame Index	EDMA.EDMA_TPCC_CIDX_n[15:0] SCIDX	ACNT × BCNT
Destination Frame Index	EDMA.EDMA_TPCC_CIDX_n[31:16] DCIDX	0x00 (to access the FIFO)
C byte count. Count for 3rd Dimension	EDMA.EDMA_TPCC_CCNT_n[15:0] CCNT	0x1: One frame in the block

Upon completion, this EDMA transfer is linked to one of the following:

- The DMA input configuration parameters transfer parameters of the next user-channel, if there is one ready to be decoded.
- Dummy DMA transfer parameters, if there are no more user channels ready to be decoded.

Note

Do not link to a NULL transfer, as the Secondary Event Register will set the event flag for Event 1. The final VCPnXEVT is generated upon the reading of the decisions and output registers, which is intended to transfer the input configuration of the next user channel. If a NULL transfer link is in place, the final VCPnXEVT will set the event 1 flag of SER and no further VCP execution will occur until it is cleared.

30.4.1.2.3 Decisions Transfer

EDMA transfers from the decision buffer are VCP1REVT and VCP2REVT frame synchronized transfers. The programming of these transfers depend on the decision type and the traceback mode.

Upon completion, this EDMA transfer is linked to one of the following:

1. The decisions EDMA transfer parameters of the next user-channel, if there is one ready to be decoded and the VCP_VCPIC5[30] OUTF bit is 0.
2. Null EDMA transfer parameters (with all zeros), if there are no more user-channels ready to be decoded and the VCP_VCPIC5[30] OUTF bit is 0.
3. The output parameters EDMA transfer parameters, if the VCP_VCPIC5[30] OUTF bit is 1.

30.4.1.2.4 Hard-Decisions Mode

Table 30-25 shows the sequence for configuring EDMA transfer for Hard-Decisions Mode. The parameters should be set as:

Table 30-25. Configuration EDMA Hard-Decisions Mode

Step	Register/Bit Field/Programming Model	Value
Intermediate transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[23] ITCCHEN	0x0: Disable
Transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[22] TCCHEN	0x0: Disable
Intermediate transfer complete interrupt is disabled	EDMA.EDMA_TPCC_OPT_n[21] ITCINTEN	0x0: Disable

Table 30-25. Configuration EDMA Hard-Decisions Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Transfer complete interrupt is disabled	EDMA.EDMA_TPCC_OPT_n[20] TCINTEN	0x0: Disable
Backward compatibility mode	EDMA.EDMA_TPCC_OPT_n[19] WIMODE	0x0: Normal operation
Transfer complete code	EDMA.EDMA_TPCC_OPT_n[17:12] TCC	1 to 63
Transfer complete code mode	EDMA.EDMA_TPCC_OPT_n[11] TCCMODE	0x0: Normal completion
FIFO width	EDMA.EDMA_TPCC_OPT_n[10:8] FWID	x
Static Entry	EDMA.EDMA_TPCC_OPT_n[3] STATIC	0x0: Entry is updated as normal.
Transfer Synchronization Dimension	EDMA.EDMA_TPCC_OPT_n[2] SYNCDIM	0x1: AB-Sync, Each event triggers the transfer of BCNT arrays of ACNT elements.
Destination Address Mode	EDMA.EDMA_TPCC_OPT_n[1] DAM	0x0: NCR, Dst addressing within an array increments. Dst is not a FIFO.
Source Address Mode	EDMA.EDMA_TPCC_OPT_n[0] SAM	0x0: INCR, Src addressing within an array increments.Source is not a FIFO.
Source Address	EDMA.EDMA_TPCC_SRC_n[31:0] SRC	xxxx: VCPRDECS Decision FIFO address

Number of arrays in a frame Where TNHD is the total number of hard decisions in bytes (Framelength/8)	EDMA.EDMA_TPCC_ABCNT_n[15:0] BCNT	$$BCNT = CEIL(TNHD/ACNT) \quad (17)$$
Destination Address	EDMA.EDMA_TPCC_DST_n[31:0] DST	xxxx: Hard Decision Array Address
Source 2nd Dimension Index	EDMA.EDMA_TPCC_BIDX_n[15:0] SBIDX	0x8 (to create incrementing transfer)
Destination 2nd Dimension Index	EDMA.EDMA_TPCC_BIDX_n[31:16] DBIDX	0x0 (to access the FIFO)
Source Frame Index	EDMA.EDMA_TPCC_CIDX_n[15:0] SCIDX	ACNT × BCNT
Destination Frame Index	EDMA.EDMA_TPCC_CIDX_n[31:16] DCIDX	0x00 (to access the FIFO)
C byte count. Count for 3rd Dimension	EDMA.EDMA_TPCC_CCNT_n[15:0] CCNT	0x1: One frame in the block

30.4.1.2.5 Soft-Decisions Mode

Table 30-26 shows the sequence for configuring EDMA transfer for Soft-Decisions Mode. The parameters should be set as:

Table 30-26. Configuration EDMA Soft-Decisions Mode

Step	Register/Bit Field/Programming Model	Value
Intermediate transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[23] ITCCHEN	0x0: Disable
Transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[22] TCCHEN	0x0: Disable
Intermediate transfer complete interrupt is disabled	EDMA.EDMA_TPCC_OPT_n[21] ITCINTEN	0x0: Disable
Transfer complete interrupt is disabled	EDMA.EDMA_TPCC_OPT_n[20] TCINTEN	0x0: Disable
Backward compatibility mode	EDMA.EDMA_TPCC_OPT_n[19] WIMODE	0x0: Normal operation
Transfer complete code	EDMA.EDMA_TPCC_OPT_n[17:12] TCC	1 to 63
Transfer complete code mode	EDMA.EDMA_TPCC_OPT_n[11] TCCMODE	0x0: Normal completion
FIFO width	EDMA.EDMA_TPCC_OPT_n[10:8] FWID	x

Table 30-26. Configuration EDMA Soft-Decisions Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Static Entry	EDMA.EDMA_TPCC_OPT_n[3] STATIC	0x0: Entry is updated as normal.
Transfer Synchronization Dimension	EDMA.EDMA_TPCC_OPT_n[2] SYNCDIM	0x1 AB-Sync, Each event triggers the transfer of BCNT arrays of ACNT elements .
Destination Address Mode	EDMA.EDMA_TPCC_OPT_n[1] DAM	0x1: NCR, Dst addressing within an array increments. Dst is not a FIFO .
Source Address Mode	EDMA.EDMA_TPCC_OPT_n[0] SAM	0x0: INCR, Src addressing within an array increments. Source is not a FIFO.
Source Address	EDMA.EDMA_TPCC_SRC_n[31:0] SRC	xxxx: VCPRDECS Decision FIFO address
Number of Hard decision bytes in an array	EDMA.EDMA_TPCC_ABCNT_n[15:0] ACNT	0x8, where $A(SYMR+1) \times 8$ (18)
Number of arrays in a frame Where TNSD is the total number of soft decisions (framelength)	EDMA.EDMA_TPCC_ABCNT_n[15:0] BCNT	$BCNT = CEIL(TNSD/ACNT)$ (19)
Destination Address	EDMA.EDMA_TPCC_DST_n[31:0] DST	xxxx: Soft Decision Array Address
Source 2nd Dimension Index	EDMA.EDMA_TPCC_BIDX_n[15:0] SBIDX	0x8 (to create incrementing transfer)
Destination 2nd Dimension Index	EDMA.EDMA_TPCC_BIDX_n[31:16] DBIDX	0x0 (to access the FIFO)
Source Frame Index	EDMA.EDMA_TPCC_CIDX_n[15:0] SCIDX	ACNT × BCNT
Destination Frame Index	EDMA.EDMA_TPCC_CIDX_n[31:16] DCIDX	0x00 (to access the FIFO)
C byte count. Count for 3rd Dimension	EDMA.EDMA_TPCC_CCNT_n[15:0] CCNT	0x1: One frame in the block

30.4.1.2.6 Output Parameters Transfer

Table 30-27 shows the sequence for configuring EDMA for Output Parameters Transfer. This transfer is optional and depends on the OUTF bit. It is a 2- to 32-bit word VCP1REVT and VCP2REVT frames synchronized transfer.

Table 30-27. Configuration EDMA Output Parameters Transfer

Step	Register/Bit Field/Programming Model	Value
Intermediate transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[23] ITCCHEN	0x0: Disable
Transfer complete chaining is disabled	EDMA.EDMA_TPCC_OPT_n[22] TCCHEN	0x0: Disable
Intermediate transfer complete interrupt is disabled	EDMA.EDMA_TPCC_OPT_n[21] ITCINTEN	0x0: Disable
Transfer complete interrupt is disabled	EDMA.EDMA_TPCC_OPT_n[20] TCINTEN	0x0: Disable
Backward compatibility mode	EDMA.EDMA_TPCC_OPT_n[19] WIMODE	0x0: Normal operation
Transfer complete code	EDMA.EDMA_TPCC_OPT_n[17:12] TCC	1 to 63
Transfer complete code mode	EDMA.EDMA_TPCC_OPT_n[11] TCCMODE	0x0: Normal completion
FIFO width	EDMA.EDMA_TPCC_OPT_n[10:8] FWID	x
Static Entry	EDMA.EDMA_TPCC_OPT_n[3] STATIC	0x0: Entry is updated as normal.
Transfer Synchronization Dimension	EDMA.EDMA_TPCC_OPT_n[2] SYNCDIM	0x0: A-sync transfer, each event triggers the transfer of ACNT elements.

Table 30-27. Configuration EDMA Output Parameters Transfer (continued)

Step	Register/Bit Field/Programming Model	Value
Destination Address Mode	EDMA.EDMA_TPCC_OPT_n[1] DAM	0x0: Destination address within an array increments. Destination is not a FIFO.
Source Address Mode	EDMA.EDMA_TPCC_OPT_n[0] SAM	0x0: Source Address within an array increments. Source is not a FIFO.
Source Address	EDMA.EDMA_TPCC_SRC_n[31:0] SRC	xxxx: VCP_VCPOUT0 - VCP OUTPUT Register 0 Address
Number of Hard decision bytes in an array	EDMA.EDMA_TPCC_ABCNT_n[15:0] ACNT	0x8
Number of arrays in a frame	EDMA.EDMA_TPCC_ABCNT_n[15:0] BCNT	0x1
Destination Address	EDMA.EDMA_TPCC_DST_n[31:0] DST	xxxx: Output Register Store Array Address
Source 2nd Dimension Index	EDMA.EDMA_TPCC_BIDX_n[15:0] SBIDX	0x0
Destination 2nd Dimension Index	EDMA.EDMA_TPCC_BIDX_n[31:16] DBIDX	0x0
Source Frame Index	EDMA.EDMA_TPCC_CIDX_n[15:0] SCIDX	0x00
Destination Frame Index	EDMA.EDMA_TPCC_CIDX_n[31:16] DCIDX	0x00
C byte count. Count for 3rd Dimension	EDMA.EDMA_TPCC_CCNT_n[15:0] CCNT	0x1: One frame in the block

Upon completion, this EDMA transfer is linked to one of the following:

1. The EDMA decisions transfer parameters of the next user-channel, if there is one ready to be decoded.
2. Null EDMA transfer parameters (with all zeros), if there are no more user-channels ready to be decoded.

30.4.2 Input Configuration Words

The input configuration words should reflect the parameters of the user-channels to be decoded.

The POLYn bits in VCP_VCPIC0 correspond to the generator polynomials in the encoder (see Figure 30-4). The values in each POLYn bit fields must be entered in reverse order. The POLYn least-significant bit is set by the VCPs logic.

- For rate 1/2, POLY0 and POLY1 are required
- For rate 1/3, POLY0, POLY1, and POLY2 are required
- For rate 1/4, all the POLYn bits are required

The VCP_VCPIC1[27:16] YAMT and VCP_VCPIC1[28]YAMEN bits are described in Section 30.5.2.

The VCP_VCPIC2[15:0] F and VCP_VCPIC2[31:15] R bits, the VCP_VCPIC3[15:0] C bit, and the VCP_VCPIC5[29:28] TB bits are described in Section 30.5.2.

The VCP_VCPIC5[7:0] IMAXI bit-field determines which state should be initialized with the maximum state metrics value (IMAXS), all the other states are initialized with the minimum state metrics value (IMINS). The IMAXI can range from 0 to 2^{K}-1-1. The IMAXS and IMINS are 13-bit signed values.

The VCP_VCPIC5[19:16] SYMX and VCP_VCPIC5[24:20] SYMR bits are described in Section 30.5.2.

The VCP_VCPIC5[30] OUTF bit indicates whether the VCP should generate a VCPnREVT for reading the output parameters. The OUTF bit setting will impact the EDMA programming (see Section 30.4.1.2.3).

30.5 VCP Register Manual

30.5.1 VCP1 and VCP2 Instance Summary

Table 30-28 shows the base address and address space for the VCP1 and VCP2 modules instances.

Table 30-28. VCP1 and VCP2 Instance Summary

Module Name	Base Address L3_MAIN	Base Address L4_PER2 Interconnect	Size
VCP1	0x4640 0000	0x4844 6000	4 KB
VCP2	0x4680 0000	0x4844 8000	4 KB

30.5.2 VCP Registers

The VCP1 and VCP2 contain several memory-mapped registers accessible by the CPU, and the EDMA module. A configuration-bus access is faster than an EDMA-bus access for isolated accesses (typically when accessing control registers). EDMA-bus accesses are used for EDMA transfers and provide maximum throughput to/from the VCP modules. The registers are listed in Table 30-29 and Table 30-30 .

The branch metric and traceback decision memories contents are not accessible and the memories can be regarded as FIFOs by the DSP, no indexing on addresses need to be performed.

30.5.2.1 VCP Register Summary

Table 30-29 summarizes the VCP1 and VCP2 data registers accessible by EDMA-bus.

Table 30-29. VCP DATA Registers Summary

Register Name	Type	Register Width (Bits)	L3 Interconnect / EDMA Bus	VCP1 Physical Address L3_MAIN	VCP2 Physical Address L3_MAIN

0x0000 F000	0x4641 B000	0x4681 D000	IO	Decoded Bits (IO)	512 Bytes

Note

Register and Memory Access

- Data Transfer Alignment: Normal (non-emulation) mode data transfers to/from the VCP1 and VCP2 must be aligned on a double-word (64-bit) boundary. Alignment can be forced in C using the 'DATA_ALIGN' pragma. Non-alignment results in data transfer failure.
  Example:

```
#pragma DATA_ALIGN(configIc, 8) // Should be double-word aligned
VCP_ConfigIc configIc; // VCP Input Configuration Reg
```

- Data Transfer Size: Normal (non-emulation) mode data transfers to/from the VCP1 and VCP2 must be of a length that is an 8-byte (double-word) multiple.
- Emulation mode transfers are performed on 32-bit boundaries and are 4 bytes in length.

30.5.2.2 VCP1 and VCP2 Data Registers Description

Table 30-32 through Table 30-50 describe the individual VCP1 and VCP2 data registers.

31.1 ATL Overview

The audio tracking logic (ATL) is used by HD Radio™ applications to synchronize the digital audio output to the baseband clock. This same IP can also be used generically to track errors between two reference signals (such as frame syncs) and generate a modulated clock output (using software-controlled cycle stealing) which averages to some desired frequency. This process can be used as a hardware assist for asynchronous sample rate conversion algorithms. The tracking range is limited, so direct conversion between the two standard sample rate groups frequencies from 44.1 to 48 kHz is not possible.

Figure 31-1 shows an overview of the ATL module.

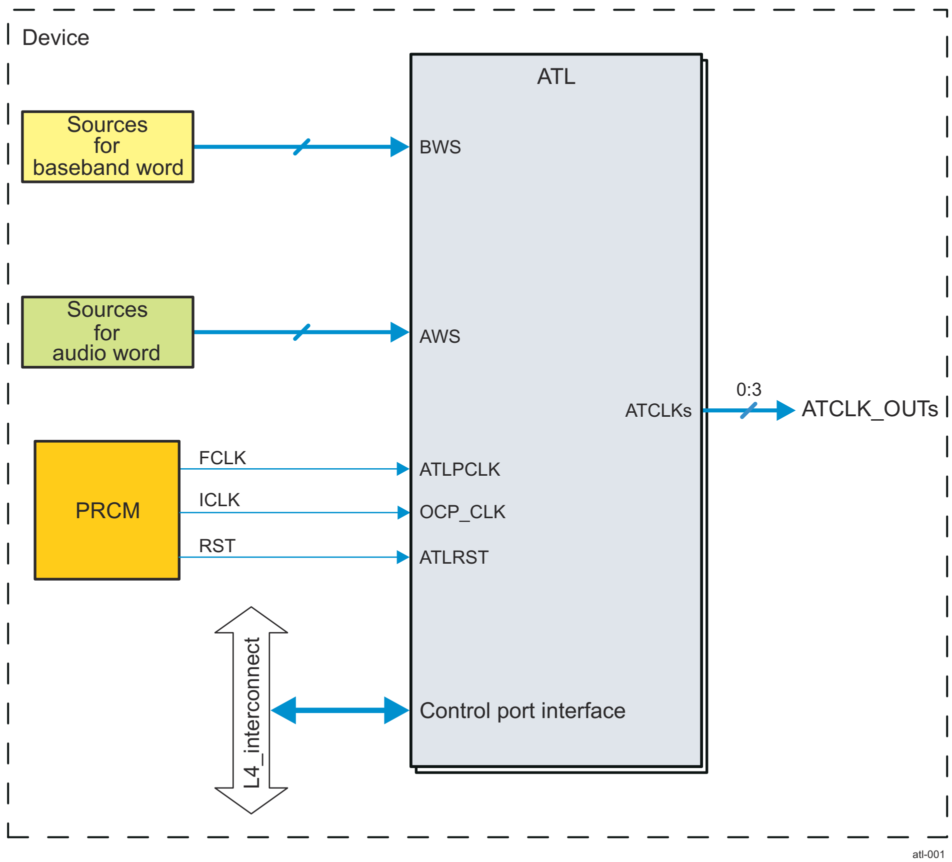

Figure 31-1. ATL Module Overview

The ATL includes the following main features:

- One ATL module, containing four ATL instances, for HD Radio support and asynchronous sample rate conversion assistance
- Each instance tracks the time error between two syncs (local audio word select [AWS] and baseband word select [BWS])
- Each instance selects between 16 mux choices for each of AWS and BWS.
- Each instance generates modulated ATCLK_OUT clock signal with software-initiated pulse stealing.
- Selection between INTERCONNECT clock or functional ATLPCLK to run error couting timers and to derive modulated ATCLK_OUT clock outputs
- Clock and reset management: Receives clock and reset signals from the device PRCM module, and has its own dedicated clock domain (CD_ATL) within the PRCM. The ATL module receives hardware reset from the CORE_RST reset domain.
- Power management: The ATL belongs to the PD_COREAON power domain.

31.2 ATL Environment

This section describes the intended functions for the ATL module from an environmental point of view (that is, external connections to SoC). This section presents the ATL connectivity options and lists the possible interface in the device.

31.2.1 ATL Functions

Four instances of the ATL module are available on the device: ATL0, ATL1, ATL2, and ATL3.

The recommended use for ATL in the device are:

- HD Radio applications to synchronize the digital audio output to the baseband clock.
- Timing reference from:
  - McASP modules
  - Audio clock signal PER_ABE_X1_GFCLK
  - Divided media local bus (MLB) clock
  - System clock modulated by audio/video bridging (AVB) transport protocol

31.2.2 ATL Signals Descriptions

Table 31-1 lists the ATL module pins, their corresponding signal names at device level, and specifies their links to functions.

Table 31-1. I/O Description

Signal Name	Device-Level Signal Name	I/O[(1)]	Description
ATLCLK0	atl_clk0	O	Audio Tracking Logic Clock 0 output
ATLCLK1	atl_clk1	O	Audio Tracking Logic Clock 1 output
ATLCLK2	atl_clk2	O	Audio Tracking Logic Clock 2 output
ATLCLK3	atl_clk3	O	Audio Tracking Logic Clock 3 output

(1) I = Input, O = Output

Note

The path from a module pin to device pad or pads is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers* of *Control Module*, and the device data manual.

31.3 ATL Integration

This section describes the integration of the ATL in the device, including information about clocks, resets, and environmental modules.

Figure 31-2 shows the integration of the ATL in the device, input and output signals, clock generators, and interconnections.

The features of the ATL modules are:

- One functional clock
- One interface clock
- Interface port to L4_PER2 interconnect
- BWS mux
- AWS mux

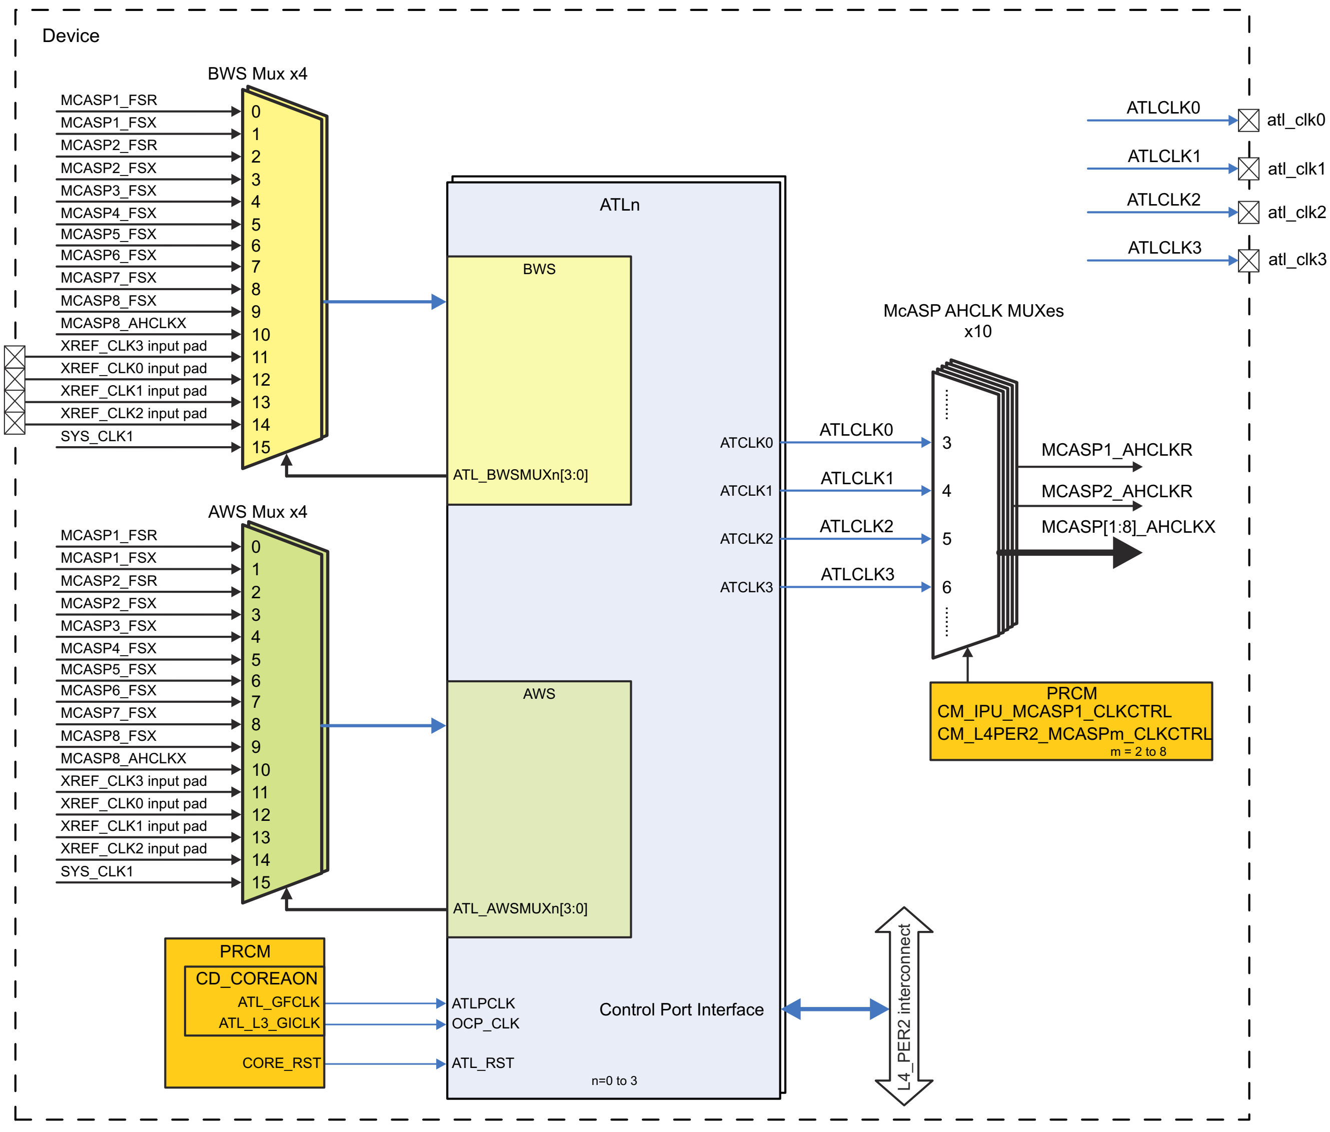

Figure 31-2. ATL Integration

Table 31-2 and Table 31-3 summarize the integration of the module in the device.

Table 31-2. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ATL	PD_COREAON	No	L4_PER2

Table 31-3. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
ATL	ATLPCLK	ATL_GFCLK	PRCM	ATL functional clock
	OCP_CLK	ATL_L3_GICLK	PRCM	ATL interface clock. Can be used as functional clock via ATL_PCLKMUX0
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**

Note

For more information about the clock and reset sources, refer to:

- Section 3.5, *Reset Management Functional Description*.
- Section 3.7, *Power Management Functional Description*.

in Chapter 3, *Power, Reset, Clock Management*.

31.3.1 ATL Distribution on Interconnects

Initiator agents (IAs) and target agents (TAs) provide the interface to connect the ATL module to its associated interconnect (see Table 31-4). For a complete description of the distribution of modules on L4 interconnects, see Section 14.3.3.1, *Module Distribution*, in Section 14.3, *Interconnect*.

Table 31-4. L4_PER2 TAs

Module Target Name	Description
TA_ATL_TARG	ATL module

31.3.2 ATL Regions Allocations

The protection mechanism for L4 interconnects is based on a hierarchical segmentation. By default, some regions are attached to specific protection group members (see Table 31-5). For a complete description of the allocation of module regions on L4 interconnects, see Section 14.3.3.3.2 Section 14.3.3.3.2, *Segments and Regions*, in Section 14.3, *L4 Interconnect*.

Note

Module refers to the configuration registers of the ATL.

TA refers to the interconnect configuration registers of the TA associated with the ATL.

Table 31-5. Region Allocations for L4_PER2 Interconnect

Module	Region	Description
ATL	24	TA
	23	Module

31.4 ATL Functional Description

This section is a functional description of the ATL modules.

31.4.1 Block Diagram

The tracking mechanism is capable of handling all input (baseband) and output (audio) sampling rates used by HD Radio. The ATL works on a single-clock domain and is insensitive to a particular choice of the master clock frequency as long as it is divisible by the desired audio frequency.

Figure 31-3 shows the functional block diagram of the four instances of the ATL module.

The ATL consists of two circuits: Measurement Circuit and Adjustment Circuit.

The main interface includes two registers: a read register in the measurement circuit, baseband sample register ATL_BBSR0; and a write register in the adjustment circuit, parts-per-milion register ATL_PPMR0.

The measurement circuit includes an 8-bit rolling counter, a 16-bit rolling counter, and the 16-bit sample count register. The 8-bit counter counts audio clock cycles. The 16-bit counter counts the number of baseband samples received by the modem. When the 8-bit counter rolls over, the content of the 16-bit counter is strobed into the sample count register ATL_BBSR0[15:0] SAMPLE_COUNT. The HD Radio library uses this content to determine the relative frequency offset between the audio clock and baseband sampling clock.

The adjusting circuit produces a timing signal at the top of the audio clock tree, which is used by dividers that make the audio timing signals including DAC oversampling clock, bit clock, and word select. The output is occasionally adjusted by altering the divide count by one “tick” of the master clock. It includes a 20-bit accumulator circuit with a 9-bit PPM ATL_PPMR0[8:0] PPM_SETTING register and an adjustable clock divider ATL_ATLCR0[4:0] ATLINTERNAL_DIVIDER. The content of the ATL_PPMR0 register is subtracted from the accumulator every master clock (ATLPCLK) cycle. On underflow, the audio clock divider adds or subtracts one master clock (ATLPCLK) period from the nominal periods of the audio clocks. The rate of adjustments in PPM (parts-per-220) is exactly the value written to ATL_PPMR0[8:0] PPM_SETTING. The MSB or ATL_PPMR0[15] PPM_SLOWDOWN of the PPM register determines whether the audio clock period is shortened or lengthened.

ATCLK is the adjusted audio clock output from the ATL. ATCLK is internally multiplexed into the McASP high-speed clock (AHCLKX) signal path per the clocking shown in the PRCM chapter (see Chapter 3, *Power, Reset, Clock Management Module*). This lets the McASP drive the master clock for an audio DAC while at the same time driving the McASP dividers for AFSX and ACLKX. ATCLK should be 128 × Fs or higher for the DAC oversampling clock.

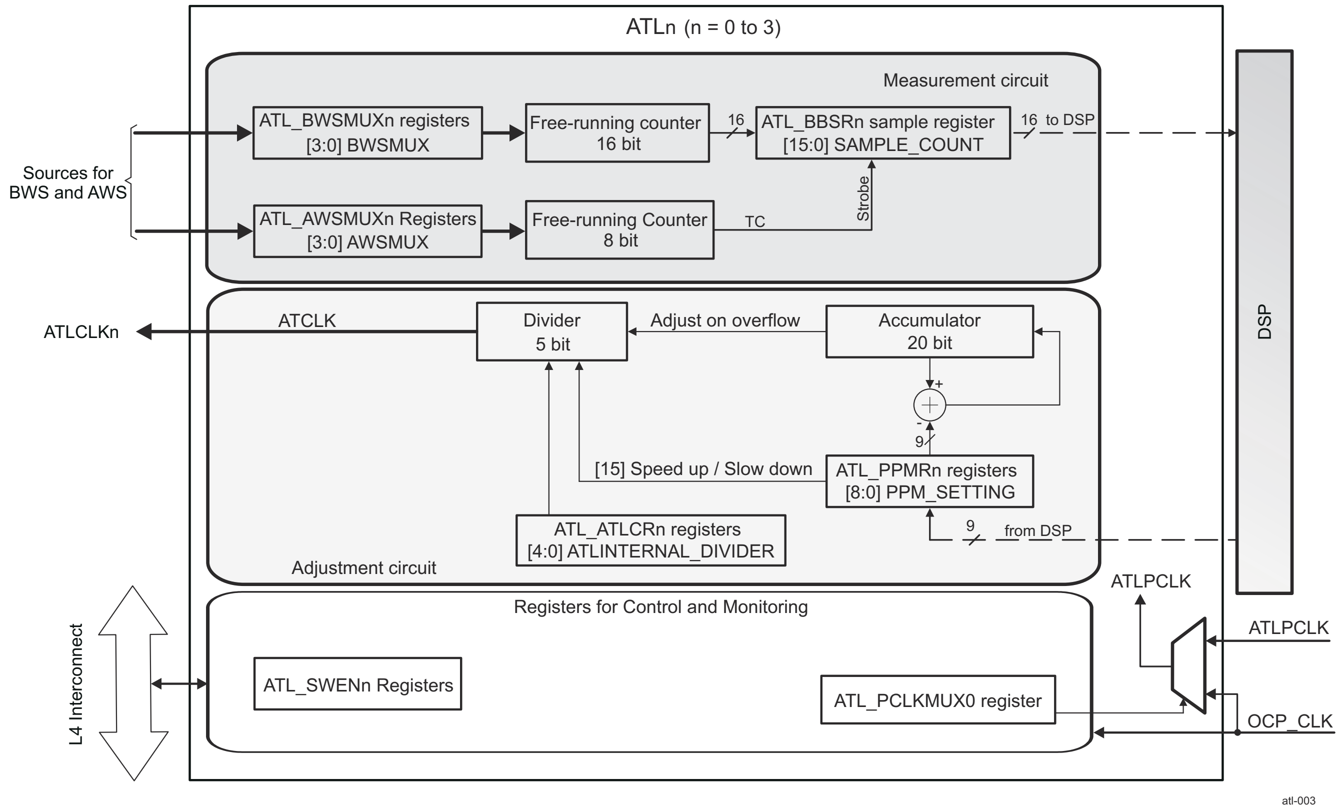

Figure 31-3. ATL Block Diagram

31.4.2 Source Signal Control

The sources for BWS and AWS inputs are defined by internal muxing from multiple reference signals.

BWS and AWS are logic inputs, not clocks, to the ATL module. ATL performs an edge detection on these signals. To minimize jitter in HD Radio clocking implementation, ATLPCLK must be higher than 100 MHz. When ATL is used for HD Radio applications, the measuring circuit is connected to the word select signal from Audio IIS output (AWS) and Baseband IIS input (BWS). The ATL_BWSMUX0 and ATL_AWSMUX0 registers select which inputs are used as the ATL BWS and AWS inputs.

31.4.3 ATL Clock and Reset Configuration

The ATL module is clocked by a functional clock (ATLPCLK) and one interface clock (OCP_CLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module. The ATLPCLK selection register mux ATL_PCLKMUX0[0] PCLKMUX chooses the functional clock for ATLPCLK input to run error counting timers and to derive modulated ATCLK_OUT clock outputs.
- OCP_CLK is used to trigger access to the ATL configuration interface through the L4_PER2 Interconnect.
- A software reset register is provided to hold the four ATL modules in reset while the AWS/BWS and ATPCLK mux selections are set and while the system-level clocking is configured. Software is required to release the module from reset. Software must enable the ATL_SWEN0[0] SWEN bit to enable the ATL. Each ATL in the device must be independently enabled.

Note

The module must be enabled in the PRCM. For more information refer to *PRCM Register Manual*, in *Power, Reset, Clock Management Module*.

31.5 ATL Register Manual

31.5.1 ATL Instance Summary

Table 31-6 shows the base address for the ATL instances in the device.

Chapter 32
Initialization

This chapter introduces the steps of the device initialization.

32.1 Initialization Overview 6937
32.2 Preinitialization 6939
32.3 Device Initialization by ROM Code 6951
32.4 Services for HLOS Support 7020

32.1 Initialization Overview

This chapter provides an overview of the requirements to initialize the device from power on to operating system (OS) and application execution, the overall initialization process (including hardware- and software-related steps), the general ROM code operational requirements, and behavior expectations.

32.1.1 Terminology

- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase
- **Configuration Header (CH):** Optional structure that precedes the initial software and allows the redefinition of the ROM code default settings
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded software launched by the ROM code during the preflashing stage. It also programs an image in external memories.
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory
- **Master CPU:** The Arm® Cortex®-A15 MPCore™ CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **ROM Code:** The on-chip software in device ROM that implements booting
- **ROM Code-controlled Boot Phase:** This phase covers the sequence operations from the time the platform releases the reset to the time first user- or customer-owned software starts execution. This phase is fully controlled by the device ROM code.
- **Slave CPU:** The Arm Cortex-A15 MPCore CPU for which CPU-ID is 1. It is brought to the wait-for-event (WFE) state by the ROM code, waiting to be woken up by the master CPU.

32.1.2 Initialization Process

Figure 32-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip
- **ROM code:** Responsible for finding, for downloading, and for executing the initial software by using the master CPU
- **Initial software:** Software that prepares and passes control to application software or to the high-level operating system (HLOS)
- **Symmetric multiprocessing (SMP)-capable HLOS** or application (primarily for diagnostics)

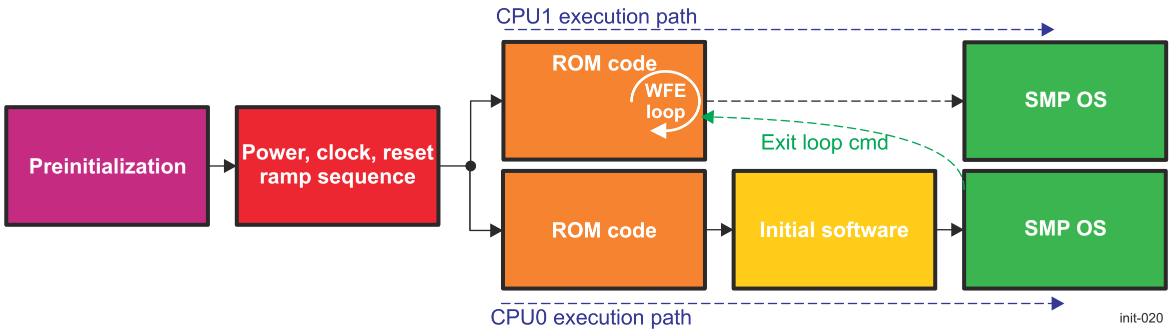

Figure 32-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins and the associated configuration registers that are vital to the correct initialization of the device.

32.2 Preinitialization

To accomplish a successful boot-up operation , certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the master CPU, must be connected and driven correctly to successfully ini

tialize the device. The following sections describe the specific requirements for the preinitialization stage.

32.2.1 Power Requirements

The device can be supplied by an external power-management integrated circuit (PMIC). TI provides a global solution with the device connected to the power-management IC companion chip. Refer to *Data Manual* for information about the power-management IC companion chips supported for this device.

Figure 32-2 shows typical power connections between the device and a PMIC companion chip.

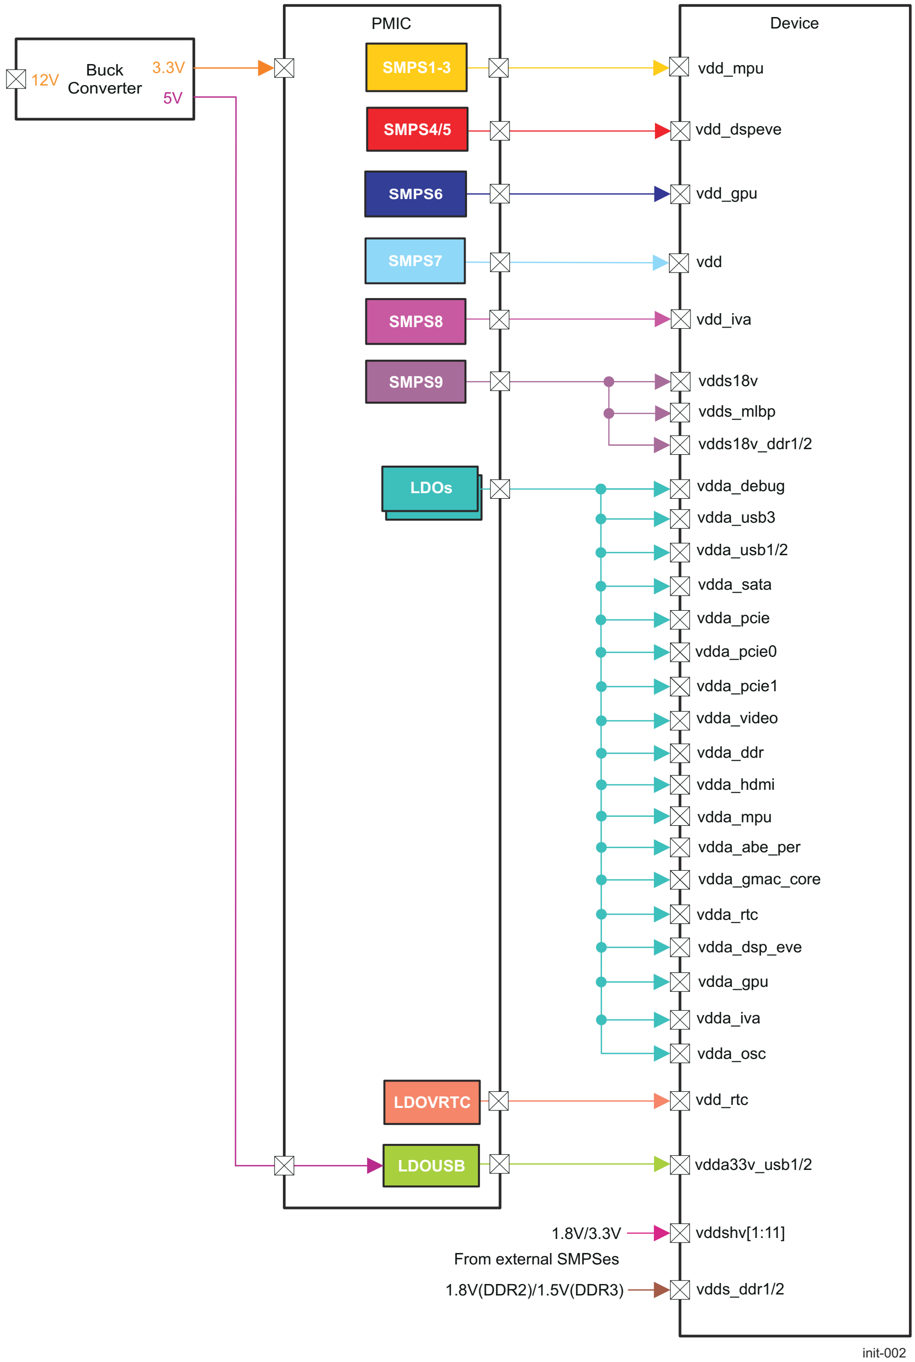

Figure 32-2. Power Supply Connections Example

Note

Figure 32-2 is an example of power connections between the device and the PMIC, representing only one of the multiple PMIC/OTP options.
These connections depend on the actual application, PMIC, and OTP used. Refer to the Device *Data Manual*, respective PMIC Data Sheet, and all related application notes before starting a new design.

Table 32-1 describes the device power balls.

Table 32-1. Device Power Balls

Voltage Ball Name	Subsystems and Peripherals
vdd	Subsystems and modules supplied by CORE voltage domain
vdd_mpu	MPU voltage domain
vdd_iva	IVA voltage domain
vdd_dspeve	DSP and EVE voltage domain
vdd_gpu	GPU voltage domain
vdd_rtc	RTC voltage domain
vdds18v	1.8V I/Os
vdds_mlbp	MLBSS I/Os
vdds_ddr1	EMIF channel 1 (1.8V for DDR2 mode/ 1.5V for DDR3 mode)
vdds_ddr2	EMIF channel 2 (1.8V for DDR2 mode/ 1.5V for DDR3 mode)
vdds18v_ddr1	EMIF channel 1 bias
vdds18v_ddr2	EMIF channel 2 bias
ddr1_vref0	EMIF channel 1 vref
ddr2_vref0	EMIF channel 2 vref
vdda_video	Analog power supply for DPLL_VIDEO0/1
vdda_ddr	Analog power supply for DPLL_DDR and DDR HSDIVIDER
vdda_mpu	Analog power supply for DPLL_MPU
vdda_abe_per	Analog power supply for DPLL_ABE, DPLL_PER, PER HSDIVIDER
vdda_gmac_core	Analog power supply for DPLL_GMAC DPLL_CORE, and CORE HSDIVIDER
vdda_hdmi	Analog power supply for HDMI I/Os and DPLL_HDMI
vdda_pcie	Analog power supply for DPLL_PCIE_REF and APLL_PCIE
vdda_pcie0	Analog power supply for PCIE0 I/Os
vdda_pcie1	Analog power supply for PCIE1 I/Os
vdda_iva	Analog power supply for DPLL_IVA
vdda_gpu	Analog power supply for DPLL_GPU
vdda_dsp_eve	Analog power supply for DPLL_DSP and DPLL_EVE
vdda_usb3	Analog power supply for USB1 DPLL_USB_OTG_SS and USB3.0 I/Os
vdda_usb1	Analog power supply for USB1 DPLL_USB and USB2.0 I/Os (1.8 V)
vdda33v_usb1	Analog power supply for USB1 I/Os (3.3 V)
vdda_usb2	Analog power supply for USB2 I/Os (1.8 V)
vdda33v_usb2	Analog power supply for USB2 I/Os (3.3 V)
vdda_sata	Analog power supply for SATA I/Os and DPLL_SATA
vdda_debug	Analog power supply for DPLL_DEBUG
vddshv1	Dual-voltage VIN2 group I/Os
vddshv2	Dual-voltage VOUT groupI/Os
vddshv3	Dual-voltage GENERAL group I/Os
vddshv4	Dual-voltage MMC4 group I/Os
vddshv5	Dual-voltage RTC group I/Os
vddshv6	Dual-voltage VIN1 group I/Os
vddshv7	Dual-voltage WIFI group I/Os
vddshv8	Dual-voltage MMC1 group I/Os
vddshv9	Dual-voltage RGMII group I/Os
vddshv10	Dual-voltage GPMC group I/Os
vddshv11	Dual-voltage MMC2 group I/Os
vdda_osc	System HF OSC0/1 XTAL oscillators

Table 32-1. Device Power Balls (continued)

Voltage Ball Name	Subsystems and Peripherals
vdda_rtc	RTC bias and LF RTC XTAL oscillator

Note

Table 32-1 is for informative purposes. For a complete description of the power balls of your device, please refer to the *Device Data Manual*.

For more information about power management, see *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.

32.2.2 Interaction With the PMIC Companion

The ROM code does not perform any I^2C transactions with the PMIC. The following system conditions must be met to perform device initialization:

- The USB transceivers (USB2.0), internal to device, are powered on reset, as expected by the USB peripheral booting feature.
- The SD card cage must be appropriately powered before entering the SD card boot feature on any reset.
- Devices must be appropriately powered and be up and ready at platform startup:
  – eMMC
  – QSPI
  – GPMC
  – SATA

Note

The ROM code does not interact with the PMIC companion chip over an I^2C or SPI interface.

32.2.3 Clock, Reset, and Control

32.2.3.1 Overview

Figure 32-3 shows the clock and reset environment where clocks and reset-related signals are gathered at the system level, the system-expansion signals, and the crystal oscillator connection.

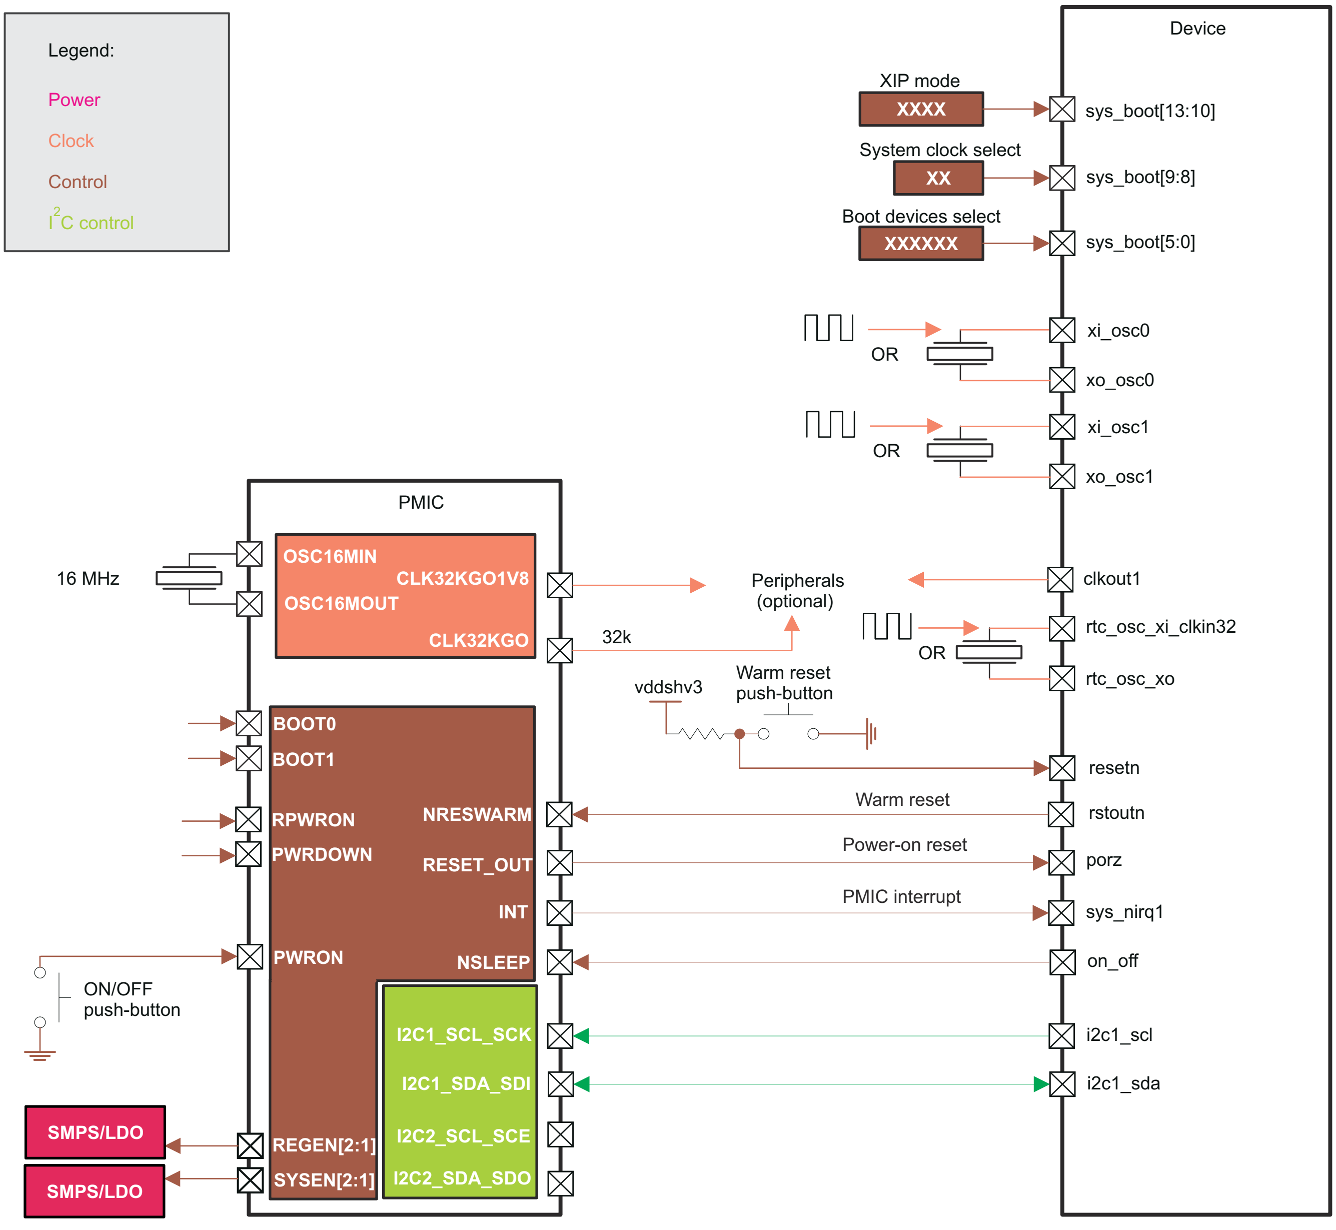

Figure 32-3. Clock, Reset, and Control Environment Overview

Note

Figure 32-3 is a typical example of clock, reset and control connections between the device and a PMIC. Refer to the Device *Data Manual* for the supported PMIC(s) for your device and for more information on these balls.
For PMIC ball description, see the respective PMIC Data Sheet.

The main features of the system interface are:

- Accepts crystals connected between device xi_osc0 and xo_osc0 pads, and xi_osc1 and xo_osc1 pads to generate SYS_CLK1 and SYS_CLK2, resepectively
- Accepts external LVCMOS clock sources connected to xi_osc0, and xi_osc1 pads for SYS_CLK1 and SYS_CLK2, respectively
- A 32-kHz LVCMOS clock input for RTC operation
- Up to four reference clock inputs
- Up to three configurable clock outputs
- sysboot[15:0] input signals to define the boot mode, system clock speed, and GPMC in XIP mode
- Two reset sources
  – Power-on reset (cold reset)
  – Warm reset
- Three external interrupt lines (sys_irq1, sys_irq2, and nmi)
- Four external DMA requests

32.2.3.2 Clocking Scheme

The device operation requires external input clocks, as follows:

- 32k clock: A 16-MHz crystal is connected to the PMIC companion chip that embeds the 32k-oscillator (a square CMOS 32-kHz clock can also be delivered on the OSC16MIN pin of Power-management IC, if the 32k-crystal is connected on another device of the system). The resulting 32k-clock is delivered to the entire system on two outputs:
  – CLK32KGO
  – CLK32KGO1V8
- System clocks: The device supports two system clocks with two clock sources each:
  – SYS_CLK1 (main system clock):
    - Crystal on OSC0 pins. An internal oscillator (OSC0) embedded in the device is used.
    - External LVCMOS clock on xi_osc0
  – SYS_CLK2 (optional system clock):
    - Crystal on OSC1 pins. An internal oscillator (OSC1) embedded in the device is used.
    - External LVCMOS clock on xi_osc1
- The device can deliver digital clocks to peripherals ICs.

The device provides wide choice of clocks that can be delivered on clkout[1:3] pads to companion devices. For more information, see Section 3.3, *PRCM Subsystem Environment*, in Chapter 3, *Power, Reset, and Clock Management*. For more information on pad multiplexing, see Chapter 18, *Control Module*.

Table 32-2 lists the mapping for the device clock input sources. Table 32-3 lists the PMIC clock requirements.

Table 32-2. Mapping for Input Sources

Clock	Clock Source	Ball Mapping	Frequency Range/List	Type
SYS_CLK1	Internal oscillator 0 (OSC0)	xi_osc0 and xo_osc0	19.2, 20, and 27 MHz	Crystal connection pins
	External	xi_osc0	19.2, 20, and 27 MHz	External LVCMOS
SYS_CLK2	Internal oscillator 1 (OSC1)	xi_osc1 and xo_osc1	19.2 ÷ 32 MHz	Crystal connection pins
	External	xi_osc1	12 ÷ 38.4 MHz	External LVCMOS

Table 32-3. PMIC Clock Requirements

Clock Source(1)	Mapping	Frequency Range/List	Type
Internal oscillator	OSC16MIN and OSC16MOUT	16.384 MHz	Crystal connection pins
External	OSC16MIN	32.768 kHz (nom.)	External LVCMOS

(1) The PMIC does not need any external clock to operate properly. PMIC can run on internal RC oscillator. The 16-MHz oscillator is in place to provide an accurate 32-kHz clock to its internal RTC, to the SoC or device in the system. See the corresponding PMIC datasheet for details.

> **CAUTION**
>
> Clock configurations depend on core voltage, and maximum clock frequencies may not apply to production. For more information, see the *Device Data Manual*.

32.2.3.3 Reset Configuration

32.2.3.3.1 ON/OFF Interconnect and Power-On-Reset

The entire system is typically awakened by an ON/OFF push button connected to the PMIC chip. This signal belongs to the VSYS - system power domain and is active low (the PMIC internal pullup ties it to VSYS). The PMIC power-up event is propagated through its NRESPWRON output pin to the device porz pad (that is, the PRM SYS_PWRON_RST signal) when the PMIC power-up sequence is achieved. The device porz input pin is held low all the time during VDD core and I/O power-up.

32.2.3.3.2 Warm Reset

A warm reset can be asserted by the device, by an external button (typically for a development platform), or by any other chip connected to it (normally tied to PMIC companion NRESWARM output pin).

The device warm reset pad (resetn - device signal SYS_WARM_IN_RST) is used to trigger a warm reset on the device, which resets part of the device when it has already booted (for example, to recover from a software crash). When an internal device reset occurs, SYS_NRES_WARM_OUT output and device pad rstoutn go low and reset all the peripherals.

The device releases the SYS_NRES_WARM_OUT output signal after SYS_PWRON_RST is deasserted.

32.2.3.3.3 Peripheral Reset by GPIO

Most peripherals can be reset and powered on or off by GPIO. By default, under POR, most device signals are in safe mode with a default value driven by the I/O cell. The value is driven by an internal pullup or pulldown. Depending on the peripheral reset active level, users must select one GPIO or another (according to the reset value).

Once POR is released, the value on the pad is driven by the default configuration of the device control module. Most of time, this configuration is aligned with the default value selected on the I/O cell.

The next step is application-dependent: Users must configure the device registers to validate GPIO use and the default configuration of the control module.

32.2.3.3.4 Warm Reset Impact on GPIOs

When a warm reset event occurs:

- The GPIO controller is reset. Consequently, the GPIO is automatically turned in input mode.
- The control module is not reset. Information related to signal multiplexing mode and pullup or pulldown configuration is still valid.

Therefore, when a warm reset event occurs, the output buffer is disabled. Consequently, two different behaviors can be defined with regard to what is expected by the platform:

- GPIO sensitive to warm reset:

  To prevent a floating pad, user software is designed to have the internal pad PU and PD resistors enabled immediately, before the software warm reset action, because the warm reset-sensitive GPIO controllers will change I/O direction to input after an device warm reset. This is necessary if the warm reset-sensitive GPIO controller pin has been configured for output before the warm reset occurrence. The pulls-enabled-before-warm-reset condition should be set by default in case the user has configured a GPIO as an input, because in this case the user is expected to have enabled the internal PU and PD pads during GPIO configuration (unless external pull resistors were used).

Note

If the PU and PD resistors are enabled immediately by software after a POR (cold reset) for a GPIO that is planned to be used only as an output, then unnecessary power consumption can occur.

While the dynamically-enable-the-pull-just-before-warm-reset condition is possible during a software warm reset (because the user software is aware of the exact moment a warm reset event occurs), it is not possible when the warm reset is triggered by hardware (for example, a watchdog reset, SYS_NRESWARM signal assertion, and so forth), because the software is not aware of the exact moment of these warm reset assertions.

- GPIO not sensitive to warm reset:

  To avoid getting a floating signal during (and after) a warm reset event and to keep the same value that was driven before the reset, users must align the pull value with the drive value each time a dedicated GPIO register is accessed.

Note

To avoid unnecessary consumption, the user software must ensure that internal pull resistor is disabled when the GPIO buffer is driving.

For the description of the reset sequences and information about the device reset management, see Section 3.5, *Reset Management Functional Description*, in Chapter 3, *Power, Reset and Clock Management*. For more information about the device reset sequences, see the device *Data Manual*.

32.2.3.4 PMIC Control

- I^2C:

  The device interfaces: system interface I/Os, and I2C1 are involved in system interactions between the device and external power, reset and clock management IC companions.

  The device and PMIC companion implement the basic power-management interface, as follows:
  - 32-kHz clock single input
  - Two system resets: power-on (cold) reset and warm reset
  - One interrupt
- INT:

  PMIC companion device can activate its output interrupt request signal (INT) at any time when requires the device to monitor its activity. When receiving such an interruption, the device checks, through the I^2C, to determine the source of the interrupt. INT pin is active low.

32.2.3.5 PMIC Request Signals

The PMIC drives three external enable-output signals, which allows switching on some external resources at different stages of the power-up sequence:

- REGEN1 and REGEN2 are driven high at the beginning of the power-up sequence, before any internal power source is turned on. They belong to the VSYS power domain. REGEN1 can typically be used for buck boost control.
- SYSEN is driven high immediately after the VCORE power output is turned on. SYSEN belongs to the VIO power domain.

The PMIC companion chip can receive two power resource requests: ENABLE1 and NSLEEP. These pins allow an external device to request PMIC internal resources. The PMIC companion power behavior when pins are activated must be programmed after the first boot (resources and ENABLE pins allocated by group, resource behavior upon group activation, and so forth).

The use of NSLEEP is especially required when PMIC chip is in sleep mode, because it cannot handle an I^2C command. Any device that requires the PMIC companion resource to wake up must first activate its associated ENABLE signal. All power-management chip power regulators are off or in sleep mode when it is in sleep mode.

32.2.4 Sysboot Configuration

The device implements 16 sampled-on-reset sysboot pads.

Table 32-4. Sysboot Pads Description

Pad (1)	Description
sysboot[15]	Must be pulled to vdd for proper device operation (SR1.1). Used to permanently disable the internal PU/PD resistors on pads gpmc_a[27:24, 22:19] (SR2.0).
sysboot[14]	Must be pulled to vss for proper device operation.
sysboot[13:10]	Used to configure the GPMC interface when booting from XIP/NAND memory connected to GPMC.
sysboot[9:8]	Selects the SYS_CLK1 clock speed. Must be set correctly according to the speed of the connected crystal.
sysboot[7:6]	Sector offset for the location of the redundant SBL images in QSPI.
sysboot[5:0]	Select interfaces or devices for the booting list

(1) Boards should be implemented with a mechanism to easily modify the pull-up/down state to enable any future modifications.

Table 32-5. MMC2 Configuration (SR2.0)

sysboot[15] (1)	mmc2_dat[7:0] Pull-down resistors
0b0	Software re-configuration of pull resistors is allowed. Internal pull-downs on gpmc_a[n:19] are enabled by default to allow GPMC boot. Pulling low gpmc_a[n:19] is required in order to access the low-order address locations in the flash memory during boot (n = [27:24, 22:19] and depends on the memory volume).
0b1	Internal pull-down resistors permanently disabled to avoid contention with the recommended per eMMC standard pull-ups that should be present on PCB. Software re-configuration of internal pull resistors is disabled.

(1) When internal pull-downs are permanently disabled (sysboot[15] = 1), gpmc_a[n:19] pads (where n = [27:24, 22:19]) require external pull-downs to enable GPMC boot.

All sysboot pads are sampled and latched onto the CTRL_CORE_BOOTSTRAP register (in control module) after POR. After booting, these pads can be used for other functions such as GPIOs, and the associated register bit field is not updated by the new functionality. For more information about pad multiplexing configuration, see Section 18.4.6.1.1, *Pad Configuration Registers*, in Chapter 18, *Control Module*.

Note

If used as GPIOs, the sysboot[15:0] pads must be used only in output mode to ensure that the input values always match a certain hardware predefined boot pattern, interpreted after each POR.

32.2.4.1 GPMC Configuration for XIP/NAND

Table 32-6 describes the GPMC interface configuration used in XIP, fast XIP and NAND modes controlled by sysboot[13:10].

Table 32-6. GPMC for XIP/NAND Configuration

sysboot[13]	Bus Width
0b0	8-bit
0b1	16-bit
sysboot[12:11]	**A/D-muxed/non-muxed Device on CS0**
0b00	Non-muxed device
0b01	A/D-muxed device
sysboot[10]	**Wait-pin Monitoring for Read Accesses**

Table 32-6. GPMC for XIP/NAND Configuration (continued)

0b0	Disabled
0b1	Enabled

32.2.4.2 System Clock Speed Selection

There are three crystal speeds available to be selected by means of sysboot[9:8], as described in Table 32-7. User is responsible to set the correct value depending on the actual clock supplied to the device.

Table 32-7. System Clock (SYS_CLK1) Speed Selection

sysboot[9:8]	SYS_CLK1 Speed
0b00	Reserved
0b01	20 MHz
0b10	27 MHz
0b11	19.2 MHz

32.2.4.3 QSPI Redundant SBL Images Offset

Four options are available to set the offset between the redundant SBL images as described in Table 32-8. If not using the redundant SBL feature, there is no change required to sysboot pins as only the primary image is used and the sector offset is a don't care.

Table 32-8. Offset Between Redundant Images

sysboot[7:6]	Offset
0b00	64 KiB
0b01	128 KiB
0b10	256 KiB
0b11	512 KiB

32.2.4.4 Booting Device Order Selection

The ROM code creates the device list (order) based on information gathered from these locations:

- The first location is the sysboot[5:0] external configuration pins sensed in the device CTRL_CORE_BOOTSTRAP register. The sysboot[5:0] configuration pads have two main purposes: configure ROM code software in terms of interfaces and devices used for booting and configuring hardware after a POR or cold reset.

The SYSBOOT pins are used to index a booting device list from a table with possible booting scenarios. The order of examined booting devices is from the first to the third devices.

The following names are used in the tables:

- Memory types:
  - Execute in place (XIP): NOR (CFI) flash memory or other XIP device
  - NAND: NAND flash memories (non-XIP)
  - SD: Removable SD card device
  - eMMC: eMMC™ memory device
  - QSPI_1: 1-bit SPI flash memories
  - QSPI_4: 4-bit (Quad) SPI flash memories
  - SATA: SATA-compatible devices such as solid state drives (SSDs) or hard-disk drives (HDDs)
- Peripheral interfaces:
  - USB: HS USB 2.0 interface
  - UART: UART interface
- Table 32-9 lists the permanent booting devices in bold typeface.

The above boot modes are described in detail in Section 32.3.5, *Peripheral Booting* and in Section 32.3.7, *Memory Booting*.

32.2.4.5

Note

After a warm reset, the ROM code builds a device list featuring only the permanent booting devices (in **bold**)

Table 32-9 lists the booting device order selected by ROM code depending on sysboot[5:0] pins.

Table 32-9. Booting Devices Order

sysboot[5:4]	sysboot[3:0]	First Device	Second Device	Third Device
Peripheral Preferred Booting				
0b00	0b0000	USB	**eMMC**	
0b00	0b0001	USB	**NAND**	
0b00	0b0010	USB	**SD**	**eMMC**
0b00	0b0011	USB	**SATA**	**SD**
0b00	0b0100	USB	UART	**XIP**
0b00	0b0101	SD	**XIP**	
0b00	0b0110	SD	**QSPI_1**	
0b00	0b0111	SD	**QSPI_4**	
0b00	0b1010	SD	**Fast XIP**	
Automotive Recovery/Upgrade or Development Booting (1)				
0b01	0b0000	**USB**		
0b01	0b0011	**UART**		
0b01	0b0100	**SD**	USB	
0b01	0b0101	**SD**	USB	
0b01	0b0110	**SD**	USB	
0b01	0b0111	**SD**	USB	
0b01	0b1000	**SD**	USB	
0b01	0b1001	**SD**	USB	
0b01	0b1010	**SD**	USB	
0b01	0b1011	**SD**	USB	
Memory Preferred Booting				
0b10	0b0000	**eMMC**	USB	
0b10	0b0001	**NAND**	USB	
0b10	0b0010	**SD**	**eMMC**	USB
0b10	0b0011	**SATA**	**SD**	USB
0b10	0b0100	**XIP**	USB	UART
0b10	0b0101	**XIP**	SD	USB
0b10	0b0110	**QSPI_1**	SD	USB
0b10	0b0111	**QSPI_4**	SD	USB
Automotive Production Booting (1)				
0b11	0b0000	**SD**		
0b11	0b0100	**SATA**		
0b11	0b0101	**XIP**		
0b11	0b0110	**QSPI_1**		

Table 32-9. Booting Devices Order (continued)

sysboot[5:4]	sysboot[3:0]	First Device	Second Device	Third Device
0b11	0b0111	**QSPI_4**		
0b11	0b1000	**eMMC**		
0b11	0b1001	**NAND**		
0b11	0b1010	**Fast XIP**		
0b11	0b1011	**eMMC (boot part.)** (2)		

(1) After 10 failed loops through the device list, ROM code initiates immediate global warm reset.
(2) The ROM code boots from eMMC boot partition. If the ROM code fails to retrieve the booting image, it does not try boot from the user area contrary to other eMMC options.

32.2.4.6 Boot Peripheral Pin Multiplexing

Table 32-10 lists the code pin multiplexing configuration done by ROM code according to selected boot peripheral. These settings are not restored to reset default values at ROM Code exit.

Note

The ROM code examines the interfaces that are selected to be searched until a valid bootable interface or device is found. The activities on the pads of the searched interfaces must be considered if they are connected to any other peripherals for any other purposes (for example, an LED connected to a GPMC pad muxed internally to a GPIO).

Table 32-10. Pin Multiplexing According to Boot Peripheral

Boot Device	Boot Interface	Device Pins	In MuxMode	Interface Signals
eMMC	MMC2	gpmc_a[19:27], gpmc_cs[1]	MuxMode=0x1	mmc2_dat[4:7], mmc2_clk, mmc2_dat[0:3], mmc2_cmd
SD	MMC1	mmc1_clk, mmc1_cmd, mmc1_dat[0:3]	MuxMode=0x0	mmc1_clk, mmc1_cmd, mmc1_dat[0:3]
NAND	GPMC	GPMC on CS0	MuxMode=0x0	GPMC on CS0
XIP	GPMC	GPMC on CS0(1)	MuxMode=0x0	GPMC on CS0, wait signal monitoring according to the SYSBOOT[10] setting
SATA	SATA	sata1_txp0, sata1_txn0, sata1_rxp0, sata1_rxn0	N/A	sata1_txp0, sata1_txn0, sata1_rxp0, sata1_rxn0
QSPI_1/QSPI_4	QSPI1	gpmc_a[13:18], gpmc_cs[2]	MuxMode=0x1	qspi1_rtclk, qspi1_d[3:0], qspi1_sclk, qspi1_cs[0]
USB	USB1	usb1_dp and usb1_dm	N/A	usb1_dp and usb1_dm
UART	UART3	uart2_rtsn uart2_ctsn	MuxMode=0x1 MuxMode=0x2	uart3_txd uart3_rxd

(1) ROM code does not use (mux) address lines above A18. These, however, are configured to pullups or pulldowns by hardware. See Table 32-5.

32.3 Device Initialization by ROM Code

This section describes high-level booting concepts and provides basic knowledge for booting on the device.

32.3.1 Booting Overview

32.3.1.1 Booting Types

Booting is the process of starting a bootstrap from one of the booting devices.

The ROM code has two functions for booting: Peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. A software (warm) reset can be performed after the image is burned.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory, memory cards, or SATA SSD or HDD memory devices and executes it. This process is normally performed after a cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (USB or UART) by using the sysboot pad configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

32.3.1.2 ROM Code Architecture

Figure 32-4 shows the ROM code architecture. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower-level layer through a unified interface.

- The high-level layer performs the main tasks of the public ROM code: multicore startup, watchdog and clock configurations, interrupt management, and main booting routine.
- The driver layer implements the logical and communication protocols for any booting device in accordance with the interface specification.
- The HAL implements the lowest level code for interacting with the hardware infrastructure modules. End booting devices (typically external flash components) are attached to the device I/O pads.

Figure 32-4 shows the three layers with their modules.

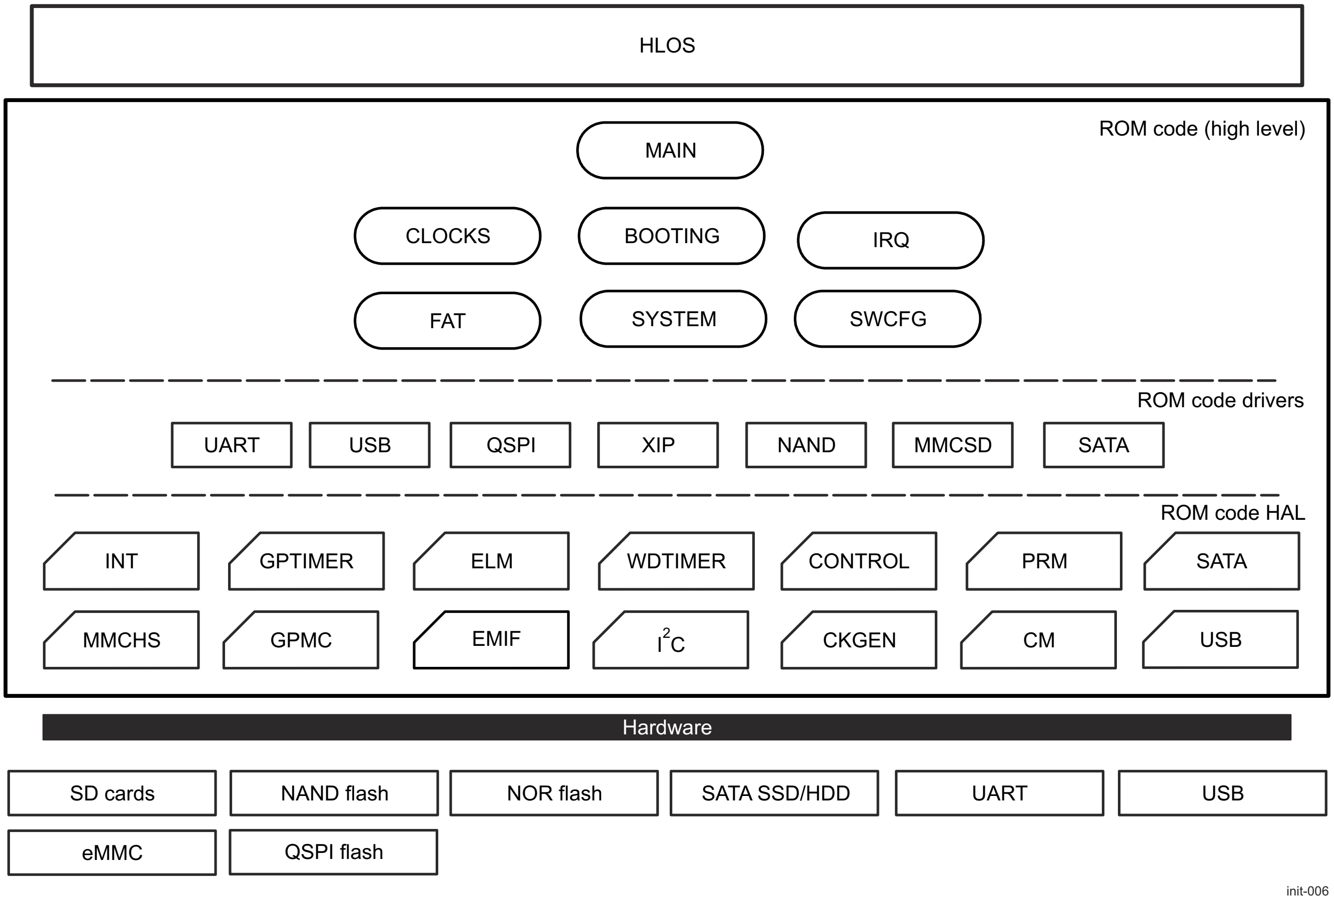

Figure 32-4. ROM Code Architecture

32.3.2 Memory Maps

32.3.2.1 ROM Memory Map

Figure 32-5 shows the 48-KiB ROM memory map.

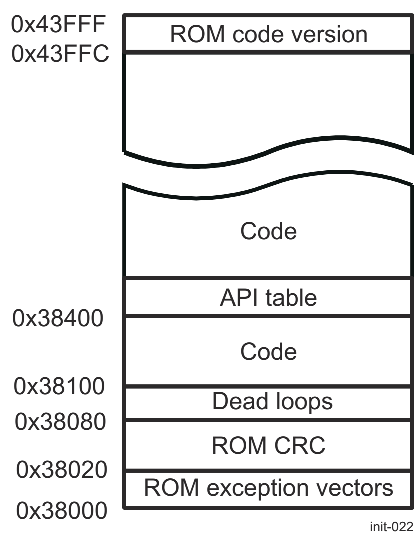

Figure 32-5. ROM Memory Map

- ROM exception vectors

Exceptions are redirected to ROM exception vectors (see Table 32-11). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses to the PC register.

Table 32-11. ROM Exception Vectors

Address	Exception	Content
0x38000	Reset	Branch to the ROM code startup
0x38004	Undefined	PC = 0x4037 F004
0x38008	Software interrupt (SWI)	PC = 0x4037 F008
0x3800C	Prefetch abort	PC = 0x4037 F00C
0x38010	Data abort	PC = 0x4037 F010
0x38014	Unused	PC = 0x4037 F014
0x38018	IRQ	PC = 0x4037 F018
0x3801C	FIQ	PC = 0x4037 F01C

- ROM code cyclic redundancy check (CRC)

  The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 0x38000–0x43FFF. The 4-byte CRC code is stored at location 0x38020.
- Dead loops

  Dead loops are branch instructions coded in Arm mode. They have multiple purposes (see Table 32-12).

Table 32-12. Dead Loops

Address	Purpose
0x38080	Undefined exception default handler
0x38084	SWI exception default handler
0x38088	Prefetch abort exception default handler
0x3808C	Data abort exception default handler
0x38090	Unused exception default handler
0x38094	IRQ exception default handler
0x38098	FIQ exception default handler

- Code

  This space is used to hold code and constant data.
- API table

  The purpose of this table is to allow external code access to system maintenance, utility, and device driver functions which are used for ensuring the ROM code boot functionality. These functions can be reused at run time by calling a fixed address hardcoded in this table.
- ROM code version

  The ROM code version consists of two BCD numbers: major and minor. It can be used to identify the ROM code release version burned in a given IC. The ROM code version is a 32-bit hexadecimal value at address 0x43FFC.

  The ROM code version numbers are:
  – 0x2601 for SR1.0
  – 0x2602 for SR1.1 and SR2.0

32.3.2.2 RAM Memory Map

The partitioning of the on-chip SRAM (L3 OCM RAM) shown in Figure 32-6 is used during the booting process. Tracing areas can also be accessed when calling API functions.

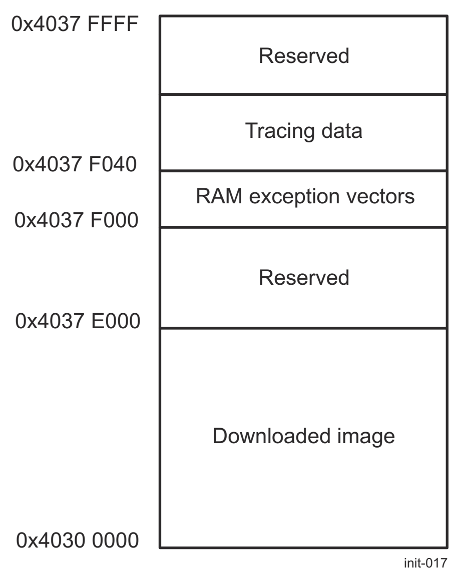

Figure 32-6. RAM Memory Map

- Downloaded image

  This space is used by the public ROM code to store a downloaded booting image. It can be up to 504 KiB.

- RAM exception vectors

  The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. Table 32-13 lists the contents of the RAM space reserved for RAM vectors. The first eight addresses are Arm instructions that load the value in the subsequent eight addresses into the PC. These instructions are executed when an exception occurs because they are called from ROM exception vectors. Undefined, SWI, unused, and FIQ exceptions are redirected to a hardcoded dead loop. Prefetch abort, data abort, and IRQ exception are redirected to predefined ROM handlers. Users can redirect an exception to another handler by writing its address to the appropriate location from 0x4037 F024 to 0x4037 F03C, or by overriding the branch (load into PC) instruction between addresses from 0x4037 F004 to 0x4037 F01C.

Table 32-13. RAM Exception Vectors

Address	Exception	Content
0x4037 F000	Reserved	Reserved
0x4037 F004	Undefined	PC = [0x4037 F024]
0x4037 F008	SWI	PC = [0x4037 F028]
0x4037 F00C	Prefetch abort	PC = [0x4037 F02C]
0x4037 F010	Data abort	PC = [0x4037 F030]
0x4037 F014	Unused	PC = [0x4037 F034]
0x4037 F018	Interrupt request (IRQ)	PC = [0x4037 F038]
0x4037 F01C	Fast interrupt request (FIQ)	PC = [0x4037 F03C]
0x4037 F020	Reserved	0x38090
0x4037 F024	Undefined	0x38080
0x4037 F028	SWI	0x38084
0x4037 F02C	Prefetch abort	Address of default prefetch abort handler(1)
0x4037 F030	Data abort	Address of default data abort handler (1)
0x4037 F034	Unused	0x38090
0x4037 F038	IRQ	Address of default IRQ handler
0x4037 F03C	FIQ	0x38098

(1) The default handlers for prefetch and data abort perform reads from CP15 debug registers to retrieve the reason for the abort:
- In case of prefetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM code jumps to the prefetch abort dead loop (38088h).
- In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM code jumps to the data abort dead loop (3808Ch).

- Tracing data

  This area contains trace vectors reflecting the execution path of the ROM code. Table 32-14 describes the public ROM code tracing data. For more information about ROM code tracing, see Section 32.3.9, *Tracing*.

Table 32-14. Tracing Data

Address	Size	Description
0x4037 F040	32 bits	Current tracing vector, word 1
0x4037 F044	32 bits	Current tracing vector, word 2
0x4037 F048	32 bits	Current tracing vector, word 3
0x4037 F04C	32 bits	Current tracing vector, word 4

Table 32-14. Tracing Data (continued)

Address	Size	Description
0x4037 F050	32 bits	Cold reset run tracing vector, word 1
0x4037 F054	32 bits	Cold reset run tracing vector, word 2
0x4037 F058	32 bits	Cold reset run tracing vector, word 3
0x4037 F05C	32 bits	Cold reset run tracing vector, word 4
0x4037 F060	32 bits	Current copy of the PRM_RSTST register (reset reasons)

32.3.3 Overall Booting Sequence

Figure 32-7 shows the ROM code flow chart.

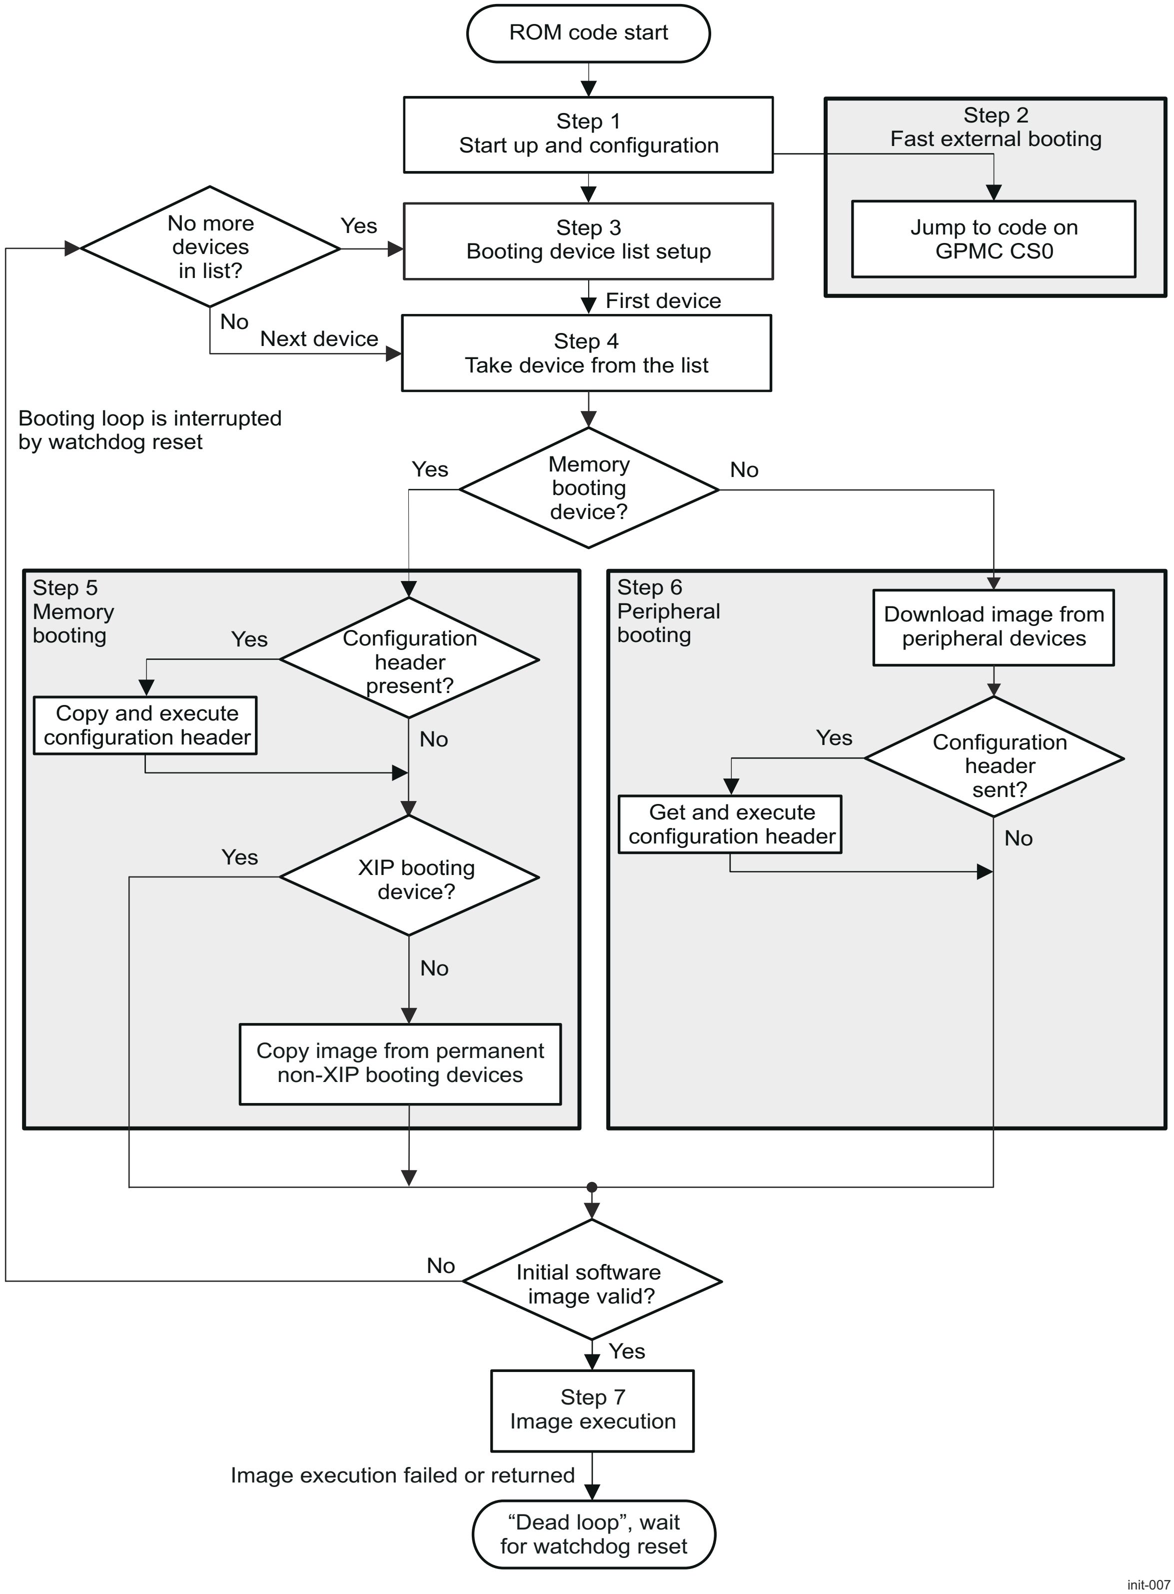

Figure 32-7. Overall Booting Sequence

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

1. Basic configuration and initialization. Reading of SYSBOOT pins .
2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to an external addressable memory. See Section 32.3.6, *Fast External Booting.*
3. A booting device list is created (see Section 32.3.4.5, *Booting Device List Setup*). The list consists of all devices to be searched for a booting image. The list is created based on the SYSBOOT pins.
4. The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or when the watchdog expires. If an image is found, ROM code executes memory booting or peripheral booting, depending on the type of the current booting device:
   - Memory booting is executed when the booting device is XIP memory, NAND, QSPI, eMMC or SD, SATA SSD/HDD.
   - Peripheral booting is executed when the booting device is UART or USB.
5. Memory booting reads data from memory-type devices. Memory booting is described in detail in Section 32.3.7, *Memory Booting*.
6. Peripheral booting downloads data from communication interfaces. Peripheral booting is described in Section 32.3.5, *Peripheral Booting*.
7. The image automatically starts.

An additional feature of the booting module is the execution of the Configuration Header (CH). The CH configures the system for faster and more flexible booting from the selected permanent or peripheral booting device. The CH, which is optional, is described in *Section 32.3.8.2, Configuration Header*.

32.3.4 Startup and Configuration

32.3.4.1 Startup

Figure 32-8 shows the ROM code start-up sequence.

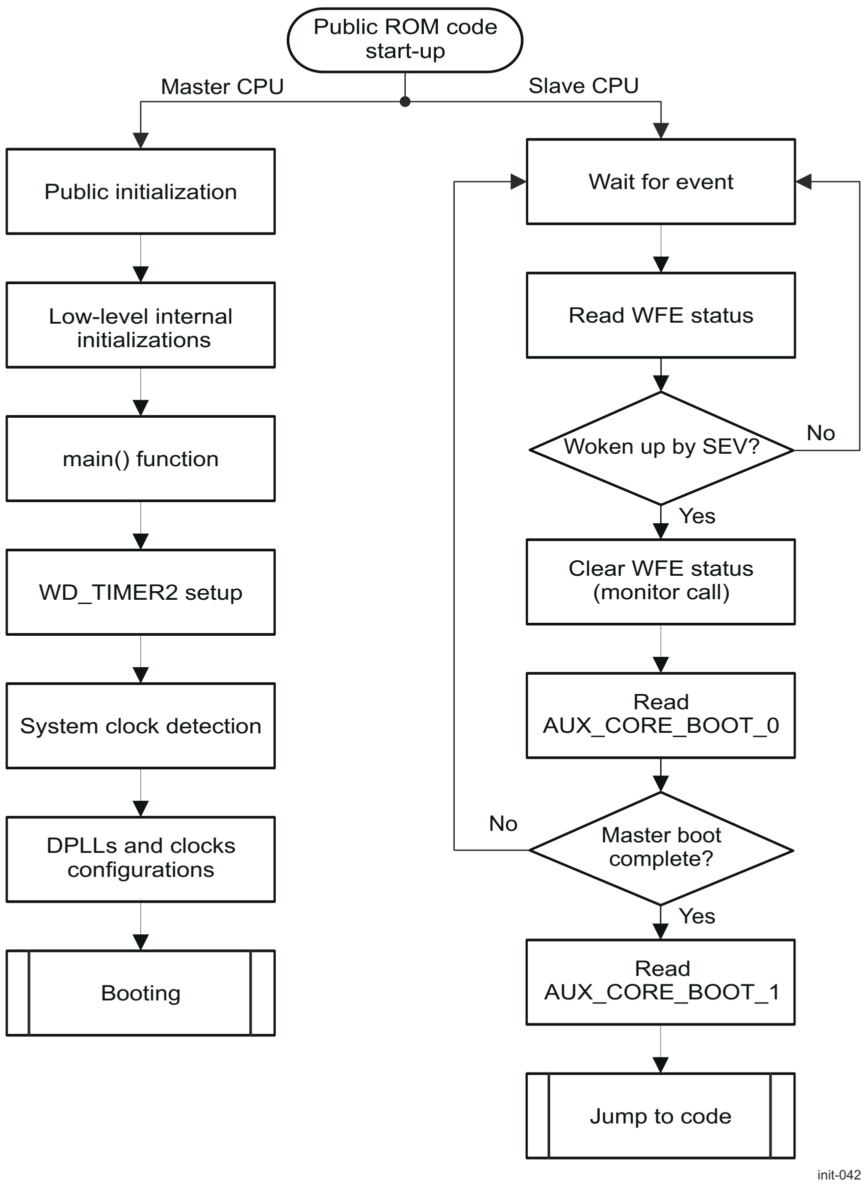

Figure 32-8. ROM Code Multiprocessor Start-Up Sequence

The master CPU L1 instruction cache and branch prediction mechanisms are activated as part of the public boot process. The base address of the public vector is configured to the reset vector of ROM code (0x38000). The memory management unit (MMU) remains switched off during boot (thus, L1 data cache is off). The master CPU performs the basic initialization of the public side. Next, the MMU configures WD_TIMER2 (set to 3 minutes), detects system clock, and configures the system clock. Finally, the MMU jumps to the booting routine.

No specific configuration is performed for the slave CPU, which keeps its default configuration after reset (L1 instruction and data caches off, branch prediction off, MMU off, no remap of the base address of the public vector). The slave CPU is rapidly held in wait-for-event (WFE) state. It stays in this state while the master CPU completes the public boot process and until jumping to the external software (for example, HLOS). At this stage, the external software can wake up the slave CPU by executing an SEV command.

Two internal memory-mapped registers are available to the OS for communicating start-up information. The AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 registers are in the MPU WakeupGen domain.

- AUX_CORE_BOOT_0 is used as a status register to signal the slave CPU that it must wake up after the send event operation initiated by the master CPU.
- AUX_CORE_BOOT_1 contains the physical address location to which the slave CPU must jump after wakeup.

See the memory mapping of these registers in Section 4.4.10, *MPU_WUGEN Registers* in *Dual Cortex-A15 MPU Subsystem*.

32.3.4.2 Control Module Configuration

Table 32-15 lists the Control Module registers modified at each ROM code startup. It is a Control Module requirement to be met prior to modify any of the pad control registers. These registers are not reverted back to default values (that is, to LOCK state) when ROM code completes.

Table 32-15. Control Module Registers Modified by ROM Code at Each Startup

Register	Value	Meaning
CTRL_CORE_MMR_LOCK_1	0x2FF1AC2B	Unlock Control Module registers starting at address offset 0x0000 0100 and ending at 0x0000 079F
CTRL_CORE_MMR_LOCK_2	0xF757FDC0	Unlock Control Module registers starting at address offset 0x0000 07A0 and ending at 0x0000 0D9F
CTRL_CORE_MMR_LOCK_3	0xE2BC3A6D	Unlock Control Module registers starting at address offset 0x0000 0DA0 and ending at 0x0000 0FFF
CTRL_CORE_MMR_LOCK_4	0x1EBF131D	Unlock Control Module registers starting at address offset 0x0000 1000 and ending at 0x0000 13FF
CTRL_CORE_MMR_LOCK_5	0x6F361E05	Unlock Control Module registers starting at address offset 0x0000 1400 and ending at 0x0000 1FFF

Once the booting device list is completed, the ROM code applies the pin multiplexing settings as described in Section 32.2.4.6, *Pin Multiplexing According to Boot Peripheral*.

32.3.4.3 PRCM Module Mode Configuration

Table 32-16 lists the PRCM module mode, clock control, and power control registers modified at each ROM code startup. These registers are not reverted back to default values when ROM code completes.

Table 32-16. PRCM Module Mode Registers Modified by ROM Code

Register	Field	Value
CM_L3INSTR_L3_INSTR_CLKCTRL	MODULEMODE	DISABLED
CM_L3INSTR_OCP_WP_NOC_CLKCTRL	MODULEMODE	DISABLED
CM_CM_CORE_PROFILING_CLKCTRL	MODULEMODE	DISABLED
CM_PRM_PROFILING_CLKCTRL	MODULEMODE	DISABLED
CM_CM_CORE_AON_PROFILING_CLKCTRL	MODULEMODE	DISABLED
CM_EMU_CLKSTCTRL	CLKTRCTRL	HW_AUTO
CM_DSP1_CLKSTCTRL	CLKTRCTRL	HW_AUTO
CM_DSP1_DSP1_CLKCTRL	MODULEMODE	DISABLED
PM_DSP1_PWRSTCTRL	POWERSTATE	OFF
CM_DSP2_CLKSTCTRL	CLKTRCTRL	HW_AUTO
CM_DSP2_DSP2_CLKCTRL	MODULEMODE	DISABLED
PM_DSP2_PWRSTCTRL	POWERSTATE	OFF
CM_IVA_CLKSTCTRL	CLKTRCTRL	HW_AUTO
PM_IVA_PWRSTCTRL	POWERSTATE	OFF

32.3.4.4 Clocking Configuration

The ROM code detects the system input clock frequency (SYS_CLK1) from the sysboot[9:8] pins value. The supported system frequencies in the device are:

- 19.2 MHz
- 20 MHz
- 27 MHz

See Section 32.2.3.2, *Clocking scheme*, and Section 32.2.4.2, *System clock speed configuration*.

After detecting the input clock, the ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- DPLL_PER: locked to provide clocks to peripheral blocks
- DPLL_CORE: locked to provide L3_MAIN interconnect, L4 interconnect, and EMIF clocks
- DPLL_MPU: locked
- DPLL_USB_OTG_SS/DPLL_USB DPLLs: Locked only in case of USB peripheral booting. It is left untouched otherwise.
- DPLL_SATA: locked only in the case of the SATA memory booting. It is left untouched otherwise.

The DPLLs and PRCM clock dividers are configured with the default values of the ROM code (depending on the detected system input clock) after cold or warm reset in order to give the same working conditions to the ROM code sequence.

Table 32-17 summarizes the default ROM code clock settings.

Table 32-17. ROM Code Default Clock Settings

Clock	Frequency (MHz)	Source
DPLL_CORE clock with F_{DPLL} locked frequency	2128	Gated SYS_CLK1
EMIF_PHY_GCLK[2]	44.33	DPLL_DDR (M2)
EMIF_DLL_GCLK	266	DPLL_DDR .HSDIVIDER (H11)
CORE_X2_CLK	266	DPLL_CORE.HSDIVIDER (H12)
CORE_CLK	266	CORE_X2_CLK
CORE_USB_OTG_SS_LFPS_TX_CLK	34.3	DPLL_CORE.HSDIVIDER (H13)
CORE_GPU_CLK	212.8	DPLL_CORE.HSDIVIDER (H14)
CORE_IPU_ISS_BOOST_CLK	212.8	DPLL_CORE.HSDIVIDER (H22)
CORE_ISS_MAIN_CLK	152	DPLL_CORE.HSDIVIDER (H23)
BB2D_GFCLK	177.3	DPLL_CORE.HSDIVIDER(H24)
L3_ICLK	133	CORE_CLK
L4_ICLK	66.5	L3_ICLK
MPU_DPLL_HS_CLK	266	CORE_X2_CLK
IVA_DPLL_HS_CLK	266	CORE_X2_CLK
DPLL_PER – clock with Fdpll locked frequency	768	Gated SYS_CLK1
FUNC_192M_CLK	192	DPLL_PER (M2)
FUNC_256M_CLK	256	DPLL_PER.HSDIVIDER (H11)
DSS_GFCLK	192	DPLL_PER.HSDIVIDER (H12)
PER_QSPI_CLK	192	DPLL_PER.HSDIVIDER(H13)
PER_GPU_CLK	192	DPLL_PER.HSDIVIDER (H14)
DPLL_MPU - clock with Fdpll locked frequency	2200	Gated SYS_CLK1
MPU_DPLL_CLK	588	PRM

Table 32-17. ROM Code Default Clock Settings (continued)

Clock	Frequency (MHz)	Source
MPU_GCLK	588	DPLL_MPU (M2)
DPLL_USB - clock with Fdpll locked frequency (1)	960	Gated SYS_CLK1
L3INIT_480M_GFCLK	480	DPLL_USB (M2)
L3INIT_60M_GFCLK	60	L3INIT_480M_GFCLK
DPLL_USB_OTG_SS - clock with F_{DPLL} locked frequency (1)	2500	Gated SYS_CLK1
DPLL_SATA - clock with Fdpll locked frequency (1)	1500	Gated SYS_CLK1

(1) This clock is locked specifically if USB peripheral or SATA memory booting is selected.
(2) This clock is intentionally set up at low frequency to ensure correct initialization of external DRAM components.

However it is possible to override the default clock settings. There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in Table 32-17. They are always applied at any reset.
- The CH, described in Section 32.3.8.2, *Configuration Header*. The CH lets users have a known configuration (about GPMC and clock registers) after memory or peripheral booting. .

32.3.4.5 Booting Device List Setup

The ROM code creates a device list based on these sources:

- The sysboot[5:0] signals latched in the control module are used to index the device table from which the list of devices is extracted.

Note

Only permanent booting devices are put to the list when the reset is not power-on and the devices are taken from the sysboot pins.

32.3.5 Peripheral Booting

32.3.5.1 Description

The ROM code can boot from these peripherals:

- USB1: High-, and Full-speed USB from USB1 internal transceivers
- UART3: 115.2 Kbps, 8 bits, even parity, 1 stop-bit, no flow control

The purpose of booting from a peripheral is to download a flash loader code from an external host. This booting method is used primarily for programming flash memories connected to the device (for example, in the case of initial flashing, firmware update or servicing). Figure 32-11 shows the overall peripheral booting procedure. It consists of a synchronization phase (handshake between the host and the device) and a transfer phase. The synchronization phase is similar for UART and USB boots. Both transfer phases use the same procedure.

When booting from the UART, the ROM code first initializes the UART3 interface. Then the ROM code sends an ASIC ID block of data. From there, it expects to receive a boot message from the host within 300 ms, by default. Figure 32-9 shows this procedure.

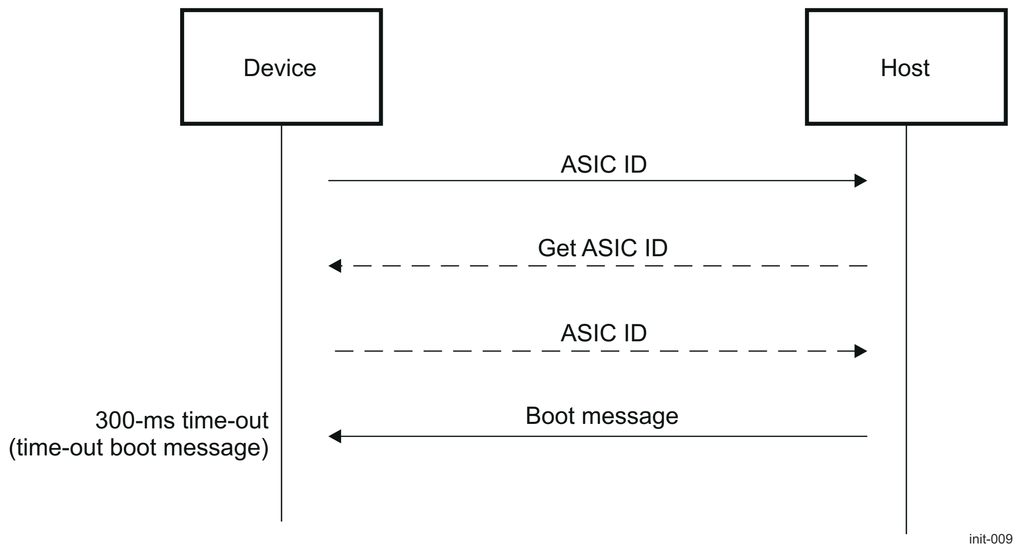

Figure 32-9. Synchronization Phase for UART

Figure 32-10 shows the procedure when booting from the USB.

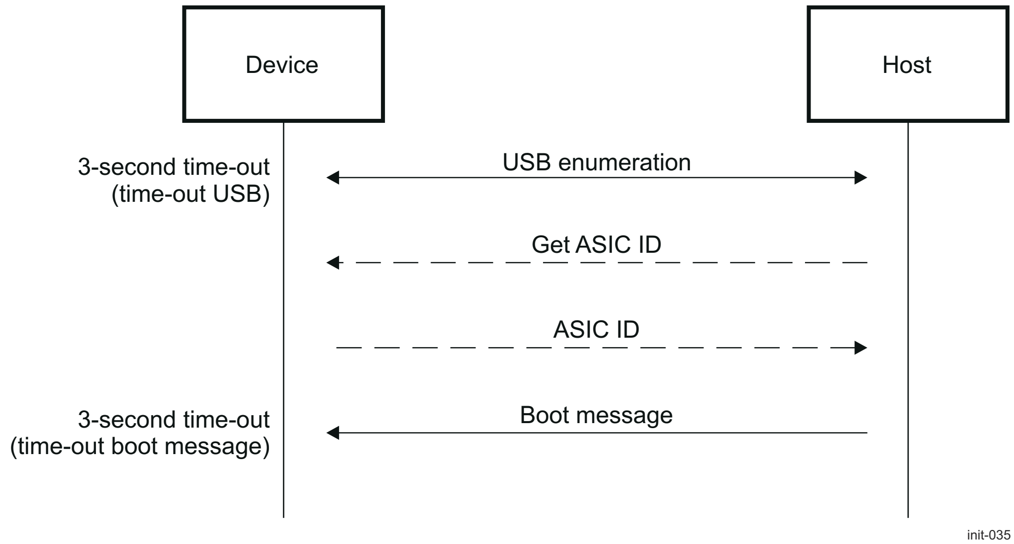

Figure 32-10. Synchronization Phase for USB

During the synchronization phase (see Figure 32-9 and Figure 32-10), the device can provide a small packet of data called the ASIC ID (described in Table 32-18). It is a simple structure that contains different kinds of information, such as ROM version, checksums, and ID.

The host can decide the desired operation by providing a booting message (see Table 32-22). This message can be: Get ASIC ID, peripheral boot, change device, or next device. If the device receives the Get ASIC ID boot message, it sends back the ASIC ID contents.

If the change device or next device message is received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which decides about the next booting device according to the boot message received.

If the peripheral boot message is received without a time-out, the device is entering the transfer phase. From there, the flash loader image size (as a 32-bit word) and the flash loader image itself are expected to be received. The ROM code waits up to 1 minute for completion of image size reception, and up to 1 more minute to download the image. If the download procedure does not complete before this time, the peripheral booting procedure aborts. ROM code continues to examine the devices included in the booting device list. If the download procedure passes, then the image can be executed.

The flash loader image is downloaded directly into internal RAM from address 0x4030 0000 and the maximum size of the downloaded image is 504 KiB.

Note

Sending an image size of zero skips the peripheral booting procedure.

The USB or UART connection is left open at the end of the transfer phase and once exiting the ROM code for the initial software to take over. It means the initial software can reuse the currently established connection. In the case of a USB connection, the endpoints can be reused as such, without closing the connection and performing a full enumeration again.

Table 32-18. ASIC ID Structure

ASIC ID Item	Size (Bytes)	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information
Reserved subblock	4	Reserved
Reserved subblock	23	Reserved

Table 32-18. ASIC ID Structure (continued)

ASIC ID Item	Size (Bytes)	Description
Reserved subblock	35	Reserved
Checksum subblock	11	CRC (4 bytes)

Table 32-19. Items

Offset	Size (Bytes)	Description
0x00	1	0x05: Number of subblocks USB 0x04: Number of subblocks UART[1]

Table 32-20. ID Subblock

Offset	Size (Bytes)	Description
0x01	1	0x01: Subblock ID
0x02	1	0x05: Subblock size
0x03	1	0x01: Fixed value
0x04	2	0x56, 0x41: Device ID number
0x06	1	0x07: CH enabled 0x17: CH disabled
0x07	1	ROM code revision 0x01: SR1.0 0x02: SR1.1 and SR2.0

Table 32-21. Checksum Subblock

Offset[1]	Size (Bytes)	Description
0x46	1	0x15: Subblock ID
0x47	1	0x09: Subblock size
0x48	1	0x01: Fixed value
0x49	4	ROM CRC
0x4D	4	0x0000 0000:

(1) The checksum subblock is not transmitted over the UART.

Table 32-22 summarizes the boot messages sent from a host.

Table 32-22. Booting Messages

Message Name	Value	Description
Peripheral boot	0xF003 0002	Continue peripheral booting.
Get ASIC ID	0xF003 0003	ASIC ID request. The Get ASIC ID request message is optional. If received, the ROM code sends its ASIC ID data to the host in return. The host can issue the Get ASIC ID message multiple times if required. Table 32-18 describes the structure of the ASIC ID.
Change device	0xF003 xx06	Skip current peripheral booting and continue booting from device type indicated by xx: 0x01: XIP 0x02: XIP (with wait monitoring) 0x03: NAND 0x05: SD card 0x06: eMMC (from boot partition BP1 or BP2) 0x07: eMMC 0x09: SATA 0x0A: QSPI_1 0x0B: QSPI_4 0x43: UART 0x45: USB (from internal transceiver) Others: Reserved

Table 32-22. Booting Messages (continued)

Message Name	Value	Description
Next device	0xFFFF FFFF	Skip current device and move to the next device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first device for memory booting.

Figure 32-11 shows the peripheral booting procedure.

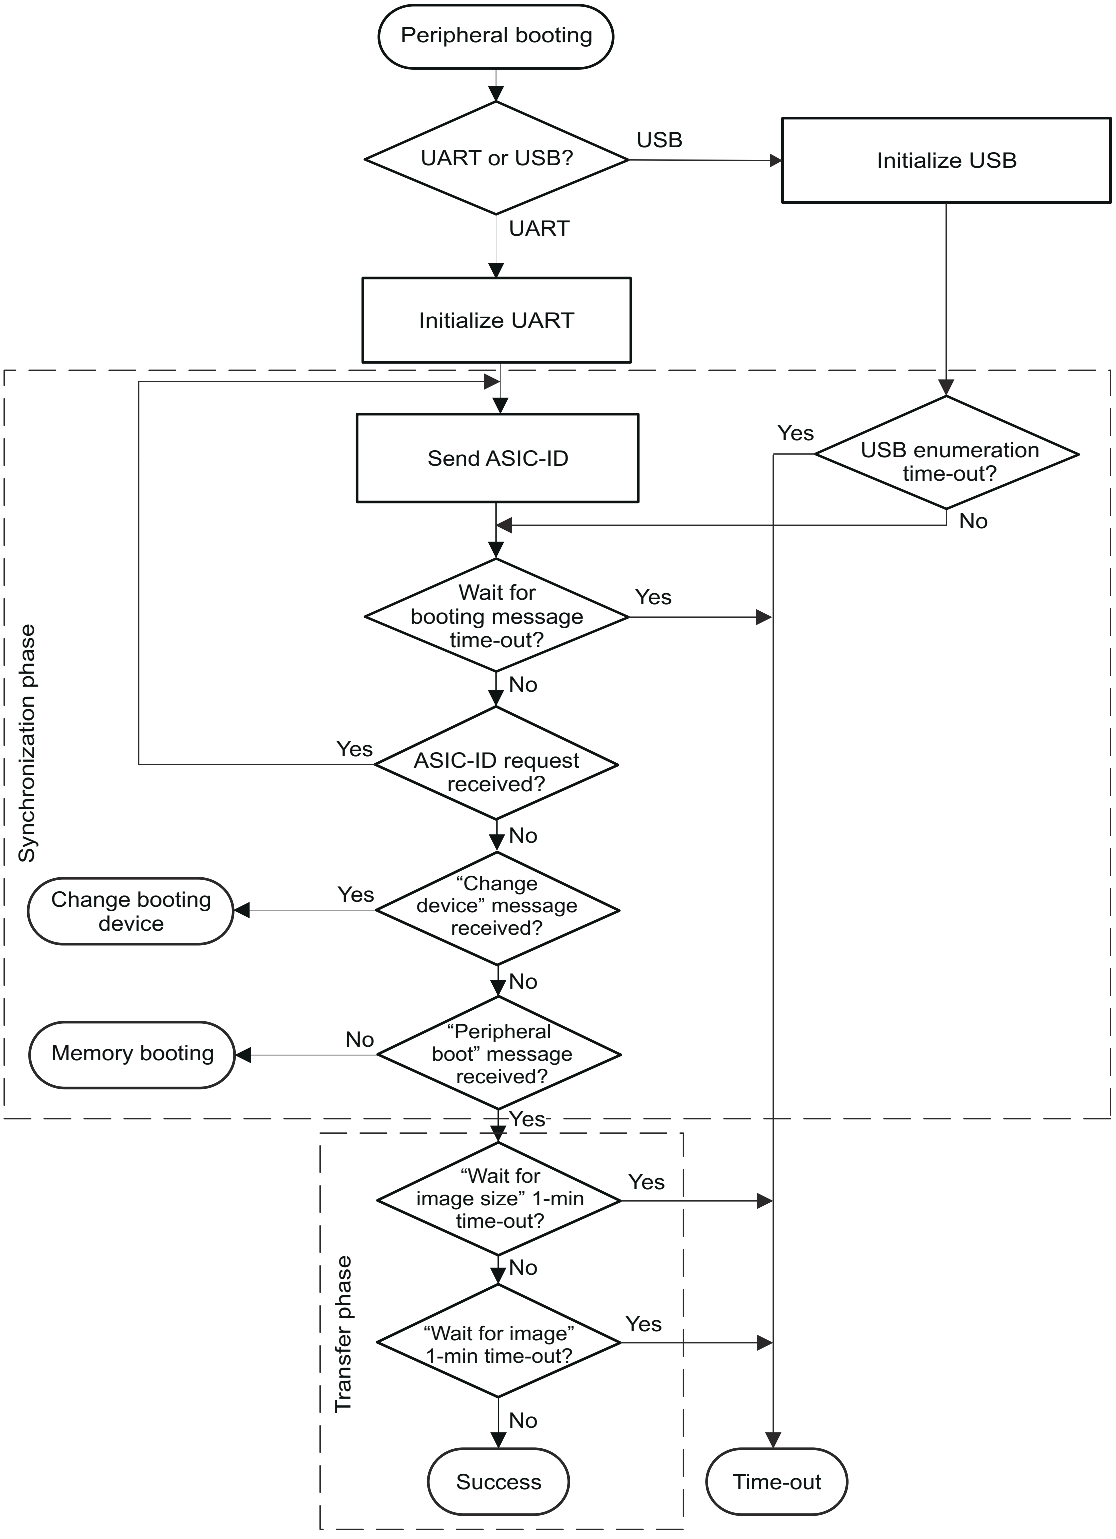

Figure 32-11. Peripheral Booting Procedure

32.3.5.2 Initialization Phase for UART Boot

The ROM code supports booting from a UART interface with the following characteristics:

- UART3 interface
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit, no flow control
- Two-pin interface: RX/TX
- The boot message default time-out is 300 ms (time-out boot message)

32.3.5.3 Initialization Phase for USB Boot

The ROM code supports booting from a USB interface with the following characteristics:

- Using the USB1 subsystem in USB2.0 mode
- Device integrated USB transceiver (USB2PHY1)
- Enumeration default time-out is 3 seconds (time-out USB)
- The boot message default time-out is 3 seconds (time-out boot message).

Note

The ROM code does not handle any OTG-specific features.

32.3.5.3.1 Initialization Procedure

Note

The internal USB2PHY1 (HS) transceiver must be powered and configured upon startup. No action is expected from the device ROM code for its configuration.

Figure 32-12 shows the USB initialization procedure.

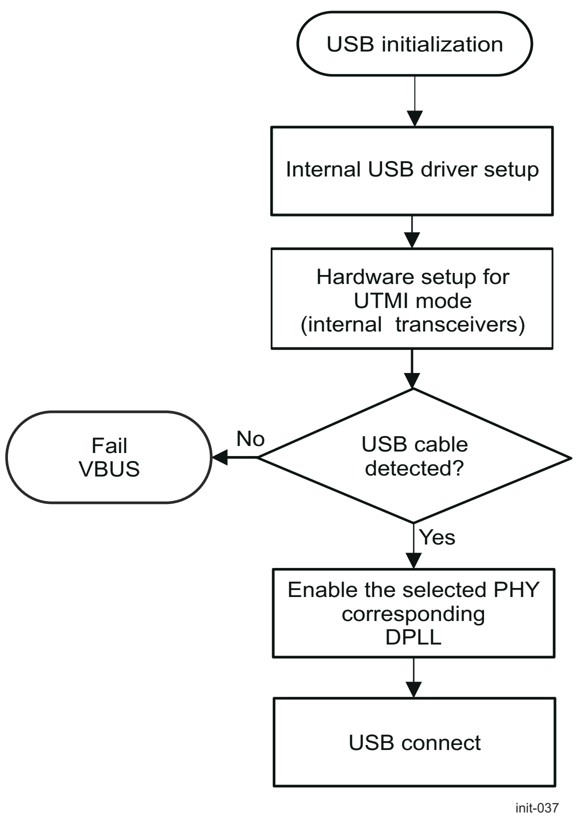

Figure 32-12. USB Initialization Procedure

Note

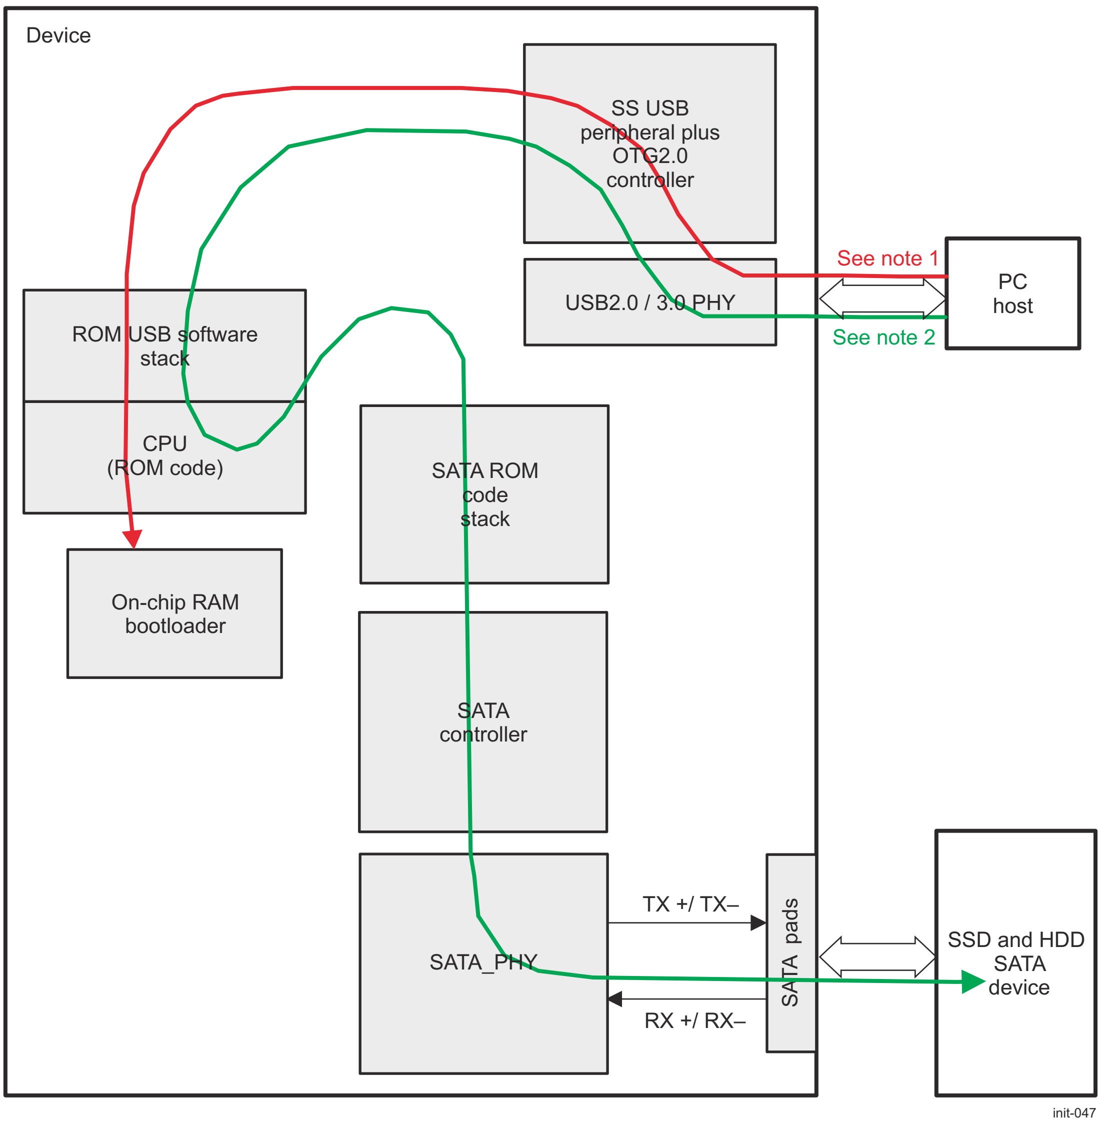
The ROM code does not consider the USB PHYs charger detection circuitry status.

Note

The ROM code assumes that VBUS is always present.

32.3.5.3.2 SATA Peripheral Device Flashing over USB Interface

In the next scheme (see Figure 32-13), it is assumed that the new version of the firmware Flash Loader Host is located in the PC host. In the same way, the application loaded to device internal L3 On-chip RAM (using the peripheral boot function of the device ROM code) is called Flash Loader Second.



A. ROM boots from USB controller and downloads deviceFlash Second in RAM.

B. The PC host is allowed to flash the device firmware located in the SATA device.

Figure 32-13. SATA Flashing Over USB

32.3.5.3.3 USB Driver Descriptors

USB devices use descriptors to report their attributes. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable description information. These descriptor details can be used for tool development or debugging:

- Device descriptor

  A device descriptor contains general information about a USB device, including global information that applies to the device and all device configurations. A USB device has only one device descriptor. A device-qualifier descriptor is required because the ROM code uses the HS feature of the USB core. Table 32-23 lists the device descriptors.

Table 32-23. Device Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x01	Device descriptor type
bcdUSB	0x0210	USB specification release number in binary coded decimal (BCD) format
bDeviceClass	Vendor-specific (0xFF)	Class code
bDeviceSubClass	Vendor-specific (0xFF)	Subclass code
bDeviceProtocol	Vendor-specific (0xFF)	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
idVendor	0x0451	Vendor ID (Texas Instruments), TI default value
idProduct	0xD013	Product ID, TI default value
bcdDevice	0x0000	Device release number
iManufacturer	See Section 32.3.5.3.5.	Index of string descriptor describing manufacturer
iProduct	See Section 32.3.5.3.5.	Index of string descriptor describing product
iSerialNumber	See Section 32.3.5.3.5.	Index of string descriptor describing device serial number
bNumConfigurations	0x01	Number of possible configurations

32.3.5.3.4

- Device-qualifier descriptor

  The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). Table 32-24 lists the device-qualifier descriptors.

Table 32-24. Device-Qualifier Descriptor

Field	Value	Description
bLength	0x0A	Size of this descriptor in bytes
bDescriptorType	0x06	Device-qualifier descriptor type
bcdUSB	0x0210	USB specification release number in BCD
bDeviceClass	0xFF	Class code
bDeviceSubClass	0xFF	Subclass code
bDeviceProtocol	0xFF	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0

Table 32-24. Device-Qualifier Descriptor (continued)

Field	Value	Description
bNumConfigurations	0x01	Number of possible configurations
bReserved	0x00	Reserved for future use

- Configuration descriptor

  This descriptor gives information about a specific device configuration. It describes the number of interfaces supported by the configuration (see Table 32-25).

Table 32-25. Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x02	Configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xC0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Other speed configuration descriptor

  This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed (see Table 32-26).

Table 32-26. Other Speed Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x07	Other speed configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xC0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Interface descriptor

  This descriptor describes a specific interface in a configuration (see Table 32-27).

Table 32-27. Interface Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x04	Interface descriptor type
bInterfaceNumber	0x00	Number of this descriptor
bAlternateSetting	0x00	Value to select the alternate setting

Table 32-27. Interface Descriptor (continued)

Field	Value	Description
bNumEndpoints	0x02	Number of endpoints used for this interface
bInterfaceClass	0xFF	Class code
bInterfaceSubClass	0xFF	Subclass code
bInterfaceProtocol	0xFF	Protocol code
iInterface	Index	Index of string descriptor describing this interface

- Endpoint descriptor

  Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request (see Table 32-28 and Table 32-29).

Table 32-28. BULK IN Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x81 (1 IN)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See [(1)].	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

(1) The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

Table 32-29. BULK OUT Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x01 (1 OUT)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See [(1)].	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

(1) The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

  String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

  For the description of the different string descriptors, see:
  – The language ID string descriptor (Table 32-30)
  – The manufacturer ID string descriptor (Table 32-31)
  – The product ID string descriptor (Table 32-32)
  – The configuration string descriptor (Table 32-33)
  – The interface string descriptor (Table 32-34)

Table 32-30. Language ID String Descriptor

Field	Value	Description
bLength	0x04	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
wLangId	0x0409 (US English)	Language ID code

Table 32-31. Manufacturer ID String Descriptor

Field	Value	Description
bLength	0x24	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	Texas Instruments	Manufacturer string

Table 32-32. Product ID String Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	<string>	Product string

Table 32-33. Configuration String Descriptor

Field	Value	Description
bLength	0x08	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbc	Configuration string

Table 32-34. Interface String Descriptor

Field	Value	Description
bLength	0x08	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbi	Interface string

32.3.5.3.5 USB Customized Vendor and Product IDs

When device ROM Code enumerates through USB, one may want to use his/her own vendor and product IDs rather than TI defaults. Product and Vendor IDs are transmitted as part of the USB Standard Device Descriptor during the USB device enumeration process (resp. idProduct and idVendor 16 bits fields).

Product IDs (PIDs) and vendor IDs (VIDs) are stored as part of device chip eFuses and readable from control module. The built-in USB ROM driver behaves differently whether the VID value is either left unfused, or fused with a customer-specific VID. Thus, two main cases are distinguished:

- VID is fused with a customer-specific ID value
- VID is left unfused

Table 32-35 lists standard USB ROM device descriptors. Table 32-36 lists USB ROM descriptor strings.

Table 32-35. USB ROM Standard Device Descriptor

Device Descriptor Field	Size (Bytes)	VID≠0x0000[1] (fused)	VID=0x0000 (unfused)[2]
bLength	1	0x12	
bDescriptorType	1	0x1	
bcdUSB	2	0x0200 (if enumerated in USB2.0 HS or FS)	

Table 32-35. USB ROM Standard Device Descriptor (continued)

Device Descriptor Field	Size (Bytes)	VID≠0x0000[1] (fused)	VID=0x0000 (unfused)[2]
bDeviceClass	1	0xFF	
bDeviceSubClass	1	0xFF	
bDeviceProtocol	1	0xFF	
bMaxPacketSize0	1	0x40 (64 bytes if enumerated in USB2.0 HS or FS)	
idVendor	2	(VID value from control module)	0x0451
idProduct	2	(PID value from control module)	0xD013
bcdDevice	2	0x0000	
iManufacturer	1	0x20	0x21
iProduct	1	0x24	0x25
iSerialNumber	1	0	
bNumConfigurations	1	1	

(1) VID other than 0x0 and VID other than 0xFFFF and VID other than 0x0451 values
(2) VID=0x0 or VID=0xFFFF or VID=0x0451

Table 32-36. USB ROM Descriptor Strings

String Descriptor	Size (bytes)	VID ≠ 0x0000	VID=0x0000(unfused)[1]
Serial Number		N/A	
Configuration	8	"pbc"	
Interface	8	"pbi"	
Product	8/18	N/A	<string>
Manufacturer	8/36	N/A	"Texas Instruments"

(1) VID=0x0451

The ROM code transmits additional descriptors as part of the enumeration procedure: configuration descriptor, device qualifier, language ID string, configuration string, interface string, and function string descriptors. Those do not depend on the VID or PID value.

32.3.5.3.6 USB Driver Functionality

- Transactions supported:
  - Control transactions: Used for standard device requests
  - Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent to the BULK IN endpoint and the image is transferred from the host over the BULK OUT endpoint.

  The device USB device first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase succeeds, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are answered with the corresponding descriptors.
- Standard device request restrictions:

  Some standard device requests are not supported by the driver because the USB driver is dedicated for use by the ROM code for peripheral booting. Table 32-37 lists the standard device requests supported by the driver.

Table 32-37. Standard Device Requests Supported

Request	Description	Support
CLEAR_FEATURE	Sets or clears a specific feature	Supported only for the ENDPOINT_HALT feature
GET_CONFIGURATION	Returns the current device configuration value	Yes
GET_DESCRIPTOR	Returns the specified descriptor	Yes

Table 32-37. Standard Device Requests Supported (continued)

Request	Description	Support
GET_INTERFACE	Returns the selected alternate setting for the specified interface	Yes
GET_STATUS	Returns the status for the specified recipient	Yes
SET_ADDRESS	Sets the device address	Yes
SET_CONFIGURATION	Sets the device configuration	Yes
SET_DESCRIPTOR	Updates existing descriptors or adds new descriptors	Runtime updating of descriptors is not supported.
SET_FEATURE	Sets or enables a specific feature	Supported only for the ENDPOINT_HALT feature
SET_INTERFACE	Selects an alternate setting in an interface	Runtime setting of alternate features is not supported.
SYNCH_FRAME	Sets and reports an endpoint synchronization frame	No, because isochronous transfers are not used

32.3.6 Fast External Booting

32.3.6.1 Overview

The fast external boot is a special memory booting mode. It consists of a blind jump to a code in an external XIP memory device connected to GPMC CS0 and lets customers create their own booting code. Fast external booting is selected by means of the SYSBOOT[5:0] pins .

The NOR device must fulfill the following requirements for fast XIP mode:

- Non-muxed or address/data multiplexed mode, configured through sysboot[12:11] (=0x1 for A/D mux)
- 8-bit or 16-bit data bus width, configured through sysboot[13] (=1 for 16-bit)
- CS0 chip select
- Device wait signal connected to the WAIT0 GPMC signal (if used)
- The wait monitoring enable/disable is based on the value of SYSBOOT[10]. SYSBOOT[10] value is exported to GPMC by hardware means.

The jump is performed with minimum on-chip ROM code execution.

32.3.6.2 Fast External Booting Procedure

Figure 32-14 shows the procedure for fast external boot. The code does not use any RAM and is designed for fast execution.

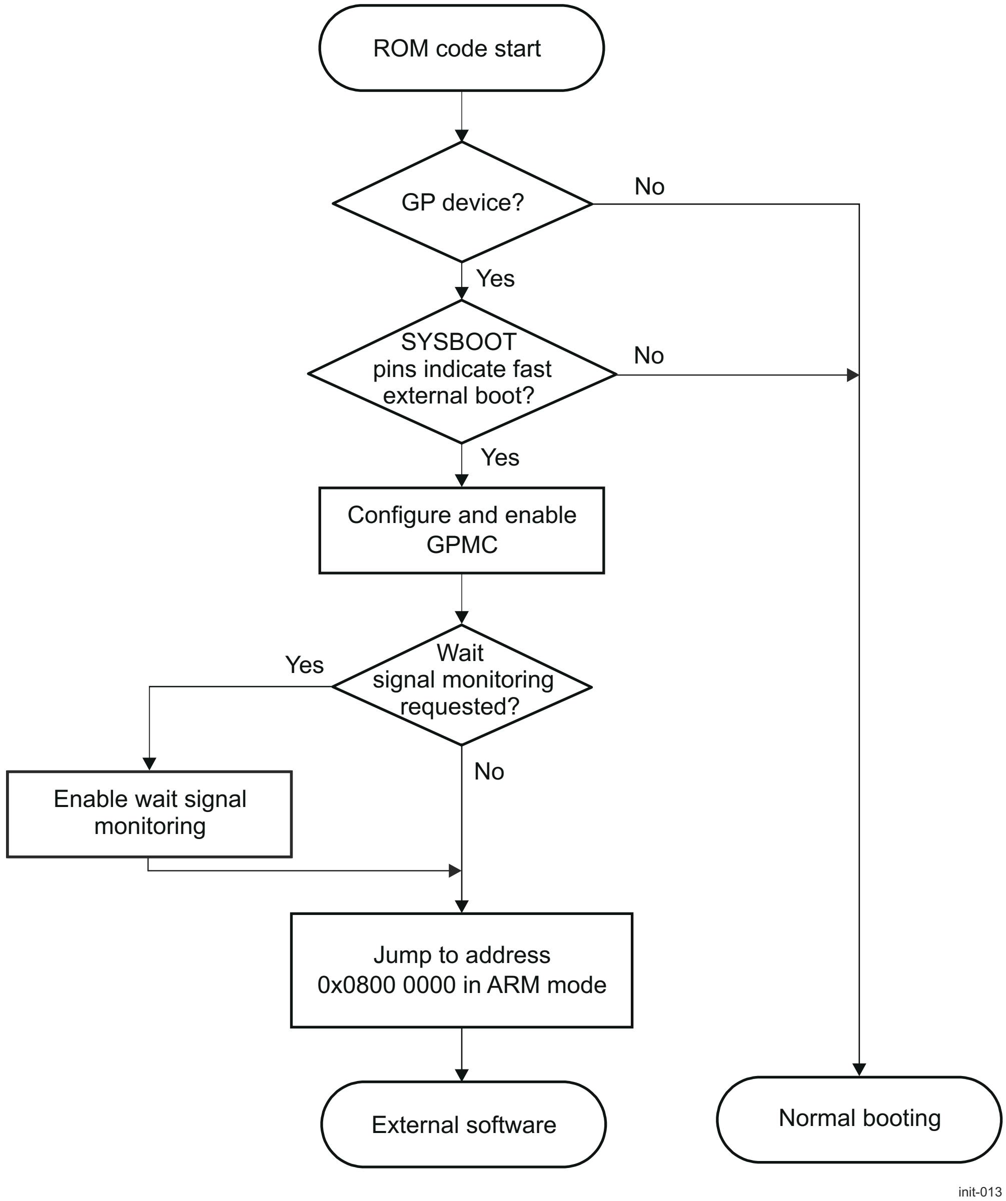


Figure 32-14. Fast External Boot Procedure

32.3.7 Memory Booting

32.3.7.1 Overview

The memory booting process starts an external code in memory devices. ROM code can use only the memory type of booting devices as permanent booting devices (that is, devices examined after both cold [POR] and warm resets). Temporary booting devices are examined only after cold resets. The supported permanent booting devices are:

- NOR flash devices
- NAND flash devices
- SPI/QSPI flash memories
- eMMC memories
- SD cards
- SATA SSD and HDD storage memory devices

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying code from a nondirectly addressable device (non-XIP) to RAM, where the code can be executed. Directly addressable devices are XIP devices.

Figure 32-15 shows the general memory booting procedure common to all types of devices. First, CH is copied to internal RAM. It is copied even for XIP devices, because the device can temporarily lose a connection with XIP memory during CH execution (for example, while updating interface timings). The second step is to shadow the image, if the device is not XIP. The last step is image execution and any return from image results in a dead loop.

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

Note

A booting image is considered to be present , when the first 4-byte word of the sector is not equal to 0000 0000h or FFFF FFFFh.

During the first read sector (512 bytes) call, sectors are copied to a temporary device on-chip SRAM buffer. Once the image is found and the destination address is known, the content of the temporary buffer is moved to the target device on-chip SRAM location so it is required to reread the first image sector. GP header is not copied into target buffer location; therefore, only executable code is in device on-chip RAM, with the first executable instruction at the destination address.

SATA, eMMC, SD cards, SPI/QSPI and NAND devices can hold up to four copies of the booting image. Therefore, the ROM code searches for one valid image out of the four copies, if present, by walking over the first blocks of mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

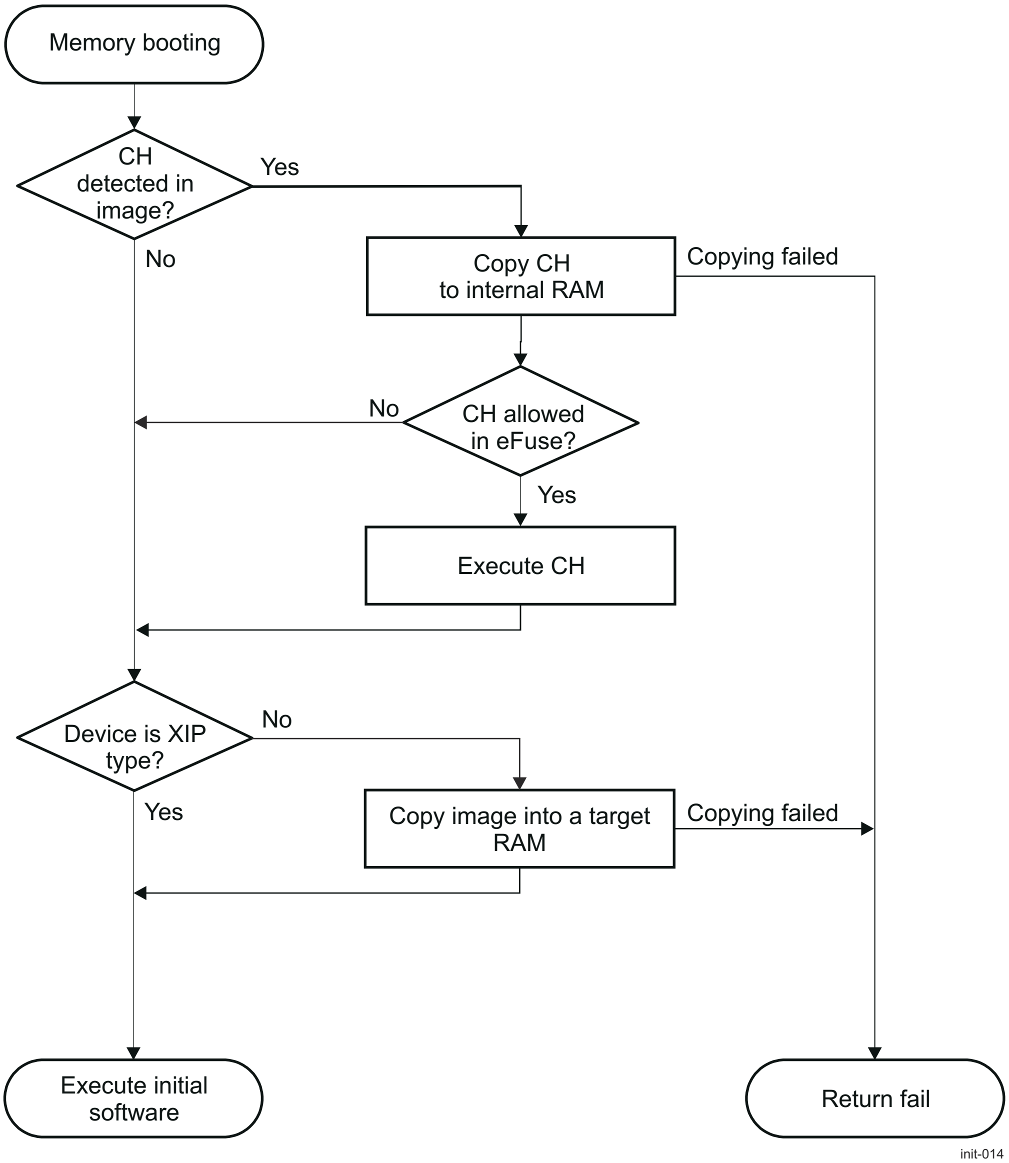

Figure 32-15. Memory Booting Procedure

32.3.7.2 Non-XIP Memory

Figure 32-16 shows the procedure used when memory booting runs with non-XIP memories. The shaded procedures are specific to each memory. The ROM code searches for the image in the first four physical blocks of the memories. Other devices use only one copy of the image and the block loop runs only once.

During image shadowing , the CH is expected to be in a separate sector before the initial software.

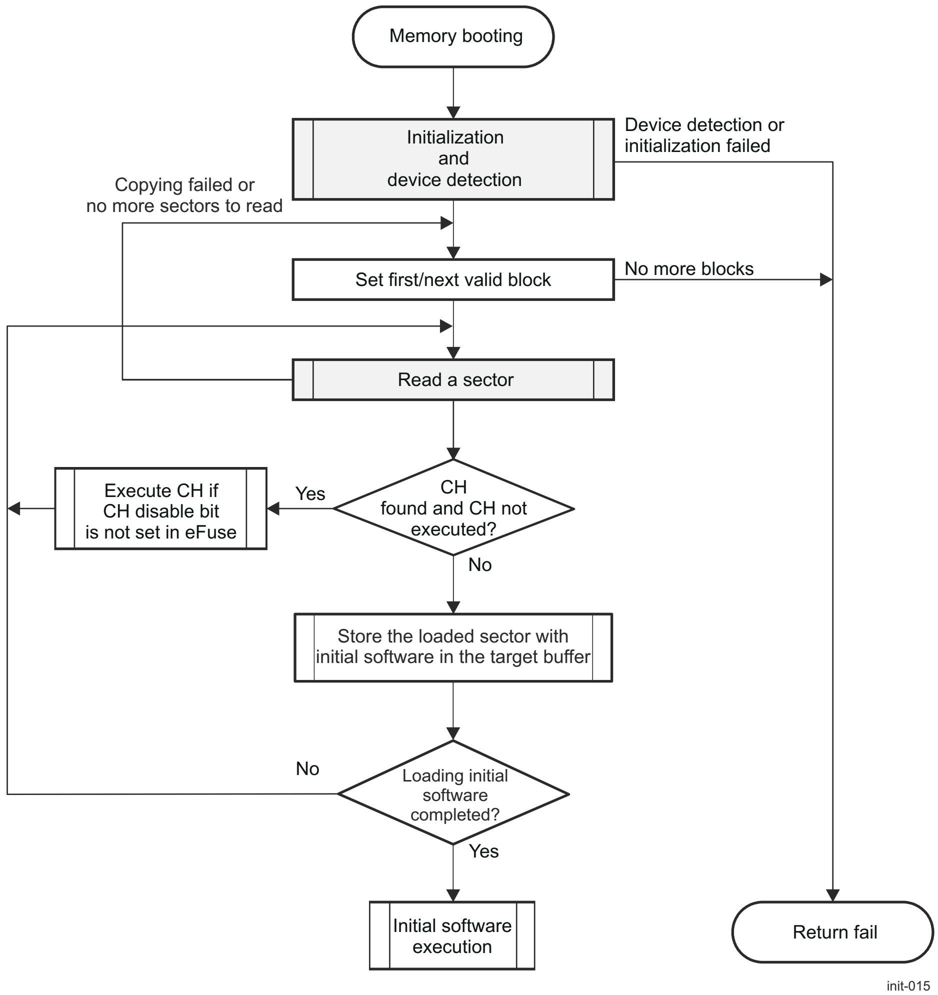

Figure 32-16. Image Shadowing

For more information about the GPMC module, see Section 15.4, *General-Purpose Memory Controller*.

The following sections describe the supported device types.

32.3.7.3 XIP Memory

The ROM code can boot directly from XIP devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 1Gibit (128MiB) can be connected.
- 8-bit or 16-bit data bus width, configured through sysboot[13] (=1 for 16-bit)
- Non-muxed or address/data multiplexed mode, configured through sysboot[12:11] (=0x1 for A/D mux)
- The GPMC clock is 133 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin gpmc_wait0 signal is monitored according to the sysboot[10] configuration pin (=1 is enabled)

For an XIP memory booting, no user intervention is required; the following debugging steps are described. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

Booting from an XIP device consists of the following steps:

1. Configure the GPMC for XIP device access.

2. Verify that the CH is present at address 0x0800 0000. If the CH is present, copy the entire sector (512 bytes) to internal RAM and execute the CH.
3. Set the image location:
   - 0x0800 0000 if the CH is not found
   - 0x0800 0200 if the CH is found
4. Verify that a bootable image is at the image location.
5. If the image is found, execute it.
6. If the image is not found, return from XIP booting to the main booting loop.

32.3.7.3.1 GPMC Initialization

Table 32-38 lists the timing settings of the GPMC when set for XIP and other address-data accessible devices. Table 32-38 is included for debug information.

Table 32-38. XIP Timing Parameters

Parameter	Value (Clock Cycles)[(1)]	Register Initialization (where i = 0)
Write cycle period	17	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11.
Read cycle period	17	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11.
CS low time	1	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1.
CS high time	16	The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10.
ADV low time	1	The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1.
ADV high time	2	The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2.
OE low time	3	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3.
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.
Data latch time	15	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF.

(1) The one clock cycle is approximately 7.5 ns, which corresponds to a 133-MHz frequency.

There is no specific identification routine executed before booting from an XIP device.

32.3.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 512 Mibit (64 MiB) to 64 Gibit (8 GiB)
- ×8 and ×16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size (4096 bytes + 128/218 spare bytes)
- Chip enable (CE) don't-care devices only
- Single-level cell (SLC) and multilevel cell (MLC) devices
- Device identification based on ONFI or ROM table
  – Note that the full ONFI spec is not supported – specifically, the NAND geometry identification uses the first parameter page only and doesn’t check CRC on that page
- ECC correction: 8 bits per sector for most devices (16 bits per sector for devices with large spare area)
  – Note that ECC detection/correction is not used on ONFI parameter pages
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 133 MHz.
- The device is connected to CS0.
- The gpmc_wait0 wait-pin signal is connected to the NAND BUSY output.
- Four physical blocks are searched for an image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

32.3.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection.

- GPMC initialization

  The GPMC interface is configured so that it can access NAND. Because NAND memories do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. Table 32-39 shows the GPMC configuration used during NAND boot. Table 32-39 is included for debug information.

Table 32-39. NAND Timing Parameters

Parameter	Value (Clock Cycles)	Register Initialization (where i = 0–7)	Reset Value
Write cycle time	20	GPMC_CONFIG5_i[12:8] WRCYCLETIME = 0x14	0x11
Read cycle time	20	GPMC_CONFIG5_i[4:0] RDCYCLETIME = 0x14	0x11
CS low time	0	GPMC_CONFIG2_i[3:0] CSONTIME = 0x0	0x1
CS low to OE low time	5	GPMC_CONFIG4_i[3:0] OEONTIME = 0x5	0x6
CS low to OE high time	16	GPMC_CONFIG4_i[12:8] OEOFFTIME = 0x10	0x10
CS low to WE low time	1	GPMC_CONFIG4_i[19:16] WEONTIME = 0x1	0x5
CS low to WE high time	15	GPMC_CONFIG4_i[28:24] WEOFFTIME = 0xF	0x10
CS low to data latch time	14	GPMC_CONFIG5_i[20:16] RDACCESSTIME = 0xE	0xF

- Device detection and parameters

  The ROM code first performs an initial wait for device auto initialization (with a 250-ms time-out) with polling of the ready information. Then, it must identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with a 100-ms time-out). The ONFI Read ID (command 90h/address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes) then a Read parameters page (command ECh) is sent. The information provided in Table 32-40 is then extracted: page size, spare area size, number of pages per block, and the addressing mode, and ECC. The remaining data bytes from the parameter page stream are ignored.

Table 32-40. ONFI Parameters Page Description

Offset	Description	Size (Bytes)
6	Features supported	2
80	Number of data bytes per page	4
84	Number of spare bytes per page	2
92	Number of pages per block	4
101	Number of address cycles	1

  If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI), then the device is reset again with polling for device to be ready (with 100-ms time-out). Then, the standard Read ID (command 90h/address 00h) is sent. If the Device ID (second byte of the ID byte stream) is recognized as being a supported device, then the device parameters are extracted from an internal ROM code table. Table 32-41 lists the supported NAND devices.

Note

Not all NAND geometries are supported – the NAND device datasheet must be compared to Table 32-41 to confirm that the Read ID matches the Geometry specified in Table 32-41.

Table 32-41. Supported NAND Devices

Capacity	Device ID	Bus Width	Page Size in Bytes
512 Mibit	F0h	8	2048
512 Mibit	C0h	16	2048
512 Mibit	A0h	8	2048
512 Mibit	B0h	16	2048
512 Mibit	F2h	8	2048
512 Mibit	C2h	16	2048
512 Mibit	A2h	8	2048
512 Mibit	B2h	16	2048
1 Gibit	F1h	8	2048
1 Gibit	C1h	16	2048
1 Gibit	A1h	8	2048
1 Gibit	B1h	16	2048
2 Gibit	DAh	8	2048
2 Gibit	CAh	16	2048
2 Gibit	AAh	8	2048
2 Gibit	BAh	16	2048
2 Gibit	83h	8	2048
2 Gibit	93h	16	2048
4 Gibit	DCh	8	2048
4 Gibit	CCh	16	2048
4 Gibit	ACh	8	2048 (4096)
4 Gibit	BCh	16	2048 (4096)
4 Gibit	84h	8	2048
4 Gibit	94h	16	2048
8 Gibit	D3h	8	2048 (4096)
8 Gibit	C3h	16	2048 (4096)
8 Gibit	A3h	8	2048 (4096)
8 Gibit	B3h	16	2048 (4096)
8 Gibit	85h	8	2048
8 Gibit	95h	16	2048
16 Gibit	D5h	8	2048 (4096)
16 Gibit	C5h	16	2048 (4096)
16 Gibit	A5h	8	2048 (4096)
16 Gibit	B5h	16	2048 (4096)

Table 32-41. Supported NAND Devices (continued)

Capacity	Device ID	Bus Width	Page Size in Bytes
16 Gibit	86h	8	2048
16 Gibit	96h	16	2048
32 Gibit	D7h	8	2048 (4096)
32 Gibit	C7h	16	2048 (4096)
32 Gibit	A7h	8	2048 (4096)
32 Gibit	B7h	16	2048 (4096)
32 Gibit	87h	8	2048
32 Gibit	97h	16	2048
64 Gibit	DEh	8	2048 (4096)
64 Gibit	CEh	16	2048 (4096)
64 Gibit	AEh	8	2048 (4096)
64 Gibit	BEh	16	2048 (4096)

After retrieving parameters from the table, the page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2 Gibit have these parameters updated. Therefore, the ROM code supports 4-KiB page devices, but only if their size, according to the table, is at least 2 Gibit. Devices that are smaller than 2 Gibit have the block size parameter set to 128 KiB (when the page size is 2 KiB). Table 32-42 lists the fourth ID data byte encoding used in the ROM code.

Table 32-42. Fourth NAND ID Data Byte

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
Page size	512 bytes							0	0
	2048 bytes							0	1
	4096 bytes							1	0
	8192 bytes							1	1
Cell type (1)	2 levels					0	0		
	4 levels					0	1		
	8 levels					1	0		
	16 levels					1	1		
Block size	64 KiB			0	0				
	128 KiB			0	1				
	256 KiB			1	0				
	512 KiB			1	1				

(1) Read by ROM code only when the manufacturer code (first ID byte) is 98h

Figure 32-17 shows the detection procedure. When the NAND device is successfully detected, the ROM code changes the GPMC to 16-bit bus width, if necessary.

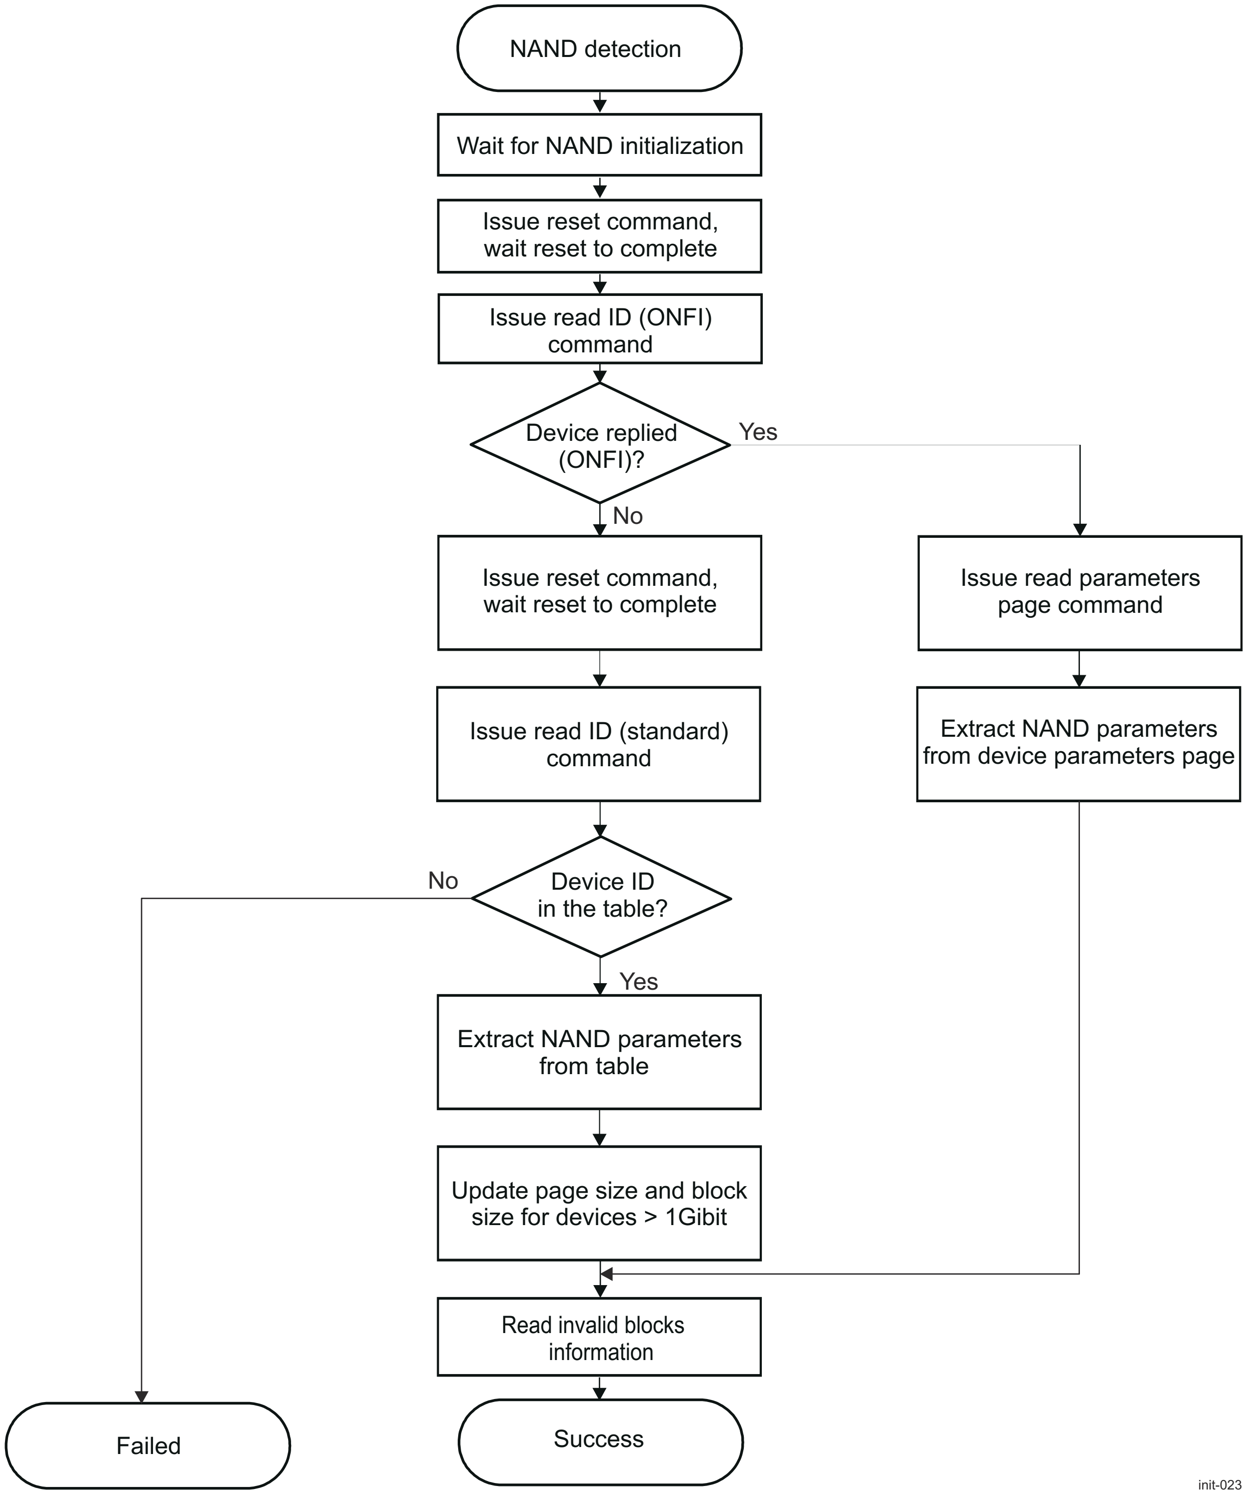

Figure 32-17. NAND Device Detection

- Bad block verification

  Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later.

Block validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in the first and second pages for an 8-bit device/first word equal to FFFFh in the first and second pages for a 16-bit device).

Figure 32-18 shows the invalid block detection routine. The routine consists in reading spare areas and checking the validity data pattern.

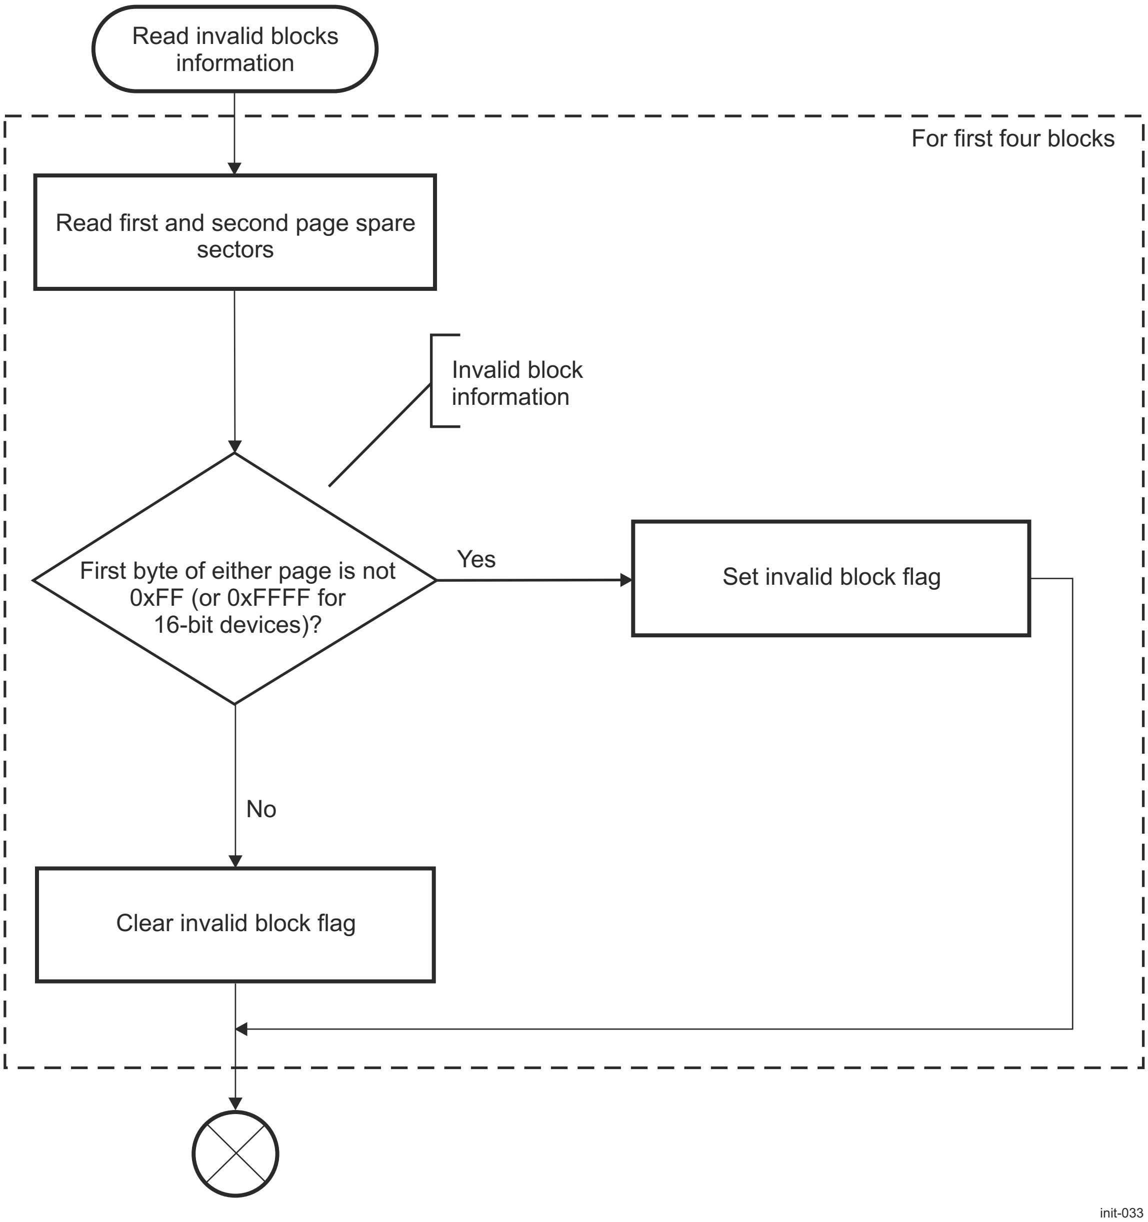

Figure 32-18. Bad NAND – Invalid Block Detection

32.3.7.4.2 NAND Read Sector Procedure

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

The ROM code uses normal read (command 00h 30h) for reading NAND page data.

Page data can contain errors caused by memory alteration. The ROM code uses an ECC correction algorithm to detect and possibly correct those errors. The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, and CEh when the manufacturer code (first ID byte) is 98h, the cell type information is checked in the fourth byte of ID data. If it is equal to 10b, the ECC correction applied is BCH 16b/sector.

The BCH data is automatically calculated by the GPMC on reading each 512-byte sector. The computed ECC is compared against the ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. Figure 32-19 and Figure 32-20 show the mapping of ECC data inside the spare area for 2-KiB page and 4-KiB page devices, respectively. If both ECC data are equal, the read sector function returns the read 512-byte sector without error. Otherwise, the ROM code tries to correct errors in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

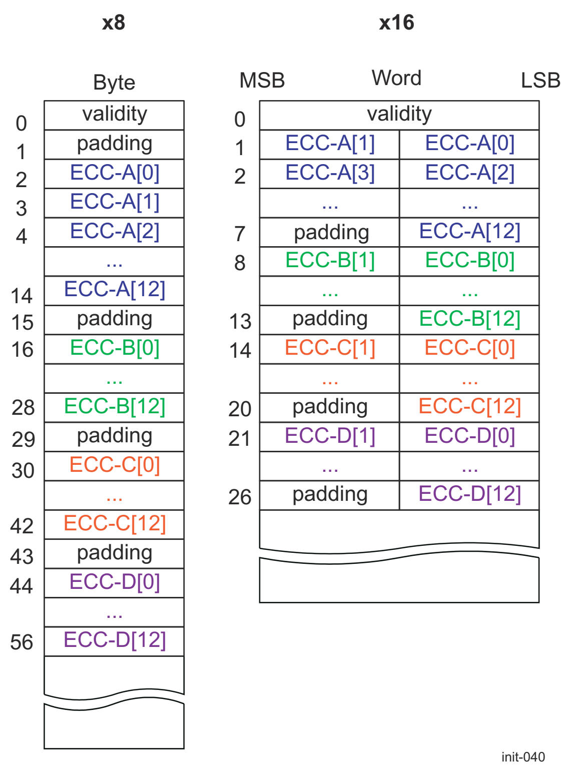

Figure 32-19. ECC Data Mapping for 2-KiB Page and 8b BCH Encoding

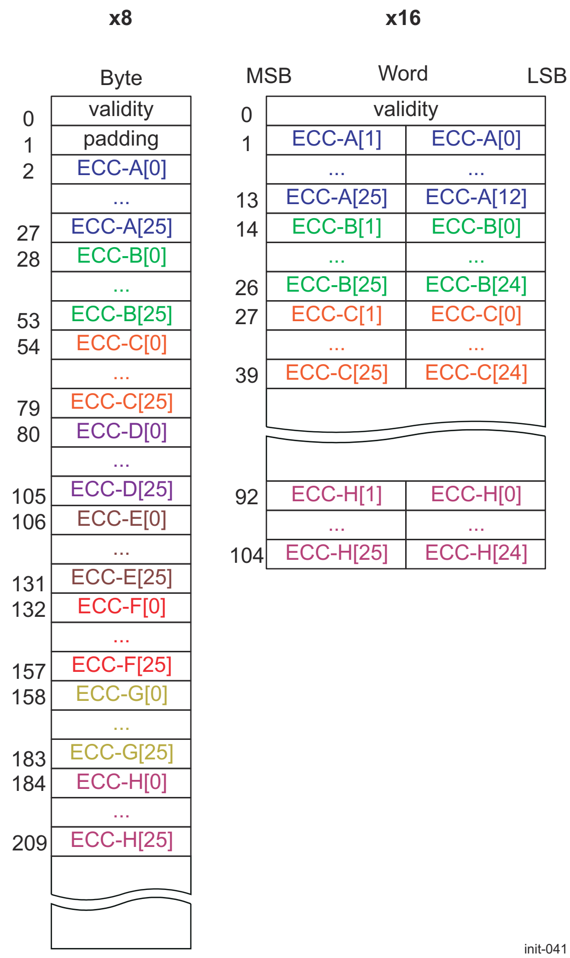

Figure 32-20. ECC Data Mapping for 4-KiB Page and 16b BCH Encoding

32.3.7.5 SPI/QSPI Flash Devices

SPI/QSPI Flash memories provide a storage solution for systems with limited space, pins, and power.

The ROM code support for SPI/QSPI devices has the following characteristics:

- 24-bit addressing, up to 128 Mbit (16 MiB), no banking
- QSPI1 on CS0 is the communication interface
- Uses Mode 3:
  - Clock inactive state = high
  - Data input captured on rising edge of clock
  - Data output generated on falling edge of clock
- QSPI 4-bit data read mode at 48 MHz in configuration port mode
  - Read command is 0x6B (Fast Quad Read), 3 address bytes,1 dummy bytes and read type is quad read
  - ROM will not perform any quad-enable sequence nor bank register update
- SPI 1-bit data read mode at 12 MHz in configuration port mode
  - Read command is 0x03 (Single Read), 3 address bytes, 0 dummy bytes and read type is normal read.
- Up to four redundant images can be stored on SPI/QSPI flash. The offset between them is set in sysboot[7:6] as described in Table 32-8. If not using the redundant SBL feature, the offset set in sysboot[7:6] is a don't care. A booting image is considered to be present , when the first 4 bytes word is not equal to 0000 0000h or FFFF FFFFh.

Note

ROM code does not perform any specific action to detect, reset or power up the QSPI device. QSPI is assumed to be properly powered and reset to be completed before every attempt to boot by ROM code.

32.3.7.6 eMMC Memories and SD Cards

The device allows booting from eMMC embedded memories or SD cards connected to device embedded MMC2 or MMC1 controllers I/Os, respectively. The booting interface is selected by configuration of the SYSBOOT pins.

The device high speed MMC/SD/SDIO host controller handles the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code.

The SD card interface supports 1.8-V/3-V digital I/Os. The selection on I/O voltage level is done using the PBIAS circuitry. The PBIAS reference level is sensed by the ROM code and PBIAS cell voltage setup appropriately before any communication with the SD card device. The eMMC interface supports also 1.8-V/3-V digital I/Os but with the difference that there is no PBIAS circuitry to select the I/O voltage level. This voltage depends only on the voltage provided to the eMMC associated power pads.

The device supports three booting modes:

- Raw (Boot): The booting image is read from one of the selectable partitions in raw mode (this mode is also called Alternative Boot Operation mode and applies to eMMC only).
- Raw (UDA): The booting image is read from the user data area (eMMC and SD).
- File system (FAT12/16/32 with or without master boot record): The image data is read from a booting file within a file system in the user data area (eMMC and SD).

Note

File system mode is only supported when booting in the eMMC user area. It is not supported in the eMMC boot area.

32.3.7.6.1 eMMC Memories

The ROM code supports booting from eMMC memories, with the following conditions:

- eMMC memory devices compliant with *Embedded MultiMediaCard (eMMC) eMMC/Card Product Standard, High Capacity, including Reliable Write Boot, and Sleep Modes, Dual Data Rate, Multiple Partitions Supports and Security Enhancement v4.5* from the MMCA Technical Committee. The exception is the hardware reset feature. For example, if the user software requires eMMC device hardware reset, it can be accomplished with a GPIO. To correctly boot from eMMC when using Alternative Boot Operation mode, it is recommended to tie the eMMC device RST_N signal to the platform warm reset.
- eMMC device connected to the device MMC2 controller I/O interface (only one device can be connected to the bus).
- The eMMC memory device is powered externally by a PMIC or other power supply.
- When booting from user area: Initial (default) 1-bit SDR mode, optional 4-bit and 8-bit SDR- and DDR-modes using Configuration Header
- Initial SDR- and DDR- modes supported
- Clock frequency when booting from user area:
  - Identification mode: 400 kHz
  - Data transfer mode: 10 MHz, optionally up to 48 MHz by Configuration Header
  - Support for eMMC boot partitions. eMMC booting from boot partitions (BPs), which is typical for booting in Alternative Boot operation mode, is always done at 8-bit, 48 MHz, DDR.

32.3.7.6.1.1 System Conditions and Limitations

The ROM code does not provide a bus direction control signaling in case of using MMC interface 2 with level shifters.

Note

The ROM Code does not support large 4-KiB sectors as defined in the latest standard.

The ROM code expects that the eMMC device is powered externally and supplies are set and stable when entering the booting procedure.

The ROM code supports the alternative boot operation mode specific to eMMC devices as described in the *Partition Management* and *Boot Operation Mode* sections of the eMMC Standard. It does not support the hardware boot operation mode (CMD line held low for 74 emmc_clk cycles) described in the same document.

32.3.7.6.1.2 eMMC Memory Connection

An eMMC device typically requires two supplies: one for the core memory array (VCC) and one for the device interface I/Os and controller (typical VCCQ = 1.8 V). Both memory device supply pins can possibly be merged into one, thus requiring only one power supply.

Figure 32-21 shows an example of the system connection between the PMIC, memory device, and device.

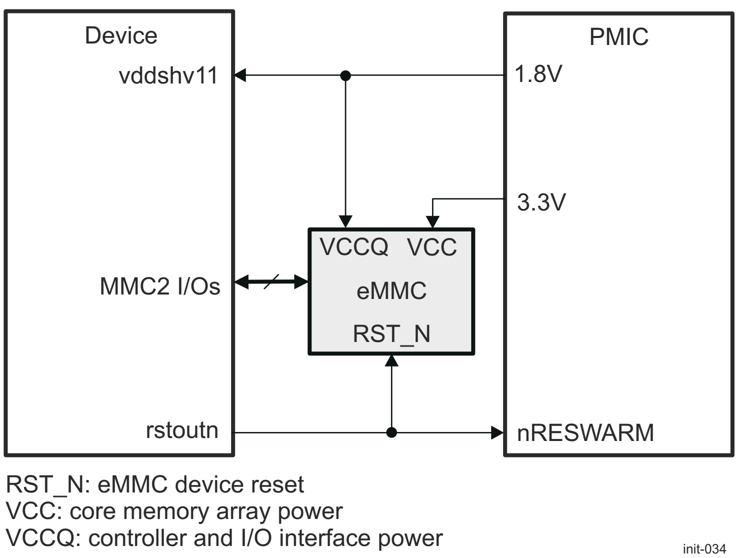

Figure 32-21. eMMC Connection

Note

For correct handling of eMMC boot partitions when using alternative boot operation mode, it is recommended to tie the eMMC RST_N signal to the signal indicating a platform warm reset (nRESWARM).

The ROM code performs the necessary I/O pin muxing configuration to route the MMC2 I/O signals on the eMMC pads depending on the selected SYSBOOT configuration.

32.3.7.6.2 SD Cards

The ROM code supports booting from SD cards under the following conditions:

- SD cards compliant with *SD Specifications Part 1 Physical Layer Specification Version 4.00*and the *SD Specifications Part 2 File System Specification Version 3.00* from the SD Association. These include low- (SDSC) and high-capacity (SDHC) cards.

- SD card connected to MMC1 controller I/Os. Only one card is allowed to be connected to the bus.
- 3-V VCC power supply
- 3-V or 1.8-V I/O voltages
- Initial 1-bit MMC mode, optional 4-bit mode
- Clock frequency:
  - Identification mode: 400 kHz
  - Data transfer mode: 10 MHz (optionally up to 19.2 MHz by Configuration Header)

32.3.7.6.2.1 System Conditions and Limitations

Even though the ROM Code identities SDXC cards, it does not handle its specificities such as exFAT support. It does neither support UHS-I nor UHS-II speed grades.

32.3.7.6.2.2 SD Card Connection

An SD card can be connected to the SD card interface, typically through a card cage.

Figure 32-22 shows the typical connection between the power IC, the card, and the device.

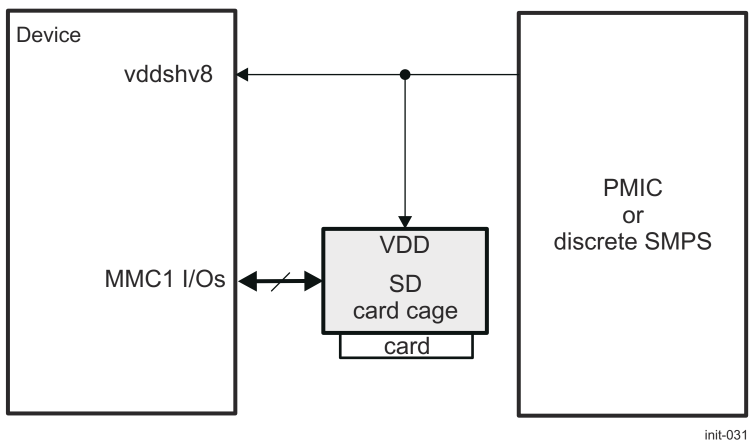

Figure 32-22. MMC/SD Card Connection

Note

The ROM code does not handle the card detection feature on the card cage.

32.3.7.6.2.3 Booting Procedure

If the selected booting device is eMMC, then a first attempt to trigger alternative boot operation mode is tried. If the eMMC device replies within a fixed timeout, then the booting image is directly retrieved from one of the possible partitions specified in the local EXT_CSD.BOOT_PARTITION_ENABLE bit field for the eMMC device (this is referred to as the Raw(Boot) mode). Raw(Boot) mode improves the boot time by avoiding the regular eMMC/SD identification phase (usually done at low speed). When the booting image is retrieved, the ROM code continues the boot process.

If the time-out elapses, then the ROM code proceeds with normal identification. SD cards do not support Alternative Boot Operation mode, and therefore are always going through normal identification.

If normal identification succeeds, then it next determines whether the SD card or eMMC device contains a known file system. If the file system is known, then the booting image is extracted from the file system hierarchy. If a file system is not detected, then the Raw(UDA) mode is assumed.

Figure 32-23 is the high level flow chart of the eMMC and SD booting procedure.

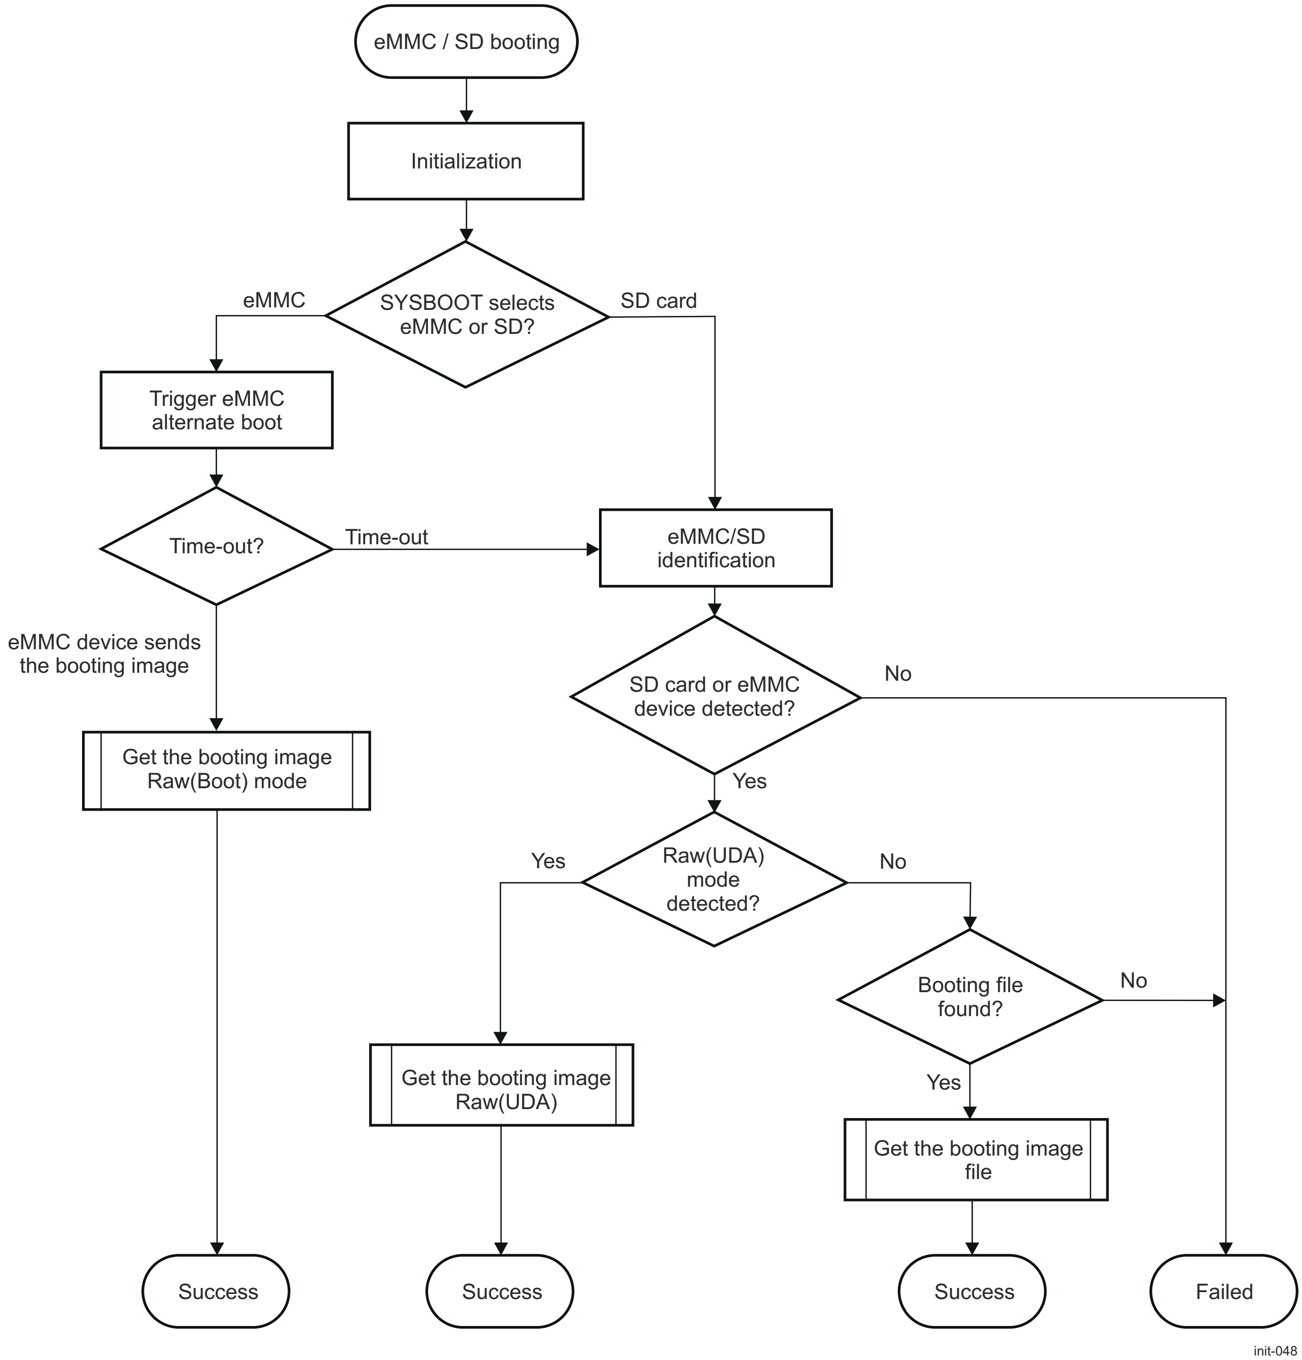

Figure 32-23. eMMC and SD Booting

32.3.7.6.2.4 eMMC Partitions Handling in Alternative Boot Operation Mode

To trigger alternative boot operation mode, the ROM code sends a specific CMD0 + Argument 0xFFFF FFFA. Then, the ROM code waits up to 50 ms for the eMMC device to return a boot-acknowledge signal. If the time-out elapses, then the ROM code skips alternative boot operation mode. Booting from eMMC partitions can be done in 8-bit mode at 48 MHz, DDR. This configuration is static and cannot be changed.

32.3.7.6.2.4.1 eMMC Devices Preflashing

For correct handling of eMMC partitions in alternative boot operation mode, it is necessary to prepare the eMMC device at flashing time with the following settings applied to the device EXT_CSD register:

- The BOOT_ACK and BOOT_PARTITION_ENABLE fields must be updated accordingly (EXT_CSD[179], bit 6 and bits [5:3], respectively) to activate the boot acknowledge signal and select the partition from which to boot. There are several boot options selectable in the BOOT_PARTITION_ENABLE bit field, as follows:
  – Booting from boot partition 1 (BP1)
  – Booting from boot partition 2 (BP2)
  – Booting from User Area

  For more details, see the eMMC Standard documentation.
- RST_N must be enabled for correct handling of the warm reset cases (EXT_CSD[162] bits [1:0] = 0x1).
- The BOOT_BUS_WIDTH fields (EXT_CSD[177]) must be updated properly based on device alternate boot operation: 8-bit, 48 MHz, DDR mode.
- Optionally the BOOT_CONFIG_PROT (EXT_CSD[178]) may be updated for altering access permissions to the selected partitions.

Note

Although an alternate boot from user area is possible, alternate booting from BP1 or BP2 is recommended.

Note

It is possible to permanently or temporarily lock the boot configuration through the use of the BOOT_CONFIG_PROT register. For more details, see the eMMC Standard documentation.

Note

- It is highly recommended to refer to the eMMC Standard for details on EXT_CSD handling.
- The EXT_CSD is updated by using a SWITCH command as detailed in the eMMC standard.
- The mentioned EXT_CSD fields are retained after a power cycle so only one “flashing” phase is required

32.3.7.6.2.4.2 eMMC Device State After ROM Code Execution

If alternative boot operation mode is successful, and the booting image is properly retrieved, then the eMMC device state remains in the BOOT state even after the execution has passed to the initial software. The initial software must bring the device out of the BOOT state.

32.3.7.6.2.4.3 Consideration on device Global Warm Reset

Once the system has booted and upon triggering a warm reset at device level (it can be triggered by the warm-reset push button, a timer, watchdog, etc.), it is important that the eMMC device is properly brought to its PRE-IDLE state so that the next Alternative Boot operation succeeds. This is ensured by the eMMC RST_N pin to be connected to device rstoutn pin (warm reset). Not doing so would make the boot procedure fail after a warm reset.

32.3.7.6.2.4.4 Booting Image Size

In Raw(Boot) mode, the size of the booting image is determined after the first sector read access. The boot image size is contained within the GP header. This ensures that the ROM code is only retrieving the necessary size of data and not the full contents of the partition.

32.3.7.6.2.4.5 Booting Image Layout

In Raw(Boot) mode only one copy of the booting image is maintained, as opposed to up to four copies in Raw(UDA) mode.

32.3.7.6.3 Initialization and Detection

If the eMMC Alternate Boot operation fails in time-out, or the requested boot device is an SD card, the ROM code initializes the memory device or card connected on the eMMC and SD card interface using 1.8 V for eMMC and standard high-voltage range (3.0 V) for SD card I/Os. If neither a card nor memory device is detected, the ROM code moves to the next booting device. The standard identification process and relative card address (RCA) assignment are performed. The ROM code assumes that only one memory or card is connected on the bus. This is done using the CMD line common to the SD and eMMC memory devices. The eMMC and SD standards describe this phase as the initialization phase. They differ in the commands involved, as described in Figure 32-25. The ROM code uses CMD55 to discriminate between eMMC and SD cards; that is, CMD55 is only supported by the SD standard. Depending on response received or not, ACMD41 (the combination of CMD55 and CMD41 for SD) or CMD1 (for MMC) is sent. If no response is received this time, no devices are connected and the ROM code exits eMMC/SD booting with FAIL.

Figure 32-24 shows the eMMC/SD detection procedure.

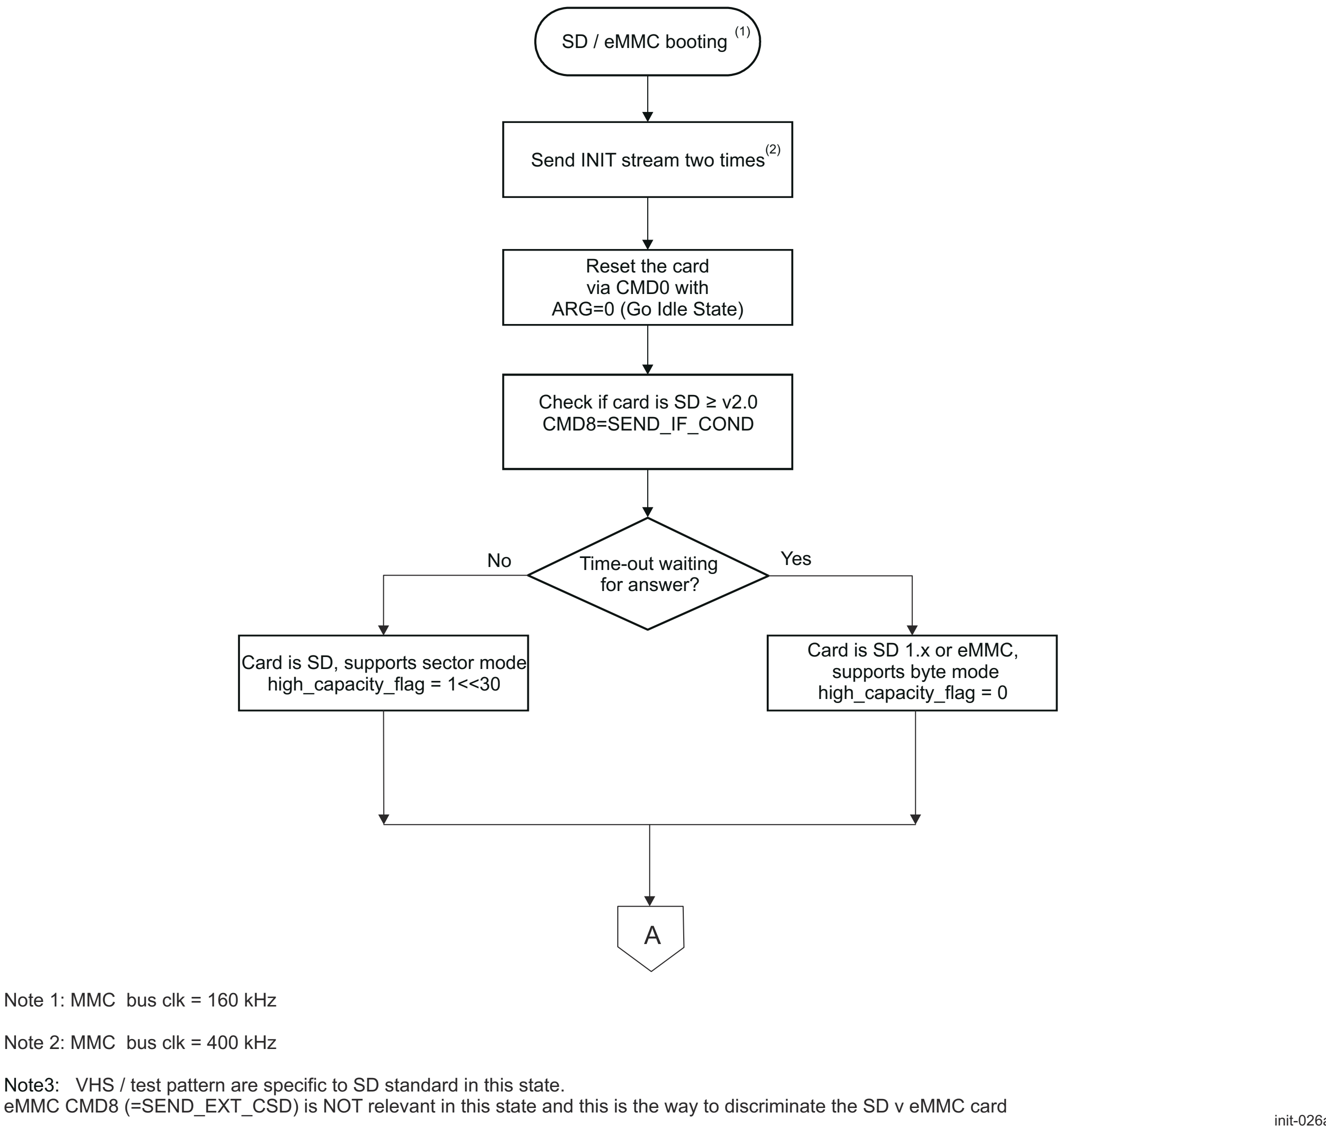

Figure 32-24. SD/eMMC Detection Procedure (part 1)

Figure 32-25 shows the eMMC/SD detection procedure.

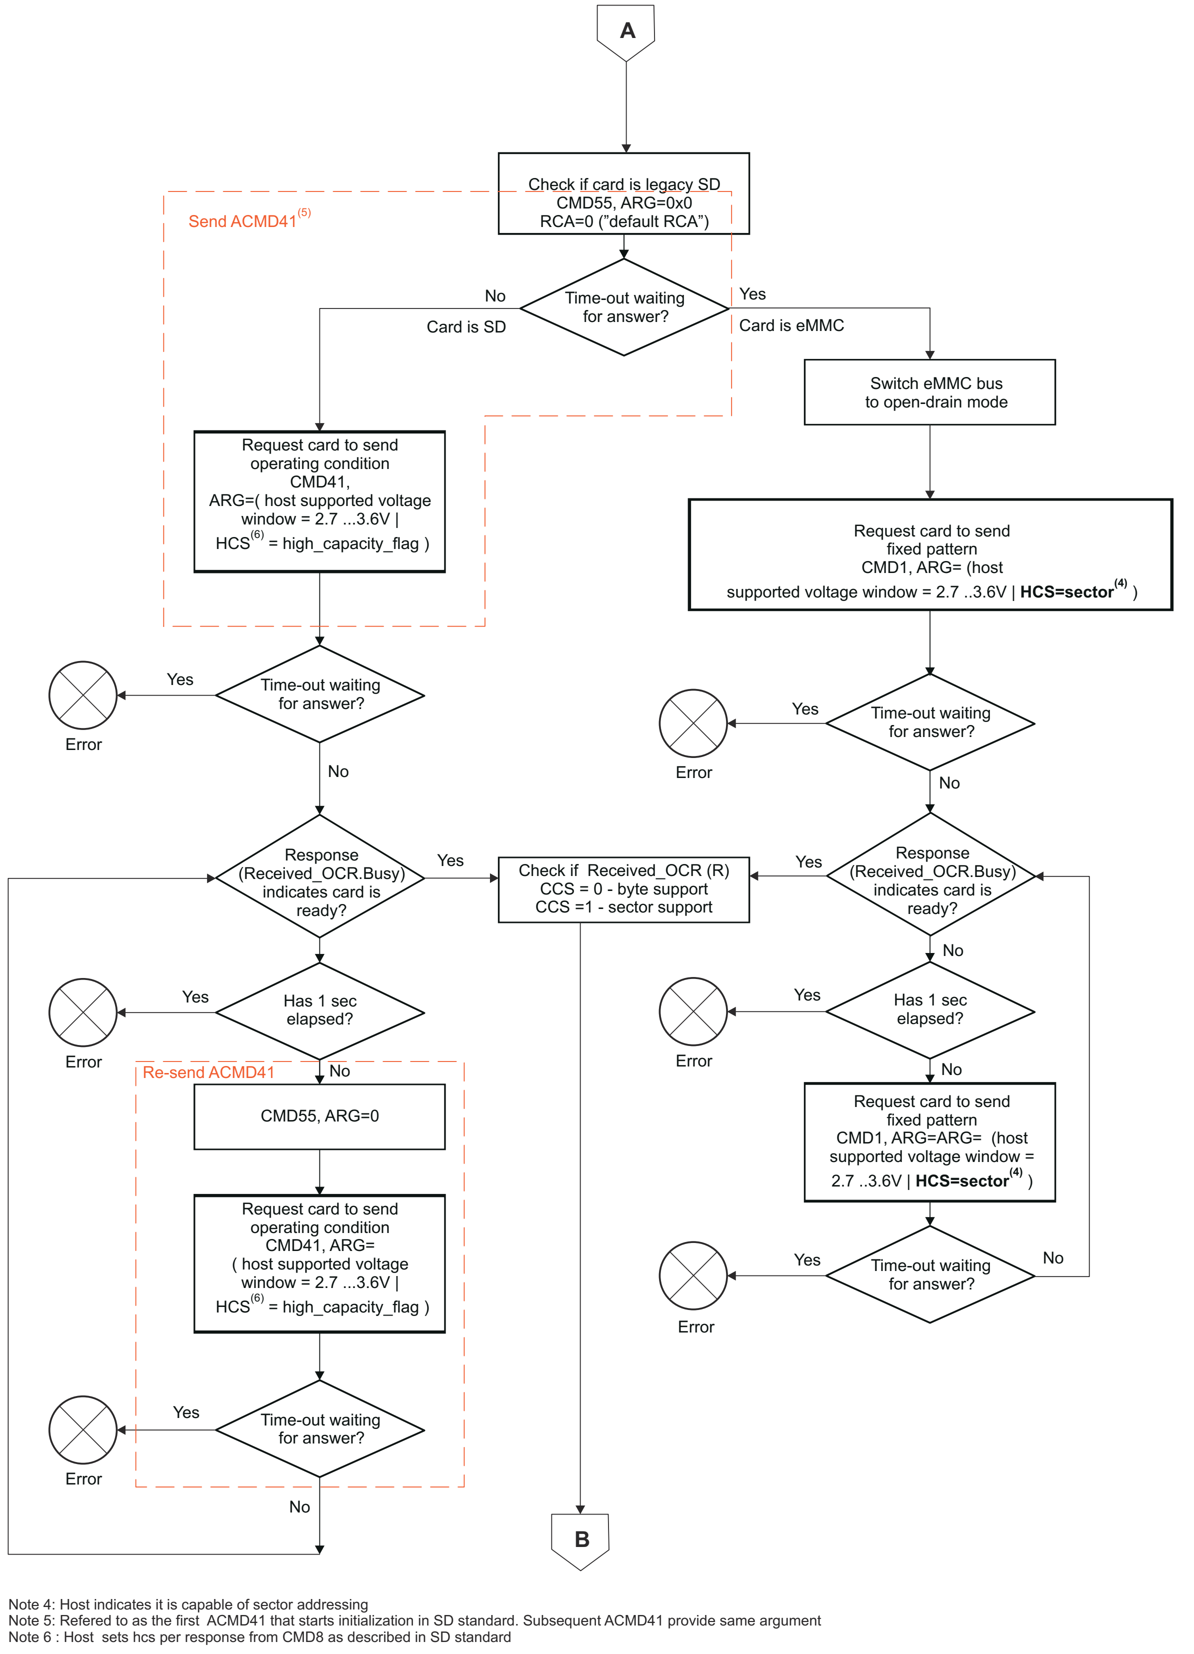

Figure 32-25. SD/eMMC Detection Procedure (part 2)

Figure 32-26 shows the eMMC/SD detection procedure.

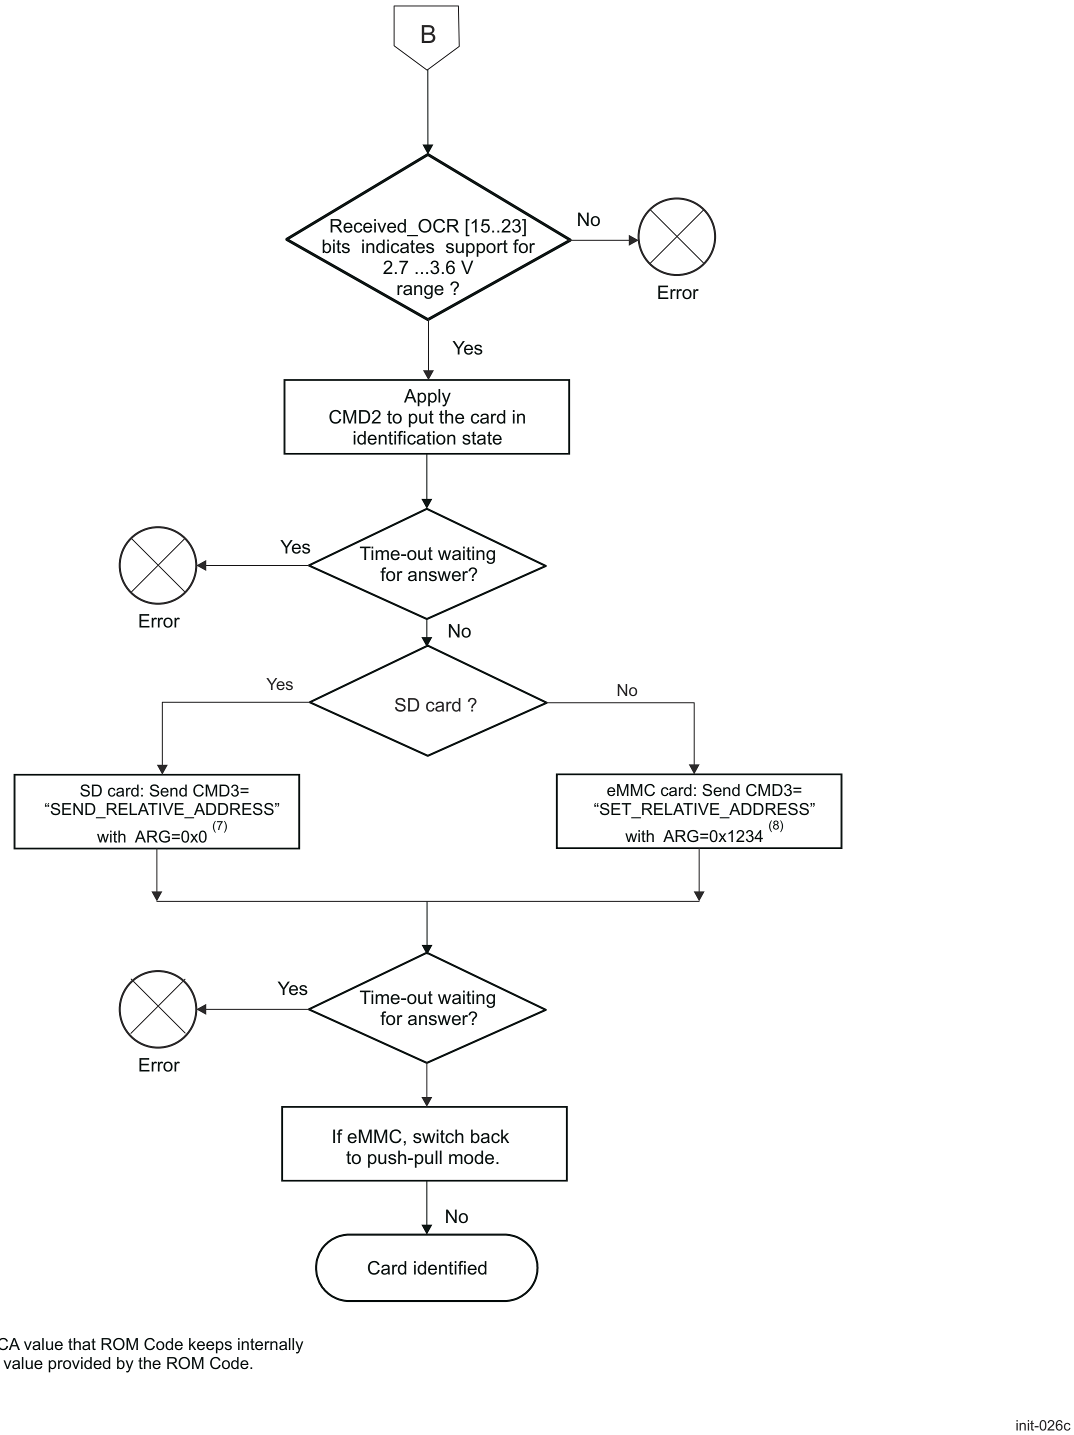

Figure 32-26. SD/eMMC Detection Procedure (part 3)

32.3.7.6.4 Read Sector Procedure

The contents of an eMMC or SD card may be formatted as raw binary (referred to as Raw(UDA) or within a FAT file system. The ROM Code reads out sectors from raw image or the booting file within the file system and boots from it.

- **Raw mode**

  In Raw(UDA) mode, an image can be at one of the four consecutive locations in the main area: offset 0x0 (0 KiB)/0x20000 (128 KiB)/0x40000 (256 KiB)/0x60000 (384 KiB). For this reason, the size of a booting image must not exceed 128 KiB. However, a device with an image greater than 128 KiB can be flash starting at one of the aforementioned locations. Therefore, the ROM code does not check the image size. The only drawback is that the image crosses the subsequent image boundary. Raw mode is detected by reading sectors 0, 256, 512, and 768. The content of these sectors is verified for the presence of a TOC structure. GP header must be located at the beginning of the booting image, as described in Section 32.3.8.2, *Configuration Header* . Image data is read directly from continuous sectors of a card. If raw mode is not detected, file system mode is assumed.
- File system handling

  The read sector procedure uses the standard SD/eMMC read data procedure. The sector address is generated based on the booting memory file map collected during initialization. Thus, the ROM code can freely address sectors in the booting file space.

32.3.7.6.5 File System Handling

The eMMC/SD cards can hold a file system that the ROM code reads. The image used by the booting procedure is taken from a booting file named MLO. This file must be in the root directory on an ***active*** primary partition of type FAT12/16 or FAT32.

An eMMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card must always hold an MBR, except when using a floppy-like file system. However, depending on the operating system used, the eMMC/SD card is formatted with or without partitions (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT. The booting file map is a collection of all FAT entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. Figure 32-27 shows the complete process.

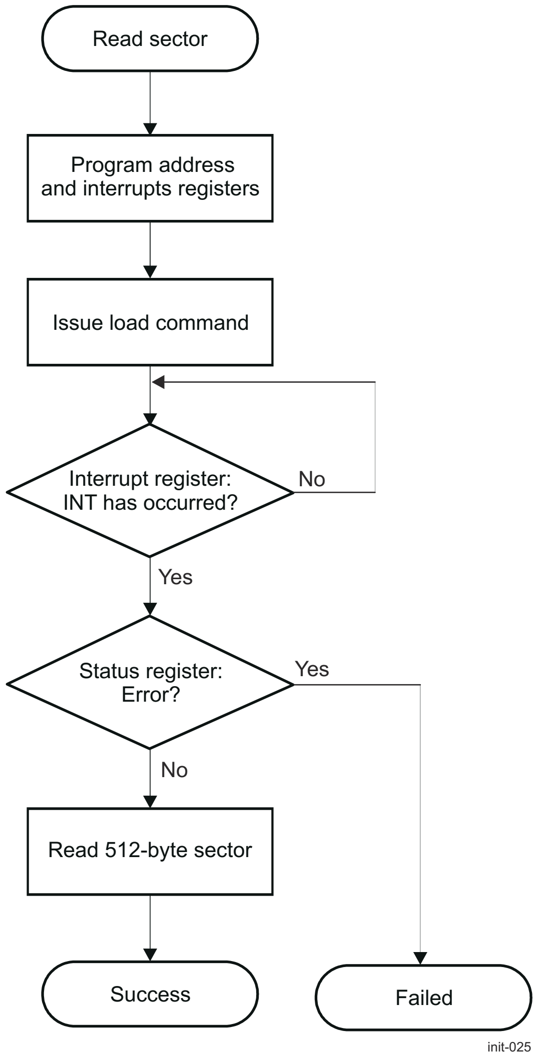

Figure 32-27. SD/MMC Get Booting File

32.3.7.6.5.1 MBR and FAT File System

This paragraph describes functions used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux® FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows®). Table 32-43 describes this structure, and Table 32-44 describes the partition table entry.

Table 32-43. Master Boot Record Structure

Offset	Length (Bytes)	Entry Description
0000h	446	Optional code
01BEh	16	Partition table entry
01CEh	16	Partition table entry
01DEh	16	Partition table entry
01EEh	16	Partition table entry

Table 32-43. Master Boot Record Structure (continued)

Offset	Length (Bytes)	Entry Description
01FEh	2	Signature (0xAA55)

Table 32-44. Partition Table Entry

Offset	Length (Bytes)	Entry Description	Value
0000h	1	Partition state	00h: Inactive 80h: Active
0001h	1	Partition start head	Hs
0002h	2	Partition start cylinder and sector	Cs[7:0] – Cs[9:8] – Ss[5:0]
0004h	1	Partition type	01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32
0005h	1	Partition end head	He
0006h	2	Partition end cylinder and sector	Ce[7:0]–Ce[9:8]–Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBAs = Cs.H.S + Hs.S + Ss – 1
000Ch	4	Number of sectors in partition	LBAe = Ce.H.S + He.S + Se – 1 Nb s = LBAe – LBAs + 1

SD/eMMC booting consists of the following steps:

1. Detection of MBR

   The ROM code first checks whether the MBR signature is present, and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the Type field. If the MBR entries are not valid, or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked to determine the following:

   a. If the partition type is set to 00h, all fields in the entry must be 00h.
   b. The partition is within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

   See Figure 32-28 for more information about MBR detection.

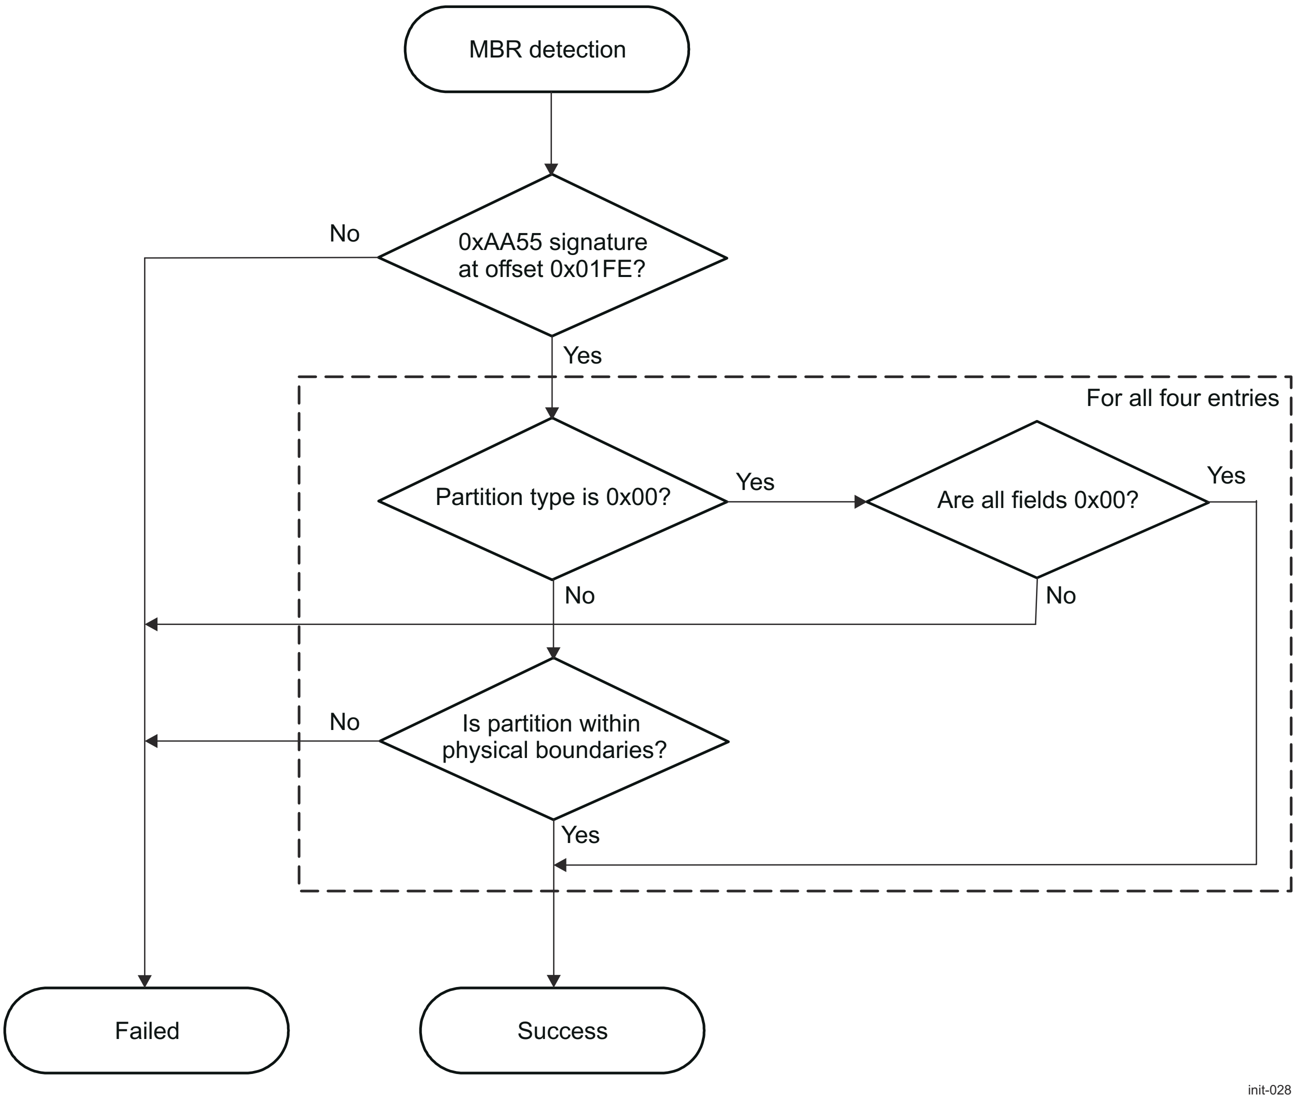

Figure 32-28. MBR Detection Procedure

2. Get the MBR partition.

   Once identified, the ROM code gets the partition using the procedure described in Figure 32-28. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active). The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or the test fails if there is more than one active partition. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, the ROM code returns with FAIL if another partition type is used (for instance, Linux FS) or if the partition is not valid.

   The FAT file system consists of several parts:
   - Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
   - FAT, which describes the use of each cluster of the partition
   - Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location)

   To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that require specific values are checked. Figure 32-29 shows more about getting the partition.

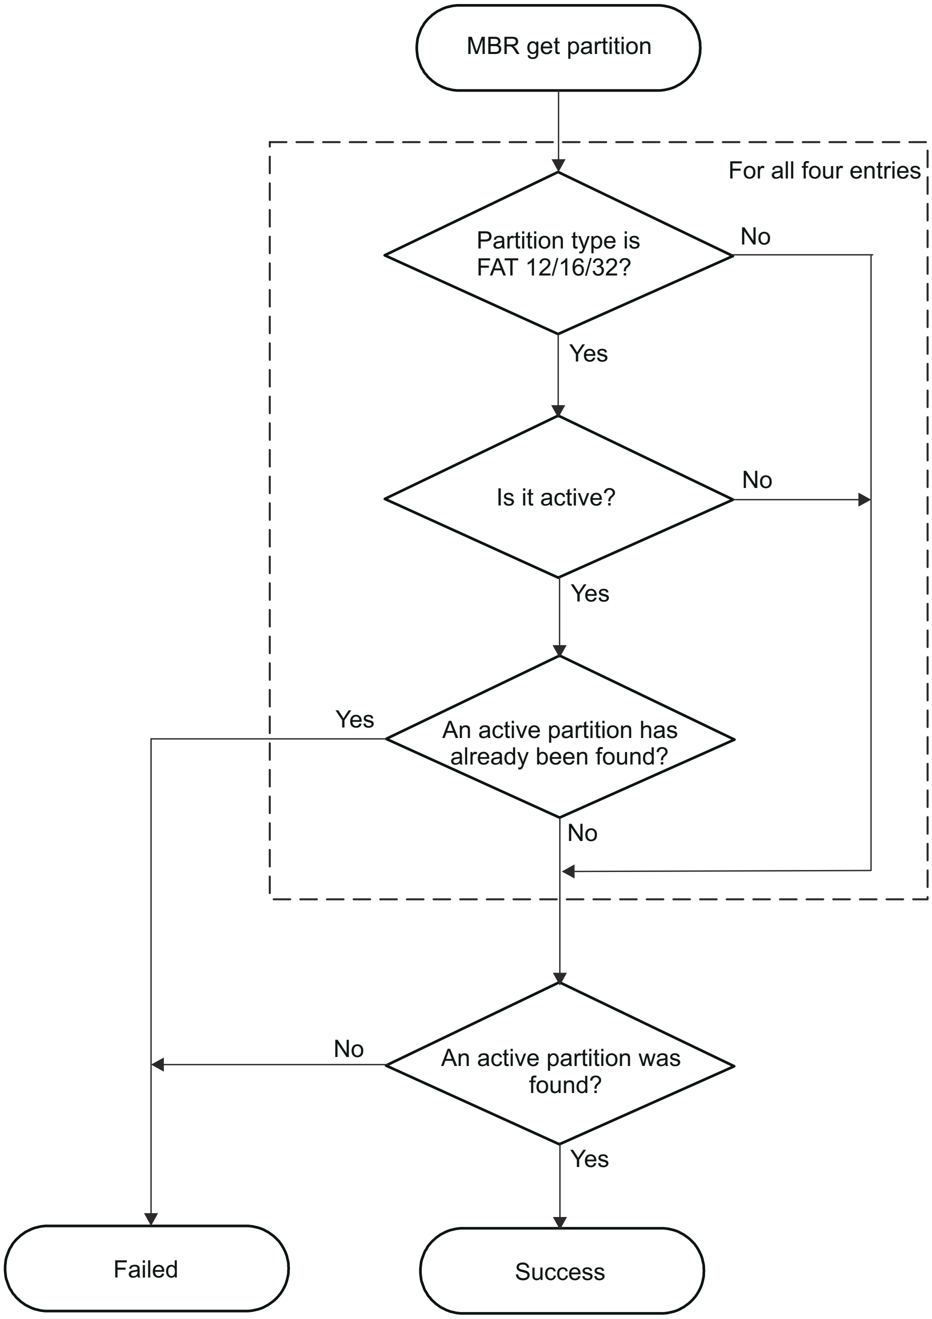

Figure 32-29. MBR, Get Partition

3. Find the booting file.

   When a partition is found, the root directory entries are searched for a booting file named MLO in the root directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the root directory has a fixed location, which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by the following equation:

$$Cluster_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BPB\_NumFATs \cdot BPB\_FATSz + Cluster \cdot BPB\_SecPerCLus$$

init-E001

Note

BPB_FATSz is BPB_FATSz16 for FAT12/16, or BPB_FATSz32 for FAT32.

Note

The BPB_HiddSec field can contain 0, even though the FAT file system is somewhere other than on sector 0 (floppy-like). The ROM code uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes and holds information about the file (the filename, date of creation, rights, cluster location, and so forth). See Table 32-45.

Table 32-45. FAT Directory Entry

Offset	Length (Bytes)	Name	Description
0000h	11	DIR_Name	Short Name (8 + 3)
000Bh	1	DIR_Attr	File attributes: 01h – ATTR_READ_ONLY 02h – ATTR_HIDDEN 04h – ATTR_SYSTEM 08h – ATTR_VOLUME_ID 10h – ATTR_DIRECTORY 20h – ATTR_ARCHIVE 0Fh – ATTR_LONG_NAME
000Ch	1	DIR_NTRes	Reserved. Set to 00h.
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation
000Eh	2	DIR_CrtTime	Time file was created.
0010h	2	DIR_CrtDate	Date file was created.
0012h	2	DIR_LstAccDate	Last access date
0014h	2	DIR_FstClusHi	High word of the first cluster number of this entry
0016h	2	DIR_WrtTime	Time of last write
0018h	2	DIR_WrtDate	Date of last write
001Ah	2	DIR_FstClusLo	Low word of the first cluster number of this entry
001Ch	4	DIR_FileSize	File size in bytes

The ROM code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with the ATTR_LONG_NAME attribute (LFN) and first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields. There is a slight difference between FAT12/16 and FAT32 when handling the root directory. On FAT12/16, this directory has a fixed location (see Table 32-45) and length fixed by BPB_RootEntCnt, which is the total of 32-byte entries. Therefore, handling this directory is straightforward. On FAT32, the root directory is like a standard file. The FAT must be used to retrieve each sector of the directory. Step 4 describes the way in which the FAT is handled.

4. Buffer FAT entries in the FAT buffer.

When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in the FAT buffer that is used during boot to access the booting file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies), after the boot sector.

$$FATn_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BP\_FatSz \cdot n$$

init-E002

The size of the FAT buffer is given by BPB_FATSz16 or BPB_FATSz32. The ROM code checks each copy of the FAT if the values are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB_ExtFlags[7]. If this flag is set, the FAT BPB_ExtFlags[3:0] bit field is used. In this case, no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster in the data area. One entry of the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. Table 32-46 describes the meaning of an entry.

Note

For compatibility, cluster 0 and cluster 1 are not used for files, and these entries must contain:

- FF8h and FFFh (for FAT12)
- FFF8h and FFFFh (for FAT16)
- 0FFFFFF8h and 0FFFFFFFh (for FAT32)

Table 32-46. FAT Entry Description

FAT12	FAT16	FAT32	Description
000h	0000h	00000000h	Free cluster
001h	0001h	00000001h	Reserved cluster
002h–FEFh	0002h–FFEFh	00000002h–0FFFFFEFh	Used cluster; value points to next cluster
FF0h–FF6h	FFF0h–FFF6h	0FFFFFF0h–0FFFFFF6h	Reserved values
FF7h	FFF7h	0FFFFFF7h	Bad cluster
FF8h–FFFh	FFF8h–FFFFh	0FFFFFF8h–0FFFFFFFh	Last cluster in file

Note

FAT32 uses only bits [27:0]; the upper 4 bits are usually 0 and must remain untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later by the booting procedure to access the file.

32.3.7.7 SATA Device Boot Operation

The SATA is a host interface dedicated for mass storage memory devices. SATA aims to connect SATA disk drive compliant SSD (SATA solid state drive) or HDD (hard disk drive) for mass storage use case only.

The mass storage device (SSD or HDD) is intended to be connected through SATA standard connector (in case of HDD) or directly soldered on the board (in case of SSD). In the latter case, the SATA mass-storage device is actually permanently attached to the device.

The device embedded SATA host controller has a single port (P0) implementation, and one internal electrical transceiver (SATA_PHY). For more information on the device-embedded SATA (SATA AHCI core and wrapper), see Section 24.8, *SATA Controller*. For more details on SATA subsystem integrated SATA PHY transceiver components, see Section 26.1, *SATA PHY Subsystem*. A system integration block diagram is provided in following section.

32.3.7.7.1 SATA Booting Overview

The device attached to the device SATA for boot operation must meet the following requirements:

- It must be compliant with the *Serial ATA Standard* specification, rev. 2.6.
- It must support READ SECTOR(s) ATA command (code 0x20) as defined in the ATA/ATAPI - 7 specification.
- It must be connected directly to the device SATA IOs – sata_tx/sata_ty, sata_rx/sata_ry (no port multiplier connected).
- It must have been already powered by the companion chip or external supply before start of the boot procedure.
- It must be taken in consideration for the device that maximum power on ready time allowed by ROM Code is 900ms. First COMRESET procedure targeting the attached device is triggered 300ms after device SATA subsystem initialization by ROM Code.

Figure 32-30 highlights the booting of the platform from the SSD device.

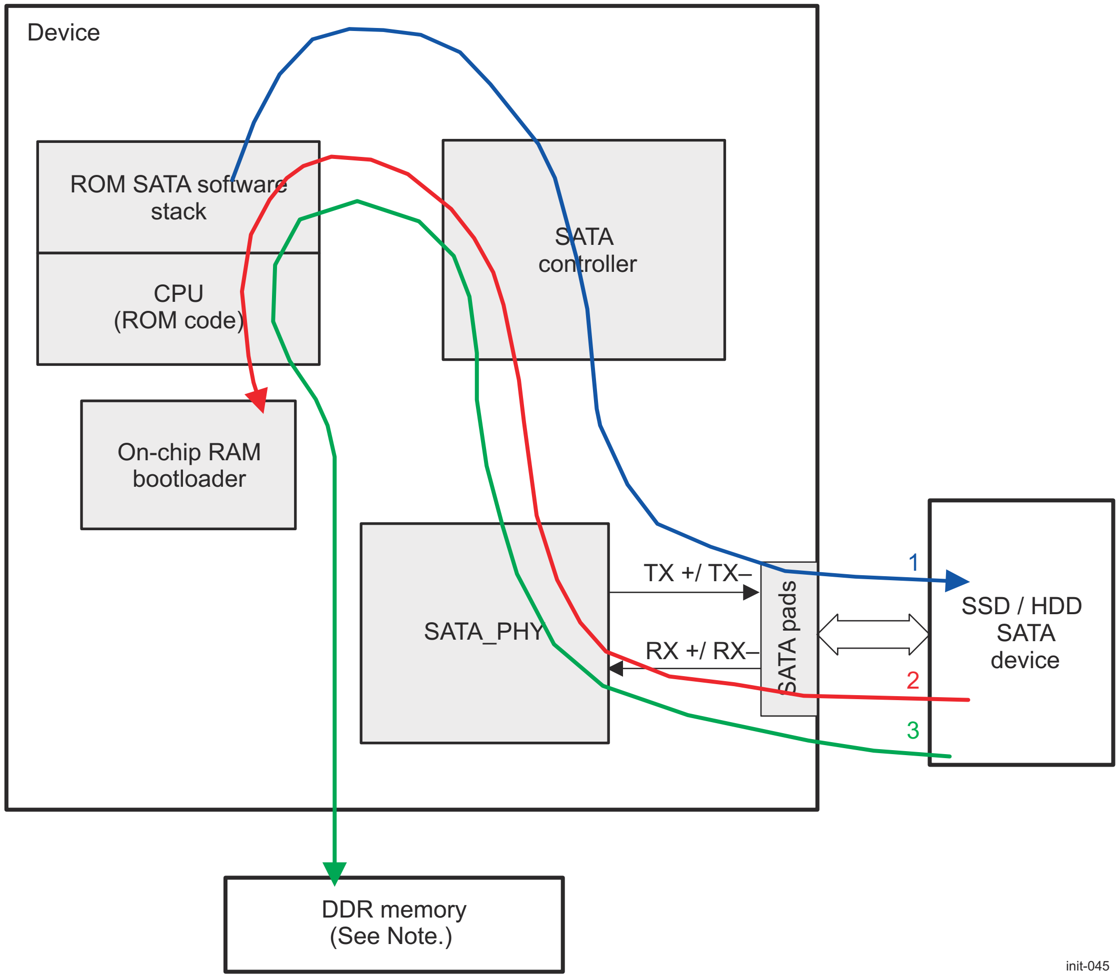

Figure 32-30. Booting from a Permanently-Attached SSD Device

The device booting from an attached SATA mass storage memory device is performed in the following steps:

1. At reset or power on, the device ROM code boots and checks for the SSD/HDD to be ready.
2. The SSD/HDD transfers the boot-loader to the internal RAM of device.
3. The OS in the SSD or HDD is downloaded into DDR memory and the platform is ready.

32.3.7.7.2 SATA Power-Up Initialization Sequence

Figure 32-31 shows all messages exchanges between power-on event up to when the platform is ready. The sequencing aims to depict the complete sequence without any specific connecting issues that may appear.

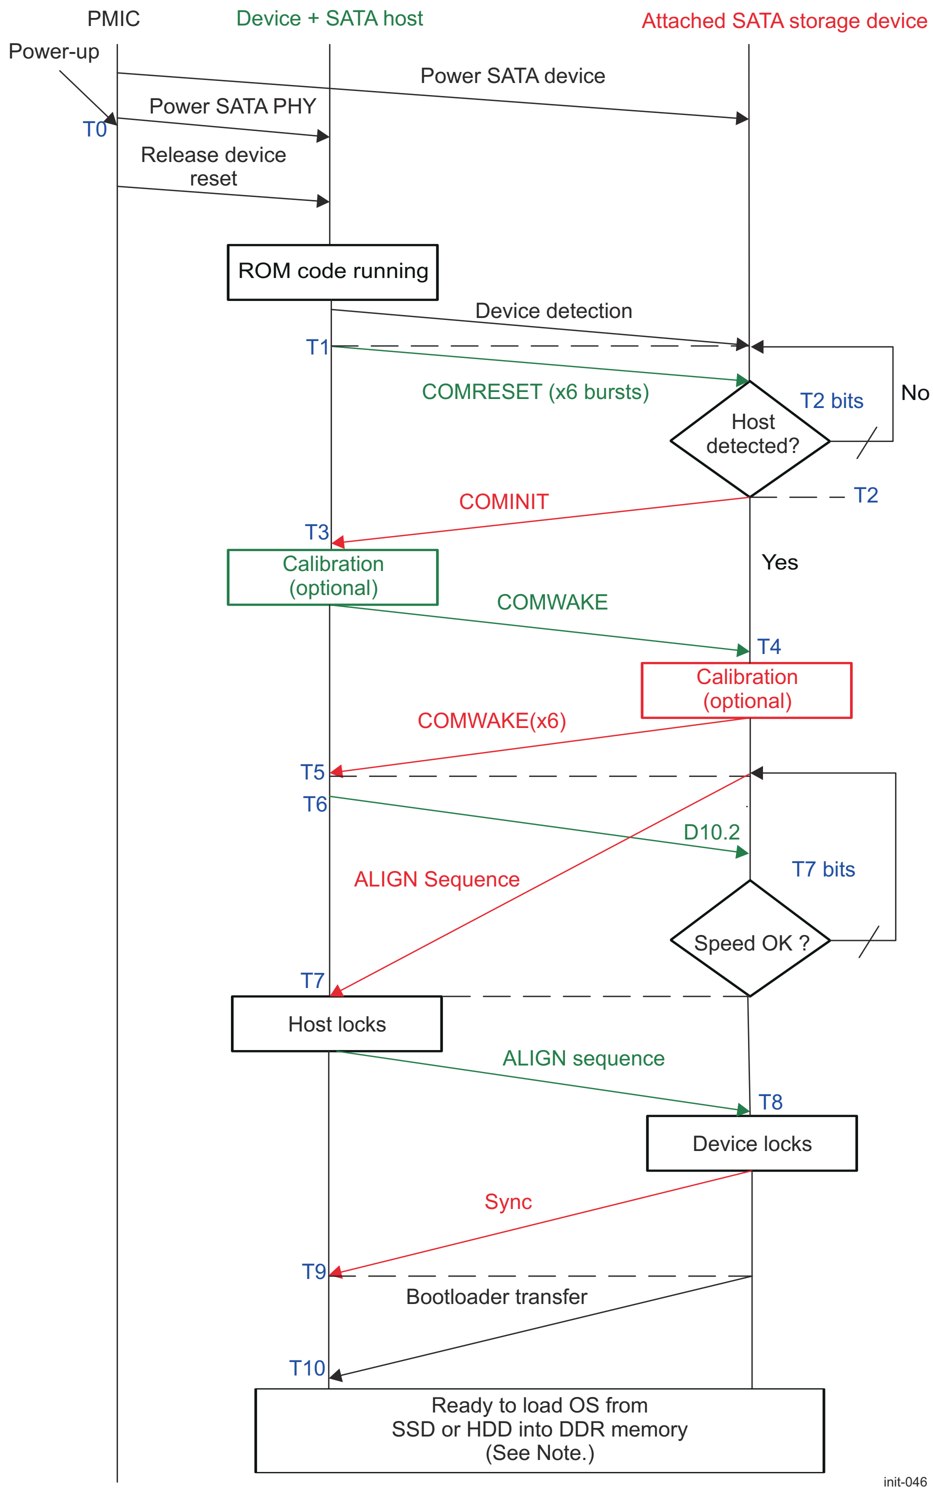

Figure 32-31. SATA Power-on Initialization Sequencing

The following time phases can be identified during booting from SATA interface:

- T0: the SATA_PHY is powered and device reset is maintained until all Power-management IC companion powers are set.
- T1: the ROM code validates a SATA SSD device detection.

- Within the T1-T2 time interval: the SATA host issues a COMRESET sequence for a minimum of 6 bursts (and a multiple of 6) to force a hardware reset to the SATA peripheral device.
- T2: As long as the attached SATA SSD device does not explicit reset request (COMINIT), the host issues COMRESET sequences
- Within the T2-T3 time interval, once the host release the COMRESET sequence (made of 6 bursts minimum), the device responds with a COMINIT to request a communication initialization (It requests a reset from the host).
- Within the T3-T4 time interval, the SATA host controller may calibrate at T3, but issues a COMWAKE sequence to the peripheral in order to inform the other part the wish to use the link.
- Within the T4-T5 time interval, the SSD device responds and may calibrate. The device response is made of 6 burst COMWAKE sequence.
- Within the T5-T6 time interval, SATA host controller shall start transmitting D10.2 characters no later than a defined moment.
- Within the T6-T7 time interval, when the device host detects the COMWAKE from the device, it starts transmitting D10.2 character at its lowest speed.
- At the same time within T5-T7 time interval, continuous stream of device ALIGN sequence (following the 6 bursts COMWAKE sequence) starting at the device highest speed.
- T7: Without any SATA host's answer (D10.2 character), the device ALIGN sequence is repeated for as many slower speeds as are supported. When host receives ALIGN sequence, it locks.
- in case no proposed speeds are supported by the host, the device enters in error state.
- in case no ALIGNp sequence is received by the host within a defined time gap after detecting the release of the device COMWAKE, the host restarts the power on sequence indefinitely until stop by user intervention.
- Within the T7-T8 time interval, as soon as the device SATA host locks, it issues an ALIGN sequence to the attached SATA SSD device that also locks
- Within the T8-T9 time interval, the SATA peripheral device sends a SYNC primitive to inform the communication link is established.
- Within the T9-T10 time interval, once the link has been set successfully, the boot loader is transferred from the SATA peripheral device to device internal on-chip RAM

After passing through all above described phases, the device is ready to load OS source from SSD to the device DDR RAM.

32.3.7.7.3 System Conditions and Limitations for SATA Boot

The following system conditions and limitations are defined by ROM Code implementation:

- The ROM Code sets Gen2 speed (3 Gbps) for a SATA boot operation.
- The ROM Code expects that the SATA I/Os are connected to device SATA subsystem at system reset (i.e. a permanently attached boot device).
- The ROM Code expects that the SATA device is powered externally and supplies are set and stable upon entering the booting procedure. The ROM Code does not perform any software action to the companion device with respect to powering the SATA device.
- The ROM Code allows the SATA device 300ms power on ready time before starting the device detection. In case that the detection fails, the ROM Code retries 3 times with 200ms delay before returning and reporting a SATA boot failure.
- The ROM Code does not handle or enable advanced SATA power modes (slumber and partial).

The ROM Code initializes SATA subsystem after SATA boot is started, as defined in this chapter. The ROM Code does not close SATA connection after it was initialized following procedure defined in Section 32.3.4.5, *Booting Device List Setup*.

32.3.7.7.4 SATA Read Sector Procedure in FAT Mode

The booting medium may hold a FAT file system which the ROM Code is able to read and process. The image used by the booting procedure is taken from a specific booting file named "HLO". This file has to be located in the root directory on an active primary partition of FAT12/16 or FAT32 type.

A SATA drive can be configured either as floppy-like or hard-drive-like.

- When acting as floppy-like, the content of the card is a single file system without any **Master Boot Record (MBR)** holding a partition table.
- When acting as hard-drive-like, a **MBR** is present in the first sector of the card. This **MBR** holds a table of partitions, one of which must be **FAT12/16/32, primary and active**.

Refer to the Section 32.3.7.6.5.1, *MBR and FAT File System*, for a more detailed description of FAT file system support.

32.3.8 Image Format

32.3.8.1 Overview

An image has two major parts:

- An optional CH
- Software to execute

The CH can contain several parameters set by users to speed up booting. It is further described in Section 32.3.8.2, *Configuration Header*.

The second part contains the software that is loaded into the memory and executed.

Figure 32-32 is an overview of the boot image formats. There are two image types:

1. Non-XIP memory booting: This image type is used for memories that require shadowing (for example, NAND). An image for non-XIP memory may not contain a CH and start straight from the GP header. Next, there must be a small header (referred to as a GP header) that contains information about the size and the destination address.
2. When the memory device is of XIP type (for example, NOR), the GP header is not required, and the image can contain code for direct execution. Optionally, the first sector can contain a CH. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

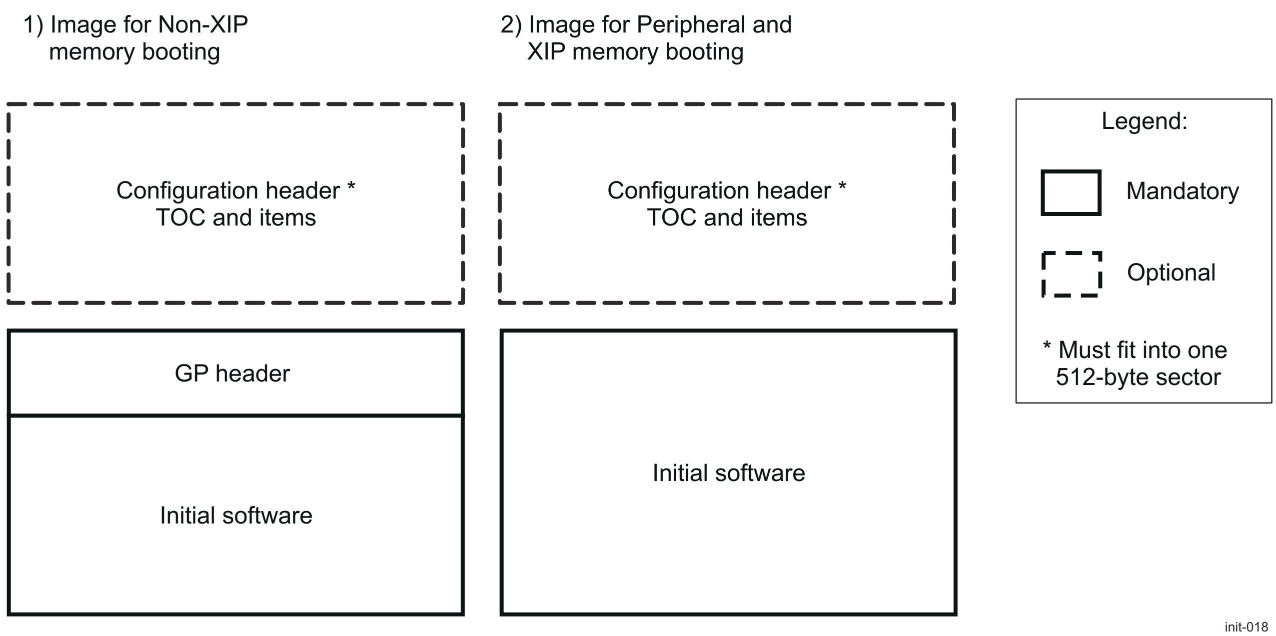

Figure 32-32. Image Formats

32.3.8.2 Configuration Header

The ROM code default settings (such as clock frequencies, EMIF, GPMC, MMCHS, or QSPI interfaces) can be tuned by the user by using the CH.

The CH can contain the following parts:

- Settings: Various clock settings (mandatory)
- FLASH: Flash interface (GPMC) settings
- eMMC/SD: MMC2/MMC1 interface settings
- QSPI: QSPI interface settings

The beginning of the CH is a table of contents (TOC), which points to each item. This is described in Figure 32-33. Each TOC item is a simple structure described in Table 32-47. The complete CH (CH TOC and items) should fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHFLASH, etc.). Next, the TOC is identified and searched until a 0xFFFF FFFF offset is found. The CH is read and parameters are executed sequentially.

For the sake of simplicity, each field represents the content of a register to be modified. Only fields required for the configuration are used; fields for status, for instance, are not modified and therefore are not shown in the tables.

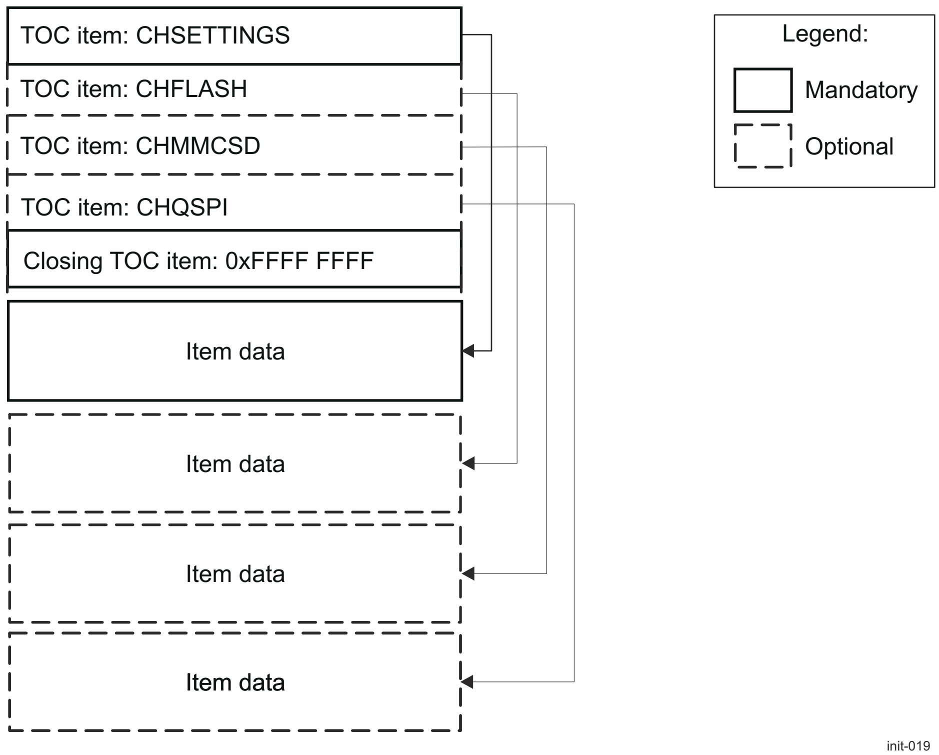

Figure 32-33. CH Format

Table 32-47. CH TOC Item

Offset	Field	Size (Bytes)	Description
0x0000	Start	4	Offset from the start address of the TOC to the actual address of item contents
0x0004	Size	4	Size of item
0x0008	Reserved	4	Unused
0x000C	Reserved	4	Unused
0x0010	Reserved	4	Unused
0x0014	TOC Filename	12	12-character name of a TOC item, including the NULL termination character. That is, this is an array where first byte accomodates the first character.

The ROM Code recognizes sections pointed to by the TOC based on the filename as described in Table 32-48

- The ‘X-LOADER’, ‘2ND', ‘MLO’, ‘ULO’, or ‘HLO’ section contains the Initial Software
- Optionally, TOC may contain CH sections. The 'CHSETTINGS' is a mandatory section of CH and is used to recognize CH presence.

Table 32-48. TOC Filenames

Filename	Item Type	Usage	Description
MLO	Initial Software	eMMC/SD Memory Booting	“Mmc LOader”
HLO	Initial Software	SATA Memory Booting	“Hdd LOader”
ULO	Initial Software	USB or UART Peripheral Booting	“Usb LOader”
2ND	Initial Software	USB or UART Peripheral Booting	“Secondary Loader”
X-LOADER	Initial Software	Other devices	“eXternal LOADER”
CHSETTINGS	Configuration Header	Memory and Peripheral Booting	Configuration Header General Setting Item
CHFLASH	Configuration Header	Memory and Peripheral Booting	Configuration Header GPMC Item
CHMMCSD	Configuration Header	Memory and Peripheral Booting	Configuration Header eMMC/SD Item
CHQSPI	Configuration Header	Memory and Peripheral Booting	Configuration Header QSPI Item

32.3.8.2.1 CHSETTINGS Item

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the device clocking to some default settings as described in Section 32.3.4.4, *Clocking Configuration*. The CH CHSETTINGS section contains a method to override the ROM code default clock settings.

Table 32-49 describes the fields.

Table 32-49. CHSETTINGS Item

Offset	Field	Description
0000h	Section key	Key used for item verification: C0C0C0C1h
0004h	Valid	Enables/disables the section: 00h: Disable Others: Enable
0005h	Version	Configuration header version 01h Others: Reserved
0006h	Reserved	
0008h	Clocking settings	See Table 32-50.

Table 32-50. Clocking Settings

Field	Size (Bytes)	Description
Flags		
Flags	4	Bit mask of various switches, active when set to 1: Bit [0]: Clock configuration defined in this structure is applied. Bit [1]: Reserved Bit [2]: Apply general clock settings. Bit [3]: Set and lock DPLL_PER. Bit [4]: Set and lock DPLL_MPU. Bit [5]: Set and lock DPLL_CORE. Bit [6]: Set and lock DPLL_USB (USB HS DPLL). Bit [7]: Bypass DPLL_PER before setting clocks. Bit [8]: Bypass DPLL_MPU before setting clocks. Bit [9]: Bypass DPLL_CORE before setting clocks. Bit [10]: Bypass DPLL_USB (USB HS DPLL) before setting clocks. Others: Reserved

32.3.8.2.2 CHFLASH Item

The CHFLASH configuration header contains settings specific to the general-purpose memory controller (GPMC). For more information, see Section 15.4, *General-Purpose Memory Controller*. Table 32-51 describes the fields.

Table 32-51. CHFLASH Item

Offset	Field	Description
0000h	Section Key	Key used for section verification: C0C0C0C3h.
0004h	Valid	Enables/disables the section: 00h: Disable Others: Enable
0005h	Reserved	
0008h	GPMC_SYSCONFIG (LSW)	Register values
000Ah	GPMC_IRQENABLE (LSW)	
000Ch	GPMC_TIMEOUT_CONTROL (LSW)	
000Eh	GPMC_CONFIG (LSW)	
0010h	GPMC_CONFIG1_0	
0014h	GPMC_CONFIG2_0	
0018h	GPMC_CONFIG3_0	
001Ch	GPMC_CONFIG4_0	
0020h	GPMC_CONFIG5_0	
0024h	GPMC_CONFIG6_0	
0028h	GPMC_CONFIG7_0	
002Ch	GPMC_PREFETCH_CONFIG1	
0030h	GPMC_PREFETCH_CONFIG2 (LSW)	
0032h	GPMC_PREFETCH_CONTROL (LSW)	
0034h	GPMC_ECC_CONFIG (LSW)	
0036h	GPMC_ECC_CONTROL (LSW)	
0038h	GPMC_ECC_SIZE_CONFIG	
003Ch	Reserved	

32.3.8.2.3 CHMMCSD Item

The CHMMCSD configuration header contains settings specific to the high-speed MMC/SD/SDIO host controller (MMCHS). For more information, see Chapter 25, *eMMC/SD/SDIO*. Table 32-52 describes the fields.

Table 32-52. CHMMCSD Item

Offset	Field	Description
0000h	Section key	Key used for section verification C0C0C0C4h
0004h	Valid	Enables/disables the section: 00h: Disable Other: Enable
0005h	Reserved	
0008h	CLKD	Functional clock divisor MMCHS_SYSCTL[15:6] CLKD = 0x0: FCLK/1 0x1: FCLK/1 0x2: FCLK/2 … 0x3FF: FCLK/1023 0xFFFF FFFF: Do not modify clock divisor

Table 32-52. CHMMCSD Item (continued)

Offset	Field	Description
000Ch	MMCHS interface bus width	Configure the MMCHS interface bus width according to the field value : 1: Configured to 1 bit (SDR) 2: Configured to 4 bits (SDR) 4: Configured to 8 bits (SDR)(1) 8: Configured to 4 bits (DDR)(1) 16: Configured to 8 bits (DDR)(1) 0xFFFF FFFF: Do not update bus width. Others: Reserved

(1) The 8 bit SDR and 4-bit/8-bit DDR (values 4, 8, and 16) are only applicable to eMMC devices.

The ROM code provides a booting parameter structure to the initial software (see Section 32.3.8.4, *Image Execution*). This structure contains a field that indicates whether the configuration header items have been correctly processed. For a CHMMCSD item, if the MMCHS_SYSCTL and bus width fields are set to 0xFFFF FFFF, the booting parameters report that the CHMMCSD section has not been executed, regardless of the value of the Valid field.

32.3.8.2.4 CHQSPI Item

The CHQSPI configuration header contains settings specific to the QSPI interface controller. For more information, see Section 24.5, *Quad Serial Peripherial Interface*. Table 32-53 describes the fields.

Table 32-53. CHQSPI Item

Offset	Register Field Modified	Description
0000h	Section key	Key used for section verification C0C0C0C6h
0004h	Valid	Enables/disables the section: 00h: Disable Other: Enable
0005h	Reserved	
0008h	SPI Clock	SPI clock rate: 0x03: 32 MHz 0x07: 16 MHz 0x13: 48 MHz 0x17: 24 MHz 0x1F: 12 MHz All other: reserved
0009h	RCMD	Read command
000Ah	READ_TYPE	Determines if the read command is a single, dual or quad read mode command
000Bh	NUM_A_BYTES	Number of address bytes to be sent
000Ch	NUM_D_BYTES	Number of dummy bytes to be used for fast read

32.3.8.3 GP Header

When the booting memory device is non-XIP (for example, NAND) the image must contain a small header, located before the executable code, and having the size of the software to load and the destination address of where to store it. Table 32-54 describes the image format. The GP header is not required when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

Table 32-54. GP Header Image Format

Field	Non-XIP Device Offset	XIP Device Offset	Size (Bytes)	Description
Size	0x0000	–	4	Size of the image (including GP header)
Destination	0x0004	–	4	Address where to store the code or code entry point
Image Code	0x0008	0x0000	x	Executable code

Note

The Destination address field stands for:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

Users must take care to locate the code entry point to the target address for image copy.

32.3.8.4 Image Execution

The image is executed when the ROM code performs the branch to the first executable instruction in the initial software. In non-XIP, the execution address is the first word after the GP header. The branch is performed in public Arm supervisor mode. The R0 register points to the booting parameter structure that contains information about booting execution. Table 32-55 shows the booting parameter structure.

Table 32-55. Booting Parameter Structure

Offset	Field	Size (Bytes)	Description
0x00	Booting message	4	Last received booting message
0x04	Memory booting device descriptor	4	Pointer to the memory device descriptor that has been used during the memory booting process
0x08	Current booting device	1	Code of device used for booting: 0x01: XIP 0x02: XIP (with wait monitoring) 0x03: NAND 0x05: SD cards 0x06: eMMC (boot partition) 0x07: eMMC 0x09: SATA 0x0A: QSPI_1 0x0B: QSPI_4 0x43: UART 0x45: USB Others: Reserved
0x09	Reset reason	1	Current reset reason bit mask (bit = 1, event present): direct copy from lower byte of PRM_RSTST (more bits exist in PRM_RSTST): [0]: Power-on (cold) reset [1]: Global software warm reset [2]: Reserved [3]: MPU watchdog reset [4]: Reserved [5]: External warm reset [6]: VDD_MPU voltage manager reset

Table 32-55. Booting Parameter Structure (continued)

Offset	Field	Size (Bytes)	Description
			[7]: VDD_MM voltage manager reset
0x0A	CH flags	1	Configuration header items flag. Each item is described by 1 bit. A set bit indicates that the item was executed: [0]: CHSETTINGS [2]: CHFLASH [3]: CHMMCSD [4]: CHQSPI Other bits: Reserved

32.3.9 Tracing

Tracing in the public ROM code consists in 32-bit vectors for which each bit corresponds to a particular way point in the ROM code execution sequence. Table 32-56 through Table 32-59 list the organization of the tracing data in RAM. Tracing vectors are initialized at the beginning of the start-up phase and are updated all along the boot process.

There are two sets of tracing vectors (Table 32-14, *Tracing Data)*. The first set is the current trace information (after a cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM code run after a cold reset. As a result, after a warm reset it is possible to have visibility on the boot scenario that occurred during a cold reset.

Table 32-56 lists the organization of tracing vector 1.

Table 32-56. Tracing Vector 1

Bit	Group	Meaning
0	Boot	Passed the public reset vector
1	Boot	Entered main function
2	Boot	Running after the cold reset
3	Boot	Main booting routine entered
4	Memory boot	Memory booting started
5	Peripheral boot	Peripheral booting started
6	Boot	Booting loop reached last device
7	Boot	GP header found
8	Peripheral Boot	Booting message Skip peripheral booting received
9	Peripheral Boot	Booting message Change device received
10	Peripheral boot	Booting message Peripheral booting received

0:23	Reserved	
24	MMC/SD	SD card detected PBIAS configuration is 1.8V
25:27	Reserved	
28	SATA	SATA is configured
29	SATA	SATA retried
30	SATA	SATA failed
31	Reserved	

32.4 Services for HLOS Support

The ROM code provides different services that can be called for L1 and L2 cache maintenance, Enter in Low Power, etc. These services are implemented in monitor mode and must be called by using the SMC instruction. The caller must ensure the save and restore of the processor registers before and after calling the Monitor Service.

The following code example shows how the monitor ROM code functions can be accessed by an application running in public mode:

```
;-------------------------------------------------------------------------------
; FUNCTION: SetL2CacheLatency
;
; DESCRIPTION: Function calls the Monitor Service to setup the L2 Cache Latency
;
; INPUTS:  r0 Tag RAM Latency to set
;          r1 Data RAM Latency to set
; RETURN:
;
;-------------------------------------------------------------------------------
SetL2CacheLatency           FUNCTION

  PUSH {R1-R12, LR}
  LDR R12, =0x105
  SMC 0x1
  POP {R1-R12, PC}
  ENDFUNC
```

32.4.1 Hypervisor

Table 32-60. Start Hypervisor

Function ID	Description	
R12 = 0x102	This function starts the CPU Hypervisor mode. Start address of the Hypervisor software must be given in R0.	
Parameters		
Type	**Location**	**Description**
Input	R0	Start address of the Hypervisor software
Output		
Return		

32.4.2 Caches Maintenance

Table 32-61. Clean L1 and/or L2 cache

Function ID	Description	
R12 = 0x103	This function cleans and invalidates the CPU L1-cache and if requested in the input parameter R0, clean the full L2-cache.	
Parameters		
Type	**Location**	**Description**
Input	R0	If not equal to 0, clean L2-cache
Output		
Return		

32.4.3 CP15 Registers

Table 32-62. Write L2 Cache Auxiliary Control

Function ID	Description
R12 = 0x104	This function writes the CP15 L2 Cache Auxiliary Control Register with the input given value in R0.
Parameters	

Table 32-62. Write L2 Cache Auxiliary Control (continued)

Function ID	Description	
Type	**Location**	**Description**
Input	R0	Value to set in the register
Output		
Return		

Table 32-63. Write Tag and Data RAM Latency Control Register

Function ID	Description	
R12 = 0x105	This function writes the L2 Cache Tag and Data RAM Latency in the CP15 L2 Control Register with the input given value in R0 and R1.	
Parameters		
Type	**Location**	**Description**
Input	R0 R1	Tag RAM Latency to set Data RAM Latency to set
Output		
Return		

Table 32-64. Write L2 Cache Prefetch Control Register

Function ID	Description	
R12 = 0x106	This function writes the CP15 L2 Cache Prefetch Control Register with the input given value in R0.	
Parameters		
Type	**Location**	**Description**
Input	R0	Value to set in the register
Output		
Return		

Table 32-65. Write Auxiliary Control Register

Function ID	Description	
R12 = 0x107	This function writes the CP15 Auxiliary Control Register with the input given value in R0.	
Parameters		
Type	**Location**	**Description**
Input	R0	Value to set in the register
Output		
Return		

32.4.4 Wakeup Generator

Table 32-66. Write AMBA IF Register

Function ID	Description	
R12 = 0x108	This function writes the WakeupGen AMBA I/F Register with the input given value in R0.	
Parameters		
Type	**Location**	**Description**
Input	R0	Value to set in the register
Output		
Return		

32.4.5 Arm Timer

Table 32-67. Set Timer CNTFRQ Register

Function ID	Description	
R12 = 0x109	This function sets the Arm Timer CNTFRQ (CP15 register) with the input given value in R0.	
Parameters		
Type	**Location**	**Description**
Input	R0	Value to set in the register
Output		
Return		

Chapter 33

On-Chip Debug Support

This chapter describes the on-chip debug support.

Note

The L3_MAIN interconnect is instantiation of the NoC interconnect from Arteris, Inc. Arteris is a registered trademark of Arteris, Inc.

33.1 Introduction

Debugging a system that contains an embedded processor involves an environment that connects high-level debugging software running on a host computer to a low-level debug interface supported by the target device. Between these levels, a debug and trace controller (DTC) facilitates communication between the host debugger and the debug support logic on the target chip.

The DTC is a combination of hardware and software that connects the host debugger to the target system. The DTC uses one or more hardware interfaces and/or protocols to convert actions dictated by the debugger user to JTAG® commands and scans that execute the core hardware.

The debug software and hardware components let the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors
- Starting and stopping of an individual processor
- Each processor can generate triggers that can be used to alter the execution flow of other processors

System topics include but are not limited to:

- System clocking and power-down issues
- Interconnection of multiple devices
- Trigger channels

For easy integration into applications, a set of application-programming interfaces (APIs) for debug-IP programming and a software message library are provided. CToolsLib is a library of embedded target APIs to enable easy programmatic access to the chip tools (CTools), which are system-level debug facilities included in the debug subsystem capabilities of TI devices. More information about the APIs, download files, and other useful links for available libraries can be found on the CToolsLib Wiki site:

http://processors.wiki.ti.com/index.php/CToolsLib

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

Note

TI also provides a Register Descriptor Tool (RDT). The RDT is a Java™- based stand-alone application. It is an interactive device register database configuration software. It allows the user to:

- Visualize device register settings
- Manipulate device registers easily
- Read in complete device configurations from various file formats into registers easily
- Dump out complete device configurations to various file formats
- Trace the register changes in time and during debugging
- See, understand, and work with device IPs, Instances, Registers, Bitfields, descriptions, and so on
- Extract and read in registers and register dumps for Code Composer Studio, and Lauterbach

The advantage of the tool is that the user can visualize the register state on power-on reset and then customize the configuration of the device for the specific use-case and identify the device register settings associated to that configuration.

Being an interactive visual tool, the RDT gives the user a global view of the device setting architecture and allows determining the exact register settings to obtain the specific configuration.

Figure 33-1 is a screenshot diagram of the RDT.

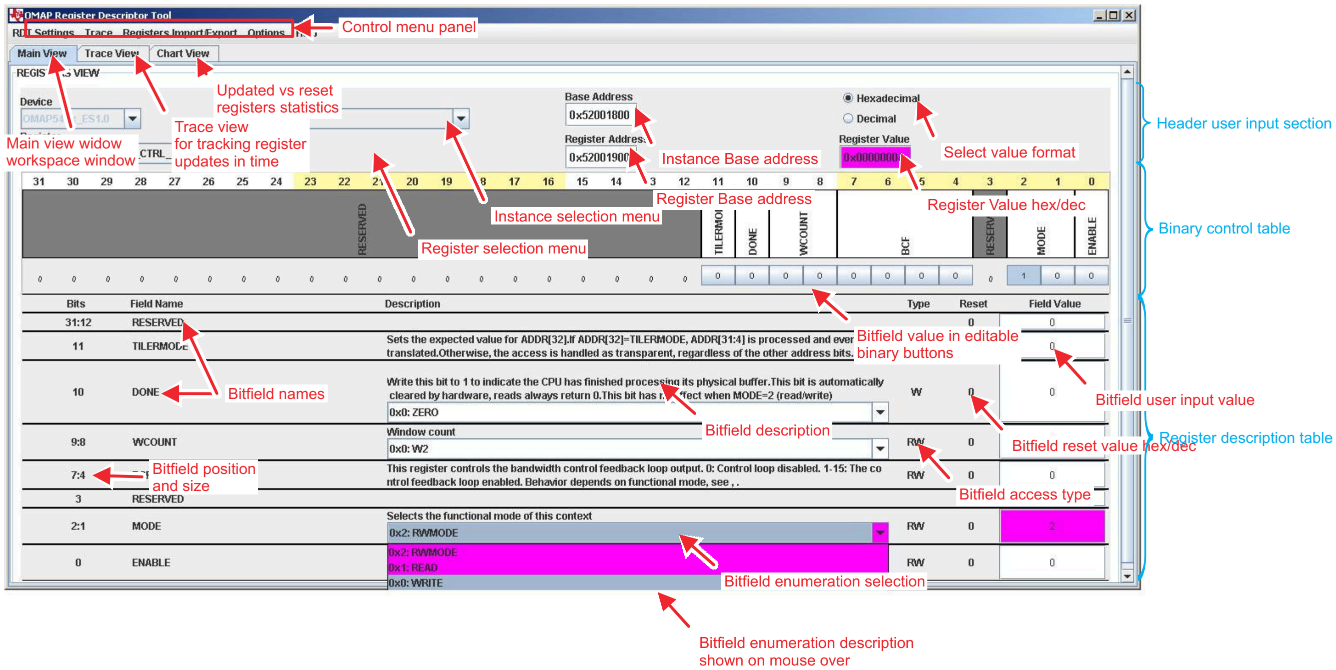

Figure 33-1. Register Descriptor Tool (RDT)

33.1.1 Key Features

The device deploys Texas Instrument's CTools debug technology for on-chip debug and trace support. It provides the following features:

- External debug interfaces:
  - Primary debug interface - IEEE1149.1 (JTAG)
    - Used for debugger connection
    - Controls ICEPick™ (generic test access port [TAP] for dynamic TAP insertion) to allow the debugger to access several debug resources through its secondary (output) JTAG ports (for more information, see Section 33.3.3.1, *ICEPick Secondary TAPs*).
    - For more information about IEEE1149.1, see Section 33.2.1, *IEEE1149.1*.
  - Debug (trace) port
    - Can be used to export processor or system trace off-chip (to an external trace receiver)
    - Can be used for cross-triggering with an external device
    - Configured through debug resources manager (DRM) module instantiated in the debug subsystem
    - For more information about debug (trace) port, see Section 33.2.2, *Debug (Trace) Port* , and Section 33.11, *Concurrent Debug Modes*.
- JTAG based processor debug on:
  - Cortex-A15 (x2) in MPU
  - C66x in DSP1, DSP2
  - Cortex-M4 (x2) in IPU1, IPU2
  - Arm968 (x2) in IVA
  - ARP32 in EVE1, EVE2
- Dynamic TAP insertion
  - Controlled by ICEPick
  - For more information, see Section 33.3.3, *Dynamic TAP Insertion.*
- Power and clock management
  - Debugger can get the status of the power domain associated to each TAP.
  - Debugger may prevent the application software switching off the power domain.
  - Application power management behavior can be preserved during debug across power transitions.

  - For more information, see Section 33.6.1, *Power and Clock Management.*
- Reset management
  - Debugger can configure ICEPick to assert, block, or extend the reset of a given subsystem.
  - For more information, see Section 33.6.2, *Reset Management.*
- Cross-triggering
  - Provides a way to propagate debug (trigger) events from one processor, subsystem, or module to another:
    - Subsystem A can be programmed to generate a debug event, which can then be exported as a global trigger across the device.
    - Subsystem B can be programmed to be sensitive to the trigger line input and to generate an action on trigger detection.
  - Two global trigger lines are implemented
  - Device-level cross-triggering is handled by the XTRIG (TI cross-trigger) module implemented in the debug subsystem
  - Various Arm® CoreSight™ cross-trigger modules implemented to provide support for CoreSight triggers distribution
    - CoreSight Cross-Trigger Interface (CS_CTI) modules
    - CoreSight Cross-Trigger Matrix (CS_CTM) modules
  - For more information about cross-triggering, see Section 33.4.2, *Cross-Triggering.*
- Suspend
  - Provides a way to stop a closely coupled hardware process running on a peripheral module when the host processor enters debug state
  - For more information about suspend, see Section 33.4.3, *Suspend.*
- MPU watchpoint
  - Embedded in MPU subsystem
  - Provides visibility on MPU to EMIF direct paths
  - For more information, see Section 33.8, *MPU Memory Adaptor (MPU_MA) Watchpoint*
- Processor trace
  - Cortex-A15 (MPU) and C66x (DSP) processor trace is supported
  - Program trace only for MPU (no data trace)
  - MPU trace supported by a CoreSight Program Trace Macrocell (CS_PTM) module (per MPU core)
  - Three exclusive trace sinks:
    - CoreSight Trace Port Interface Unit (CS_TPIU) – trace export to an external trace receiver
    - CTools Trace Buffer Router (CT_TBR) in system bridge mode – trace export through USB
    - CT_TBR in buffer mode – trace history store into on-chip trace buffer
  - For more information, see Section 33.9, *Processor Trace.*
- System instrumentation (trace)
  - Supported by a CTools System Trace Module (CT_STM), implementing MIPI System Trace Protocol (STP) (rev 2.0)
  - Real-time software trace
    - MPU software instrumentation through CoreSight STM (CS_STM) (STP2.0)
    - System-on-chip (SoC) software instrumentation through CT_STM (STP2.0)
  - OCP watchpoint (OCP_WP_NOC)
    - OCP target traffic monitoring: OCP_WP_NOC can be configured to generate a trigger upon watchpoint match (that is, when target transaction attributes match the user-defined attributes).
    - SoC events trace
    - DMA transfer profiling
  - Statistics collector (performance probes)
    - Computes traffic statistics within a user-defined window and periodically reports to the user through the CT_STM interface
    - Embedded in the L3_MAIN interconnect
    - 10 instances:
      - 1 instance dedicated to target (SDRAM) load monitoring
      - 9 instances dedicated to master latency monitoring

  - IVA instrumentation (hardware accelerator [HWA] profiling)
    - Supported through a software message and system trace event (SMSET) module embedded in the IVA subsystem
  - EVE instrumentation (hardware accelerator [HWA] profiling)
    - Supported through a software message and system trace event (SMSET) module embedded in the EVE subsystem
  - Power-management events profiling (PM instrumentation [PMI])
    - Monitoring major power-management events. The PM state changes are handled as generic events and encapsulated in STP messages.
  - Clock-management events profiling (CM instrumentation [CMI]) for CM_CORE_AON clocks
    - Monitoring major clock management events. The CM state changes are handled as generic events and encapsulated in STP messages.
  - For more information, see Section 33.10, *System Instrumentation.*
- Performance monitoring
  - Supported by subsystem counter timer module (SCTM) for IPU
  - Supported by performance monitoring unit (PMU) for MPU subsystem
  - For more information, see Section 33.7, *Performance Monitoring*.

33.2 Debug Interfaces

33.2.1 IEEE1149.1

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals: nTRST, TCK, TMS, TDI, and TDO
- A return clock (RTCK) due to the clocking requirements of the Arm968™ processor
- Two EMU [1:0] TI extensions

Table 33-1 describes the IEEE1149.1 signals.

Table 33-1. IEEE1149.1 Signals

Device Pad Name	Internal Signal Name	Type(1)	Function	Description
trstn	nTRST	I	Test reset	When asserted (active low), resets all test and debug logic in the device along with the IEEE1149.1 interface.
tclk	TCK	I	Test clock	This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. This is either a free-running clock or a gated clock, depending on the DTC attached to the device and the RTCK monitoring.
rtck	RTCK	O	Returned (synchronized) test clock	Depending on the DTC attached to the device, the JTAG signals are either clocked from RTCK or the RTCK is monitored by the DTC to the gate TCK.
tms	TMS	I/O	Test mode select input	Directs the next state of the IEEE1149.1 TAP state-machine.
tdi	TDI	I	Test data input	Scans data input to the device.
tdo	TDO	O	Test data output	Scans data output by the device.
emu0	EMU0	I/O	Emulation 0	Channel 0 trigger or boot mode or trace port.
emu1	EMU1	I/O	Emulation 1	Channel 1 trigger or boot mode or trace port.

(1) I = Input; O = Output; I/O = bidirectional

Note

For more information about device pads pull type resistors, see the device Data Manual, Section Signal Descriptions in Chapter Terminal Configuration and Functions.

Note

The device JTAG ID code can be accessed through ICEPick. For information about the JTAG ID code value, see Chapter 1, *Introduction*.

33.2.2 Debug (Trace) Port

On-chip debug and trace events can be exported to external equipment through the debug (trace) port of the device. The following exportable debug events and trace sources are supported:

- Debug events
  - Triggers. For more information about triggers, see Section 33.4.2, *Cross-Triggering*.
- Trace sources
  - Processor trace: Cortex-A15 MPU and C66x DSP traces are supported. For more information about the processor trace, see Section 33.9, *Processor Trace*.
  - System trace: Trace coming from various system instrumentation modules, and supported by the CT_STM module. For more information about the system trace, see Section 33.10, *System Instrumentation*.

Note that not all debug and trace features can be supported concurrently because of the limited number of pins allocated to debug. Thus, multiplexing among debug and trace sources is implemented. The configuration and the debug/trace source selection occur through the DRM module embedded in the debug subsystem.

Table 33-2 describes the trace port signals.

Table 33-2. Trace Port Signals

Pin Name	Internal Signal Name	I/O(1)	Pull Type (2)	Description
emu19	EMU19	O	PD	Emulator pin 19
emu18	EMU18	O	PD	Emulator pin 18
emu17	EMU17	O	PD	Emulator pin 17
emu16	EMU16	O	PD	Emulator pin 16
emu15	EMU15	O	PD	Emulator pin 15
emu14	EMU14	O	PD	Emulator pin 14
emu13	EMU13	O	PD	Emulator pin 13
emu12	EMU12	O	PD	Emulator pin 12
emu11	EMU11	O	PD	Emulator pin 11
emu10	EMU10	O	PD	Emulator pin 10
emu9	EMU9	O	PD	Emulator pin 9
emu8	EMU8	O	PD	Emulator pin 8
emu7	EMU7	O	PD	Emulator pin 7
emu6	EMU6	O	PD	Emulator pin 6
emu5	EMU5	O	PD	Emulator pin 5
emu4	EMU4	O	PD	Emulator pin 4
emu3	EMU3	O	PD	Emulator pin 3
emu2	EMU2	O	PD	Emulator pin 2
emu1	EMU1	I/O	PU	Emulator pin 1
emu0	EMU0	I/O	PU	Emulator pin 0

(1) I = Input; O = Output; I/O = bidirectional
(2) PU = internal pullup; PD = internal pulldown

Note

The emu[19:0] pins are shared with other functional (application) pins on the device boundary. To use the emu[19:0] pins, the user must program the device application pin manager (Control Module) appropriately. For more information, see Chapter 18, *Control Module*.

For more information about DRM multiplexing and concurrent debug modes, see Section 33.11, *Concurrent Debug Modes*.

33.2.3 Trace Connector and Board Layout Considerations

Texas Instruments supports a variety of eXtended Development System (XDS) JTAG controllers with various debug capabilities beyond only JTAG support. Because this device supports the export of processor trace and system trace over the EMU pins, if you want your target to be compatible with XDS products capable of acquiring either trace types, see the following document for guidelines: *Emulation and Trace Headers* (literature number SPRU655). You can also find more information at the “XDS Target Connection Guide” TI wiki page:

http://processors.wiki.ti.com/index.php/XDS_Target_Connection_Guide

The previous link connects to TI community resources. Linked contents are provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

33.3 Debugger Connection

33.3.1 ICEPick Module

The debugger connects to the device through its JTAG interface. The first level of debug interface seen by the debugger is the ICEPick module embedded in the debug subsystem.

Note

ICEPick version D (ICEPick-D) is used in the device.

SoC designs typically have multiple processors, each having a JTAG TAP embedded in the processor. The ICEPick module manages these TAPs and the power, reset, and clock controls for modules that have TAPs.

The ICEPick module is visible only from the debugger point of view and thus cannot be programmed by application software. The debugger can configure ICEPick through its own TAP controller. The ICEPick TAP has an instruction length of 6 bits and is the primary TAP. It is always visible in the scan chain and is used to control and monitor the other secondary TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion
  – Serially linking up to 32 TAP controllers
  – Individually selecting one or more of the TAPs for scan without disrupting the instruction register (IR) state of other TAPs
- Power, reset, and clock management (PRCM)
  – Provides the power and clock states of each domain
  – Provides debugger control of the power domain of a processor. Can force the domain power and clocks on, and prohibit the domain from being clock-gated or powered down while a debugger is connected.
  – Applies system reset
  – Provides wait-in-reset (WIR) boot mode
  – Provides global and local WIR release
  – Provides global and local reset blocking

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. Once the debug connect key is properly programmed, ICEPick signals and subsystems emulation logics should be turned on.

For more information about ICEPick dynamic TAP insertion, see Section 33.3.3, *Dynamic TAP Insertion*.

For more information about ICEPick PRCM features, see Section 33.6, *Power, Reset, and Clock Management Debug Support*.

33.3.2 ICEPick Boot Modes

The initial configuration of ICEPick is determined by the level of the EMU0 and EMU1 pins at POR release. At POR, EMU0 and EMU1 are automatically configured as inputs. The EMU0 and EMU1 pins are free when POR is released.

Table 33-3 summarizes the ICEPick boot modes.

Table 33-3. ICEPick Boot Modes at POR

EMU1	EMU0	TAPs in the TDI → TDO Path	Other Effects/Comments
0	0	None	Reserved (do not use)
0	1	None	Reserved (do not use)
1	0	ICEPick	TAP only + WIR mode
1	1	ICEPick	TAP only (default mode)

33.3.2.1 Default Boot Mode

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This mode is the recommended boot mode.

33.3.2.2 Wait-In-Reset

The device can boot to invoke WIR mode. If the device is booted in this mode, all processors within the device that support a TAP through ICEPick are held in reset until released. Individual processors can be released from reset (local), or all processors held in the reset state can be released at the same time (global).

33.3.3 Dynamic TAP Insertion

33.3.3.1 ICEPick Secondary TAPs

To include more or fewer secondary TAPs in the scan chain, the debugger must use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the DTC selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. From the external JTAG interface point of view, secondary TAPs that are not selected appear not to exist.

Table 33-4 lists the secondary debug TAPs connected to the ICEPick scan chain along with the modules that can be accessed. The TAP number shows the position of the TAP in the scan chain.

Table 33-4. ICEPick Secondary Debug TAPs Mapping

Note

1. MPU_MA watchpoint programming is restricted to the MPU. Programming from the CS_DAP APB access port is not supported.
2. The MPU timestamp registers are part of the MPU_PRCM programming model and can be accesses from the two MPU cores.

For more information about ICEPick scan sequences (adding one or more TAPs to the scan chain), see:

http://processors.wiki.ti.com/images/f/f6/Router_Scan_Sequence-ICEpick-D.pdf

The preceding links connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect the views of TI; see the TI Terms of Use.

Besides secondary debug TAPs, ICEPick also supports power, reset, and clock controls for non-JTAG debug cores. The debug cores are accessible through CS_DAP.

Table 33-5 summarizes the ICEPick debug core mapping.

33.4 Primary Debug Support

33.4.1 Processor Native Debug Support

33.4.1.1 Cortex-A15 Processor

The dual Cortex-A15 processor supports the following native debug features:

- Halt mode and monitor mode debugging
- Six breakpoints and four watchpoints
- Asynchronous aborts
- Performance monitoring
- Cross-triggering: Allows stopping one CPU upon debug event (for example, breakpoint) detection in the other CPU

For more information about Cortex-A15 native debug support features, see the *Cortex-A15 Technical Reference Manual*.

33.4.1.2 Cortex-M4 Processor

The Cortex-M4 processor supports the following native debug features:

- Program halt and stepping
- Hardware breakpoints, breakpoint instruction
- Data watchpoint on access to data add, add range, and data value
- Register value accesses
- Debug monitor exception
- Memories accesses

For more information about Cortex-M4 native debug support features, see the *Cortex-M4 Technical Reference Manual*.

33.4.1.3 DSP C66x

The main components of the DSP subsystem are:

- TMS320C66x DSP core with an execution control and analysis module that uses TI's ICEMaker™ technology. The core includes the following debug capabilities:
  - Up to four hardware breakpoints and a breakpoint counter
  - Software breakpoints
  - Internally and externally generated triggers
  - Reset control
  - Emulation interrupt support
  - Modes for debugging without halting time-critical blocks of code
  - Options to protect user-selected blocks of code against debug activity
- Emulation memory access hardware. This hardware enables several methods for reading and writing memory and registers in the DSP subsystem during debugging.
- Advanced Event Triggering (AET) unit is used to generate debug actions for managing breakpoints, watchpoint, trace, timers/counters, event outputs to external logic of DSP, based on events detected by instruction and data bus comparators or by auxiliary event detectors. DSP's AET can also handle complex events with event state machine and event counters.

33.4.1.4 IVA Arm968

The Arm968E-S processor (in each ICONT) supports the following native debug features through its EmbeddedICE-RT logic:

- Two hardware watchpoints/breakpoints
- Halt mode and monitor mode debugging
- Debug control and status registers
- Debug communications channel

For more information about Arm968 native debug support features, see the *Arm968E-S Technical Reference Manual*.

33.4.1.5 ARP32

The APR32 processor in the EVE subsystem offers the following debug capabilities:

- Manual halt
- Single-step execution
- Breakpoint
- Cross-triggering
- Global run

33.4.1.6

33.4.2 Cross-Triggering

The device supports a cross-triggering feature that provides a way to propagate debug (trigger) events from one processor subsystem/module to another. For example, a given subsystem A can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another subsystem B can be programmed to be sensitive to the trigger line input and to generate an action on trigger detection.

Examples of debug events are: Processor entering debug state, watchpoint match, CS_PTM trigger, and so forth.

Examples of debug actions are: Debug request generation, restart (Cortex-A15 synchronous run), interrupt request generation, start/stop trace, and so forth.

The device implements two global cross-triggering lines: Trigger0 and Trigger1, also referred to as EMU0 and EMU1, respectively.

Subsystem cross-triggering is consolidated at the device level by the XTRIG module, which is embedded in the debug subsystem.

Note

XTRIG is not programmatically visible from the JTAG interface or any device processor. Thus, cross-triggering is programmed at the subsystem level.

The Trigger0 and Trigger1 lines can also be configured as external triggers and contribute to cross-triggering.

33.4.2.1 SoC-Level Cross-Triggering

Device-level cross-triggering is handled by the XTRIG module. XTRIG manages two emulation triggers: Trigger0 and Trigger1. These trigger lines are shared by all the device subsystems implementing cross-triggering and are used to facilitate co-emulation.

Table 33-6 summarizes the device cross-triggering capabilities.

Table 33-6. Device Cross-Triggering

33.4.2.2 Cross-Triggering With External Device

Based on DRM settings, the Trigger0 and Trigger1 lines may also be used as external triggers. Trigger0 is connected to the EMU0 device pin, and Trigger1 is connected to the EMU1 device pin. The user must make sure to program the DRM module in accordance with Table 33-34.

33.4.3 Suspend

The device supports a suspend feature, which provides a way to stop a closely coupled hardware process running on a peripheral-IP when the host processor enters debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

An entry is provided for each peripheral-IP that must consider the suspend signals from a number of processors (MPU or DSP). For each peripheral-IP, sensitivity to the suspend signals is defined within two possibilities (and so coded using 1 bit):

- Peripheral-IP is sensitive to the suspend line request.
- Peripheral-IP ignores the suspend line request.

For more information about how to program the sensitivity, see the corresponding peripheral-IP TRM chapter.

33.4.3.1 Debug Aware Peripherals and Host Processors

Table 33-7 lists the mapping of the device processors to the suspend control input lines.

DCC_UART_TX	DEBUGSS	CT_UART (BDX client)	Transmit empty
DCC_UART_RX			Receiver data available

33.6 Power, Reset, and Clock Management Debug Support

The global PRCM module implements facilities to support debug across power and clock domain cycles. The debugger can control or get the status of each power and clock domain associated with an ICEPick secondary TAP.

ICEPick provides a set of directives allowing the debugger to:

- Get visibility on the associated power and clock domains state. This includes:
  – Current power setting indicating whether the power domain is on or off
  – Loss of power detected since the software last checked the status
  – Current clock setting indicating whether the clock domain is on or off
  – Sleep desired (PM and CM indicate that the debug settings in ICEPick are changing the application state. If it were not for the ICEPick controls, the power or clock would be turned off.)
  – Subsystem reset state
  – Subsystem has entered a debug state that requires the attention of the host debug software.
- Override power/clock control settings to wake up a power or clock domain or to prevent a power or clock domain from going to sleep once it is in ACTIVE state
- Assert/block/extend reset; release from extended reset (WIR)

33.6.1 Power and Clock Management

33.6.1.1 Power and Clock Control Override From Debugger

The debugger can override the application software power and clock management settings through the ICEPick module. It can configure ICEPick to force a domain active or prevent it from going to sleep once it is active. This can be achieved through the following debugger directives:

- FORCEACTIVE
- INHIBITSLEEP

33.6.1.1.1 Debugger Directives

33.6.1.1.1.1 FORCEACTIVE Debugger Directive

To ensure that the subsystem debug registers can always be accessed, regardless of the application power-management scenarios, a FORCEACTIVE directive can be issued through the debugger along the entire debug session. From an application standpoint, the system state, status, and timing are preserved, but the subsystem power domain is never shut down. Therefore, the emulation setup is preserved across power transitions, regardless of where the debug hardware is implemented.

If the debugger connects and the subsystem were previously powered down, a FORCEACTIVE directive wakes up the system and allows the debugger to take control of the system.

33.6.1.1.1.2 INHIBITSLEEP Debugger Directive

The debugger can use the INHIBITSLEEP directive to keep a subsystem powered and clocked, even if the applicative settings request that this subsystem go to sleep. Contrary to the FORCEACTIVE directive, the INHIBITSLEEP command does not wake up a subsystem that is already powered down by the application.

The typical use of the INHIBITSLEEP directive is to prevent power and clock transitions on the subsystem during a debug session. In this situation, when the applicative scenario initiates a transition, the transition does not take place, but from an applicative point of view the subsystem is not accessible.

33.6.1.1.2 Intrusive Debug Model

The use of debugger directives is intrusive from the standpoint of the power and clock controls, because they affect the power-management behavior of the application.

33.6.1.2 Debug Across Power Transition

33.6.1.2.1 Nonintrusive Debug Model

To preserve the power-management behavior of the device and allow the subsystem power and clock to be switched off by application software, the subsystem TAP must be disconnected from the ICEPick scan chain. The subsystem is then completely ignored by the debugger and the host-to-target communication is no longer affected by the state of the subsystem power and clocks. The debugger can still be informed that the disconnected subsystem entered the debug state by polling the Debug Attention status bit from ICEPick. The debugger can then insert the TAP, take control of the subsystem power and clock, and examine the system state.

This debug model is nonintrusive, because it allows the power-management behavior of the application to be preserved.

33.6.1.2.2 Debug Context Save and Restore

33.6.1.2.2.1 Debug Context Save

The device partitioning is such that not all the debug components are mapped to an always-on domain. Typically, the programmer wants the debug setup to be preserved along a debug session, including subsystem power cycling. When debug registers are memory mapped and not implemented within the emulation power domain, the application software must save the state of the debug registers before going to sleep and restore them upon wakeup.

33.6.1.2.2.2 Debug Context Restore

When the application software performs a context restore, it must be able to write to all the debug registers to restore their contents, regardless of the previous ownership. After subsystem power domain ramp up, the debug resources are in the available state, and ownership is restored. The debug context save and restore sequences are protected. All debug functionality is disabled and debugger accesses are blocked.

33.6.2 Reset Management

The debugger can take control of the system reset for each subsystem through ICEPick. The debugger can configure ICEPick to assert, block, or extend the subsystem reset.

33.6.2.1 Debugger Directives

33.6.2.1.1 Assert Reset

The debugger can program ICEPick to generate a subsystem reset request to the device reset management module. The debugger reset event is then merged with system reset events.

33.6.2.1.2 Block Reset

The debugger can program ICEPick to request the device reset management module to block an unsafe application system or subsystem reset event.

A reset originated by some safe reset sources cannot be blocked by the debugger.

33.6.2.1.3 Wait-In-Reset

WIR mode is latched from boot mode (see Section 33.3.2, *Boot Modes*) and allows the user to hold a secondary TAP module in reset state when a reset is applied (and thus, extend the reset). This mode lets the user control the following system level activities:

- Gain emulation control of any processor in a power domain at POR
- Capture and extend system-generated functional resets while running (under emulation control or not)
- Hold an entire power domain in reset until emulation control of the subsystem can be established
- Stall the entire system while reset is extended to a power domain
- Reset extension is visible external to the power domain.
- Debug execution of code from the first cycle of execution
- Prevent processor execution of random instructions in uninitialized program memory at power up
- Download code before any code execution takes place
- Coordinate debug initialization across multiple cores before code execution begins

WIR mode extends only the processor reset. During reset extension, the debugger can still access modules such as L2 memory and MMU, even if they are embedded in the device subsystem affected by WIR.

When the debugger task is complete, the DTC releases the subsystem reset by programming the corresponding ICEPick TAP control register.

33.7 Performance Monitoring

33.7.1 MPU Subsystem Performance Monitoring

33.7.1.1 Performance Monitoring Unit

The Cortex-A15 processor includes a PMU that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU provides six counters to gather statistics about the operation of the processor and memory system. Each counter can count any of the events available in Cortex-A15. Upon counter overflow, PMU can generate an interrupt on its PMUIRQ output. This interrupt signal is mapped to the CTITRIGIN[1] input and routed to an MPU_INTC input (MPU_IRQ_131 for Cortex-A15 CPU0 PMU; MPU_IRQ_132 for Cortex-A15 CPU1 PMU).

The Cortex-A15 PMU outputs events to CS_PTM. For details of PMU events, please refer to the Arm Cortex-A15 TRM, available at http://infocenter.arm.com/help/index.jsp.

33.7.1.2 L2 Cache Controller

The MPU subsystem includes 2 MiB of L2 cache (L2CACHE_MPU) and L2 cache controller (L2CACHE_CTRL_MPU). The L2 cache controller includes logic to support cache event monitoring.

Table 33-10 summarizes the L2 cache events.

Table 33-10. L2 Cache Events

Event	Event Description
0	Eviction of a line from the L2 cache
1	Data read hit in the L2 cache
2	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
3	Data write hit in the L2 cache
4	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
5	Data write lookup to the L2 cache with Write-Through attribute. Subsequently results in a hit or miss.
6	Instruction read hit in the L2 cache
7	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
8	Prefetch line-fill sent to L3
9	Allocation into the L2 cache caused by a write (with Write-Allocate attribute) miss

The L2 cache controller implements two 32-bit event counters. The L2 cache controller can be configured to generate interrupts on error conditions or event counter overflow or increment. The L2 cache controller interrupt is routed to MPU_IRQ_0. When an interrupt occurs, software can look at the relevant interrupt status register to determine the source of the interrupt.

33.7.2 IPU Subsystem Performance Monitoring

33.7.2.1 Subsystem Counter Timer Module

The IPU subsystem includes a subsystem counter timer module (SCTM), which is embedded in shared cache and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect:

- Forty-four shared cache events
- Four sleep/deep-sleep events from Cortex-M4 cores (one sleep and one deep sleep event per core)

Table 33-11 describes the repartition of the IPU SCTM counters.

Table 33-11. IPU SCTM Counters Repartition

Counters	Features
0–1	Timer and event
2–3	64-bit chained + shadowing
4–5	64-bit chained + shadowing

48	IPU_C0 sleep

Note

Input index [0] is reserved for free-running subsystem clock (used for total cycle profiling).

33.7.3 DSP Subsystem Performance Monitoring

33.7.3.1 Advanced Event Triggering

The Advanced Event Trigger (AET) unit has the capability to generate the debug actions based on events detected by instruction and data bus comparators or by auxiliary event detectors to manage:

- Hardware Program Breakpoints: specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- Data Watchpoints: specify data variable address, address ranges, or data values that can generate events such as halting the processor or triggering the trace captures.
- Counters: count the occurrence of an event of cycles for performance monitoring.
- State Sequencing: allows combinations of hardware program breakpoint and data Watchpoints to precisely generate events for complex sequences.

For more information on AET, see the following documents:

- *Using Advanced Event triggering to Find and Fix Intermittent Real-Time Bugs* application report (SPRA753).
- *Using Advanced Event Triggering to Debug Real-Time Problems in High Speed Embedded Microprocessor System* application report (SPRA387)

33.7.4 EVE Subsystem Performance Monitoring

33.7.4.1 EVE Subsystem Counter Timer Module

The EVE subsystem includes an SCTM, which is embedded in the EVE subsystem and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect:

- ARP32 program cache events
- EDMA events
- Interrupt events
- VCOP processor events

Table 33-13 describes the configuration of the EVE SCTM counters.

Table 33-13. EVE SCTM Counters Configuration

Counters	Features
0–1	Timer and event
2–3	64-bit chained + shadowing
4–5	64-bit chained + shadowing
6–7	Event

33.7.4.2 EVE Subsystem SCTM Events

Table 33-14 summaries the SCTM events for EVE subsystem.

Table 33-14. SCTM Events for EVE Subsystem

Input Index	Event Description

29	VCOP done

33.8 MPU Memory Adaptor (MPU_MA) Watchpoint

The MPU subsystem implements a watchpoint allowing the user tracking the MPU_MA transactions from/to external memory.

The watchpoint can be programmed to generate a trigger when a MPU_MA transaction satisfies a set of user-defined attributes:

- Access within or outside an address region
- Access type (instruction, data, read, write)
- Transaction target (on-chip, memory channel, chip select)
- Qualifier
- Transaction originating from a specific core
- Specific transaction followed by memory barrier (DSB, DMB)
- Memory barrier (DSB, DMB) followed by specific transaction

When the MPU_MA transaction attributes match the debug use case setup, the MPU debug logic captures the transaction data and associated qualifiers:

- Read or write data (128-bit) for the specific beat of the burst
- Address (MSB field)
- MReqInfo (19-bit)
- Byte enables
- Burst type
- Burst length
- Target

When the MPU_MA watchpoint is configured to track memory barriers in order to investigate potential ordering issues, the debugger will report:

- Attributes of the transaction immediately following the memory barrier
- Attributes of the matching transaction chained to the memory barrier

33.9 Processor Trace

The device supports:

- MPU Cortex-A15 processor trace
- DSP (C66x) processor trace for each DSP subsystem

Figure 33-2 shows an overview of the MPU and DSP processor traces flow.

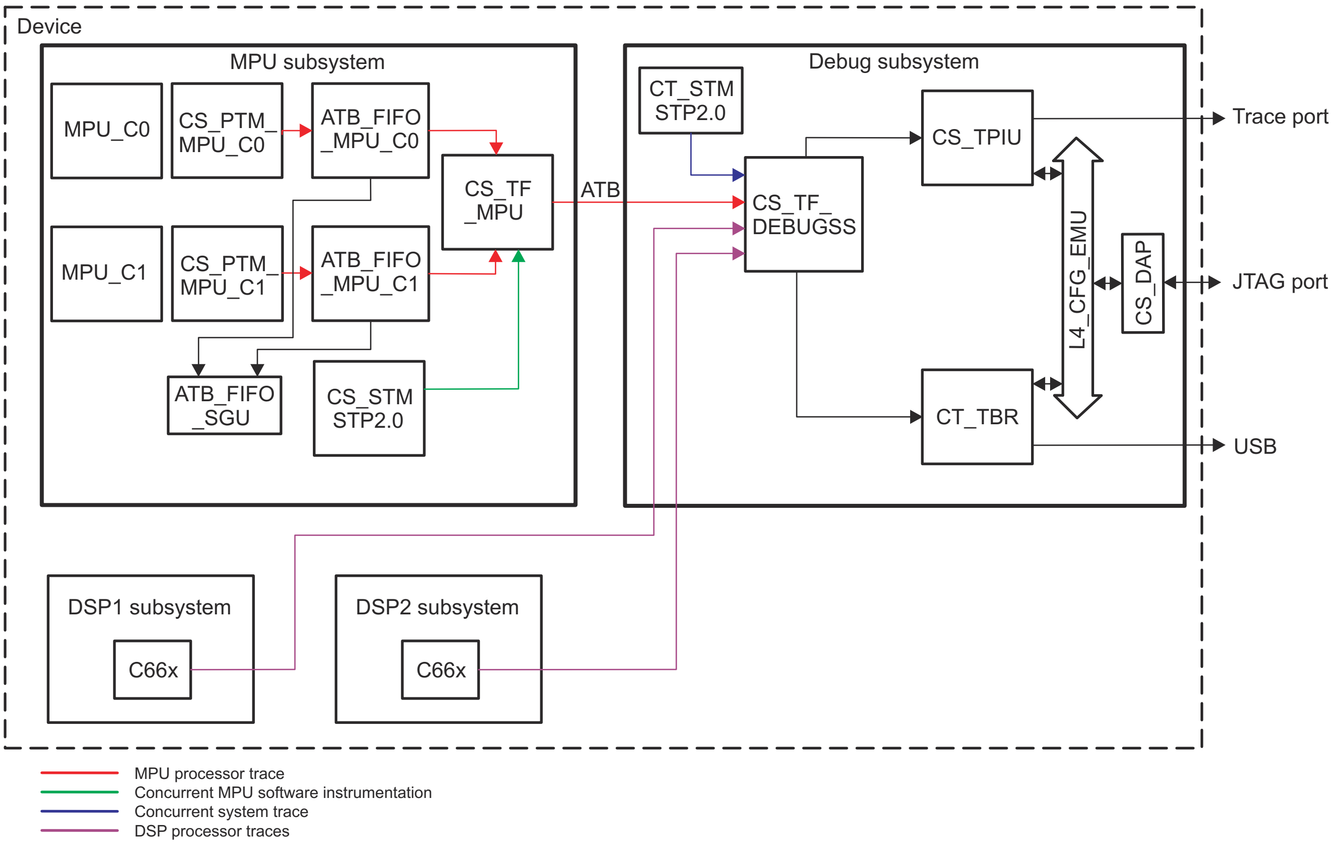

Figure 33-2. MPU and DSP Processor Traces Flow

Note

Mapping of trace funnels inputs:

- CS_TF_MPU:
  - Port 0 – ATB_FIFO_MPU_C0
  - Port 1 – ATB_FIFO_MPU_C1
  - Port 2 – CS_STM
- CS_TF_DEBUGSS_1
  - Port 0 – MPU ATB interface
  - Port 1 – DSP1 ATB interface
  - Port 2 – DSP2 ATB interface
  - Port 7 – CT_STM ATB interface

33.9.1 Cortex-A15 Processor Trace

The main MPU trace characteristics are:

- Program trace only (no data trace)
- Separate CS_PTM for each MPU core

- Three exclusive trace sinks:
  – CS_TPIU – trace exported to an external trace receiver
  – CT_TBR (buffer mode) – trace stored into on-chip buffer
  – CT_TBR (system bridge mode) – trace exported through USB
- Trace can be optionally:
  – Cycle accurate useful for profiling sections of code
  – Locally time-stamped using a 48-bit free-running graycode counter exported to the CS_PTM of each MPU core
  – Interleaved dynamically between the two MPU cores by CS_TF_MPU

Note

Depending on use case, the device may not be able to interleave two cycle accurate traces without overflow (bandwidth restriction).

33.9.2 DSP Processor Trace

Trace targets the debug of unstable code, performance analysis, and quality assurance. This infrastructure component use bus snoopers to collect and export trace data using hardware dedicated to the trace function. The use of dedicated hardware to both collect, buffer, transfer trace data to the host makes trace non-intrusive. DSP processor trace characteristics are:

- Program trace
- Data trace (address and value)
- Time stamp
- Three exclusive trace sinks:
  – CS_TPIU – trace exported to an external trace receiver
  – CT_TBR – trace history stored into on-chip buffer
  – CT_TBR – trace exported through USB

The trace function can collect and export a record of the program flow and timing at the same rate generated by the CPU. Tracing data references must be restricted however as the export mechanism is generally limited to size of on-chip CT_TBR to sustain tracing of all memory references. In the case of data trace, the Advanced Event Triggering facilities provide a means to restrict the trace data exported to data of interest to maintain the non-intrusive aspect of trace. This reduces the export bandwidth needs and facilitates the successful collection of the data of interest. Error indications are embedded in the debug stream in the event the export logic is unable to keep up with the data rate generated by the collection logic. This notification allows the user to scale back the amount of requested data collection.

The user can optionally select the export of all specified trace data. In this case the CPU is stalled to avoid the loss of trace data, with trace becoming intrusive to the application if trace related stalls are generated. The user is notified that trace stalls.

33.9.3 Trace Export

The debug subsystem implements three exclusive trace sinks:

- CS_TPIU
- CT_TBR (buffer mode)
- CT_TBR (system bridge mode)

Two MPU trace streams are supported, one per MPU core. The two MPU cores program traces are exported to the PD_EMU domain (through asynchronous bridges) and then interleaved by the CS_TF_MPU.

A concurrent software instrumentation flow from the local CS_STM component (STP 2.0) can also be interleaved with the MPU program traces.

Two ATB_FIFO modules (ATB_FIFO_MPU_C0 and ATB_FIFO_MPU_C1) are implemented in the trace path between the Cortex-A15 CPUs and the CS_TF_MPU module. The ATB_FIFO allows concurrent trace capture and export. It provides buffering in the trace export path and therefore allows absorbing peaks of trace data. The depth of the ATB_FIFOs is 16 entries.

The CS_TF_MPU sends the MPU trace (or CS_STM software instrumentation) to a trace funnel in the debug subsystem (CS_TF_DEBUGSS) through a single ATB interface. The CS_TF_DEBUGSS redirects the MPU trace to the three exclusive trace sinks.

Note

It is strongly recommended to disable trace sinks not in use when generating trace to an in-use trace sink to eliminate undesirable throughput throttling effects.

Besides the ATB_FIFOs, the MPU subsystem also instantiates an ATB_FIFO statistics gathering unit (ATB_FIFO_SGU) which provides silicon and presilicon characterization information of ATB_FIFO. The FIFO_LEVEL_OUT output of ATB_FIFO, which gives visibility of the number of used entries, is used for the statistics gathering. ATB_FIFO may be full under the following conditions:

- Arbitration collisions in the trace funnel when more than one ATB trace stream is being generated at the same time (tracing of multiple CPUs simultaneously)
- Trace sink does not have the bandwidth to meet peak bandwidth demands from the trace generator on a single ATB trace stream

The following statistics are gathered per ATB_FIFO:

- Peak utilization depth of the FIFO
- Number of consecutive cycles that FIFO level is at or above the programmable FIFO threshold when there is an ATB command pending
- Number of ATB bus stall cycles

33.9.3.1 Trace Exported to External Trace Receiver

Processor trace can be exported to an external trace receiver through the CS_TPIU module. To achieve this, the debugger or application software must ensure to program the DRM module properly (that is, according to Table 33-34).

The CS_TPIU has a configurable export width of maximum 16 data pins (TRACEDATA) plus a dedicated export clock (TRACECLK) and a control signal (TRACECTL).

Note

In case of MPU trace streams interleaved, the trace receiver software must demultiplex the two trace streams before decoding each individual stream.

33.9.3.2 Trace Captured Into On-Chip Trace Buffer

Processor trace flow can be redirected to the on-chip trace buffer (CT_TBR working in buffer mode). The CT_TBR provides on-chip storage of trace data using a 32-KiB RAM memory.

The CT_TBR receives trace flow data through its ATB port. The debugger can then access trace data through CS_DAP (APB port).

The CT_TBR supports two modes when in buffer mode configuration:

- Circular buffer mode for continuous capture. In this mode, the CT_TBR functions as a circular buffer where the oldest data is overwritten with the most recent entries.
- Stop-on-full mode for no-loss (single shot) capture. In this mode, the buffer fills linearly and then halts when the last entry is written.

33.9.3.3 Trace Exported Through USB

Processor trace can be exported off-chip through an application interface (USB). For this purpose, the debug subsystem instantiates a CTools trace buffer rooter (CT_TBR) module, which operates in a system bridge configuration and basically represents a temporary buffer that holds data that is awaiting transfer to the L3_MAIN interconnect for export on functional I/O interfaces (USB) or storage in system memory.

The CT_TBR allows concurrent trace capture and export. A USB3.0 DMA engine (L3_MAIN) master can read trace data from the CT_TBR slave port as soon as a block is available for transfer.

The CT_TBR supports a DMA request generation via a read-only burst-capable interface. The primary purpose of the DMA event generation is to signal a DMA engine when the CT_TBR export FIFO has enough data to satisfy a burst read request on the system interface. The threshold for the DMA trigger is software configurable. A new DMA event is generated when the threshold is met again with new data being written to the FIFO.

The USB3.0 DMA engine supports hardware DMA requests. The CT_TBR can generate a DMA request (CT_TBR_DREQ) to the DMA_SYSTEM module (mapped to DMA_SYSTEM_DREQ_6 request line) for system memory storage.

The USB3.0 master only uses a single AXI-ID and does not support out of order execution. Therefore tracing through USB will prevent application software using USB simultaneously due to stalls from CT_TBR.

Such configuration allows supporting program trace on end product without additional debug pins taking advantage of the USB PHY throughput.

33.10 System Instrumentation

The device supports the following system instrumentation features:

- Real-time software trace
  - MPU software instrumentation via CS_STM (STP2.0) (see Section 33.10.3.1, *MPU Software Instrumentation*)
  - SoC software instrumentation via CT_STM (STP2.0) (see Section 33.10.3.2, *SoC Software Instrumentation*)
- OCP watchpoint
  - OCP target traffic monitoring (see Section 33.10.4.1, *OCP Target Traffic Monitoring*)
  - SoC events trace (see Section 33.10.4.2, *Messages Triggered from System Events*)
  - DMA transfer profiling (see Section 33.10.4.3, *DMA Transfer Profiling*)
- Statistics collector
  - L3 Target Load Monitoring (see Section 33.10.7.1, *L3 Target Load Monitoring*)
  - L3 Master Latency Monitoring (see Section 33.10.7.2, *L3 Master Latency Monitoring*)
- IVA HWA load monitoring (see Section 33.10.5, *IVA Pipeline*)
- PM events trace (see Section 33.10.8, *PM Instrumentation* [PMI])
- CM events trace (see Section 33.10.9, *CM Instrumentation* [CMI])

33.10.1 MIPI STM (CT_STM)

CT_STM is a trace module that aids in software debugging. The main features of this module are:

- Implements MIPI STP protocol (rev 2.0) with the following characteristics:
  - Highly optimized for software-generated traces
  - Automatic timestamping of messages
  - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
  - Software messages
  - Hardware instrumentation trace from hardware agents:
    - OCP_WP_NOC
    - PMI
    - CMI
    - SMSET
    - L3 NoC statistics collectors
- Supports the following trace export paths:
  - ATB export - to CS_TPIU or CT_TBR
- Available in 1-, 2-, or 4-pin mode with single- or dual-edge clock, depending on the trace bandwidth requirements and characteristics of the trace receiver
- Timestamps:
  - Can use local relative timestamp if exported to the CS_TPIU/CT_TBR (through ATB)
- Dedicated 128 × 48-bit FIFO buffer
- Mechanism to generate repeat MASTER and C8 messages periodically even if not needed

A maximum of 255 different bus masters can be connected to the STM trace port through a bus arbiter. STP recognizes two distinct modes of tracing (software and hardware types), which use slightly different message combinations to output different types of data. The bus masters can be configured for either type to optimize the system for the different types of trace data.

33.10.2 System Trace Export

33.10.2.1 CT_STM ATB Export

If a trace receiver cannot be attached to the device, or relevant CT_STM trace port pins are unavailable for a particular reason, the user can configure the CT_STM module to redirect the STP trace stream as an ATB stream to the CS_TPIU or CT_TBR and enable local timestamp. This is accomplished by outputting a local timestamp granularity (LTSG) message, which is a TI addition to the MIPI standard messages.

33.10.2.2 Trace Streams Interleaving

Two levels of interleaving system instrumentation flows and arbitrating between instrumentation masters are implemented:

- CORE L3 instrumentation interconnect interleaves data coming from the following bus masters:
  - OCP_WP_NOC
  - L3 NoC statistics collectors, or software instrumentation (interleaving at the L3 level)
  - IVA SMSET and Arm968 (software instrumentation)
- EMU L3 instrumentation interconnect interleaves data coming from the following bus masters:
  - CORE L3 instrumentation interconnect
  - CMI
  - PMI

33.10.3 Software Instrumentation

33.10.3.1 MPU Software Instrumentation

The CS_STM embedded in the MPU subsystem provides extended stimulus port registers designated to be accessible by software with minimum instrumentation cycles overhead.

Each extended stimulus port occupies 256 consecutive bytes in the memory map and is write-only. Up to 64K instrumentation channels are available at MPU level.

The CS_STM supports "guaranteed" or invariant timing transactions:

- Guaranteed transactions are guaranteed to be traced. This might involve stalling the MPU core to ensure the transaction is accepted by the CS_STM.
- Invariant timing transactions are not guaranteed to be traced. These transactions take an invariant amount of time regardless of the state of the CS_STM.

The CS_STM implements tracing of software writes to its stimulus ports using a dedicated AXI slave interface. In addition to the AXI interface, the CS_STM provides a hardware event input interface (HWEVENTS[31:0]). The HWEVENTS[31:0] input bus is connected to the MPU hardware debug observability signals going out to the MPU hardware debug port (MPUHWDBGOUT[31:0]). This enables any of the signals observed on MPUHWDBGOUT[31:0] to act as a hardware event to the CS_STM. The CS_STM can be programmed to generate a debug packet on a rising edge transition on any signal of the HWVENTS[31:0] input bus. Because some of the signals mapped on the MPUHWDBGOUT[31:0] bus are active low, a 32-bit programmable register – MPU.STM_HWEVENTS_INV, is implemented for polarity inversion. Each bit of MPU.STM_HWEVENTS_INV when set to 0x1 inverts the polarity of the corresponding signal of MPUHWDBGOUT[31:0] going to HWEVENTS[31:0]. This programmable register is part of the MPU_WUGEN address map (see Chapter 4, *Dual Cortex-A15 MPU Subsystem*, for its description).

Note

The MPUHWDBGOUT[31:0] signals can be routed to the hw_dbg[31:0] device pads through various hardware debug observability MUXes controlled by device control module (CTRL_MODULE). For more information, see Chapter 18, *Control Module*.

To save power, the output port can be gated off (to all zeros) by setting the CTRL_MODULE. CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE bit to 0x0. Ungated version of MPUHWDBGOUT[31:0] (not gated with CTRL_MODULE. CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE) is sent to HWEVENTS[31:0] input of STM so each of these signals can generate a debug packet on the trace port.

The message structures in STP-2.0 are optimized to provide an efficient transport.

33.10.3.2 SoC Software Instrumentation

The CT_STM module embedded in the debug subsystem provides a flexible interface for trace instrumentation.

The device provides support for real-time software trace through user-defined message writes to specific memory mapped register (MMR) locations. Software masters can transmit trace data from the operating system (OS) processes or tasks on 256 different channels, with each channel being defined by the software protocol implemented. The different channels can be used to group different types of data logically so that it is easy to filter out the data irrelevant to the ongoing debugging task. The message structures in STP-2.0 are optimized to provide an efficient transport for software data through the CT_STM module.

The software masters are:

- Cortex-A15 MPU subsystem
- DAP (for testing purpose)
- DSP subsystem
- IPU subsystem
- EVE subsystem
- SDMA controller write port (DMA_SYSTEM_WR)
- IVA subsystem
- EDMA TPTC WR1 and WR2 channels

Each software master has a master-ID assigned to it (see Section 33.10.10, *Master-ID Encoding*, for more information).

Software messages can be interleaved with other hardware messages.

Software messages are intrusive and use both processor cycles and memory.

33.10.4 OCP Watchpoint

33.10.4.1 OCP Target Traffic Monitoring

The L3_MAIN interconnect provides several functional probes embedded and attached to the following L3_MAIN targets:

- GPMC
- L4_PER1, L4_PER2, L4_PER3
- L4_CFG
- DMM_P1 (DMM target port 1)
- DMM_P2 (DMM target port 2)
- OCMC_RAM1

The probes output are muxed together and then sent to the L3_MAIN interconnect debug port. A component called OCP_WP_NOC is used to collect data from functional probes and then transmit captured data to the CT_STM module. The OCP_WP_NOC drives a probe-ID signal to the L3_MAIN interconnect for probe selection. The probe selection is exclusive, meaning that interleaving is not possible.

The OCP_WP_NOC provides the following main features:

- Monitoring the OCP traffic originated by all initiators that can access the selected target where the probe is attached
- Filtering OCP monitored bus traffic by:
  - Address range
  - Initiator-ID (see Table 33-16)
  - Transaction type
  - Transaction qualifier
- Generating a trigger upon watchpoint match
- Starting and stopping OCP traffic monitoring upon:
  - WP address match
  - External trigger
- Profiling DMA transfers

- Generating hardware message upon system event
- OCP_WP_NOC messages can be interleaved with software messages
- Programming from:
  - Debugger
  - Application

Note

The OCP_WP_NOC is restricted to monitor request flow only.

Table 33-15 summarizes the OCP targets that can be monitored by the OCP_WP_NOC and their respective probe-ID.

Table 33-15. L3_MAIN Interconnect Functional Probe Mapping

Probe-ID	L3 OCP Target
0000	Reserved
0001	GPMC
0010	L4_PER1
0011	L4_CFG
0100	DMM_P1 (DMM target port 1)[(1)]
0101	DMM_P2 (DMM target port 2)[(1)]
0110	OCMC_RAM1
0111	L4_PER2
1000	L4_PER3

(1) Does not allow tracking MPU transactions routed through Memory Adapter and DMM.

The user can program the OCP_WP to extract the traffic from a specific set of initiators (maximum four master-IDs). Table 33-16 lists the master-ID reported by the L3_MAIN debug port for the device initiators.

Note

For information about master-ID values from a protection/error logging point of view, see Chapter 14, *Interconnect*.

33.10.4.2 Messages Triggered from System Events

The OCP_WP_NOC can be programmed to export a message through the CT_STM upon detection of a system event (interrupt, DMA request, etc.). A bus of 16 system events pre-selected at SoC level from a large number of observable events is routed to the OCP_WP_NOC. This can be useful to determine interrupts latencies:
- Interrupt request traced through OCP_WP_NOC system event detection
- ISR boundary tracked either through CT_STM software trace or OCP_WP_NOC address range detection

33.10.4.3 DMA Transfer Profiling

The OCP_WP_NOC can be configured to profile DMA transfers. This feature provides to the user visibility on:
- DMA logical channel interleaving
- DMA channel ID
- DMA transfer duration (time stamp)
- DMA burst size
- DMA reads
- DMA writes

When operating in this mode, the OCP_WP_NOC exports to CT_STM:
- DMA channel ID
- Burst size
- R/W

The CT_STM module encapsulates the information above in a compact STP message.

The address range filtering remains active but OCP address data are not encapsulated into the trace message to maximize CT_STM throughput.

33.10.5 IVA Pipeline

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding IVA microtask sequencing. This is supported through a SMSET module instantiated in the IVA subsystem. The microtask boundaries are handled as generic events and encapsulated in STP messages with an event-ID and local timestamp and exported through the CT_STM module.

The IVA instrumentation scheme allows the user to understand microtask dependencies, hardware accelerators load balancing, and potential bottlenecks. DMA transfer boundaries are reported as IVA events. Software messages from Arm968 execution can be interleaved with IVA events.

33.10.6 EVE SMSET

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding EVE VCOP micro-task sequencing. This is supported through a SMSET module instantiated in the EVE subsystem. The VCOP start and done events are handled as generic events and encapsulated in STP messages with an event-ID and local timestamp and exported through the CT_STM module.

The EVE instrumentation scheme allows the user to understand micro-task dependencies, and potential bottlenecks. DMA transfer boundaries are reported as EVE events. Software messages from ARP32 execution can be interleaved with EVE VCOP events.

33.10.7 L3 NOC Statistics Collector

The L3_MAIN interconnect supports a built-in performance monitoring feature by implementing a statistics collector (NOC_SC) component, which computes traffic statistics within a user-defined window and periodically reports to the user through the CT_STM interface. Ten NOC_SC instances are instantiated in the device:

- One statistics collector dedicated to SDRAM load monitoring – SC_SDRAM (see Section 33.10.7.1, *L3 Target Load Monitoring*, for more information)
- Nine statistics collectors dedicated to L3 Master Latency Monitoring – SC_LAT0 through SC_LAT8 (see Section 33.10.7.2, *L3 Master Latency Monitoring* , for more information)

Statistics collectors (SC_SDRAM and SC_LAT) can report:

- Average burst length in bytes/packet per sampling window
- Average throughput in bytes/cycle
- Percent link occupancy on the request link (for store transactions) during a sampling window
- Percent link occupancy on the response link (for load transactions) during a sampling window
- Percent arbitration conflict cycles on the request link
- Percent initiator busy cycles on the response link
- Histogram of payload length in bytes (for example, 0–16, 16–32, 32–128) each sampling window.
- Histogram of quality of service (QoS) metric for IVA initiator (for example, low priority, high priority) each sampling window.

The performance metrics are interleaved with software instrumentation data at the L3_MAIN interconnect level.

The performance monitoring probes implement three main functions:

- Events detection
- Transactions filtering
- Aggregation

The probes can be configured to detect the NTTP and OCP link events summarized in Table 33-17.

Table 33-17. Performance Monitoring Events Detection

Link Event	NTTP	OCP	Definition
NONE	✓	✓	No event selected
ANY	✓	✓	Any clock cycles
TRANSFER	✓	✓	Word has been accepted by the receiver.
WAIT	✓	–	Transfer has been initiated but the transmitter currently has no data to send.
BUSY	✓	✓	Receiver applies flow control
PKT	✓	✓	Transfer of a new packet header
DATA	✓	✓	Transfer of a payload word
IDLES	✓	✓	No communication over the link
LATENCY	✓	–	Debug bit detection

The probes can be configured to filter the traffic based on the criteria summarized in Table 33-18.

Table 33-18. Performance Filtering Options

Filters	Comment
Master address	Mask and match
Slave address(2)

The probes implement a user-defined set of counters that aggregate the events sampled by the detector and filtered according to the user setup.

Note

Statistics collectors counter values are accessible by application software.

Table 33-21 summarizes the performance probe aggregation modes.

Table 33-21. Aggregation Modes

Aggregation Mode	Description
FILTER_HIT	The counter increments by 1 when the filter hits.
MIN_MAX_HIT	The counter increments by 1 when the filter hits and the selected event information is within range.

Table 33-21. Aggregation Modes (continued)

Aggregation Mode	Description
	– Payload length (bytes) – Pressure value – Request/response latency (clock cycles)
EVT_INFO	The selected event information is added to the counter value when the filter hits. Payload length (bytes) Pressure value Request/response latency (clock cycles)
AND_FILTER	The counter increments by 1 when all unit filters hit.
OR_FILTER	The counter increments by 1 when at least one unit filter hits.
SUM_REQ_EVT	The counter sums the events from any request port.
SUM_RSP_EVT	The counter sums the events from any response port.
SUM_ALL_EVT	The counter sums the events from any port.
EXT_EVT	The counter increments by 1 when selected external event input signal is sampled high.

33.10.7.1 L3 Target Load Monitoring

The L3_MAIN interconnect implements five performance monitoring probes on DDR memory channels. The traffic statistics are computed within a user-defined window and periodically reported to the user through the CT_STM interface.

SC_SDRAM supports the following main features:

- Four probe inputs:
  - Probe 0 (128 bit-wide) – EMIF1_SYS
  - Probe 1 (128 bit-wide) – EMIF2_SYS
  - Probe 2 (128 bit-wide) – MPU_MA_P1
  - Probe 3 (128 bit-wide) – MPU_MA_P2
- Eight 32-bit counters shared concurrently:
  - Counter 0 with two filters
  - Counter 1 with one filter
  - Counter 2 with two filters
  - Counter 3 with one filter
  - Counter 4 with one filter
  - Counter 5 with one filter
  - Counter 6 with one filter
  - Counter 7 with one filter
- Simple (with one element) or complex (with several elements) filters available
- Filtering according to:
  - Initiator of traffic
  - Access priorities
  - OCP address
- No latency counter. Only bandwidth measurement on this collector.
- 32-bit collecting window counter
- Dump identifier is 0x0 (tie-off value)
- Dumps frames at L3_MAIN interconnect slave address 0x19 (L3_INSTR)

Table 33-22 shows the SC_SDRAM port mapping.

Table 33-22. SC_SDRAM Port Mapping

Probe	Description	Link	Port
0	EMIF1_SYS	OCP REQ	0
		OCP RSP	1

		OCP RSP	5
3	MPU_MA_P2	OCP REQ	6
		OCP RSP	7

33.10.7.2 L3 Master Latency Monitoring

The L3 interconnect implements performance monitoring probes on initiator (master) interfaces. The master latency statistics are computed within a user-defined window and periodically reported to the user through the CT_STM interface.

The probes can be configured to filter latencies in four classes and report to the user a latency distribution along execution.

Because the performance metrics and the software events are exported through a unified export channel, it is possible to correlate latency trends with ongoing execution and system context.

Because computing latency requires maintaining the state between request and response ports, the probe cannot compute latency statistics on 100 percent of the initiator traffic. Hence, latency histograms must be extracted on large execution windows to be accurate.

33.10.7.2.1 SC_LAT0 Configuration

SC_LAT0 supports the following main features:

- Six probe inputs:
  - Probe 0: MPU
  - Probe 1: MMU1
  - Probe 2: EDMA_TC0_RD
  - Probe 3: EDMA_TC0_WR
  - Probe 4: EDMA_TC1_RD
  - Probe 5: EDMA_TC1_WR
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x1 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

Table 33-23 shows the SC_LAT0 port mapping.

Table 33-23. SC_LAT0 Port Mapping

33.10.7.2.2 SC_LAT1 Configuration

SC_LAT1 supports the following main features:

- Eight probe inputs:
  - Probe 0: VIP1 P1
  - Probe 1: VIP1 P2
  - Probe 2: VIP2 P1
  - Probe 3: VIP2 P2
  - Probe 4: VIP3 P1
  - Probe 5: VIP3 P2
  - Probe 6: VPE P1
  - Probe 7: VPE P2
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x2 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

Table 33-24 shows the SC_LAT1 port mapping.

33.10.7.2.3 SC_LAT2 Configuration

SC_LAT2 supports the following main features:

- Eight probe inputs:
  - Probe 0: EVE1 TC0
  - Probe 1: EVE1 TC1
  - Probe 2: EVE2 TC0
  - Probe 3: EVE2 TC1
  - Probe 4: Reserved
  - Probe 5: Reserved
  - Probe 6: Reserved
  - Probe 7: Reserved
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x3 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

33.10.7.2.4 SC_LAT3 Configuration

SC_LAT3 supports the following main features:

- Eight probe inputs:
  - Probe 0: DSP1 MDMA
  - Probe 1: DSP1 EDMA
  - Probe 2: DSP2 MDMA
  - Probe 3: DSP2 EDMA
  - Probe 4: IVA
  - Probe 5: GPU P1
  - Probe 6: GPU P2
  - Probe 7: BB2D P1
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x4 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

33.10.7.2.5 SC_LAT4 Configuration

SC_LAT4 supports the following main features:

- Eight probe inputs:
  - Probe 0: DSS
  - Probe 1: Reserved
  - Probe 2: MMU2
  - Probe 3: IPU1
  - Probe 4: IPU2
  - Probe 5: DMA SYSTEM RD
  - Probe 6: DMA SYSTEM WR
  - Probe 7: Reserved
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x5 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

33.10.7.2.6 SC_LAT5 Configuration

SC_LAT5 supports the following main features:

- Eight probe inputs:
  - Probe 0: USB1
  - Probe 1: USB2

  - Probe 2: USB3
  - Probe 3: USB4
  - Probe 4: PCIe_SS1
  - Probe 5: PCIe_SS2
  - Probe 6: DSP1 CFG
  - Probe 7: DSP2 CFG
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x6 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

33.10.7.2.7 SC_LAT6 Configuration

SC_LAT6 supports the following main features:

- Seven probe inputs:
  - Probe 0: GMAC_SW
  - Probe 1: Reserved
  - Probe 2: Reserved
  - Probe 3: Reserved
  - Probe 4: Reserved
  - Probe 5: Reserved
  - Probe 6: Reserved
  - Probe 7: MPU

- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x7 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

Table 33-24 shows the SC_LAT6 port mapping.

Table 33-29. SC_LAT6 Port Mapping

Probe	Description	Link	Port
0	GMAC_SW	NTTP REQ	0

		NTTP RSP	15

33.10.7.2.8 SC_LAT7 Configuration

SC_LAT7 supports the following main features:

- Eight probe inputs:
  - Probe 0: MMC1
  - Probe 1: MMC2
  - Probe 2: SATA
  - Probe 3: MLB
  - Probe 4: BB2D_P2
  - Probe 5: IEEE1500
  - Probe 6: DEBUGSS
  - Probe 7: VCP1
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:

  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x8 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

Table 33-24 shows the SC_LAT7 port mapping.

33.10.7.2.9 SC_LAT8 Configuration

SC_LAT8 supports the following main features:

- Eight probe inputs:
  - Probe 0: OCMC_RAM1
  - Probe 1: OCMC_RAM2
  - Probe 2: OCMC_RAM3
  - Probe 3: GPMC
  - Probe 4: McASP1
  - Probe 5: McASP2
  - Probe 6: McASP3
  - Probe 7: VCP2
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x9 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

33.10.7.2.10 Statistics Collector Alarm Mode

Statistic collectors can be used to provide the application software with information about the NoC or SDRAM reaching corner cases (for example, too much traffic for a given OPP) while in application mode where for an end product use case the debug subsystem (which is normally exporting the statistic frames) is off. An interrupt-based scheme using a dedicated signal (L3_MAIN_IRQ_STAT_ALARM) is implemented to avoid CPU polling periodically statistic registers. This interrupt alert is fired when a given metric is out of specified range (below the programmed MIN threshold or above the programmed MAX threshold). The L3_MAIN_IRQ_STAT_ALARM interrupt is connected to the IRQ_CROSSBAR_16 input and the user can map it to any device INTC via Control Module.

Note

NTTP statistic collectors (SC_LAT) support latency measurement. However, comparison cannot be done on the latency counter. In case of latency measurement the comparison has to be done on number of latencies in user defined range, not on the latency value itself.

33.10.7.2.11 Statistics Collector Suspend Mode

The statistics collector module implements a suspend input that is used to avoid statistics collector counters to be updated while the processor has entered the debug state. This avoids triggering false alerts upon execution resume. When the statistics collector is asserted to 1, it freezes the monitoring process. When it goes back to 0, the monitoring resumes. If a frame is being dumped, it will not be stopped by suspend.

Note

Each statistic collector has an ignore suspend register, which can be used to disable the suspend feature.

33.10.8 PM Instrumentation

The device takes advantage of the system trace infrastructure to provide visibility to the user about the major power-management events. This is supported through a PMI module (PM profiler) instantiated in the

PRM module. The PRM state changes are handled as generic events and encapsulated in STP hardware messages and exported through the CT_STM module. The nature of the PM events does not require accurate timestamping and thus, timestamping is handled at CT_STM or trace receiver level.

The PM events are organized by class. Any PM state change from a specific class refreshes the entire instrumentation frame associated with that class. The STP message structure includes a PM event-ID indicating the class of the PM events.

The PM event classes supported are:

- Logic voltage domain OPP change
- Memory voltage domain OPP change
- Logic power domain state change
- Memory power domain state change

The PMI has a unique hardware master-ID assigned to it (see Section 33.10.10, *Master-ID Encoding*).

The PMI supports the possibility to report on activity in different event classes in the same sampling window. The user can size the capture sampling window.

Software events from the PM routines instrumentation can be interleaved with the PM hardware events. The user can take advantage of that feature to understand latencies for a specific power-management scenario or strategy.

The PM module implements an instrumentation port that directly interfaces with the debug subsystem (used to export PM events to CT_STM).

33.10.9 CM Instrumentation

The device instantiates a CMI module (CM profiler). It has a unique hardware master-ID assigned to it (for more information, see Section 33.10.10, *Master-ID Encoding*).

Note

Only CM_CORE_AON instrumentation is supported in this device. CM_CORE instrumentation is not supported.

The CM events profiling is similar to the PMI. Two exclusive instrumentation modes are supported:

- Clock activity:
  – Exposes to the user a snapshot of the state of all the clock domains derived from the same DPLL when CM detects a state change in the clock domain
  – Exposes to the user a snapshot of the DPLL settings when the CM signals a DPLL programming
- Module activity:
  – Exposes to the user periodically the active cycles count of the target modules
  – Exposes to the user periodically the active cycles count of the initiator modules

It provides visibility to the user about the state of the major clock domains along the application code execution. The STP message reports the effective state of the clock domain and therefore can highlight scenarios where a particular dependency is preventing the clock domain from being switched off.

The CM event classes supported are:

- Events capture mode – four classes:
  – Clock domain state
  – DPLL settings update
  – Clock frequency divider ratio
  – Clock source selection update
- Module activity collection mode – two classes:
  – Target module activity

– Initiator module activity

When in events capture mode, the CMI supports the possibility of reporting on activity in different event classes in the same sampling window. The user can size the capture sampling window.

33.10.10 Master-ID Encoding

A master-ID (MReqMstID[7:0]) field is used by the CT_STM to encode a MASTER type of message:

- MReqMstID[7] – Differentiates software versus hardware masters (0 for software masters; 1 for hardware masters)
- MReqMstID[6:2] – Master address exported by the L3_MAIN interconnect debug subsystem target
- MReqMstID[1:0] – Additional qualifier for multicore masters (MPU, IPU)

33.10.10.1 Software Masters

The CT_STM module allows:

- Enabling a maximum of four SoC software masters
- Masking MReqMstID[1:0]
- Differentiating multicore software masters through MReqMstID[1:0]

Table 33-32 summarizes the software initiators that can export trace messages through the CT_STM.

Table 33-32. STM Message Software Masters

Initiator	MReqMstID				Restriction/Comment
	ConnID	[7]	[6:2]	[1:0]	
MPU (SMP)	0x1	0	00001	00	MPU_C0

33.10.10.2 Hardware Masters

The CT_STM module allows enabling a subset of SoC hardware masters (maximum = 4).

Table 33-33 summarizes the hardware initiators that can export trace messages through the STM.

Table 33-33. STM Message Hardware Masters

Initiator	MReqMstID

33.11 Concurrent Debug Modes

The debugger or application software can program the DRM to route a specific debug function to each device debug port pin.

Because of the limited number of pins allocated to debug, debug and trace source signals are multiplexed.

Table 33-34 summarizes the trace port configuration.

Table 33-34. Trace Port Configuration

Pin Name	Internal Signal Name	I/O	Trigger	CS_TPIU (CS_PTM, DSP, CS_STM, CT_STM)	
				Mode A (up to 16 data pins)	Mode B[(1)] (up to 18 data pins)
emu19	EMU19	O		TRACEDATA[15]	TRACEDATA[17]
emu18	EMU18	O		TRACEDATA[14]	TRACEDATA[16]
emu17	EMU17	O		TRACEDATA[13]	TRACEDATA[15]
emu16	EMU16	O		TRACEDATA[12]	TRACEDATA[14]
emu15	EMU15	O		TRACEDATA[11]	TRACEDATA[13]
emu14	EMU14	O		TRACEDATA[10]	TRACEDATA[12]
emu13	EMU13	O		TRACEDATA[9]	TRACEDATA[11]
emu12	EMU12	O		TRACEDATA[8]	TRACEDATA[10]
emu11	EMU11	O		TRACEDATA[7]	TRACEDATA[9]
emu10	EMU10	O		TRACEDATA[6]	TRACEDATA[8]
emu9	EMU9	O		TRACEDATA[5]	TRACEDATA[7]
emu8	EMU8	O		TRACEDATA[4]	TRACEDATA[6]
emu7	EMU7	O		TRACEDATA[3]	TRACEDATA[5]
emu6	EMU6	O		TRACEDATA[2]	TRACEDATA[4]
emu5	EMU5	O		TRACEDATA[1]	TRACEDATA[3]
emu4	EMU4	O		TRACEDATA[0]	TRACEDATA[2]
emu3	EMU3	O		TRACECTL	TRACECTL
emu2	EMU2	O		TRACECLK	TRACECLK
emu1	EMU1	I/O	Trigger1		TRACEDATA[1]
emu0	EMU0	I/O	Trigger0		TRACEDATA[0]

(1) This is the recommended mode for primary use.

Note

The configuration of the trace port must comply with Table 33-34; otherwise, it will be ignored by DRM hardware. For example, if Trigger0 is programmed on EMU3 and Trigger1 is programmed on EMU4, this configuration will be ignored.

Table 33-35 summarizes the concurrent debug and trace in the device.

Table 33-35. Concurrent Debug and Trace

Debug Use Case	Concurrent Debug Flows	Debug Pins	Trace Pins		
		Triggers	Data	Control	Clock
1	CS_PTM		16	1	1
	CT_STM				
	Triggers	2			

Table 33-35. Concurrent Debug and Trace (continued)

Debug Use Case	Concurrent Debug Flows	Debug Pins	Trace Pins		
		Triggers	Data	Control	Clock
2	CS_PTM		16	1	1
	CT_STM		1	–	1
	Triggers				
3	CS_PTM		8	1	1
	CT_STM		4	–	1

Bits	Field Name	Description	Type	Reset
8:4	SUSPEND_SEL	Suspend signal selection. Selects which suspend signal affects the peripheral. Only valid when SUSPEND_DEFAULT_OVERRIDE=0 and SENSCTRL=1. When read, these bits reflect the default suspend signal. 0000b: CPU suspend signal. All other values are reserved.	RW	0x0
3	SUSPEND_DEFAULT_OVERRIDE	Enable or disable the override value in SUSPEND_SEL. 0: SUSPEND_SEL field will select which suspend signal reaches the peripheral. 1: SUSPEND_SEL field ignored. Default suspend signal will reach the peripheral.	R	0x0
2:1	RESERVED	Reserved	R	0x0
0	SENSCTRL	Sensitivity Control for suspend signals. When SUSPEND_DEFAULT_OVERRIDE=1, this bit is ignored and read as a 1. When SUSPEND_DEFAULT_OVERRIDE=0, 0: Suspend signal will not reach the peripheral. Peripheral will act as normal even during a debug halt. 1: Suspend signal will reach the peripheral. Peripheral will be suspended during debug halt.	RW	0x0
