20	MUX20	R/W	0h	Selects the output of Mux20 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux20 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux20 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-107. OUTPUT3MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux19 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux19 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-107. OUTPUT3MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-107. OUTPUT3MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux2 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux2 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux1 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux1 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive OUTPUT3 of OUTPUT-XBAR 0: Respective output of Mux0 is disabled to drive the OUTPUT3 of OUTPUT-XBAR 1: Respective output of Mux0 is enabled to drive the OUTPUT3 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.6.20 OUTPUT4MUXENABLE Register (Offset = 26h) [Reset = 00000000h]

OUTPUT4MUXENABLE is shown in Figure 8-99 and described in Table 8-108.

Return to the Summary Table.

Output X-BAR Mux Enable for Output 4

Figure 8-99. OUTPUT4MUXENABLE Register

31	30	29	28	27	26	25	24

Table 8-108. OUTPUT4MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux31 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux31 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux30 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux30 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux29 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux29 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux28 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux28 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-108. OUTPUT4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux27 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux27 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux26 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux26 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux25 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux25 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux24 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux24 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux23 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux23 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux22 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux22 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux21 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux21 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux20 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux20 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-108. OUTPUT4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux19 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux19 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-108. OUTPUT4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-108. OUTPUT4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux2 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux2 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux1 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux1 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive OUTPUT4 of OUTPUT-XBAR 0: Respective output of Mux0 is disabled to drive the OUTPUT4 of OUTPUT-XBAR 1: Respective output of Mux0 is enabled to drive the OUTPUT4 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.6.21 OUTPUT5MUXENABLE Register (Offset = 28h) [Reset = 00000000h]

OUTPUT5MUXENABLE is shown in Figure 8-100 and described in Table 8-109.

Return to the Summary Table.

Output X-BAR Mux Enable for Output 5

Table 8-109. OUTPUT5MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux31 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux31 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux30 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux30 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux29 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux29 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux28 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux28 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-109. OUTPUT5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux27 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux27 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux26 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux26 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux25 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux25 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux24 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux24 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux23 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux23 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux22 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux22 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux21 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux21 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux20 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux20 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-109. OUTPUT5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux19 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux19 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-109. OUTPUT5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-109. OUTPUT5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux2 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux2 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux1 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux1 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive OUTPUT5 of OUTPUT-XBAR 0: Respective output of Mux0 is disabled to drive the OUTPUT5 of OUTPUT-XBAR 1: Respective output of Mux0 is enabled to drive the OUTPUT5 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.6.22 OUTPUT6MUXENABLE Register (Offset = 2Ah) [Reset = 00000000h]

OUTPUT6MUXENABLE is shown in Figure 8-101 and described in Table 8-110.

Return to the Summary Table.

Output X-BAR Mux Enable for Output 6

Figure 8-101. OUTPUT6MUXENABLE Register

31	30	29	28	27	26	25	24

Table 8-110. OUTPUT6MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux31 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux31 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux30 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux30 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux29 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux29 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux28 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux28 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-110. OUTPUT6MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux27 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux27 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux26 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux26 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux25 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux25 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux24 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux24 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux23 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux23 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux22 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux22 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux21 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux21 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux20 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux20 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-110. OUTPUT6MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux19 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux19 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-110. OUTPUT6MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-110. OUTPUT6MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux2 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux2 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux1 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux1 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux0 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux0 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.6.23 OUTPUT7MUXENABLE Register (Offset = 2Ch) [Reset = 00000000h]

OUTPUT7MUXENABLE is shown in Figure 8-102 and described in Table 8-111.

Return to the Summary Table.

Output X-BAR Mux Enable for Output 7

Figure 8-102. OUTPUT7MUXENABLE Register

Table 8-111. OUTPUT7MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux31 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux31 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux30 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux30 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux29 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux29 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux28 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux28 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-111. OUTPUT7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux27 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux27 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux26 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux26 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux25 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux25 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux24 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux24 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux23 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux23 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux22 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux22 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux21 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux21 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux20 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux20 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-111. OUTPUT7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux19 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux19 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-111. OUTPUT7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-111. OUTPUT7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux2 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux2 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux1 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux1 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive OUTPUT7 of OUTPUT-XBAR 0: Respective output of Mux0 is disabled to drive the OUTPUT7 of OUTPUT-XBAR 1: Respective output of Mux0 is enabled to drive the OUTPUT7 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.6.24 OUTPUT8MUXENABLE Register (Offset = 2Eh) [Reset = 00000000h]

OUTPUT8MUXENABLE is shown in Figure 8-103 and described in Table 8-112.

Return to the Summary Table.

Output X-BAR Mux Enable for Output 8

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux31 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux31 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux30 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux30 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux29 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux29 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux28 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux28 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-112. OUTPUT8MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux27 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux27 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux26 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux26 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux25 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux25 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux24 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux24 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux23 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux23 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux22 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux22 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux21 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux21 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of Mux20 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux20 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux20 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-112. OUTPUT8MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of Mux19 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux19 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux19 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-112. OUTPUT8MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-112. OUTPUT8MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of Mux3 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux3 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux3 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux2 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux2 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux1 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux1 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive OUTPUT8 of OUTPUT-XBAR 0: Respective output of Mux0 is disabled to drive the OUTPUT8 of OUTPUT-XBAR 1: Respective output of Mux0 is enabled to drive the OUTPUT8 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.6.25 OUTPUTLATCH Register (Offset = 30h) [Reset = 00000000h]

OUTPUTLATCH is shown in Figure 8-104 and described in Table 8-113.

Return to the Summary Table.

Output X-BAR Output Latch

Chapter 9

Analog Subsystem

The analog subsystem module is described in this chapter.

9.1 Introduction

The analog modules on this device include the Analog-to-Digital Converter (ADC), Temperature Sensor, Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

9.1.1 Features

The analog subsystem has the following features:

- Flexible voltage references
  - The ADCs are referenced to VREFHIx and VREFLOx pins
    - VREFHIx pin voltage must be driven in externally
- The buffered DACs are referenced to VREFHIx and VSSA
  - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- The comparator DACs are referenced to VDDA and VSSA
  - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- Flexible pin usage
  - Buffered DAC and comparator subsystem functions multiplexed with ADC inputs
- Internal connection to VREFLO on all ADCs for offset self-calibration

9.1.2 Block Diagram

The following analog subsystem block diagrams show the connections between the different integrated analog modules to the device pins. These pins fall into two categories: analog module inputs/outputs and reference pins.

The reference pins, VREFHIA to VREFHID and VREFLOA to VREFLOD, can be used to externally supply the reference to the ADC. VREFHIA can also be used to supply the reference voltage to DAC A and DAC B and VREFHIB can be used to supply the reference to DAC C.

The analog module input and outputs are all ADC inputs by default. The pins that connect to CMPSS inputs can be used for the CMPSS without further action and without preventing use as an ADC input simultaneously. DAC outputs must be enabled; this prevents the channel from simultaneously being used as an ADC input (but the ADC can be used to sample the DAC output voltage, if desired).

The VDAC reference pin can be used to set an alternate range for DAC A, DAC B, and DAC C and for the DACs inside the CMPSS modules (the CMPSS DACs are referenced to VDDA and VSSA by default). Using this pin as a reference prevents the channel from being used as an ADC input (but the ADC can be used to sample the VDAC voltage, if desired). The choice of reference is configurable per-module for each CMPSS or buffered DAC, and the selection is made using the module's configuration registers.

The following notes apply to all packages:

- Not all analog pins are available on all devices. See the device data sheet to determine which pins are available.
- See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
- An external capacitor is required on the VREFHI pins. See the device data sheet for the specific value required.
- For buffered DAC modules, VSSA is the low reference whether VREFHIx or VDAC is selected as the high reference.
- For CMPSS modules, VSSA is the low reference whether VDAC or VDDA is selected as the high reference.

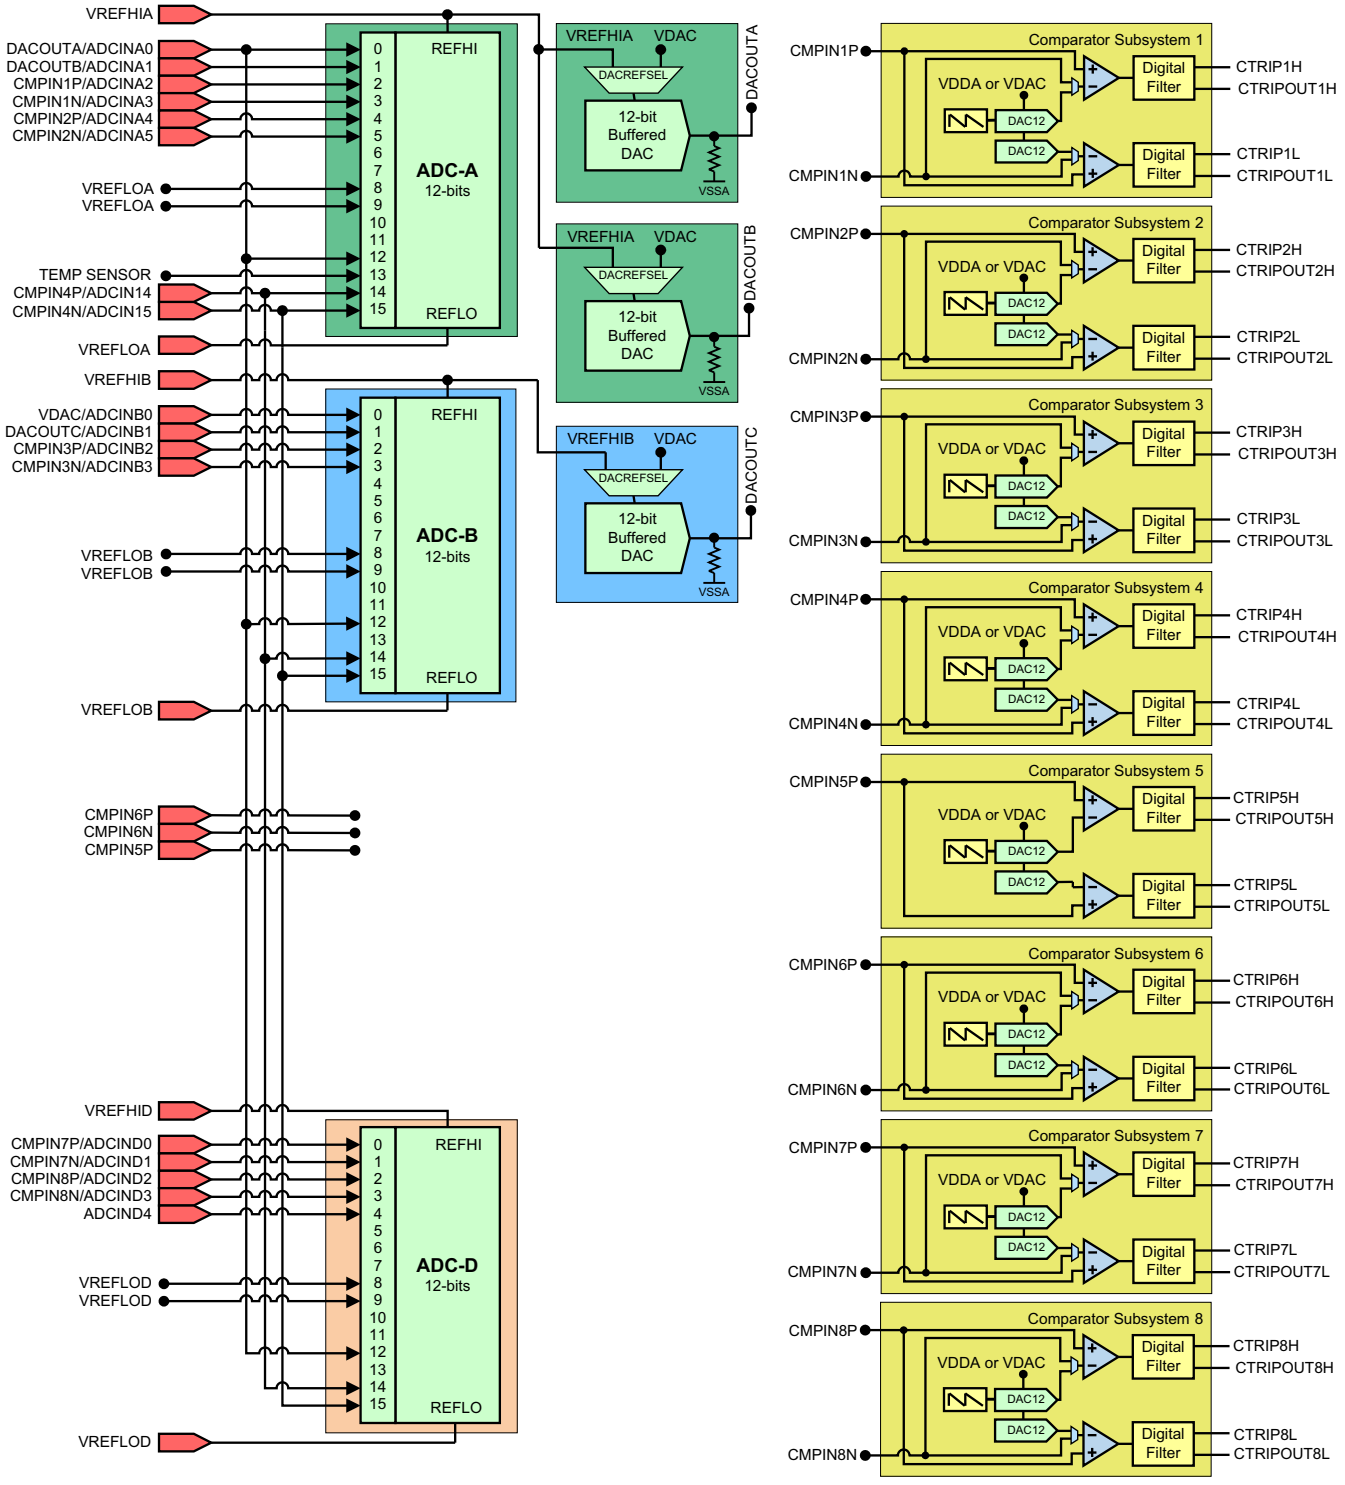

Figure 9-1. Analog Subsystem Block Diagram (176-Pin PTP)

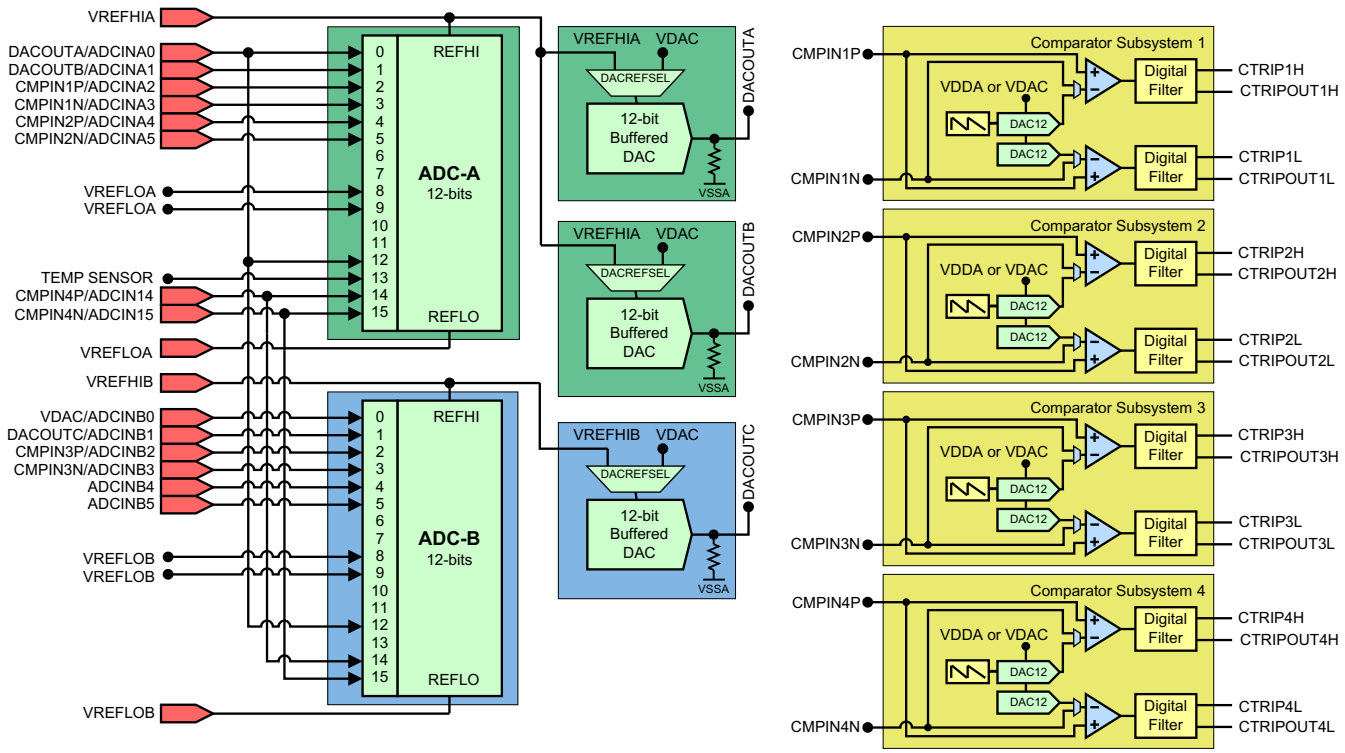

Figure 9-2. Analog Subsystem Block Diagram (100-Pin PZP)

Table 9-1. Analog Signal Descriptions

Signal Name	Description
ADCINAx	ADC A Input
ADCINBx	ADC B Input
ADCINDx	ADC D Input
CMPINxP	Comparator subsystem positive input
CMPINxN	Comparator subsystem negative input
DACOUTx	Buffered DAC Output
TEMP SENSOR	Internal temperature sensor
VDAC	Optional external reference voltage for on-chip DACs. There is a 100pF capacitor to VSSA on this pin whether used for ADC input or DAC reference that cannot be disabled. If this pin is being used as a reference for the on-chip DACs, place at least a 1µF capacitor on this pin.

Table 9-2. Reference Summary

Module	Reference Option	Configured Where?	Register	Driverlib Function	Notes
ADC	External or Internal	Not Configurable	N/A	N/A	VREFHI must always be driven externally on this device.
Buffered DAC	VREFHI or VDAC	DAC Module	DacxRegs. DACCTL.bit.DACREFSEL	DAC_CTL_DACREFSEL	
	External or Internal	Not Configurable	N/A	N/A	VREFHI must always be driven externally on this device.
CMPSS DACs	VDDA or VDAC	CMPSS Module	CmpssxRegs. COMPDACCTL.bit.SELREF	CMPSS_COMPDACCTL_SELREF	

9.2 Optimizing Power-Up Time

The analog-to-digital converters (ADC) and buffered digital-to-analog converters (DAC) share a common reference circuit. If needed, an application using one or more of these modules can optimize power-up time by taking advantage of the shared reference. Once one of the modules using the shared reference has been initialized in internal reference mode, the power-up time for subsequent modules can be optimized by subtracting the reference power-up time from the minimum power-up time requirement.

For instance, if ADCA requires $t_{ADCPUINT}$ to power up in internal reference mode, and $t_{ADCPUEXT}$ to power up in external reference mode, the application does not need to wait $t_{ADCPUINT}$ to power up a second ADC instance such as ADCC in internal reference mode. In this case, the application can simply wait for $t_{ADCPUEXT}$ after powering up ADCC, even though both ADCs are used in internal reference mode. In the same scenario, if the application wished to use DACA in internal reference mode, the required wait time after power-up is $t_{DACPUEXT}$, not the longer $t_{DACPUINT}$.

There is also a wait time associated with power-up in internal reference mode when switching between 2.5V and 3.3V range. See the device data sheet for wait time values.

9.3 Analog Subsystem Registers

This section describes the Analog Subsystem Registers.

9.3.1 Analog Subsystem Base Addresses

Table 9-3. Analog Subsystem Base Address Table

Device Registers	Register Name	Start Address	End Address
AnalogSubsysRegs	ANALOG_SUBSYS_REGS	0x0005_D180	0x0005_D1FF

9.3.2 ANALOG_SUBSYS_REGS Registers

Table 9-4 lists the memory-mapped registers for the ANALOG_SUBSYS_REGS registers. All register offset addresses not listed in Table 9-4 should be considered as reserved locations and the register contents should not be modified.

Table 9-4. ANALOG_SUBSYS_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
20h	INTOSC1TRIM	Internal Oscillator 1 Trim Register	EALLOW	Go
22h	INTOSC2TRIM	Internal Oscillator 2 Trim Register	EALLOW	Go
26h	TSNSCTL	Temperature Sensor Control Register	EALLOW	Go
2Eh	LOCK	Lock Register	EALLOW	Go
36h	ANAREFTRIMA	Analog Reference Trim A Register	EALLOW	Go
38h	ANAREFTRIMB	Analog Reference Trim B Register	EALLOW	Go
3Ch	ANAREFTRIMD	Analog Reference Trim D Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 9-5 shows the codes that are used for access types in this section.

Table 9-5. ANALOG_SUBSYS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Write once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

9.3.2.1 INTOSC1TRIM Register (Offset = 20h) [Reset = 00000000h]

INTOSC1TRIM is shown in Figure 9-3 and described in Table 9-6.

Return to the Summary Table.

Internal Oscillator 1 Trim Register

Chapter 10

Analog-to-Digital Converter (ADC)

The analog-to-digital converter (ADC) module described in this chapter is a Type 4 ADC. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

10.1 Introduction

The ADC module is a 12-bit successive approximation (SAR) style ADC . The ADC is composed of a core and a wrapper. The core is composed of the analog circuits which include the channel select MUX, the sample-and-hold (S/H) circuit, the successive approximation circuits, voltage reference circuits, and other analog support circuits. The wrapper is composed of the digital circuits that configure and control the ADC. These circuits include the logic for programmable conversions, result registers, interfaces to analog circuits, interfaces to the peripheral buses, post-processing circuits, and interfaces to other on-chip modules.

Each ADC module consists of a single sample-and-hold (S/H) circuit. The ADC module is designed to be duplicated multiple times on the same chip, allowing simultaneous sampling or independent operation of multiple ADCs. The ADC wrapper is start-of-conversion (SOC) based (see Section 10.3).

10.1.2 Features

Each ADC has the following features:

- 12-bit resolution
- Ratiometric external reference set by VREFHI and VREFLO pins
- Single-ended signal conversions
- Input multiplexer with up to 16 channels
- 16 configurable SOCs
- 16 individually addressable result registers
- Multiple trigger sources
  - S/W - software immediate start
  - All ePWMs - ADCSOC A or B
  - GPIO XINT2
  - CPU Timers 0/1/2
  - ADCINT1/2
- Four flexible PIE interrupts
- Configurable interrupt placement
- Burst mode
- Four post-processing blocks, each with:
  - Saturating offset calibration
  - Error from set-point calculation
  - High, low, and zero-crossing compare, with interrupt and ePWM trip capability
  - Trigger-to-sample delay capture

Note

Not every channel is pinned out from all ADCs. Check the device data sheet to determine which channels are available.

10.1.3 Block Diagram

Figure 10-1 shows the block diagram for the ADC core and ADC wrapper.

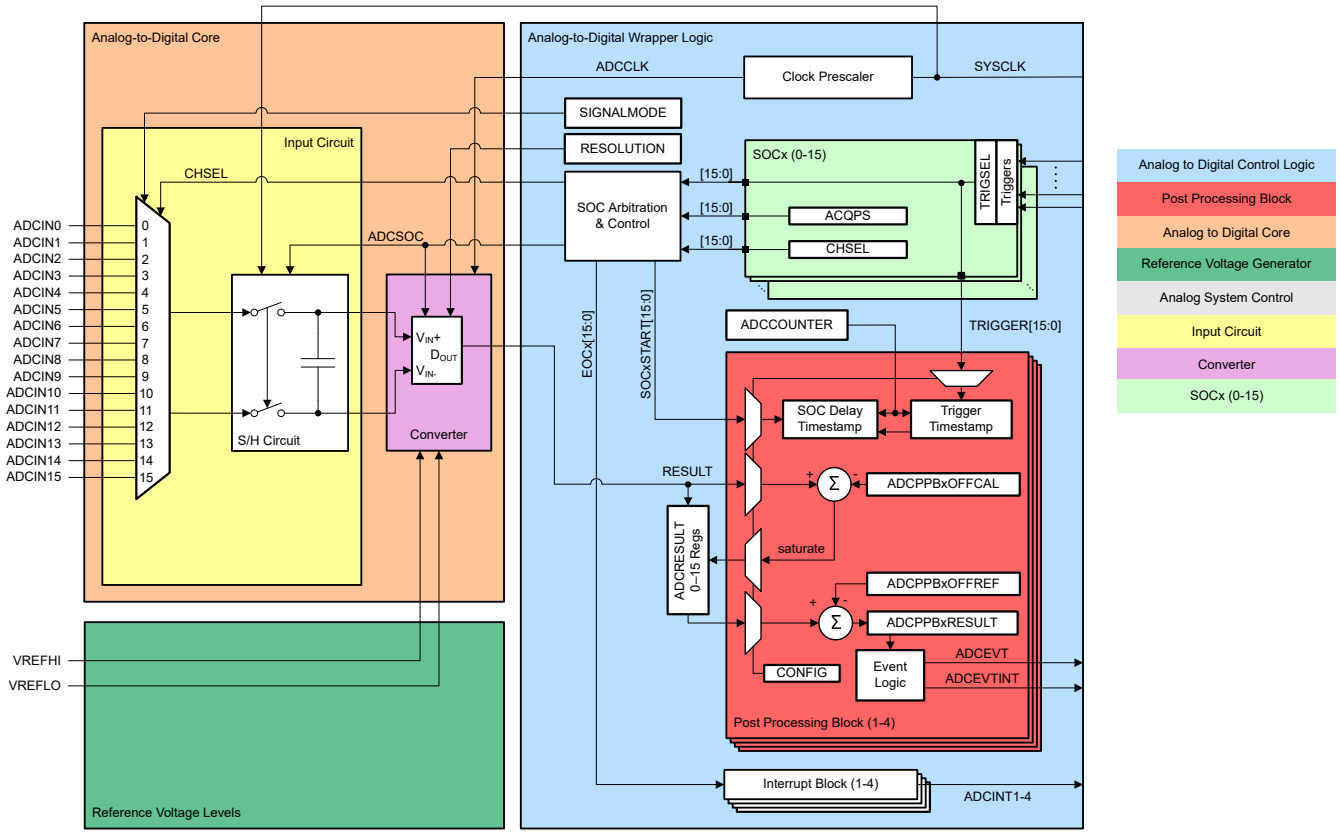

Figure 10-1. ADC Module Block Diagram

Note

The ADC block diagram reflects the number of ADC channels internally configurable on the device. The actual number of available external ADC inputs varies depending on part and package.

10.2 ADC Configurability

Some ADC configurations are individually controlled by the SOCs, while others are globally controlled per ADC module. Table 10-1 summarizes the basic ADC options and the level of configurability. The subsequent sections discuss these configurations.

Table 10-1. ADC Options and Configuration Levels

Options	Configurability
Clock	Per module(1)
Resolution	Not configurable (12-bit only)
Signal mode	Not configurable (single-ended only)
Reference voltage source	Not configurable (external reference only)
Trigger source	Per SOC(1)
Converted channel	Per SOC
Acquisition window duration	Per SOC(1)
EOC location	Per module (early or late)
Burst Mode	Per module(1)

(1) Writing these values differently to different ADC modules can cause the ADCs to operate asynchronously. See Section 10.13.1 for guidance on when the ADCs are operating synchronously or asynchronously.

10.2.1 Clock Configuration

The base ADC clock is provided directly by the system clock (SYSCLK). SYSCLK is used to generate the ADC acquisition window. The register ADCCTL2 has a PRESCALE field that determines the ADCCLK. ADCCLK is used to clock the converter, and is only active during the conversion phase. At all other times, including during the sample-and-hold window, the ADCCLK signal is gated off.

The core requires approximately 10.5 ADCCLK cycles to process a voltage into a conversion result. The user must determine the required duration of the acquisition window, see Section 10.13.2.

Note

To determine an appropriate value for ADCCTL2.PRESCALE, see the device data sheet to determine the maximum SYSCLK and ADCCLK frequency.

10.2.2 Resolution

The resolution of the ADC determines how finely the analog range is quantized into digital values. Each ADC module supports a fixed resolution of 12 bits.

The resolution must be configured by using either the AdcSetMode() or ADC_setMode() functions, depending on the header files used, provided in C2000ware in F2807x_Adc.c. These functions make sure that the correct trim is loaded into the ADC trim registers, and must be called at least once after a device reset. Do not configure the resolution by directly writing to the ADCCTL2 register.

10.2.3 Voltage Reference

10.2.3.1 External Reference Mode

Each ADC has a VREFHI input and a VREFLO input. In external reference mode, these pins are used as a ratiometric reference to determine the ADC conversion input range.

See Section 10.13.6 for information on how to supply the reference voltage.

Note

- On devices with no external VREFLO pin, VREFLO is internally connected to the device analog ground, VSSA.
- See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
- The external reference mode requires an external capacitor on the VREFHI pin. See the device data sheet for the specific value required.

10.2.4 Signal Mode

The ADC supports single-ended signaling.

In single-ended mode, the input voltage to the converter is sampled through a single pin (ADCINx), referenced to VREFLO.

10.2.5 Expected Conversion Results

Based on a given analog input voltage, the expected digital conversion is given in Table 10-2. Fractional values are truncated.

Table 10-2. Analog to 12-bit Digital Formulas

Analog Input	Digital Result
when ADCINy ≤ VREFLO	ADCRESULTx = 0
when VREFLO < ADCINy < VREFHI	$\text{ADCRESULTx} = 4096 \left(\frac{\text{ADCINy - VREFLO}}{\text{VREFHI - VREFLO}} \right)$
when ADCINy ≥ VREFHI	ADCRESULTx = 4095

10.2.6 Interpreting Conversion Results

Based on a given ADC conversion result, the corresponding analog input is given in Table 10-3. This corresponds to the center of the possible range of analog voltages that can produce this conversion result.

Table 10-3. 12-Bit Digital-to-Analog Formulas

Digital Value	Analog Equivalent	
when ADCRESULTy = 0	$\text{ADCINx} \leq \text{VREFLO}$	(1)
when 0 < ADCRESULTy < 4095	$\text{ADCINx} = (\text{VREFHI} - \text{VREFLO})\left(\frac{\text{ADCRESULTy}}{4096}\right) + \text{VREFLO}$	(2)
when ADCRESULTy = 4095	$\text{ADCINx} \geq \text{VREFHI}$	(3)

10.3 SOC Principle of Operation

The ADC triggering and conversion sequencing is accomplished through configurable start-of-conversions (SOCs). Each SOC is a configuration set defining the single conversion of a single channel. In that set, there are three configurations: the trigger source that starts the conversion, the channel to convert, and the acquisition (sample) window duration. Upon receiving the trigger configured for a SOC, the wrapper makes sure that the specified channel is captured using the specified acquisition window duration.

Multiple SOCs can be configured for the same trigger, channel, and acquisition window as desired. Configuring multiple SOCs to use the same trigger allows the trigger to generate a sequence of conversions. Configuring multiple SOCs to use the same trigger and channel allows for oversampling.

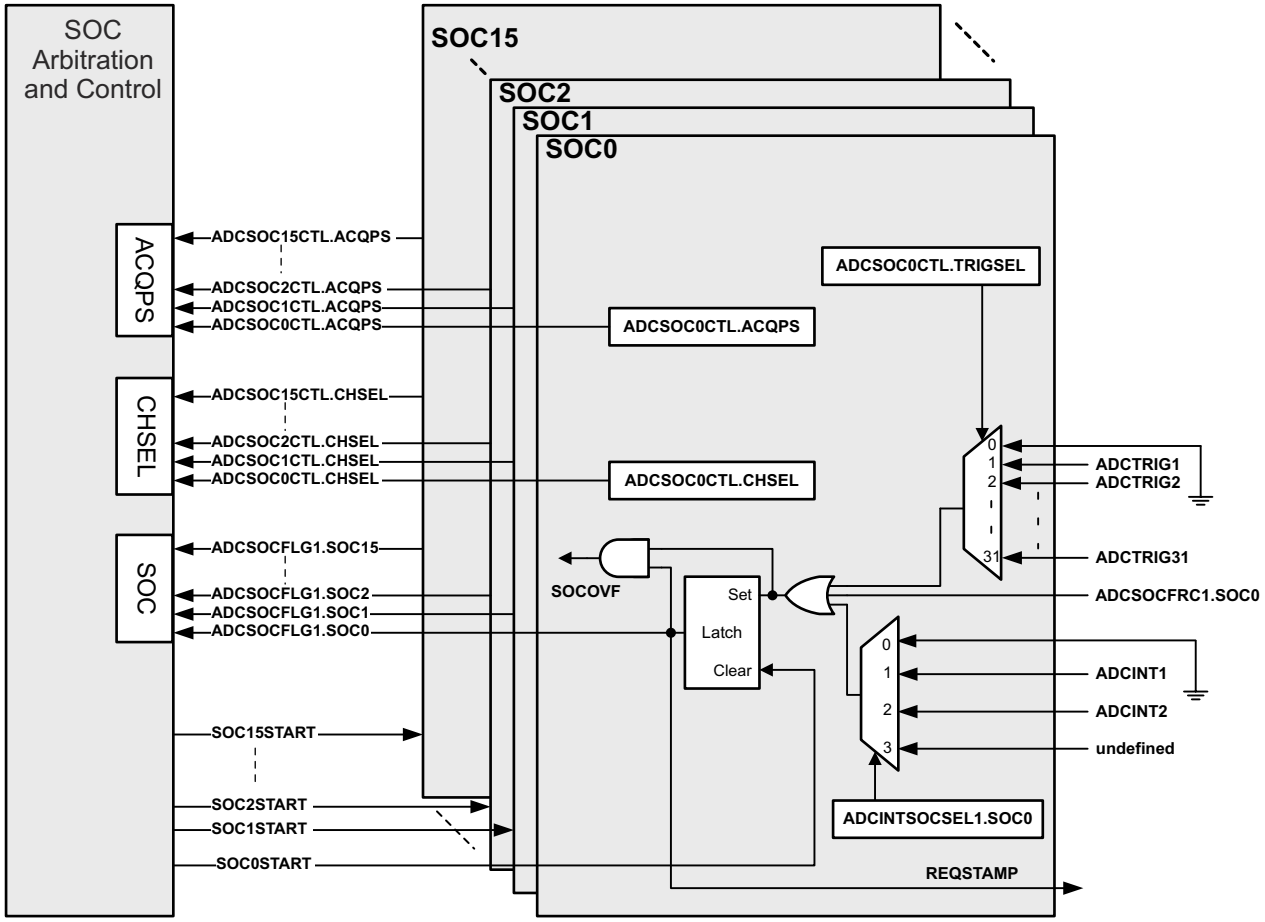

Figure 10-2. SOC Block Diagram

10.3.1 SOC Configuration

Each SOC has a configuration register, ADCSOCxCTL. Within this register, SOCx can be configured for trigger source, channel to convert, and acquisition (sample) window duration.

10.3.2 Trigger Operation

Each SOC can be configured to start on one of many input triggers. The primary trigger select for SOCx is in the ADCSOCxCTL.TRIGSEL register, which can select between:

- Disabled (software only)
- CPU Timers 0/1/2
- GPIO: Input X-Bar INPUT5
- ADCSOCA or ADCSOCB from each ePWM module

In addition, each SOC can also be triggered when the ADCINT1 flag or ADCINT2 flag is set. This is achieved by configuring the ADCINTSOCSEL1 register (for SOC0 to SOC7) or the ADCINTSOCSEL2 register (for SOC8 to SOC15). This is useful for creating continuous conversions.

10.3.3 ADC Acquisition (Sample and Hold) Window

External signal sources vary in the ability to drive an analog signal quickly and effectively. To achieve rated resolution, the signal source needs to charge the sampling capacitor in the ADC core to within 0.5 LSBs of the signal voltage. The acquisition window is the amount of time the sampling capacitor is allowed to charge and is configurable for SOCx by the ADCSOCxCTL.ACQPS register.

ACQPS is a 9-bit register that can be set to a value between 0 and 511, resulting in an acquisition window duration of:

Acquisition window = (ACQPS + 1) * (System Clock (SYSCLK) cycle time)

- The acquisition window duration is based on the System Clock (SYSCLK), not the ADC clock (ADCCLK).
- The selected acquisition window duration must be at least as long as one ADCCLK cycle.
- The data sheet specifies a minimum acquisition window duration (in nanoseconds). The user is responsible for selecting an acquisition window duration that meets this requirement.

10.3.4 ADC Input Models

For single-ended operation, the ADC input characteristics for values in the single-ended input model (see Figure 10-3) can be found in the device data sheet.

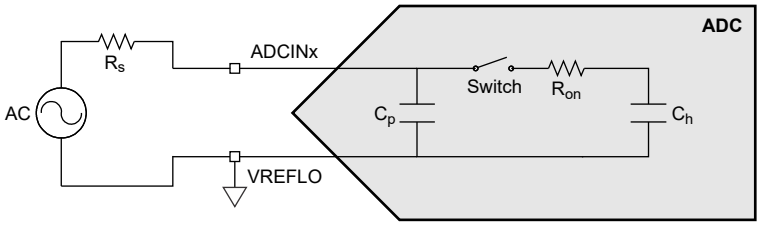

Figure 10-3. Single-Ended Input Model

These input models must be used along with actual signal source impedance to determine the acquisition window duration. See Section 10.13.2 for more information.

10.3.5 Channel Selection

Each SOC can be configured to convert any of the ADC channels. This behavior is selected for SOCx by the ADCSOCxCTL.CHSEL register. This is summarized in Table 10-4.

Table 10-4. Channel Selection of Input Pins

Input Mode	CHSEL	Input
Single-Ended	0	ADCIN0
	1	ADCIN1
	2	ADCIN2
	3	ADCIN3
	4	ADCIN4
	5	ADCIN5
	6	ADCIN6
	7	ADCIN7
	8	ADCIN8
	9	ADCIN9
	10	ADCIN10
	11	ADCIN11
	12	ADCIN12
	13	ADCIN13
	14	ADCIN14
	15	ADCIN15

10.4 SOC Configuration Examples

The following sections provide some specific examples of how to configure the SOCs to produce some conversions.

10.4.1 Single Conversion from ePWM Trigger

To configure ADCA to perform a single conversion on channel ADCIN1 when the ePWM timer reaches the period match, a few things are necessary. First, ePWM3 must be configured to generate an SOCA or SOCB signal (in this statement, SOC refers to a signal in the ePWM module). See the *Enhanced Pulse Width Modulator Module (ePWM)* chapter on how to do this. Assume that SOCB was chosen.

SOC5 is chosen arbitrarily. Any of the 16 SOCs can be used.

Assuming a 100ns sample window is desired with a SYSCLK frequency of 120MHz, then the acquisition window duration must be 100ns/8.333ns = 12 cycles. The ACQPS field must be set to 12 - 1 = 11.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 converts ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 11;     //SOC5 uses a sample duration of 12 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;   //SOC5 begins conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches the period and generates the SOCB signal, the ADC begins sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 begins sampling when SOC5 gains priority (see Section 10.5). The ADC control logic samples ADCINA1 with the specified acquisition window width of 100ns. Immediately after the acquisition is complete, the ADC begins converting the sampled voltage to a digital value. When the ADC conversion is complete, the results are available in the ADCRESULT5 register (see Section 10.12 for exact sample, conversion, and result latch timings).

10.4.2 Oversampled Conversion from ePWM Trigger

To configure the ADC to oversample ADCINA1 4 times, we use the same configurations as the previous example, but apply them to SOC5, SOC6, SOC7, and SOC8.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;        //SOC5 converts ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 11;       //SOC5 uses a sample duration of 12 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;     //SOC5 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC6CTL.bit.CHSEL = 1;        //SOC6 converts ADCINA1
AdcaRegs.ADCSOC6CTL.bit.ACQPS = 11;       //SOC6 uses a sample duration of 12 SYSCLK cycles
AdcaRegs.ADCSOC6CTL.bit.TRIGSEL = 10;     //SOC6 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC7CTL.bit.CHSEL = 1;        //SOC7 converts ADCINA1
AdcaRegs.ADCSOC7CTL.bit.ACQPS = 11;       //SOC7 uses a sample duration of 12 SYSCLK cycles
AdcaRegs.ADCSOC7CTL.bit.TRIGSEL = 10;     //SOC7 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC8CTL.bit.CHSEL = 1;        //SOC8 converts ADCINA1
AdcaRegs.ADCSOC8CTL.bit.ACQPS = 11;       //SOC8 uses a sample duration of 12 SYSCLK cycles
AdcaRegs.ADCSOC8CTL.bit.TRIGSEL = 10;     //SOC8 begins conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches the period and generates the SOCB signal, the ADC begins sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 begins sampling when SOC5 gains priority (see Section 10.5). Once the conversion is complete for SOC5, SOC6 begins converting ADCINA1 and the results for SOC5 are placed in the ADCRESULT5 register. All four conversions eventually are completed sequentially, with the results in ADCRESULT5, ADCRESULT6, ADCRESULT7, and ADCRESULT8 for SOC5, SOC6, SOC7, and SOC8, respectively.

Note

It is possible, but unlikely, that the ADC can begin converting SOC6, SOC7, or SOC8 before SOC5 depending on the position of the round-robin pointer when the ePWM trigger is received. See Section 10.5 to understand how the next SOC to be converted is chosen.

10.4.3 Multiple Conversions from CPU Timer Trigger

This example shows how to sample multiple signals with different acquisition window requirements. CPU1 Timer 2 is used to generate the trigger. To see how to configure the CPU timer, see the *System Control and Interrupts* chapter.

A good first step when designing a sampling scheme with many signals is to list out the signals and the required acquisition window. From this, calculate the necessary number of SYSCLK cycles for each signal, then the ACQPS register setting. This is shown in Table 10-5, where a SYCLK of 120MHz is assumed (8.333ns cycle time).

Table 10-5. Example Requirements for Multiple Signal Sampling

Signal Name	Acquisition Window Requirement	Acquisition Window (SYSCLK Cycles)	ACQPS Register Value
Signal 1	>200ns	200ns/8.333ns = 24	24 – 1 = 23
Signal 2	>740ns	740ns/8.333ns = 89 (round up)	89 – 1 = 88
Signal 3	>183.33ns	183.333ns/8.333ns = 22	22 – 1 = 21
Signal 4	>485ns	485ns/8.333ns = 59 (round up)	59 – 1 = 58

Next decide which ADC pins to connect to each signal. This is highly dependent on the application board layout. Once the pins are selected, determining the value of CHSEL is straightforward (see Table 10-6).

Table 10-6. Example Connections for Multiple Signal Sampling

Signal Name	ADC Pin	CHSEL Register Value
Signal 1	ADCINA5	5
Signal 2	ADCINA0	0
Signal 3	ADCINA3	3
Signal 4	ADCINA2	2

With the information tabulated, generate the SOC configurations:

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 5;        //SOC0 converts ADCINA5
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 23;       //SOC0 uses a sample duration of 24 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 3;      //SOC0 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC1CTL.bit.CHSEL = 0;        //SOC1 converts ADCINA0
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 88;       //SOC1 uses a sample duration of 89 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 3;      //SOC1 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC2CTL.bit.CHSEL = 3;        //SOC2 converts ADCINA3
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 21;       //SOC2 uses a sample duration of 22 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 3;      //SOC2 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC3CTL.bit.CHSEL = 2;        //SOC3 converts ADCINA2
AdcaRegs.ADCSOC3CTL.bit.ACQPS = 58;       //SOC3 uses a sample duration of 59 SYSCLK cycles
AdcaRegs.ADCSOC3CTL.bit.TRIGSEL = 3;      //SOC3 begins conversion on CPU1 Timer 2
```

As configured, when CPU1 Timer 2 generates an event, SOC0, SOC1, SOC2, and SOC3 eventually is sampled and converted, in that order. The conversion results for ACINA5 (Signal 1) are in ADCRESULT0. Similarly, The results for ADCINA0 (Signal 2), ADCINA3 (Signal 3), and ADCINA2 (Signal 4) are in ADCRESULT1, ADCRESULT2, and ADCRESULT3, respectively.

Note

There is a possibility, but unlikely, that the ADC can begin converting SOC1, SOC2, or SOC3 before SOC0 depending on the position of the round-robin pointer when the CPU Timer trigger is received. See Section 10.5 to understand how the next SOC to be converted is chosen.

10.4.4 Software Triggering of SOCs

At any point, whether or not the SOCs have been configured to accept a specific trigger, a software trigger can set the SOCs to be converted. This is accomplished by writing bits in the ADCSOCFRC1 register.

Software triggering of the previous example without waiting for the CPU1 Timer 2 to generate the trigger can be accomplished by the statement:

```
AdcaRegs.ADCSOCFRC1.all = 0x000F;        //set SOC flags for SOC0 to SOC3
```

10.5 ADC Conversion Priority

When multiple SOC flags are set at the same time, one of two forms of priority determines the converted order. The default priority method is round-robin. In this scheme, no SOC has an inherent higher priority than another. Priority depends on the round-robin pointer (RRPOINTER). The RRPOINTER reflected in the ADCSOCPRIORITYCTL register points to the last SOC converted. The highest priority SOC is given to the next value greater than the RRPOINTER value, wrapping around back to SOC0 after SOC15. At reset the value is 16 since 0 indicates a conversion has already occurred. When RRPOINTER equals 16 the highest priority is given to SOC0. The RRPOINTER is reset when the ADC module is reset or when the reset value is written to the SOCPRICTL register. The ADC module is reset by writing and clearing the SOFTPRES bit corresponding to the ADC instance.

An example of the round-robin priority method is given in Figure 10-4.

The SOCPRIORITY field in the ADCSOCPRIORITYCTL register can be used to assign high priority from a single to all of the SOCs. When configured as high priority, an SOC interrupts the round-robin wheel after any current conversion completes and inserts in as the next conversion. After the conversion completes, the round-robin wheel continues where the conversion was interrupted. If two high priority SOCs are triggered at the same time, the SOC with the lower number takes precedence.

High priority mode is assigned first to SOC0, then in increasing numerical order. The value written in the SOCPRIORITY field defines the first SOC that is not high priority. In other words, if a value of 4 is written into SOCPRIORITY, then SOC0, SOC1, SOC2, and SOC3 are defined as high priority, with SOC0 the highest.

An example using high priority SOC's is given in Figure 10-5.

A After reset, SOC0 is highest priority SOC; SOC7 receives trigger; SOC7 configured channel is converted immediately.

B RRPOINTER changes to point to SOC 7; SOC8 is now highest priority SOC .

C SOC2 & SOC12 triggers rcvd. simultaneously; SOC12 is first on round robin wheel ; SOC12 configured channel is converted while SOC2 stays pending.

D RRPOINTER changes to point to SOC 12; SOC2 configured channel is now converted .

E RRPOINTER changes to point to SOC 2; SOC3 is now highest priority SOC .

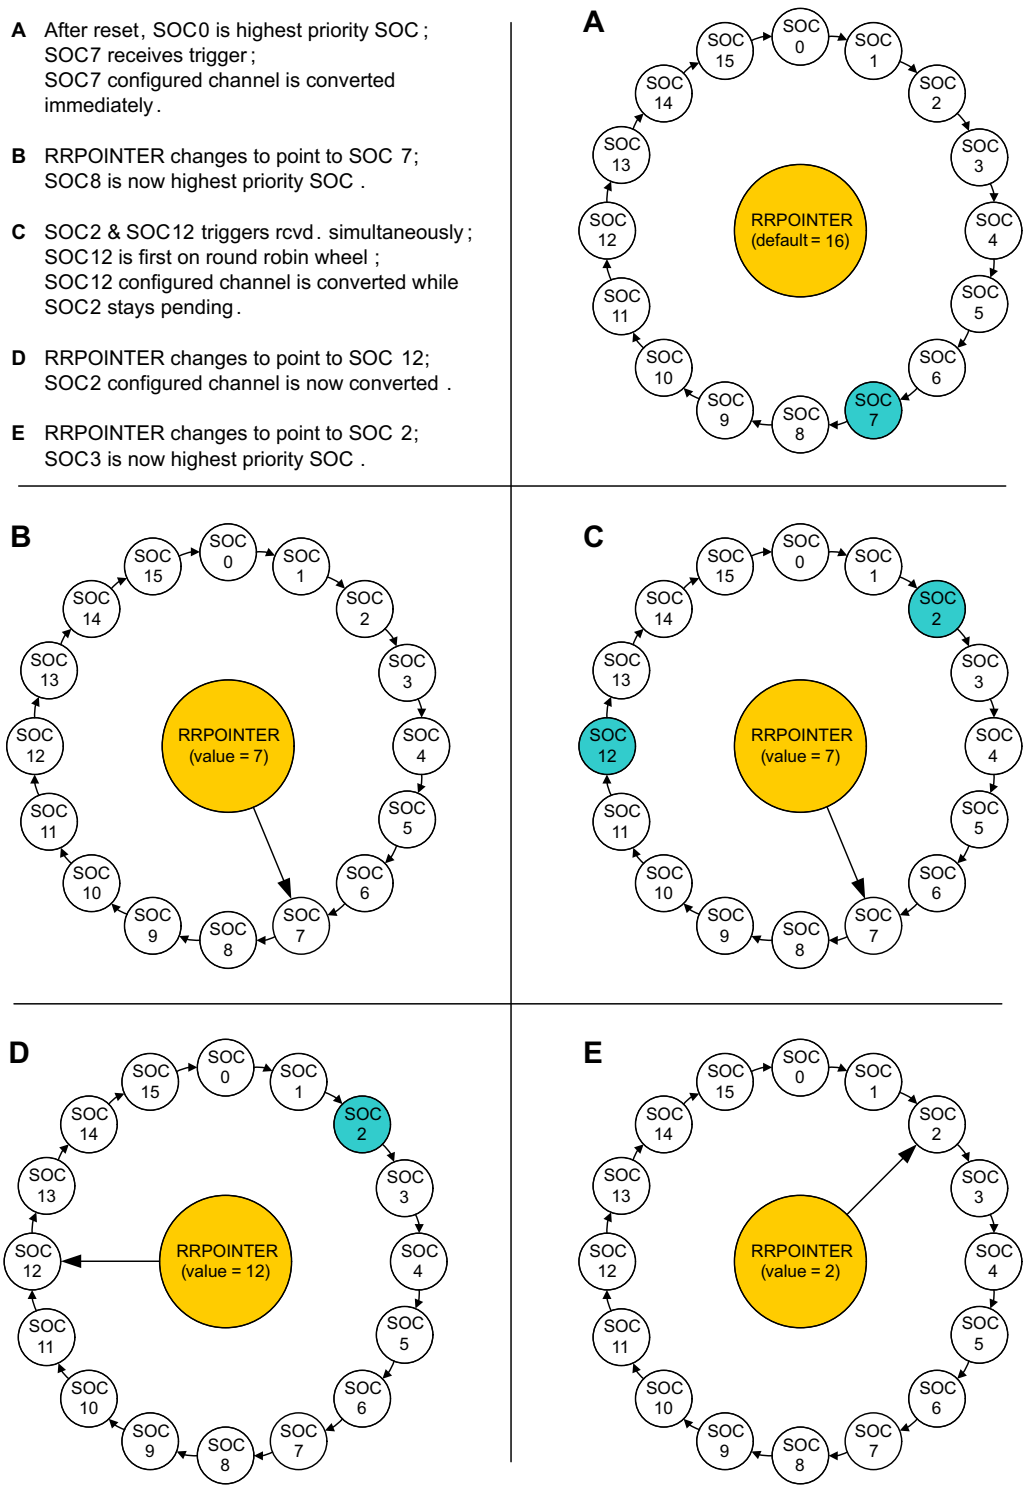

Figure 10-4. Round Robin Priority Example

Example when SOCPRIORITY = 4

A After reset, SOC4 is 1st on round robin wheel ;
SOC7 receives trigger ;
SOC7 configured channel is converted immediately .

B RRPOINTER changes to point to SOC 7;
SOC8 is now 1st on round robin wheel .

C SOC2 & SOC12 triggers rcvd . simultaneously ;
SOC2 interrupts round robin wheel and SOC 2 configured channel is converted while SOC 12 stays pending .

D RRPOINTER stays pointing to 7;
SOC12 configured channel is now converted .

E RRPOINTER changes to point to SOC 12;
SOC13 is now 1st on round robin wheel .

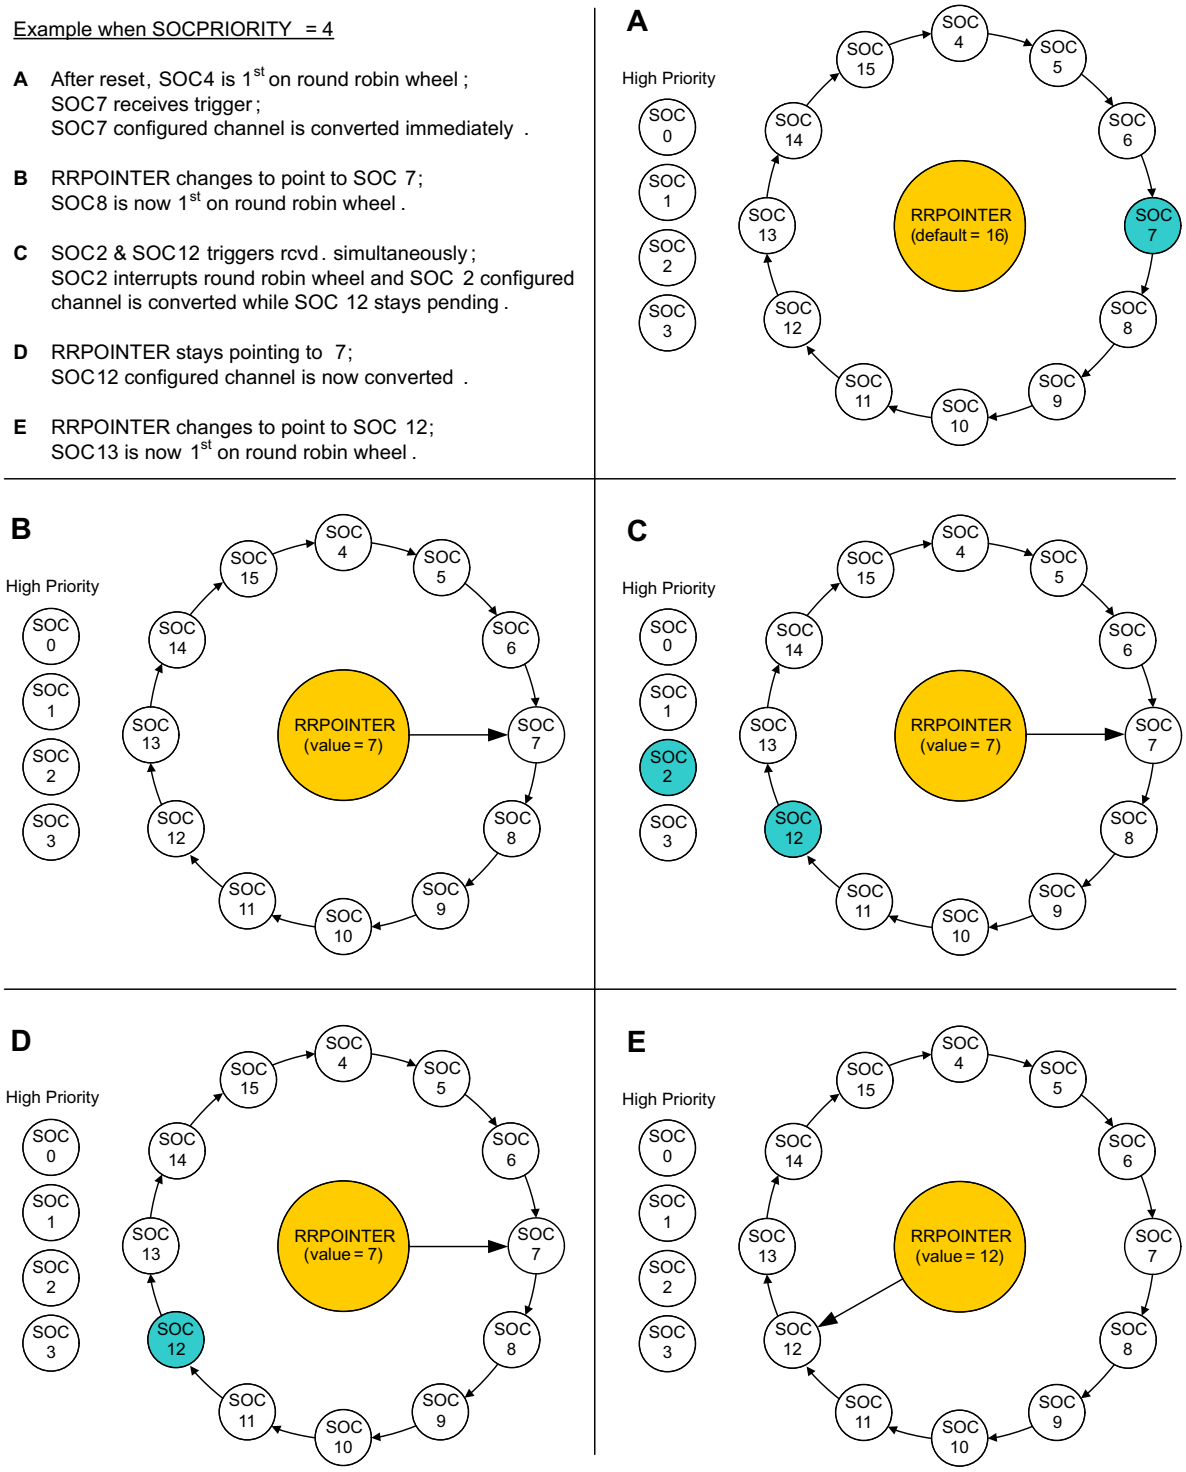

Figure 10-5. High Priority Example

10.6 Burst Mode

Burst mode allows a single trigger to walk through the round-robin SOCs one or more at a time. Setting the bit BURSTEN in the ADCBURSTCTL register configures the ADC wrapper for burst mode. This causes the TRIGSEL field to be ignored, but only for SOCs that are configured for round-robin operation (not high priority). Instead of the TRIGSEL field, all round-robin SOCs are triggered based on the BURSTTRIG field in the ADCBURSTCTL register. Upon reception of the burst trigger, the ADC wrapper does not set all round-robin SOCs to be converted, but only (ADCBURSTCTL.BURSTSIZE + 1) SOCs. The first SOC to be set is the SOC with the highest priority based on the round-robin pointer, and subsequent SOCs are set until BURSTSIZE SOCs have been set.

Note

When configuring the ADC for burst mode, the user is responsible for ensuring that each burst of conversions is allowed to complete before the next burst trigger is received. The value of (ADCBURSTCTL.BURSTSIZE + 1) must be less than or equal to the number of SOCs configured for round-robin priority.

For example, if SOCPRIORITY = 12, that is, SOC12, SOC13, SOC14, and SOC15 are in round-robin, ADCBURSTCTL.BURSTSIZE setting must be ≤3 for burst mode to operate correctly.

10.6.1 Burst Mode Example

Burst mode can be used to sample a different set of signals on every other trigger. In the following example, ADCIN7 and ADCIN5 are converted on the first trigger from CPU1 Timer 2 and every other trigger thereafter. ADCIN2 and ACIN3 are converted on the second trigger from CPU1 Timer 2 and every other trigger thereafter. All signals are converted with 20 SYSCLK cycle wide acquisition windows, but different durations can be configured for each SOC as desired.

```
AdcaRegs.BURSTCTL.BURSTEN = 1;              //Enable ADC burst mode
AdcaRegs.BURSTCTL.BURSTTRIG = 3;            //CPU1 Timer 2 triggers burst of conversions
AdcaRegs.BURSTCTL.BURSTSIZE = 1;            //conversion bursts are 1 + 1 = 2 conversions long
AdcaRegs.SOCPRICTL.bit.SOCPRIORITY = 12;    //SOC0 to SOC11 are high priority
AdcaRegs.ADCSOC12CTL.bit.CHSEL = 7;         //SOC12 converts ADCINA7
AdcaRegs.ADCSOC12CTL.bit.ACQPS = 19;        //SOC12 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC13CTL.bit.CHSEL = 5;         //SOC13 converts ADCINA5
AdcaRegs.ADCSOC13CTL.bit.ACQPS = 19;        //SOC13 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC14CTL.bit.CHSEL = 2;         //SOC14 converts ADCINA2
AdcaRegs.ADCSOC14CTL.bit.ACQPS = 19;        //SOC14 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC15CTL.bit.CHSEL = 3;         //SOC15 converts ADCINA3
AdcaRegs.ADCSOC15CTL.bit.ACQPS = 19;        //SOC15 uses sample duration of 20 SYSCLK cycles
```

When the first CPU1 Timer 2 trigger is received, SOC12 and SOC13 are converted immediately if the ADC is idle. If the ADC is busy, SOC12 and SOC13 are converted once the SOCs gain priority. The results for SOC12 and SOC13 are in ADCRESULT12 and ADCRESULT13, respectively. After SOC13 completes, the round-robin pointer gives the highest priority to SOC14. Because of this, when the next CPU1 Timer 2 trigger is received, SOC14 and SOC15 is set as pending and eventually converted. The results for SOC14 and SOC15 are in ADCRESULT14 and ADCRESULT15, respectively. Subsequent triggers continue to toggle between converting SOC12 and SOC13, and converting SOC14 and SOC15.

While the above example toggles between two sets of conversions, three or more different sets of conversions can be achieved using a similar approach.

10.6.2 Burst Mode Priority Example

An example of priority resolution using burst mode and high-priority SOCs is presented in Figure 10-6.

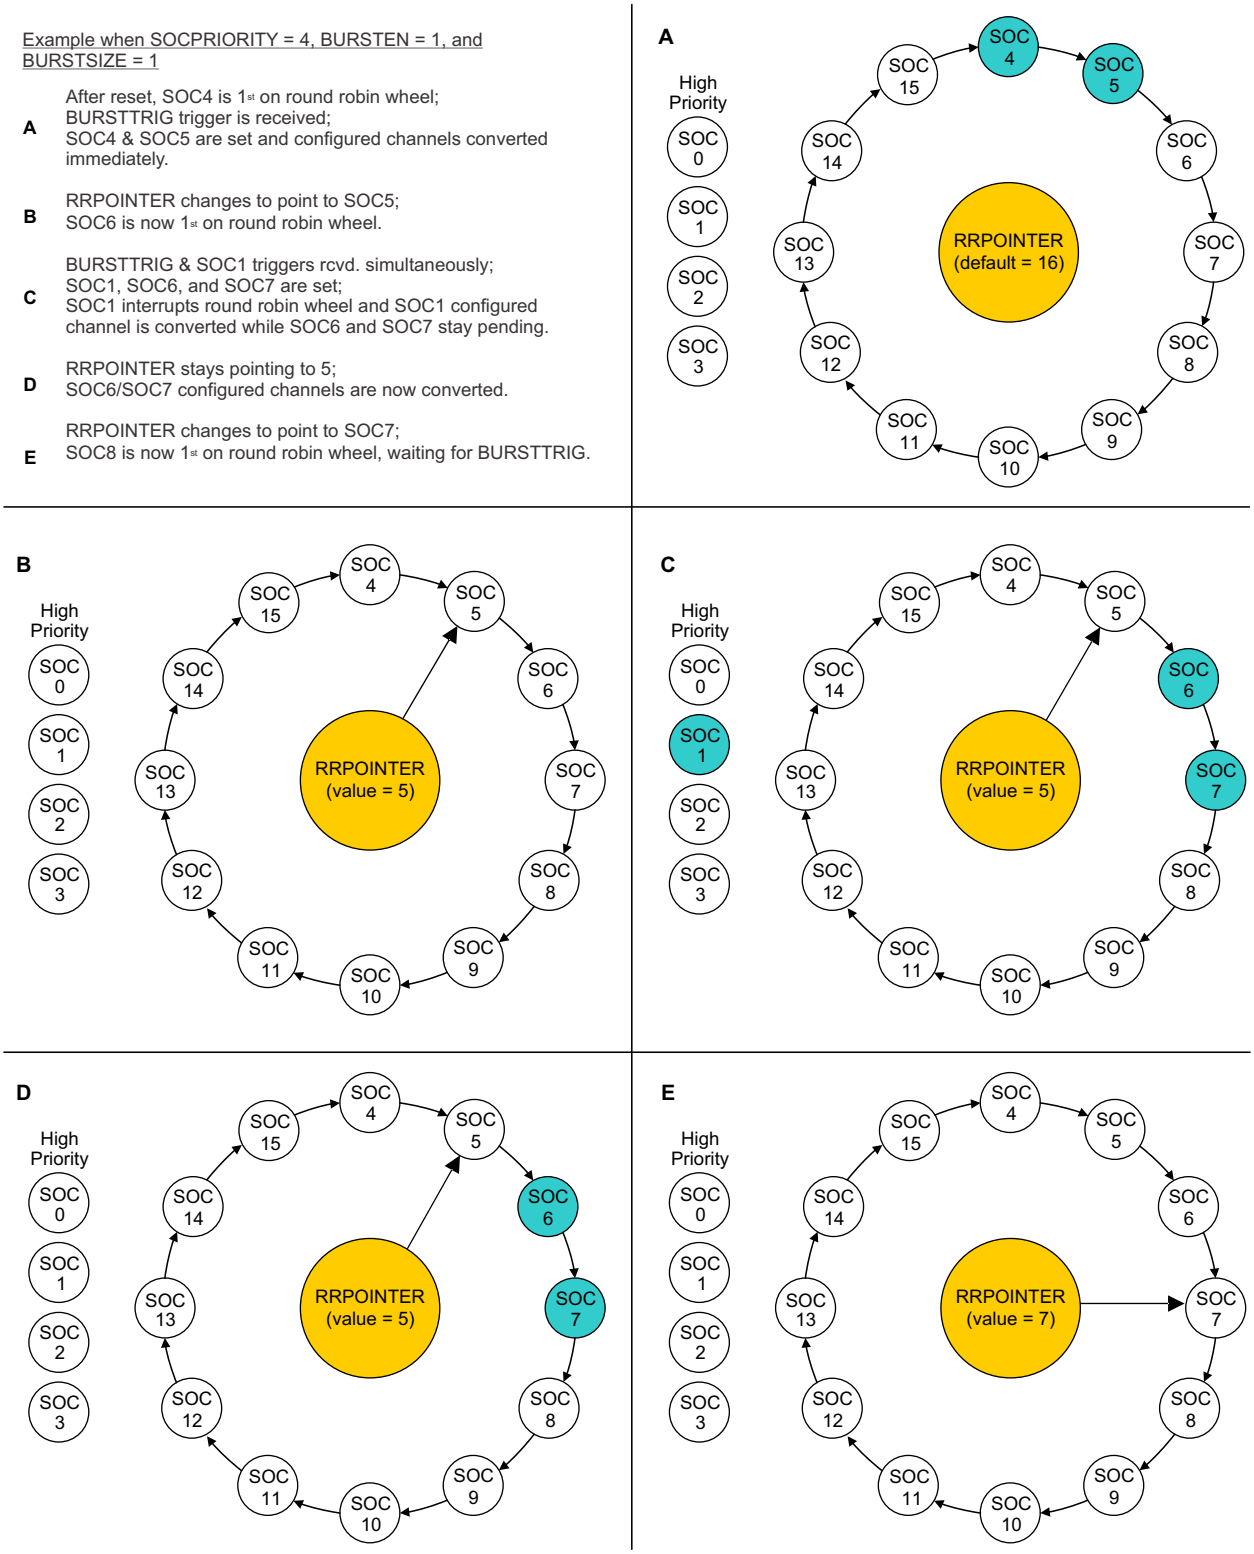

Figure 10-6. Burst Priority Example

10.7 EOC and Interrupt Operation

Each SOC has a corresponding end-of-conversion (EOC) signal. This EOC signal can be used to trigger an ADC interrupt. The ADC can be configured to generate the EOC pulse at either the end of the acquisition window or at the end of the voltage conversion. This is configured using the bit INTPULSEPOS in the ADCCTL1 register. See Section 10.12 for exact EOC pulse location.

Each ADC module has 4 configurable ADC interrupts. These interrupts can be triggered by any of the 16 EOC signals. The flag bit for each ADCINT can be read directly to determine if the associated SOC is complete or the interrupt can be passed on to the PIE.

Note

The ADCCTL1.ADCBSY bit being clear does not indicate that all conversions in a set of SOCs have completed, only that the ADC is ready to process the next conversion. To determine if a sequence of SOCs is complete, link an ADCINT flag to the last SOC in the sequence and monitor that ADCINT flag.

Figure 10-7 shows a block diagram of the ADC interrupt structure.

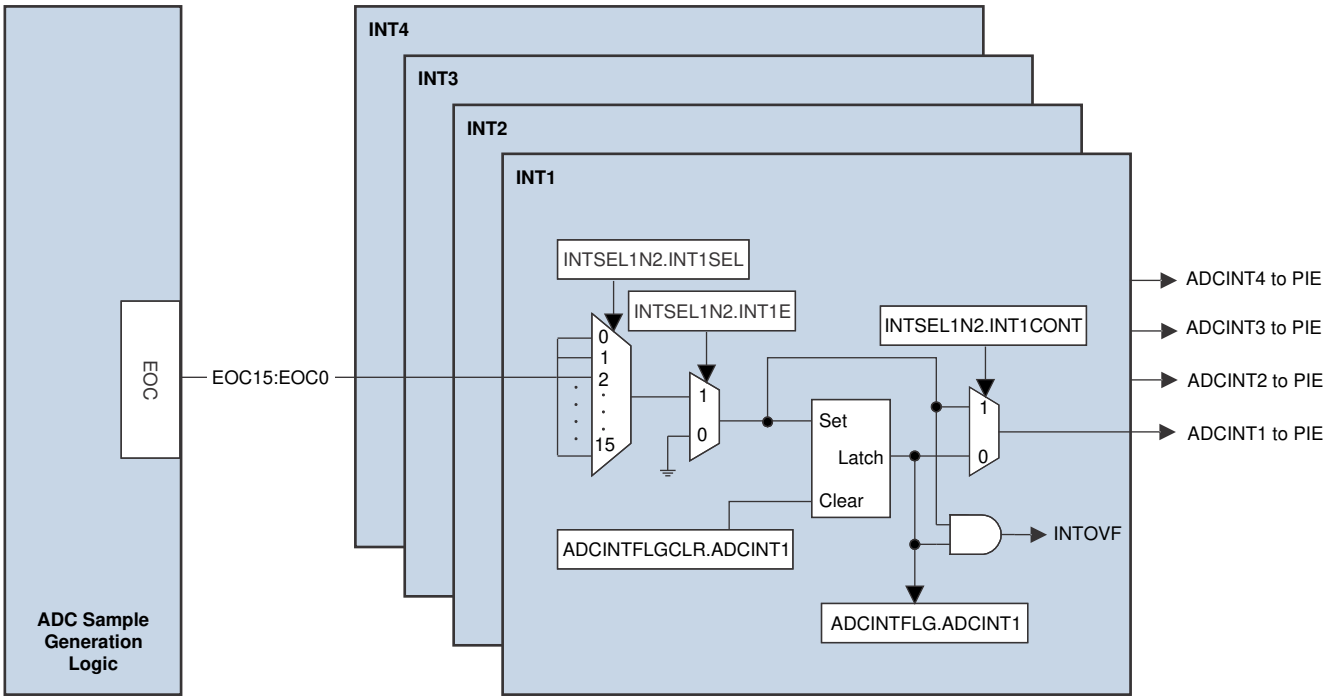

Figure 10-7. ADC EOC Interrupts

10.7.1 Interrupt Overflow

If the EOC signal sets a flag in the ADCINTFLG register, but that flag is already set, an interrupt overflow occurs. By default, overflow interrupts are not passed on to the PIE module. When an overflow occurs on a given flag in the ADCINTFLG register, the corresponding flag in the ADCINOVF register is set. This overflow flag is only used to detect that an overflow has occurred; the flag does not block further interrupts from propagating to the PIE module.

When an ADC interrupt overflow occurs, the application must check the appropriate ADCINTOVF flag inside the ISR or in the background loop and take appropriate action when an overflow is detected. The following code snippets demonstrate how to check the ADCINTOVF flag inside the ISR after attempting to clear the ADCINT flag.

```
// Clear the interrupt flag
AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1;      //clear INT1 flag for ADC-A

// Check if an overflow has occurred
if(1 == AdcaRegs.ADCINTOVF.bit.ADCINT1)     //ADCINT overflow occurred
{
    AdcaRegs.ADCINTOVFCLR.bit.ADCINT1 = 1   //Clear overflow flag
    AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1   //Re-clear ADCINT flag
}
```

```
//
// Clear the interrupt flag
//
ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);

//
// Check if an overflow has occurred
//
if(true == ADC_getInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1))
{
    ADC_clearInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1);
    ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);
}
```

10.7.2 Continue to Interrupt Mode

The INTxCONT bits in the ADCINTSEL1N2 and ADCINTSEL3N4 registers configure how interrupts are handled when an ADCINTFLG has not yet been cleared from a prior interrupt. This mode is disabled by default and additional overlapping interrupts are not issued to the PIE. By activating this mode, ADC interrupts always reach the PIE. If interrupts occur while ADCINTFLG is set, the ADCINTOVF register remains set regardless of the configuration of the INTxCONT bits.

10.7.3 Early Interrupt Configuration Mode

Enabling early interrupt mode can allow the application to enter the ADC interrupt service routine before the ADC results are ready. This allows the application to do any necessary pre-work so that the application can act on the ADC results immediately when the ADC results become available. If the timing of the early interrupt is too early, then the application needs to waste time until the updated ADC results become available. To prevent this situation, the time the ADC interrupt is entered in early interrupt mode is configurable by way of the DELAY field in the ADCINTCYCLE register.

- To use the configurable interrupt time, the ADC must be in early interrupt mode. To achieve this, clear the bit INTPULSEPOS to 0 in ADCCTL1.
- The DELAY value in the ADCINTCYCLE register sets the number of additional SYSCLK cycles after the falling edge of the SOC pulse before the ADCINT flag is set.
- If the value of DELAY goes beyond EOC, the ADC interrupt is generated along with EOC.
- Writing values to DELAY when INTPULSEPOS is set to 1 does not have any effect on the interrupt generation.

10.8 Post-Processing Blocks

Each ADC module contains four post-processing blocks (PPB). These blocks can be associated with any of the 16 RESULT registers using the ADCPPBxCONFIG.CONFIG bit field. The post-processing blocks have the ability to:

- Remove an offset associated with the ADCIN channel
- Subtract out a reference value
- Flag a zero-crossing point, with the option to trip a PWM and generate an interrupt
- Flag a high or low compare limit, with the option to trip a PWM and generate an interrupt
- Record the delay between the associated SOC trigger and when sampling actually begins

Figure 10-8 presents the structure of each PPB. Subsequent sections explain the use of each submodule.

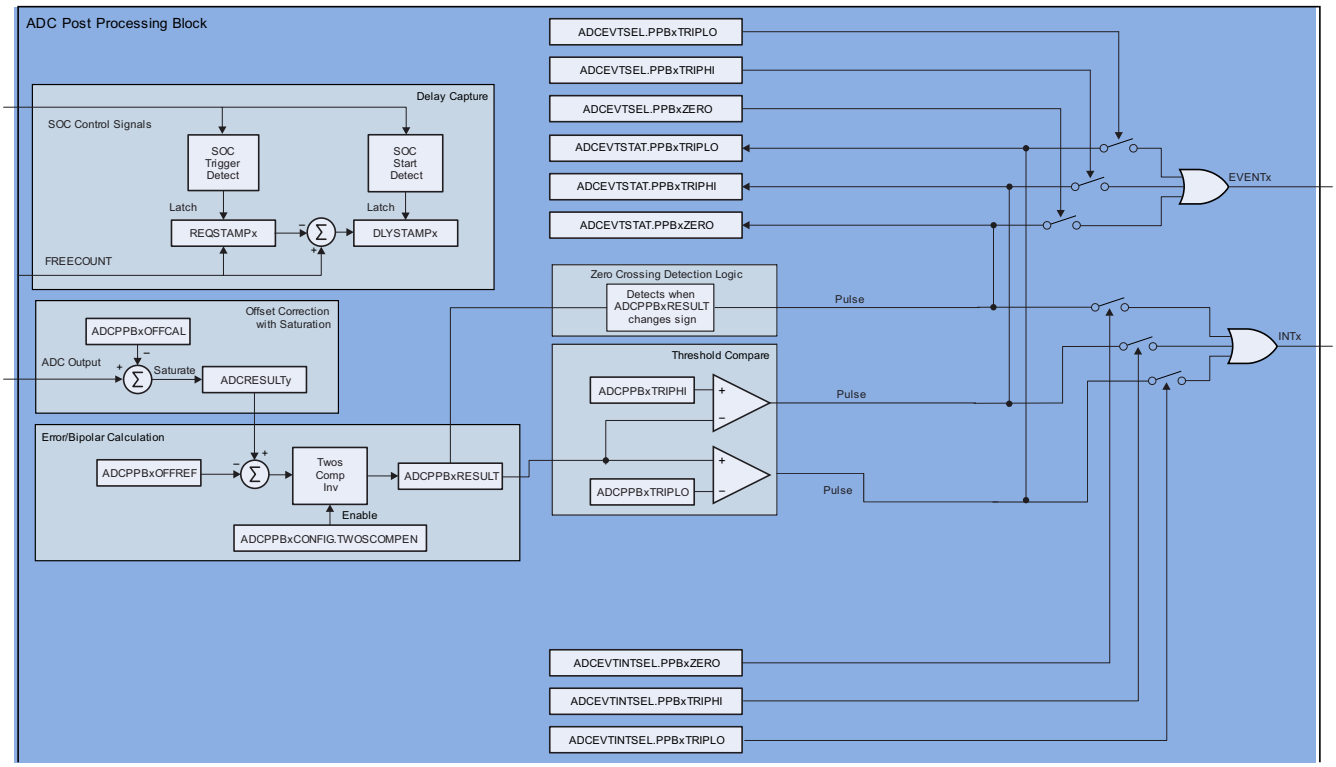

Figure 10-8. ADC PPB Block Diagram

10.8.1 PPB Offset Correction

In many applications, external sensors and signal sources produce an offset. A global trimming of the ADC offset is not enough to compensate for these offsets, which vary from channel to channel. The post-processing block can remove these offsets with zero overhead, saving numerous cycles in tight control loops.

Offset correction is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing an offset correction value to the ADCPPBxOFFCAL.OFFCAL register. The post-processing block automatically adds or subtracts the value in the OFFCAL register from the raw conversion result and stores the value in the ADCRESULT register. This addition/subtraction saturates at 0 on the low end and 4095 on the high end.

Note

- Writing a 0 to the OFFCAL register effectively disables the offset correction feature, passing the raw result unchanged to the ADCRESULT register.
- To point multiple PPBs to the same SOC is possible. In this case, the OFFCAL value that is actually applied comes from the PPB with the highest number.
- In particular, care needs to be taken when using the PPB on SOC0, as all PPBs point to this SOC by default. This can cause unintentional overwriting of offset correction of a lower numbered PPB by a higher numbered PPB.

10.8.2 PPB Error Calculation

In many applications, an error from a set point or expected value must be computed from the digital output of an ADC conversion. In other cases, a bipolar signal is necessary or convenient for control calculations. The PPB can perform these functions automatically, reducing the sample to output latency and reducing software overhead.

Error calculation is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing a value to the ADCPPBxOFFCAL.OFFREF register. The post-processing block automatically subtracts the value in the OFFREF register from the ADCRESULT value and stores the value in the ADCPPBxRESULT register. This subtraction produces a sign-extended 32-bit result. It is also possible to selectively invert the calculated value before storing in the ADCPPBxRESULT register by setting the TWOSCOMPEN bit in the ADCPPBxCONFIG register.

Note

- Do not write a value larger than 12 bits to the ADCPPBxOFFREF register.
- Since the ADCPPBxRESULT register is unique for each PPB, to point multiple PPBs to the same SOC and get different results for each PPB is possible.
- Writing a 0 to the ADCPPBxOFFREF register effectively disables the error calculation feature, passing the ADCRESULT value unchanged to the ADCPPBxRESULT register.
- Writing a new value to ADCPPBxOFFREF causes an immediate update to the ADCPPBxRESULT register. However, the flags coming out of the PPB do not change until the next end-of-conversion (EOC). For instance, if changing the ADCPPBxOFFREF register causes ADCPPBxRESULT to change signs, but the next conversion brings the result back to the same sign as before the OFFREF change, no ADCPPBxZERO flag is set.

10.8.3 PPB Limit Detection and Zero-Crossing Detection

Many applications perform a limit check against the ADC conversion results. The PPB can automatically perform a check against high and low limits, or whenever ADCPPBxRESULT changes sign. Based on these comparisons, the PPB can generate a trip to the PWM and an interrupt automatically, lowering the sample to

ePWM latency and reducing software overhead. This functionality also enables safety-conscious applications to trip the ePWM based on an out-of-range ADC conversion without any CPU intervention.

To enable this functionality, first point the ADCPPBxCONFIG.CONFIG to the desired SOC, then write a value to one or both of the registers ADCPPBxTRIPHI.LIMITHI and ADCPPBxTRIPLO.LIMITLO (zero-crossing detection does not require further configuration). Whenever these limits are exceeded, the PPBxTRIPHI bit or PPBxTRIPLO bit is set in the ADCEVTSTAT register. Note that the PPBxZERO bit in the ADCEVTSTAT register is gated by end-of-conversion (EOC), not by the sign change in the ADCPPBxRESULT register. The ADCEVTCLR register has corresponding bits to clear these event flags. The ADCEVTSEL register has corresponding bits which allow the events to propagate through to the PWM. The ADCEVTINTSEL register has corresponding bits that allow the events to propagate through to the PIE.

One PIE interrupt is shared between all the PPBs for a given ADC module as shown in Figure 10-9.

Note

- Zero-crossing and limit compare reference the ADCPPBxRESULT register. This includes any correction applied by the OFFCAL and OFFREF registers. TRIPHI and TRIPLO do not perform a signed comparison. It is recommended to leave OFFREF as 0 when using limit compare functionality.
- If different actions need to be taken for different PPB events from the same ADC module, then the ADCEVTINT ISR has to read the PPB event flags in the ADCEVTSTAT register to determine which event caused the interrupt.
- If different ePWM trips need to be generated separately for high compare, low compare, and zero-crossing, this can be achieved by pointing multiple PPBs to the same SOC.
- The zero-crossing detect circuit considers a result of zero to be positive.

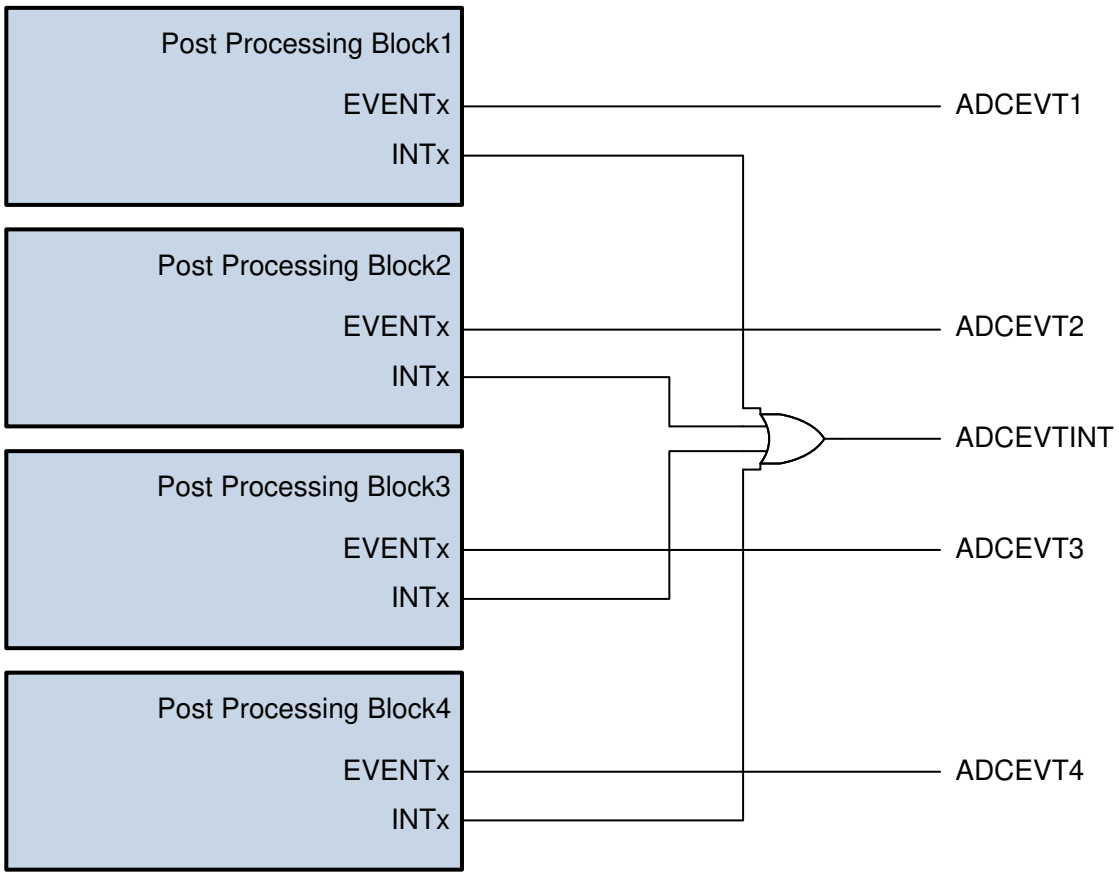

Figure 10-9. ADC PPB Interrupt Event

10.8.4 PPB Sample Delay Capture

When multiple control loops are running asynchronously on the same ADC, there is a chance that an ADC request from two or more loops collide, causing one of the samples to be delayed. This shows up as a measurement error in the system. By knowing when this delay occurs and the amount of delay that has occurred, software can employ extrapolation techniques to reduce the error.

To this effect, each PPB has the field DLYSTAMP in the ADCPPBxSTAMP register. This field contains the number of SYSCLK cycles between when the associate SOC was triggered and when the SOC began converting.

This is achieved by having a global 12-bit free running counter based off of SYSCLK, which is in the field FREECOUNT in the ADCCOUNTER register. When the trigger for the associated SOC arrives, the value of this counter is loaded into the bit field ADCPPBxTRIPLO.REQSTAMP. When the actual sample window for that SOC begins, the value in REQSTAMP is subtracted from the current FREECOUNT value and stored in DLYSTAMP.

Note

If more than 4096 SYSCLK cycles elapse between the SOC trigger and the actual start of the SOC acquisition, the FREECOUNT register can overflow more than once, leading to incorrect DLYSTAMP value. Be cautious when using very slow conversions to prevent this from happening.

The sample delay capture does not function, if the associated SOC is triggered using software. The sample delay capture, however, correctly records the delay, if the software triggering of a different SOC causes the SOC associated with the PPB to be delayed

10.9 Opens/Shorts Detection Circuit (OSDETECT)

The opens/shorts detection circuit (OSDETECT) can be used to detect pin faults in the system. The circuit connects to the ADC input after the channel select multiplexer but before the S+H circuit as shown in Figure 10-10.

Note

- The divider resistance tolerances can vary widely; hence, this feature must not be used to check for conversion accuracy.
- See the data sheet for implementation and availability of analog input channels.
- Due to high drive impedance, a S+H duration much longer than the ADC minimum is needed.

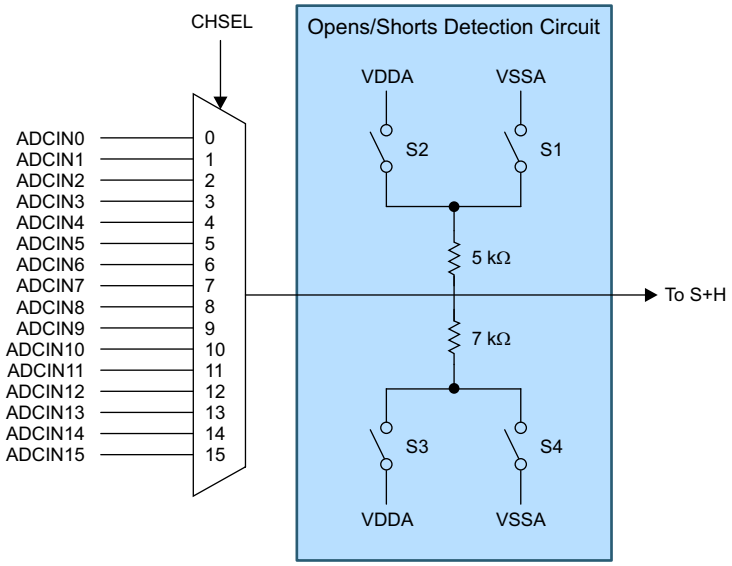

Figure 10-10. Opens/Shorts Detection Circuit

The circuit can be operated by writing a value to the DETECTCFG field in the ADCOSDETECT register. This causes the circuit to source a voltage onto the input during the S+H phase of any conversion. The voltage and drive strength of the OSDETECT circuit for different DETECTCFG settings is given in Table 10-7.

Table 10-7. DETECTCFG Settings

ADCOSDETECT. DETECTCFG	Source Voltage	S4	S3	S2	S1	Drive Impedance
0	Off	Open	Open	Open	Open	Open
1	Zero Scale	Closed	Open	Open	Closed	5K || 7K
2	Full Scale	Open	Closed	Closed	Open	5K || 7K
3	5/12 VDDA	Open	Closed	Open	Closed	5K || 7K
4	7/12 VDDA	Closed	Open	Closed	Open	5K || 7K
5	Zero Scale	Open	Open	Open	Closed	5K
6	Full Scale	Open	Open	Closed	Open	5K
7	Zero Scale	Closed	Open	Open	Open	7K

10.9.1 Implementation

A representative circuit with the OSDETECT implementation consists of the signal source with series resistance R_S, shunt capacitor C_P, the equivalent OSDETECT resistance $R_{OSDETECT}$ and voltage $V_{OSDETECT}$ is shown in Figure 10-11 and can be used as a basis to calculate the signal level going in to the sampling capacitor. $R_{OSDETECT}$ and $V_{OSDETECT}$ are the equivalent input resistance and voltage source contributed by the OSDETECT circuit with values shown in Table 10-7 for the different configuration settings. Refer to Figure 10-11 when deriving the input signal to S/H if signal source V_S is driving while the OSDETECT feature is enabled.

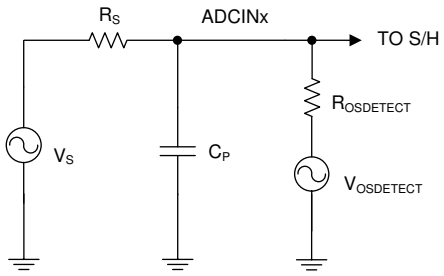

Figure 10-11. Input Circuit Equivalent with OSDETECT Enabled

The input impedance R_S and C_P are integral parts of the signal source or can have been implemented in the design to precondition the signal or to control signal settling time to meet S/H requirements. The input path has to be considered when using the OSDETECT feature, as this affects the conversion results. For instance, driving an input signal when this feature is enabled connects signal V_S to the OSDETECT circuit through R_S and affects the ADC results. Larger C_P values (in the order greater than hundreds of pF) require using higher ACQPS to make sure the signal at the input has settled prior to conversion.

To enable the circuit:

1. Configure the ADC for conversion (for example, channel, SOC, ACQPS, prescaler, trigger, and so on).
2. Set up the ADCOSDETECT register for the desired voltage divider connection as shown in Table 10-7.
3. Initiate a conversion and inspect the conversion result.

Interpret the results based on what is driving on the input side and what are the values of R_S and C_P. If the V_S signal can be disconnected from the input pin, the circuit can be used to detect open and shorted input pins as described in the following sections.

10.9.2 Detecting an Open Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with good drive strength (pin not open) is minimally affected. However, if the pin is open, the sampled voltages is close to the source voltages specified in Table 10-7.

10.9.3 Detecting a Shorted Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with finite drive strength (pin not shorted) is pulled toward each sourced voltage. However, if the pin is shorted, the signal remains at the same voltage.

10.10 Power-Up Sequence

Upon device power-up or system level reset, the ADC is powered down and disabled. When powering up the ADC, use the following sequence:

1. Set the bit to enable the desired ADC clock in the PCLKCR13 register.
2. Set the desired ADC clock divider in the PRESCALE field of ADCCTL2.
3. Power up the ADC by setting the ADCPWDNZ bit in ADCCTL1.
4. Allow a delay before sampling. See the data sheet for the necessary time.

If multiple ADCs are powered up simultaneously, steps 1 and step 3 can each be done for all ADCs in one write instruction. Also, only one delay is necessary as long as the delay occurs after all the ADCs have begun powering up.

10.11 ADC Calibration

During the fabrication and test process, Texas Instruments calibrates the gain, offset, and linearity of the ADCs and the offset of the buffered DACs. These trim settings are stored in TI reserved OTP memory, and can be loaded using C-callable functions.

- The Device_cal() function copies the trim values for ADC and DAC offset from OTP memory to the respective trim registers.
- The CalAdcINL() function copies the trim values for linearity from OTP memory to the respective trim registers for the specified ADC.
- A different offset trim is required for each possible combination of resolution and signal mode. The GetAdcOffsetTrimOTP(Uint16) function takes an input value corresponding to the ADC, resolution, and signal mode and returns the corresponding offset trim value from OTP memory, which the user then moves into the ADC offset trim register.

Until the appropriate factory trim is loaded, the ADC and other analog modules are not specified to operate within the data sheet specifications. Similarly, if trim values other than the factory settings are placed into the trim registers, the ADC (and other modules) is not specified to operate within the data sheet specifications.

The boot ROM calls the calibration functions, so trim values are initially populated without user intervention. However, if the trims are cleared due to a module reset or modified for some other reason, then the user must call the calibration functions (defined in the C2000Ware header files).

10.11.1 ADC Zero Offset Calibration

ADC offset error is determined and calibrated during factory testing. However, the user still has the option to perform offset calibration if the end application specifically requires this. This section describes how to perform offset calibration using internal VREFLO connection for single-ended operation.

Zero offset error is defined as the difference from 0 that occurs when converting a voltage at VREFLO. The zero offset error can be positive or negative. To correct this error, an adjustment of equal magnitude and opposite polarity is written into the ADCOFFTRIM register. The value contained in this register is applied before the results are available in the ADC result registers. This operation is fully contained within the ADC core, so the timing of the results is not affected, and the full dynamic range of the ADC is maintained for any trim value.

Using the GetAdcOffsetTrimOTP(Uint16) function, the ADCOFFTRIM register can be loaded with the factory calibrated offset error correction. The user can modify the ADCOFFTRIM register to compensate for additional offset error induced by the application environment if desired, but this is not typically necessary to achieve data manual specified performance.

Note

Regardless of the converter resolution, the size of each ADCOFFTRIM step is (VREFHI-VREFLO)/ 65536.

Use the following procedure to re-calibrate the ADC offset in 12-bit single-ended mode:

1. Set ADCOFFTRIM to +112 steps (0x70). This adds an artificial offset to account for negative offset that can reside in the ADC core.
2. Perform some multiple of 16 conversions on VREFLO (internal connection), accumulating the results (for example, 32*16 conversions = 512 conversions). Use the maximum value of ACQPS to make sure longer settling time to account for parasitic impedance of internal VREFLO connections.
3. Divide the accumulated result by the multiple of 16 (for example, for 512 conversions, divide by 32).
4. Set ADCOFFTRIM to 112 – result from step 3.

10.12 ADC Timings

The process of converting an analog voltage to a digital value is broken down into an S+H phase and a conversion phase. The ADC sample and hold circuits (S+H) are clocked by SYSCLK while the ADC conversion process is clocked by ADCCLK. ADCCLK is generated by dividing down SYSCLK based on the PRESCALE field in the ADCCTL2 register.

The S+H duration is the value of the ACQPS field of the SOC being converted, plus one, times the SYSCLK period. The user must make sure that this duration exceeds both 1 ADCCLK period and the minimum S+H duration specified in the data sheet. The conversion time is approximately 10.5 ADCCLK cycles. The exact conversion time is always a whole number of SYSCLK cycles. See the timing diagrams and tables in Section 10.12.1 for exact timings.

10.12.1 ADC Timing Diagrams

The following diagrams show the ADC conversion timings for two SOCs given the following assumptions:

- SOC0 and SOC1 are configured to use the same trigger.
- No other SOCs are converting or pending when the trigger occurs.
- The round robin pointer is in a state that causes SOC0 to convert first.
- ADCINTSEL is configured to set an ADCINT flag upon end of conversion for SOC0 (whether this flag propagates through to the CPU to cause an interrupt is determined by the configurations in the PIE module).

Table 10-8 describes the parameters in the following timing diagrams. Table 10-9 lists the ADC timings..

Table 10-8. ADC Timing Parameter Descriptions

Parameter	Description
t_{SH}	The duration of the S+H window. At the end of this window, the value on the S+H capacitor becomes the voltage to be converted into a digital value. The duration is given by (ACQPS + 1) SYSCLK cycles. ACQPS can be configured individually for each SOC, so t_{SH} is not necessarily the same for different SOCs. **Note:** The value on the S+H capacitor is captured approximately 5ns before the end of the S+H window regardless of device clock settings.
t_{LAT}	The time from the end of the S+H window until the ADC results latch in the ADCRESULTx register. If the ADCRESULTx register is read before this time, the previous conversion results are returned.
t_{EOC}	The time from the end of the S+H window until the S+H window for the next ADC conversion can begin. The subsequent sample can start before the conversion results are latched.
t_{INT}	The time from the end of the S+H window until an ADCINT flag is set (if configured). If the INTPULSEPOS bit in the ADCCTL1 register is set, t_{INT} coincides with the end of conversion (EOC) signal. If the INTPULSEPOS bit is 0, and the OFFSET field in the ADCINTCYCLE register is not 0, then there is a delay of OFFSET SYSCLK cycles before the ADCINT flag is set. This delay can be used to enter the ISR exactly when the sample is ready. If the INTPULSEPOS bit is 0, t_{INT} coincides with the end of the S+H window. If t_{INT} triggers a read of the ADC result register (directly through DMA or indirectly by triggering an ISR that reads the result), care must be taken to make sure the read occurs after the results latch (otherwise, the previous results are read).

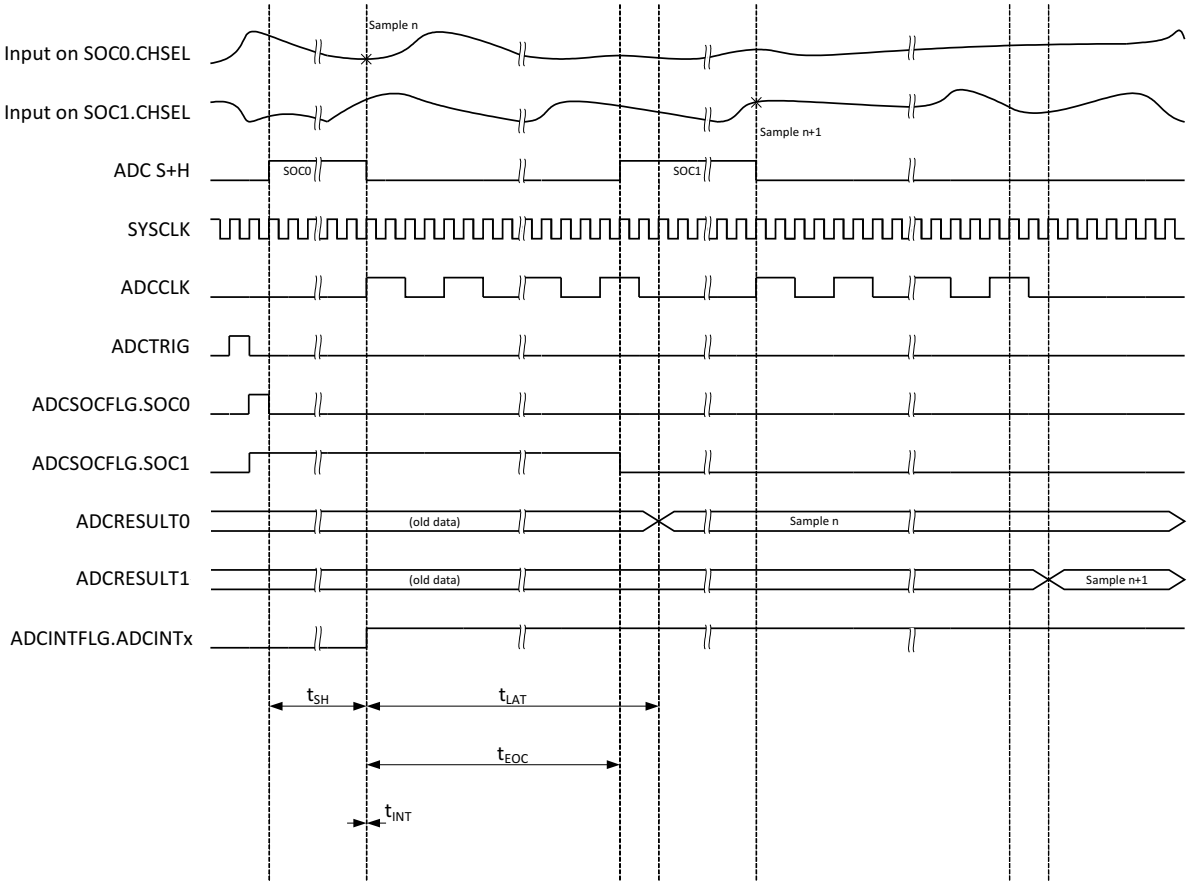

Figure 10-12. ADC Timings for 12-bit Mode in Early Interrupt Mode

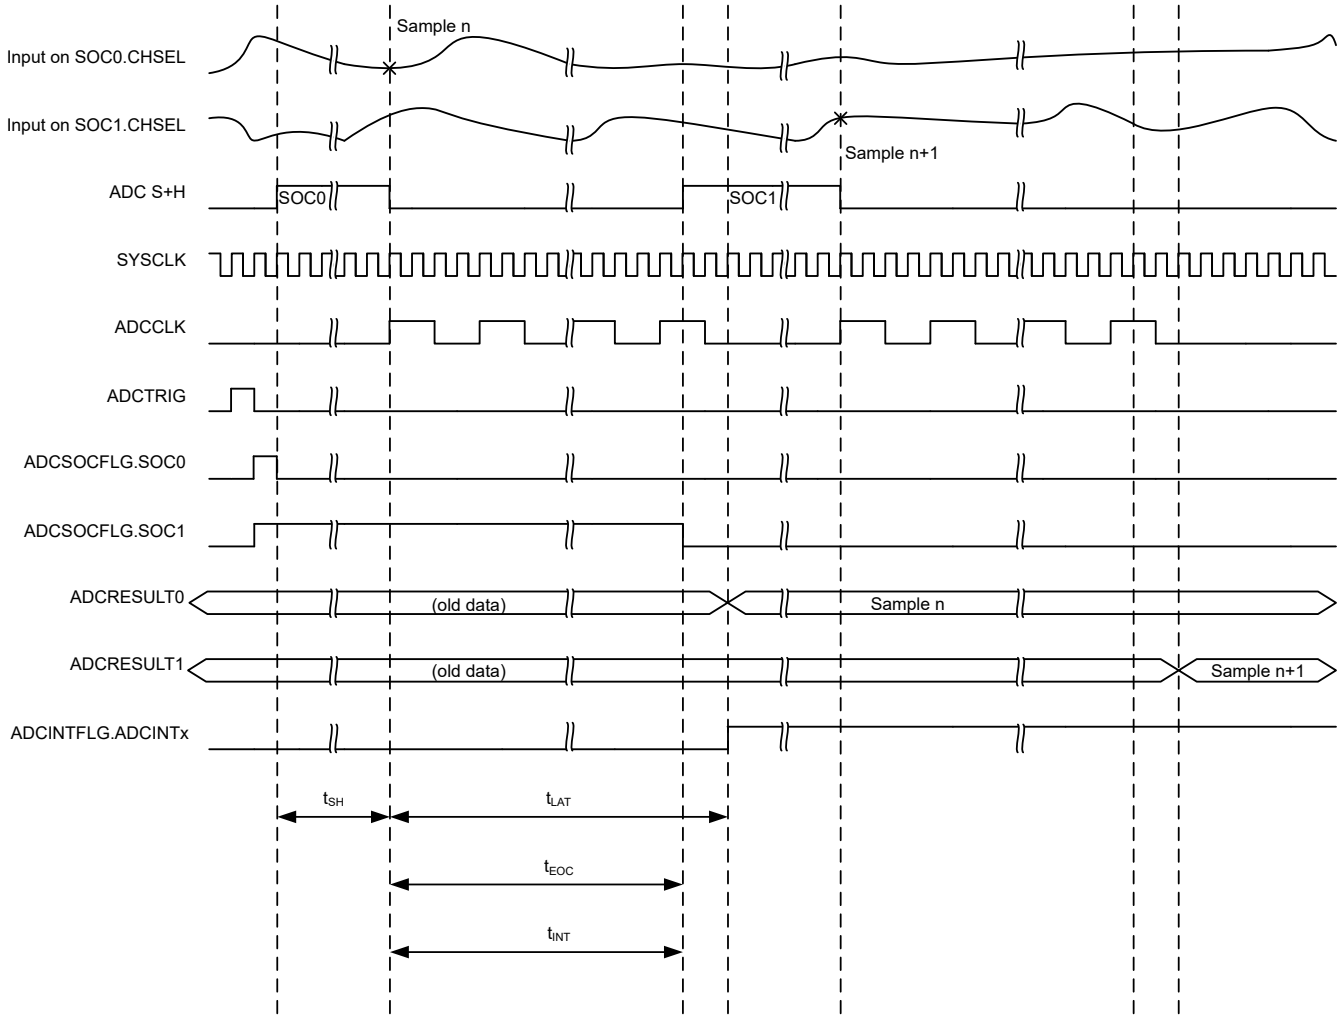

Figure 10-13. ADC Timings for 12-bit Mode in Late Interrupt Mode

Table 10-9. ADC Timings in 12-bit Mode

ADCCLK Prescale		SYSCLK Cycles			
ADCCTL2. PRESCALE	Prescale Ratio	t_{EOC}	t_{LAT} (1)	t_{INT} (Early)(2)	t_{INT} (Late)
0	1	11	13	0	11
2	2	21	23	0	21
3	2.5	26	28	0	26
4	3	31	34	0	31
5	3.5	36	39	0	36
6	4	41	44	0	41
7	4.5	46	49	0	46
8	5	51	55	0	51
9	5.5	56	60	0	56
10	6	61	65	0	61
11	6.5	66	70	0	66
12	7	71	76	0	71
13	7.5	76	81	0	76
14	8	81	86	0	81
15	8.5	86	91	0	86

(1) Refer to the "ADC: DMA Read of Stale Result" advisory in the *TMS320F2807x MCUs Silicon Errata*.
(2) By default, t_{INT} occurs one SYSCLK cycle after the S+H window if INTPULSEPOS is 0.

10.13 Additional Information

The following sections contain additional practical information.

10.13.1 Ensuring Synchronous Operation

For best performance, all ADCs on the device must be operated synchronously. The device data sheet specifies the performance in both synchronous and asynchronous mode for those parameters which differ between the modes of operation.

To make sure synchronous operation, all ADCs on the device must operate in lockstep. This is accomplished by writing configurations to all ADCs that cause the sampling and conversion phases of all ADCs to be exactly aligned. The easiest way to accomplish this is to write identical values to the SOC configurations for each ADC for trigger select and ACQPS (S+H duration). In addition, synchronous ADCs must also configure identical values for the SOC priority control, burst mode, burst trigger, and burst size.

10.13.1.1 Basic Synchronous Operation

The following example configures two SOCs each on ADCA and ADCB with identical trigger select and ACQPS values. This results in synchronous operation between ADCA and ADCB. For devices with more than two ADCs, the same principles can be used to synchronize all the ADCs.

```
Example: Basic Synchronous Operation
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1;      //SOC1 converts ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
```

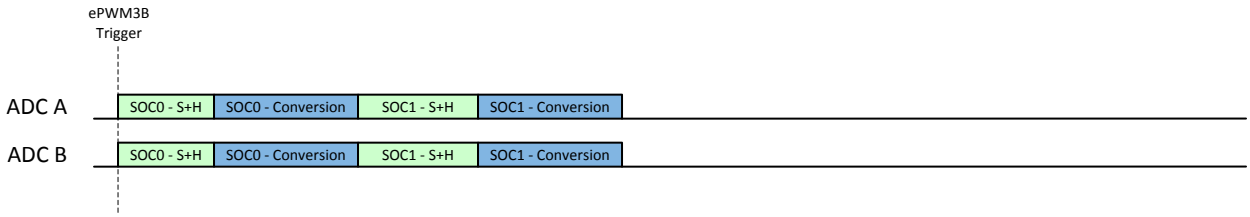

Figure 10-14. Example: Basic Synchronous Operation

Several things can be noted from Figure 10-14. First, while the ACQPS values must be the same for SOCs with the same number, different ACQPS values can be used for SOCs with different numbers. Because of this, synchronous operation does not require a single global S+H time, but instead only channels sampled simultaneously require identical S+H durations. Another important point from this example is that any channel select value can be used for any SOC. Finally, this example assumes round-robin operation. If high-priority SOCs are to be used, the priority must be configured the same on all ADCs.

10.13.1.2 Synchronous Operation with Multiple Trigger Sources

As long as each set of SOCs has identical trigger select and ACQPS settings, multiple trigger sources can be used while still achieving synchronous operation.

The following example demonstrates synchronous operation between ADCA and ADCB while using three SOCs and two trigger sources. Figure 10-15 demonstrates that any combination of relative trigger timings still results in synchronous operation.

```
Example: Synchronous Operation With Multiple Trigger Sources
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1;      //SOC1 converts ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0;      //SOC2 converts ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19;     //SOC2 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 2;    //SOC2 begins conversion on CPU Timer1
AdcbRegs.ADCSOC2CTL.bit.CHSEL = 2;      //SOC2 converts ADCINB2
AdcbRegs.ADCSOC2CTL.bit.ACQPS = 19;     //SOC2 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC2CTL.bit.TRIGSEL = 2;    //SOC2 begins conversion on CPU Timer1
```

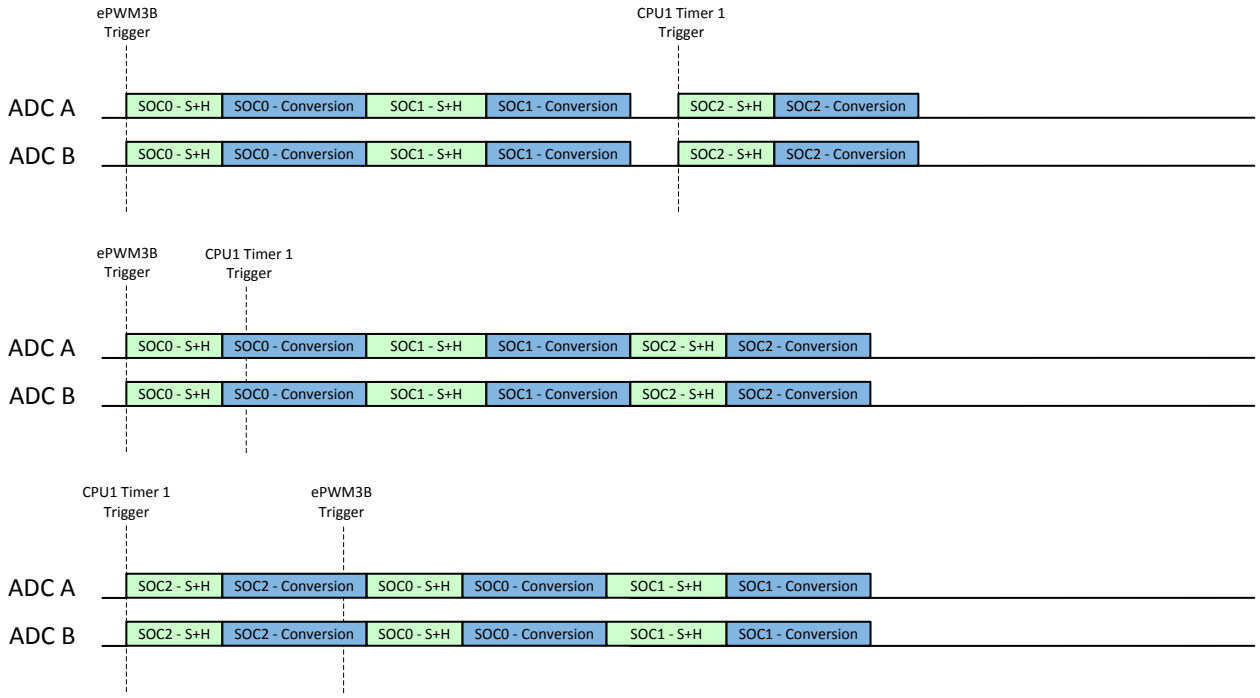

Figure 10-15. Example: Synchronous Operation with Multiple Trigger Sources

Note that any trigger source that can be selected in the TRIGSEL field can be used except for software triggering. There is no way to issue the software triggers for all ADCs simultaneously, so likely results in asynchronous operation. ADCINT1 or ADCINT2 can also be used as a trigger as long as the ADCINTSOCSEL1 and ADCINTSOCSEL2 registers are configured identically for all ADCs and software triggering is not used to start the chain of conversions.

10.13.1.3 Synchronous Operation with Uneven SOC Numbers

If only one trigger source is used, one ADC can use more SOCs than the other ADCs while still operating synchronously.

```
Example: Synchronous Operation With Uneven SOC Numbers
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4;      //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC1CTL.bit.CHSEL = 1;      //SOC1 converts ADCINB1
AdcbRegs.ADCSOC1CTL.bit.ACQPS = 30;     //SOC1 uses sample duration of 31 SYSCLK cycles
AdcbRegs.ADCSOC1CTL.bit.TRIGSEL = 10;   //SOC1 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0;      //SOC2 converts ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19;     //SOC2 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 10;   //SOC2 begins conversion on ePWM3 SOCB
```

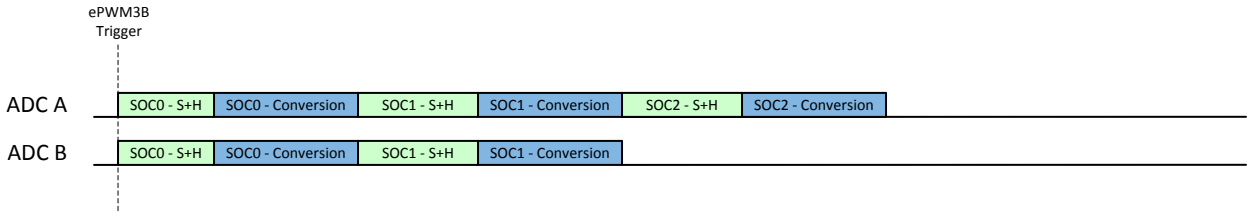

Figure 10-16. Example: Synchronous Operation with Uneven SOC Numbers

Note that if the trigger comes again before all SOCs have completed the conversions, ADCB begins converting immediately on SOC0 while ADCA does not start converting SOC0 again until SOC2 is complete. This results in asynchronous operation, so care must be taken to not overflow the trigger.

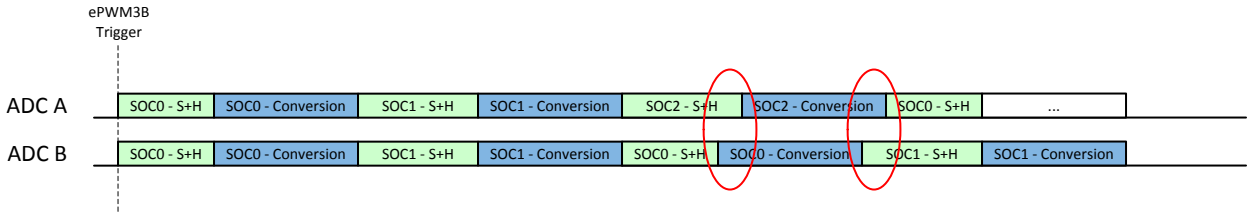

Figure 10-17. Example: Asynchronous Operation with Uneven SOC Numbers – Trigger Overflow

10.13.1.4 Non-overlapping Conversions

If conversion timings can be made sure to not overlap by the user, then it is not necessary to configure all SOCs identically on all ADCs to achieve performance equivalent to synchronous operation. For example, if the two ADC triggers in a system come from two ePWM sources that are always 180-degrees out-of-phase, then SOC0 can be used for both ADCA and ADCB with different trigger sources and different ACQPS values.

```
Example: Operation with Non-overlapping Conversions
//ePWM3 SOCA and SOCB are 180 degrees out of phase
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 converts ADCINB0
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;     //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 9;    //SOC0 begins conversion on ePWM3 SOCA
```

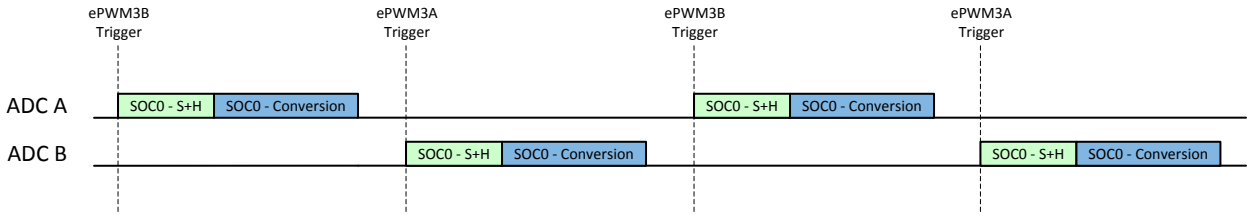

Figure 10-18. Example: Synchronous Equivalent Operation with Non-Overlapping Conversions

10.13.2 Choosing an Acquisition Window Duration

For correct operation, the input signal to the ADC must be allowed adequate time to charge the sample and hold capacitor, Ch. Typically, the S+H duration is chosen such that the sampling capacitor is charged to within ½ LSB or ¼ LSB of the final value, depending on the tolerable settling error.

The best methodology to determine the required settling time is to simulate the ADC and ADC driving circuits to make sure adequate settling performance. See *ADC Input Circuit Evaluation for C2000 MCUs* and *Charge-Sharing Driving Circuits for C2000 ADCs* for additional guidance on ADC signal conditioning circuit design and evaluation.

An approximation of the required settling time can also be determined using an RC settling model. The time constant for the model is given by the equation:

$$\tau = (R_S + R_{on}) \times C_h + R_S \times (C_S + C_p) \quad (4)$$

And the number of time constants needed is given by the equation:

$$k = ln\left(\frac{2^n}{settling\ error}\right) - ln\left(\frac{C_S + C_P}{CH}\right) \quad (5)$$

So the total S+H time must be set to at least:

$$t = k \cdot \tau \quad (6)$$

Where the following parameters are provided by the ADC input model in the device data sheet:

- n = ADC resolution (in bits)
- R_{ON} = ADC sampling switch resistance (provided in Ω)
- C_H = ADC sampling capacitor (provided in pF)
- C_p = ADC channel parasitic input capacitance (provided in pF)

And the following parameters are dependent on the application design:

- settling error = tolerable settling error (in LSBs)
- R_s = ADC driving circuit source impedance (typically in Ω or kΩ)
- C_S = capacitance on ADC input pin (typically in pF or nF)

For example, assuming the following parameters:

- n = 12-bits
- R_{ON} = 500Ω
- C_H = 12.5pF
- C_p = 12.7pF
- settling error = ¼ LSB
- R_s = 180Ω
- C_s = 150pF

The time constant is calculated as:

$$\tau = (180\Omega + 500\Omega) \times 12.5pF + 180\Omega \times (150pF + 12.7pF) = 37.8ns \quad (7)$$

And the number of required time constants is:

$$k = ln\left(\frac{2^{12}}{0.25}\right) - ln\left(\frac{150pF + 12.7pF}{12.5pF}\right) = 9.70 - 2.57 = 7.13 \quad (8)$$

So the S+H time must be set to at least: 37.8ns × 7.13 = 270ns

If SYSCLK = 120MHz , then each SYSCLK cycle is 8.33ns. S+H duration is 270ns/8.33ns = 32.4 SYSCLK cycles, so ACQPS for this input is set to at least CEILING(32.4) – 1 = 31.

While this gives a rough estimate of the required acquisition window, a better method is to setup a circuit with the ADC input model, a model of the source impedance/capacitance, and any board parasitics in SPICE (or similar software) and simulate to verify that the sampling capacitor settles to the desired accuracy.

Note

The device data sheet specifies a minimum ADC S+H window duration. Do not use an ACQPS value that gives a duration less than this specification.

10.13.3 Achieving Simultaneous Sampling

While each ADC does not have dual S+H circuits, achieving simultaneous sampling is accomplished by setting the SOC triggers on two or more ADC modules to use the same trigger source. The following example demonstrates simultaneous sampling on 3 ADCs based on an ePWM3 event. ADCINA3, ADCINB5, and ADCIND2 are sampled. An acquisition window of 20 SYSCLK cycles is used, but different durations are possible.

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 3;        //SOC0 converts ADCINA3
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 5;        //SOC0 converts ADCINB5
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
AdcdRegs.ADCSOC0CTL.bit.CHSEL = 2;        //SOC0 converts ADCIND2
AdcdRegs.ADCSOC0CTL.bit.ACQPS = 19;       //SOC0 uses sample duration of 20 SYSCLK cycles
AdcdRegs.ADCSOC0CTL.bit.TRIGSEL = 10;     //SOC0 begins conversion on ePWM3 SOCB
```

When the ePWM3 trigger is received, all 3 ADCs begin converting in parallel immediately. All results are stored in the ADCRESULT0 register for each ADC. Note that this assumes that all ADCs are idle when the trigger is received. If one or more ADCs is busy, the samples do not happen at exactly the same time.

10.13.4 Result Register Mapping

The ADC results and the ADC PPB results are duplicated for each memory bus controller in the system. Bus controllers include all CPUs, DMAs, and CLAs present on the specific part family and part number. For each bus controller, no access configuration is needed to allow read access to the result registers, and no contention occurs in cases where multiple bus controllers try to read the ADC results simultaneously.

10.13.5 Internal Temperature Sensor

The internal temperature sensor measures the junction temperature of the device. The output of the sensor can be sampled with the ADC through an internal connection. This can be enabled on channel ADCIN13 on ADCA by setting the ENABLE bit in the TSNSCTL register.

To convert the temperature sensor reading into a temperature, pass the temperature sensor reading to the GetTemperatureC() function in F2807x_TempSensorConv.c.

Note that this function assumes that the temperature reading is taken with VREFHI = 2.5V. If a different reference voltage is used, the sample can be scaled appropriately before passing the sample to the function by using the following formula:

adjusted sensor reading = raw sensor reading * (VREFHI / 2.5V)

10.13.6 Designing an External Reference Circuit

Figure 10-19 shows the basic organization of the external voltage reference generation circuitry. TI recommends that a single reference voltage generation source is shared by all ADC modules. This minimizes reference voltage mismatch between ADC modules. For best performance, the externally generated reference voltage must be buffered by a precision op-amp with good bandwidth and low output impedance before being driven into the ADC reference pin. A capacitor between the high and low reference pins must be placed on the PCB as close to the pins as practical to help absorb high-frequency currents. A series resistor (typically <1Ω) in series with this capacitor is sometimes necessary to maintain op-amp stability.

To share two reference pins between one op-amp driver is possible. This organization is shown in Figure 10-20. This can give slightly reduced performance compared to the case where each reference pin has a dedicated op-amp buffer, but can still be possible to achieve all ADC specifications in the data sheet.

10.14 Software

10.14.1 ADC Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/adc

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

10.14.1.1 ADC Software Triggering

FILE: adc_ex1_soc_software.c

This example converts some voltages on ADCA and ADCC based on a software trigger.

The ADCC will not convert until ADCA is complete, so the ADCs will not run asynchronously. However, this is much less efficient than allowing the ADCs to convert synchronously in parallel (for example, by using an ePWM trigger).

External Connections

Watch Variables
- *myADC0Result0* - Digital representation of the voltage on pin A0
- *myADC0Result1* - Digital representation of the voltage on pin A1

10.14.1.2 ADC ePWM Triggering

FILE: adc_ex2_soc_epwm.c

This example sets up ePWM1 to periodically trigger a conversion on ADCA.

External Connections
- A0 should be connected to a signal to convert

Watch Variables
- *myADC0Results* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is determined based on the period of the ePWM timer.

10.14.1.3 ADC Temperature Sensor Conversion

FILE: adc_ex3_temp_sensor.c

This example sets up the ePWM to periodically trigger the ADC. The ADC converts the internal connection to the temperature sensor, which is then interpreted as a temperature by calling the ADC_getTemperatureC() function.

Watch Variables
- *sensorSample* - The raw reading from the temperature sensor
- *sensorTemp* - The interpretation of the sensor sample as a temperature in degrees Celsius.

10.14.1.4 ADC Synchronous SOC Software Force (adc_soc_software_sync)

FILE: adc_ex4_soc_software_sync.c

This example converts some voltages on ADCA and ADCC using input 5 of the input X-BAR as a software force. Input 5 is triggered by toggling GPIO0, but any spare GPIO could be used. This method will ensure that both ADCs start converting at exactly the same time.

External Connections

Watch Variables
- *myADC0Result0* : a digital representation of the voltage on pin A2
- *myADC0Result1* : a digital representation of the voltage on pin A3

10.14.1.5 ADC Continuous Triggering (adc_soc_continuous)

FILE: adc_ex5_soc_continuous.c

This example sets up the ADC to convert continuously, achieving maximum sampling rate.
External Connections

- A0 pin should be connected to signal to convert

Watch Variables

- *adcAResults* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is the minimum possible based on the ADC speed.

10.14.1.6 ADC PPB Offset (adc_ppb_offset)

FILE: adc_ex7_ppb_offset.c

This example software triggers the ADC. Some SOCs have automatic offset adjustment applied by the post-processing block. After the program runs, the memory will contain ADC & post-processing block(PPB) results.

External Connections

Watch Variables

- *myADC0Result* : a digital representation of the voltage on pin A2
- *myADC0PPBResult* : a digital representation of the voltage on pin A2, minus 100 LSBs of automatically added offset

10.14.1.7 ADC PPB Limits (adc_ppb_limits)

FILE: adc_ex8_ppb_limits.c

This example sets up the ePWM to periodically trigger the ADC. If the results are outside of the defined range, the post-processing block will generate an interrupt.

The default limits are 1000LSBs and 3000LSBs. With VREFHI set to 3.3V, the PPB will generate an interrupt if the input voltage goes above about 2.4V or below about 0.8V.

External Connections

- A0 should be connected to a signal to convert

Watch Variables

- None

10.14.1.8 ADC PPB Delay Capture (adc_ppb_delay)

FILE: adc_ex9_ppb_delay.c

This example demonstrates delay capture using the post-processing block.

Two asynchronous ADC triggers are setup:

- ePWM1, with period 2048, triggering SOC0 to convert on pin A0
- ePWM2, with period 9999, triggering SOC1 to convert on pin A2
  Each conversion generates an ISR at the end of the conversion. In the ISR for SOC0, a conversion counter is incremented and the PPB is checked to determine if the sample was delayed.
  After the program runs, the memory will contain:

conversion : the sequence of conversions using SOC0 that were delayed

- *delay* : the corresponding delay of each of the delayed conversions

10.14.1.9 ADC ePWM Triggering Multiple SOC

FILE: adc_ex10_multiple_soc_epwm.c

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA and ADCC. This example demonstrates multiple ADCs working together to process of a batch of conversions using the available parallelism across multiple ADCs.

ADCA Interrupt ISRs are used to read results of both ADCA and ADCC.

External Connections

Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcCResult1* - Digital representation of the voltage on pin C3
- *adcCResult2* - Digital representation of the voltage on pin C4

10.14.1.10 ADC Burst Mode

FILE: adc_ex11_burst_mode_epwm.c

This example sets up ePWM1 to periodically trigger ADCA using burst mode. This allows for different channels to be sampled with each burst.

Each burst triggers 3 conversions. A0 and A1 are part of every burst while the third conversion rotates between A2, A3, and A4. This allows high importance signals to be sampled at high speed while lower priority signals can be sampled at a lower rate.

ADCA Interrupt ISRs are used to read results for ADCA.

External Connections

- A0, A1, A2, A3, A4

Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcAResult3* - Digital representation of the voltage on pin A3
- *adcAResult4* - Digital representation of the voltage on pin A4

10.14.1.11 ADC Burst Mode Oversampling

FILE: adc_ex12_burst_mode_oversampling.c

This example is an ADC oversampling example implemented with software. The ADC SOCs are configured in burst mode, triggered by the ePWM SOC A event trigger.

External Connection

- A2

Watch Variables

- *lv_results* - Array of digital values measured on pin A2 (oversampling is configured by Oversampling_Amount)

10.14.1.12 ADC SOC Oversampling

FILE: adc_ex13_soc_oversampling.c

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA including multiple SOCs that all convert A2 to achieve oversampling on A2.

ADCA Interrupt ISRs are used to read results of ADCA.

External Connections

- A0, A1, A2 should be connected to signals to be converted.

Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2

10.14.1.13 ADC PPB PWM trip (adc_ppb_pwm_trip)

FILE: adc_ex14_ppb_pwm_trip.c

This example demonstrates EPWM tripping through ADC limit detection PPB block. ADCAINT1 is configured to periodically trigger the ADCA channel 2 post initial software forced trigger. The limit detection post-processing block(PPB) is configured and if the ADC results are outside of the defined range, the post-processing block will generate an ADCxEVTy event. This event is configured as EPWM trip source through configuring EPWM XBAR and corresponding EPWM's trip zone and digital compare sub-modules. The example showcases

- one-shot
- and direct tripping of PWMs through ADCAEVT1 source via Digital compare submodule.

The default limits are 0LSBs and 3600LSBs. With VREFHI set to 3.3V, the PPB will generate a trip event if the input voltage goes above about 2.9V.

External Connections

- A2 should be connected to a signal to convert
- Observe the following signals on an oscilloscope
  - ePWM1(GPIO0 - GPIO1)
  - ePWM2(GPIO2 - GPIO3)
  - ePWM3(GPIO4 - GPIO5)

Watch Variables

- adcA2Results - digital representation of the voltage on pin A2

10.15 ADC Registers

This section describes the Analog-to-Digital Converter Registers.

10.15.1 ADC Base Addresses

Table 10-10. ADC Base Address Table

Device Registers	Register Name	Start Address	End Address
AdcaResultRegs	ADC_RESULT_REGS	0x0000_0B00	0x0000_0B1F
AdcbResultRegs	ADC_RESULT_REGS	0x0000_0B20	0x0000_0B3F
AdcdResultRegs	ADC_RESULT_REGS	0x0000_0B60	0x0000_0B7F
AdcaRegs	ADC_REGS	0x0000_7400	0x0000_747F
AdcbRegs	ADC_REGS	0x0000_7480	0x0000_74FF
AdcdRegs	ADC_REGS	0x0000_7580	0x0000_75FF

10.15.2 ADC_RESULT_REGS Registers

Table 10-11 lists the memory-mapped registers for the ADC_RESULT_REGS registers. All register offset addresses not listed in Table 10-11 should be considered as reserved locations and the register contents should not be modified.

Table 10-11. ADC_RESULT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	ADCRESULT0	ADC Result 0 Register		Go
1h	ADCRESULT1	ADC Result 1 Register		Go

Complex bit access types are encoded to fit into small table cells. Table 10-12 shows the codes that are used for access types in this section.

Table 10-12. ADC_RESULT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.15.2.1 ADCRESULT0 Register (Offset = 0h) [Reset = 0000h]

ADCRESULT0 is shown in Figure 10-21 and described in Table 10-13.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 10-34 shows the codes that are used for access types in this section.

Table 10-34. ADC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		

Table 10-34. ADC_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.15.3.1 ADCCTL1 Register (Offset = 0h) [Reset = 0000h]

ADCCTL1 is shown in Figure 10-41 and described in Table 10-35.

Return to the Summary Table.

Table 10-47. ADCSOCFLG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	SOC15	R	0h	SOC15 Start of Conversion Flag. Indicates the state of SOC15 conversions. 0 No sample pending for SOC15. 1 Trigger has been received and sample is pending for SOC15. This bit will be automatically cleared when the SOC15 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
14	SOC14	R	0h	SOC14 Start of Conversion Flag. Indicates the state of SOC14 conversions. 0 No sample pending for SOC14. 1 Trigger has been received and sample is pending for SOC14. This bit will be automatically cleared when the SOC14 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
13	SOC13	R	0h	SOC13 Start of Conversion Flag. Indicates the state of SOC13 conversions. 0 No sample pending for SOC13. 1 Trigger has been received and sample is pending for SOC13. This bit will be automatically cleared when the SOC13 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

Table 10-47. ADCSOCFLG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	SOC12	R	0h	SOC12 Start of Conversion Flag. Indicates the state of SOC12 conversions. 0 No sample pending for SOC12. 1 Trigger has been received and sample is pending for SOC12. This bit will be automatically cleared when the SOC12 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
11	SOC11	R	0h	SOC11 Start of Conversion Flag. Indicates the state of SOC11 conversions. 0 No sample pending for SOC11. 1 Trigger has been received and sample is pending for SOC11. This bit will be automatically cleared when the SOC11 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
10	SOC10	R	0h	SOC10 Start of Conversion Flag. Indicates the state of SOC10 conversions. 0 No sample pending for SOC10. 1 Trigger has been received and sample is pending for SOC10. This bit will be automatically cleared when the SOC10 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
9	SOC9	R	0h	SOC9 Start of Conversion Flag. Indicates the state of SOC9 conversions. 0 No sample pending for SOC9. 1 Trigger has been received and sample is pending for SOC9. This bit will be automatically cleared when the SOC9 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
8	SOC8	R	0h	SOC8 Start of Conversion Flag. Indicates the state of SOC8 conversions. 0 No sample pending for SOC8. 1 Trigger has been received and sample is pending for SOC8. This bit will be automatically cleared when the SOC8 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

Table 10-47. ADCSOCFLG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	SOC7	R	0h	SOC7 Start of Conversion Flag. Indicates the state of SOC7 conversions. 0 No sample pending for SOC7. 1 Trigger has been received and sample is pending for SOC7. This bit will be automatically cleared when the SOC7 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
6	SOC6	R	0h	SOC6 Start of Conversion Flag. Indicates the state of SOC6 conversions. 0 No sample pending for SOC6. 1 Trigger has been received and sample is pending for SOC6. This bit will be automatically cleared when the SOC6 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
5	SOC5	R	0h	SOC5 Start of Conversion Flag. Indicates the state of SOC5 conversions. 0 No sample pending for SOC5. 1 Trigger has been received and sample is pending for SOC5. This bit will be automatically cleared when the SOC5 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
4	SOC4	R	0h	SOC4 Start of Conversion Flag. Indicates the state of SOC4 conversions. 0 No sample pending for SOC4. 1 Trigger has been received and sample is pending for SOC4. This bit will be automatically cleared when the SOC4 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
3	SOC3	R	0h	SOC3 Start of Conversion Flag. Indicates the state of SOC3 conversions. 0 No sample pending for SOC3. 1 Trigger has been received and sample is pending for SOC3. This bit will be automatically cleared when the SOC3 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

Table 10-47. ADCSOCFLG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	SOC2	R	0h	SOC2 Start of Conversion Flag. Indicates the state of SOC2 conversions. 0 No sample pending for SOC2. 1 Trigger has been received and sample is pending for SOC2. This bit will be automatically cleared when the SOC2 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
1	SOC1	R	0h	SOC1 Start of Conversion Flag. Indicates the state of SOC1 conversions. 0 No sample pending for SOC1. 1 Trigger has been received and sample is pending for SOC1. This bit will be automatically cleared when the SOC1 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn
0	SOC0	R	0h	SOC0 Start of Conversion Flag. Indicates the state of SOC0 conversions. 0 No sample pending for SOC0. 1 Trigger has been received and sample is pending for SOC0. This bit will be automatically cleared when the SOC0 conversion is started. If contention exists where this bit receives both a request to set and a request to clear on the same cycle, regardless of the source of either, this bit will be set and the request to clear will be ignored. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether this bit was previously set or not. Reset type: SYSRSn

10.15.3.14 ADCSOCFRC1 Register (Offset = Dh) [Reset = 0000h]

ADCSOCFRC1 is shown in Figure 10-54 and described in Table 10-48.

Return to the Summary Table.

ADC SOC Force 1 Register

Table 10-48. ADCSOCFRC1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	SOC15	R-0/W1S	0h	SOC15 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC15 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC15 flag bit to 1. This will cause a conversion to start once priority is given to SOC15. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC15 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
14	SOC14	R-0/W1S	0h	SOC14 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC14 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC14 flag bit to 1. This will cause a conversion to start once priority is given to SOC14. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC14 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
13	SOC13	R-0/W1S	0h	SOC13 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC13 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC13 flag bit to 1. This will cause a conversion to start once priority is given to SOC13. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC13 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Table 10-48. ADCSOCFRC1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	SOC12	R-0/W1S	0h	SOC12 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC12 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC12 flag bit to 1. This will cause a conversion to start once priority is given to SOC12. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC12 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
11	SOC11	R-0/W1S	0h	SOC11 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC11 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC11 flag bit to 1. This will cause a conversion to start once priority is given to SOC11. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC11 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
10	SOC10	R-0/W1S	0h	SOC10 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC10 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC10 flag bit to 1. This will cause a conversion to start once priority is given to SOC10. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC10 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
9	SOC9	R-0/W1S	0h	SOC9 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC9 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC9 flag bit to 1. This will cause a conversion to start once priority is given to SOC9. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC9 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Table 10-48. ADCSOCFRC1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	SOC8	R-0/W1S	0h	SOC8 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC8 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC8 flag bit to 1. This will cause a conversion to start once priority is given to SOC8. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC8 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
7	SOC7	R-0/W1S	0h	SOC7 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC7 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC7 flag bit to 1. This will cause a conversion to start once priority is given to SOC7. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC7 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
6	SOC6	R-0/W1S	0h	SOC6 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC6 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC6 flag bit to 1. This will cause a conversion to start once priority is given to SOC6. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC6 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
5	SOC5	R-0/W1S	0h	SOC5 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC5 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC5 flag bit to 1. This will cause a conversion to start once priority is given to SOC5. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC5 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Table 10-48. ADCSOCFRC1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	SOC4	R-0/W1S	0h	SOC4 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC4 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC4 flag bit to 1. This will cause a conversion to start once priority is given to SOC4. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC4 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
3	SOC3	R-0/W1S	0h	SOC3 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC3 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC3 flag bit to 1. This will cause a conversion to start once priority is given to SOC3. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC3 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
2	SOC2	R-0/W1S	0h	SOC2 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC2 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC2 flag bit to 1. This will cause a conversion to start once priority is given to SOC2. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC2 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn
1	SOC1	R-0/W1S	0h	SOC1 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC1 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC1 flag bit to 1. This will cause a conversion to start once priority is given to SOC1. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC1 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

Table 10-48. ADCSOCFRC1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	SOC0	R-0/W1S	0h	SOC0 Force Start of Conversion Bit. Writing a 1 will force to 1 the SOC0 flag in the ADCSOCFLG1 register. This can be used to initiate a software initiated conversion. Writes of 0 are ignored. This bit will always read as a 0. 0 No action. 1 Force SOC0 flag bit to 1. This will cause a conversion to start once priority is given to SOC0. If software tries to set this bit on the same clock cycle that hardware tries to clear the SOC0 bit in the ADCSOCFLG1 register, then software has priority and the ADCSOCFLG1 bit will be set. In this case the overflow bit in the ADCSOCOVF1 register will not be affected regardless of whether the ADCSOCFLG1 bit was previously set or not. Reset type: SYSRSn

10.15.3.15 ADCSOCOVF1 Register (Offset = Eh) [Reset = 0000h]

ADCSOCOVF1 is shown in Figure 10-55 and described in Table 10-49.

Return to the Summary Table.

ADC SOC Overflow 1 Register

Figure 10-55. ADCSOCOVF1 Register

15	14	13	12	11	10	9	8
SOC15	SOC14	SOC13	SOC12	SOC11	SOC10	SOC9	SOC8

Table 10-49. ADCSOCOVF1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	SOC15	R	0h	SOC15 Start of Conversion Overflow Flag. Indicates an SOC15 event was generated in hardware while an existing SOC15 event was already pending. 0 No SOC15 event overflow. 1 SOC15 event overflow. An overflow condition does not stop SOC15 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
14	SOC14	R	0h	SOC14 Start of Conversion Overflow Flag. Indicates an SOC14 event was generated in hardware while an existing SOC14 event was already pending. 0 No SOC14 event overflow. 1 SOC14 event overflow. An overflow condition does not stop SOC14 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
13	SOC13	R	0h	SOC13 Start of Conversion Overflow Flag. Indicates an SOC13 event was generated in hardware while an existing SOC13 event was already pending. 0 No SOC13 event overflow. 1 SOC13 event overflow. An overflow condition does not stop SOC13 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
12	SOC12	R	0h	SOC12 Start of Conversion Overflow Flag. Indicates an SOC12 event was generated in hardware while an existing SOC12 event was already pending. 0 No SOC12 event overflow. 1 SOC12 event overflow. An overflow condition does not stop SOC12 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

Table 10-49. ADCSOCOVF1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	SOC11	R	0h	SOC11 Start of Conversion Overflow Flag. Indicates an SOC11 event was generated in hardware while an existing SOC11 event was already pending. 0 No SOC11 event overflow. 1 SOC11 event overflow. An overflow condition does not stop SOC11 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
10	SOC10	R	0h	SOC10 Start of Conversion Overflow Flag. Indicates an SOC10 event was generated in hardware while an existing SOC10 event was already pending. 0 No SOC10 event overflow. 1 SOC10 event overflow. An overflow condition does not stop SOC10 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
9	SOC9	R	0h	SOC9 Start of Conversion Overflow Flag. Indicates an SOC9 event was generated in hardware while an existing SOC9 event was already pending. 0 No SOC9 event overflow. 1 SOC9 event overflow. An overflow condition does not stop SOC9 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
8	SOC8	R	0h	SOC8 Start of Conversion Overflow Flag. Indicates an SOC8 event was generated in hardware while an existing SOC8 event was already pending. 0 No SOC8 event overflow. 1 SOC8 event overflow. An overflow condition does not stop SOC8 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
7	SOC7	R	0h	SOC7 Start of Conversion Overflow Flag. Indicates an SOC7 event was generated in hardware while an existing SOC7 event was already pending. 0 No SOC7 event overflow. 1 SOC7 event overflow. An overflow condition does not stop SOC7 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
6	SOC6	R	0h	SOC6 Start of Conversion Overflow Flag. Indicates an SOC6 event was generated in hardware while an existing SOC6 event was already pending. 0 No SOC6 event overflow. 1 SOC6 event overflow. An overflow condition does not stop SOC6 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

Table 10-49. ADCSOCOVF1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SOC5	R	0h	SOC5 Start of Conversion Overflow Flag. Indicates an SOC5 event was generated in hardware while an existing SOC5 event was already pending. 0 No SOC5 event overflow. 1 SOC5 event overflow. An overflow condition does not stop SOC5 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
4	SOC4	R	0h	SOC4 Start of Conversion Overflow Flag. Indicates an SOC4 event was generated in hardware while an existing SOC4 event was already pending. 0 No SOC4 event overflow. 1 SOC4 event overflow. An overflow condition does not stop SOC4 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
3	SOC3	R	0h	SOC3 Start of Conversion Overflow Flag. Indicates an SOC3 event was generated in hardware while an existing SOC3 event was already pending. 0 No SOC3 event overflow. 1 SOC3 event overflow. An overflow condition does not stop SOC3 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
2	SOC2	R	0h	SOC2 Start of Conversion Overflow Flag. Indicates an SOC2 event was generated in hardware while an existing SOC2 event was already pending. 0 No SOC2 event overflow. 1 SOC2 event overflow. An overflow condition does not stop SOC2 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
1	SOC1	R	0h	SOC1 Start of Conversion Overflow Flag. Indicates an SOC1 event was generated in hardware while an existing SOC1 event was already pending. 0 No SOC1 event overflow. 1 SOC1 event overflow. An overflow condition does not stop SOC1 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn
0	SOC0	R	0h	SOC0 Start of Conversion Overflow Flag. Indicates an SOC0 event was generated in hardware while an existing SOC0 event was already pending. 0 No SOC0 event overflow. 1 SOC0 event overflow. An overflow condition does not stop SOC0 events from being processed. It simply is an indication that a hardware trigger was missed. A write to the ADCSOCFRC1 register does not affect this bit. Reset type: SYSRSn

10.15.3.16 ADCSOCOVFCLR1 Register (Offset = Fh) [Reset = 0000h]

ADCSOCOVFCLR1 is shown in Figure 10-56 and described in Table 10-50.

Return to the Summary Table.

ADC SOC Overflow Clear 1 Register

Figure 10-56. ADCSOCOVFCLR1 Register

Table 10-50. ADCSOCOVFCLR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	SOC15	R-0/W1S	0h	SOC15 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC15 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC15 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
14	SOC14	R-0/W1S	0h	SOC14 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC14 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC14 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
13	SOC13	R-0/W1S	0h	SOC13 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC13 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC13 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
12	SOC12	R-0/W1S	0h	SOC12 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC12 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC12 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn

Table 10-50. ADCSOCOVFCLR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	SOC11	R-0/W1S	0h	SOC11 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC11 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC11 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
10	SOC10	R-0/W1S	0h	SOC10 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC10 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC10 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
9	SOC9	R-0/W1S	0h	SOC9 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC9 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC9 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
8	SOC8	R-0/W1S	0h	SOC8 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC8 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC8 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
7	SOC7	R-0/W1S	0h	SOC7 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC7 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC7 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
6	SOC6	R-0/W1S	0h	SOC6 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC6 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC6 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn

Table 10-50. ADCSOCOVFCLR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SOC5	R-0/W1S	0h	SOC5 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC5 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC5 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
4	SOC4	R-0/W1S	0h	SOC4 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC4 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC4 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
3	SOC3	R-0/W1S	0h	SOC3 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC3 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC3 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
2	SOC2	R-0/W1S	0h	SOC2 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC2 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC2 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
1	SOC1	R-0/W1S	0h	SOC1 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC1 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC1 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn
0	SOC0	R-0/W1S	0h	SOC0 Clear Start of Conversion Overflow Bit. Writing a 1 will clear the SOC0 overflow flag in the ADCSOCOVF1 register. Writes of 0 are ignored. Reads will always return a 0. 0 No action. 1 Clear SOC0 overflow flag. If software tries to set this bit on the same clock cycle that hardware tries to set the overflow bit in the ADCSOCOVF1 register, then hardware has priority and the ADCSOCOVF1 bit will be set.. Reset type: SYSRSn

10.15.3.17 ADCSOC0CTL Register (Offset = 10h) [Reset = 00000000h]

ADCSOC0CTL is shown in Figure 10-57 and described in Table 10-51.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	PPB4ZERO	R	0h	Post Processing Block 4 Zero Crossing Flag. When set indicates the ADCPPB4RESULT register has changed sign. This bit is gated by EOC signal. Note: these bits are set even when the corresponding enable in ADCEVTINTSEL is not set. Because of this, an ISR may need to examine both the ADCEVTSTAT and ADCEVTINTSEL registers to determine the source of the interrupt. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority Reset type: SYSRSn
13	PPB4TRIPLO	R	0h	Post Processing Block 4 Trip Low Flag. When set indicates a digital compare trip low event has occurred. Note: these bits are set even when the corresponding enable in ADCEVTINTSEL is not set. Because of this, an ISR may need to examine both the ADCEVTSTAT and ADCEVTINTSEL registers to determine the source of the interrupt. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority Reset type: SYSRSn
12	PPB4TRIPHI	R	0h	Post Processing Block 4 Trip High Flag. When set indicates a digital compare trip high event has occurred. Note: these bits are set even when the corresponding enable in ADCEVTINTSEL is not set. Because of this, an ISR may need to examine both the ADCEVTSTAT and ADCEVTINTSEL registers to determine the source of the interrupt. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority Reset type: SYSRSn
11	RESERVED	R	0h	Reserved
10	PPB3ZERO	R	0h	Post Processing Block 3 Zero Crossing Flag. When set indicates the ADCPPB3RESULT register has changed sign. This bit is gated by EOC signal. Note: these bits are set even when the corresponding enable in ADCEVTINTSEL is not set. Because of this, an ISR may need to examine both the ADCEVTSTAT and ADCEVTINTSEL registers to determine the source of the interrupt. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority Reset type: SYSRSn

Table 10-67. ADCEVTSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	PPB3TRIPLO	R	0h	Post Processing Block 3 Trip Low Flag. When set indicates a digital compare trip low event has occurred. Note: these bits are set even when the corresponding enable in ADCEVTINTSEL is not set. Because of this, an ISR may need to examine both the ADCEVTSTAT and ADCEVTINTSEL registers to determine the source of the interrupt. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority Reset type: SYSRSn
8	PPB3TRIPHI	R	0h	Post Processing Block 3 Trip High Flag. When set indicates a digital compare trip high event has occurred. Note: these bits are set even when the corresponding enable in ADCEVTINTSEL is not set. Because of this, an ISR may need to examine both the ADCEVTSTAT and ADCEVTINTSEL registers to determine the source of the interrupt. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority Reset type: SYSRSn
7	RESERVED	R	0h	Reserved
6	PPB2ZERO	R	0h	Post Processing Block 2 Zero Crossing Flag. When set indicates the ADCPPB2RESULT register has changed sign. This bit is gated by EOC signal. Note: these bits are set even when the corresponding enable in ADCEVTINTSEL is not set. Because of this, an ISR may need to examine both the ADCEVTSTAT and ADCEVTINTSEL registers to determine the source of the interrupt. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority Reset type: SYSRSn
5	PPB2TRIPLO	R	0h	Post Processing Block 2 Trip Low Flag. When set indicates a digital compare trip low event has occurred. Note: these bits are set even when the corresponding enable in ADCEVTINTSEL is not set. Because of this, an ISR may need to examine both the ADCEVTSTAT and ADCEVTINTSEL registers to determine the source of the interrupt. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority Reset type: SYSRSn
4	PPB2TRIPHI	R	0h	Post Processing Block 2 Trip High Flag. When set indicates a digital compare trip high event has occurred. Note: these bits are set even when the corresponding enable in ADCEVTINTSEL is not set. Because of this, an ISR may need to examine both the ADCEVTSTAT and ADCEVTINTSEL registers to determine the source of the interrupt. 9-0	OFFCAL	R/W	0h	ADC Post Processing Block 3 Offset Correction. This bit field can be used to digitally remove any system level offset inherent in the ADCIN circuit. This 10-bit signed value is subtracted from the ADC output before being stored in the ADCRESULT register. 000h No change. The ADC output is stored directly into ADCRESULT. 001h ADC output - 1 is stored into ADCRESULT. 002h ADC output - 2 is stored into ADCRESULT. ... 200h ADC output + 512 is stored into ADCRESULT. ... 3FFh ADC output + 1 is stored into ADCRESULT. NOTE: In 16-bit mode, the subtraction will saturate at 0000h and FFFFh before being stored into the ADCRESULT register. In 12-bit mode, the subtraction will saturate at 0000h and 0FFFh before being stored into the ADCRESULT register. Note: in the case that multiple PPBs point to the same SOC, only the OFFCAL of the highest numbered PPB will be applied. Reset type: SYSRSn

10.15.3.56 ADCPPB3OFFREF Register (Offset = 53h) [Reset = 0000h]

ADCPPB3OFFREF is shown in Figure 10-96 and described in Table 10-90.

Return to the Summary Table.

Table 10-90. ADCPPB3OFFREF Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	OFFREF	R/W	0h	ADC Post Processing Block 3 Offset Correction. This bit field can be used to either calculate the feedback error or convert a unipolar signal to bipolar by subtracting a reference value. This 16-bit unsigned value is subtracted from the ADCRESULT register before being passed through an optional two's complement function and stored in the ADCPPB3RESULT register. This subtraction is not saturated. 0000h No change. The ADCRESULT value is passed on. 0001h ADCRESULT - 1 is passed on. 0002h ADCRESULT - 2 is passed on. ... 8000h ADCRESULT - 32,768 is passed on. ... FFFFh ADCRESULT - 65,535 is passed on. NOTE: In 12-bit mode the size of this register does not change from 16-bits. It is the user's responsibility to ensure that only a 12-bit value is written to this register when in 12-bit mode. Reset type: SYSRSn

10.15.3.57 ADCPPB3TRIPHI Register (Offset = 54h) [Reset = 00000000h]

ADCPPB3TRIPHI is shown in Figure 10-97 and described in Table 10-91.

Return to the Summary Table.

Chapter 11

Buffered Digital-to-Analog Converter (DAC)

The buffered digital-to-analog converter (DAC) is an analog module that can output a programmable, arbitrary reference voltage.

11.1 Introduction

The buffered DAC module consists of an internal 12-bit DAC and an analog output buffer that is capable of driving an external load. An integrated pull-down resistor on the DAC output helps to provide a known pin voltage when the output buffer is disabled. This pull-down resistor cannot be disabled and remains as a passive component on the pin, even for other shared pinmux functions. The buffered DAC is a general-purpose DAC that can be used to generate a DC voltage in addition to AC waveforms such as sine waves, square waves, triangle waves and so forth. Software writes to the DAC value register can take effect immediately or can be synchronized with EPWMSYNCPER events.

11.1.1 DAC Related Collateral

Foundational Materials

- C2000 Academy - DAC
- *High Speed, Digital to Analog Converters Basics Application Report*
- *Real-Time Control Reference Guide*
  - Refer to the DAC section
- *Understanding Data Converters Application Report*

Getting Started Materials

- MathWorks F2807x/F2837xD/F2837xS/F28004x/F2838x DAC
  - NOTE: This is a non-TI (third party) site.

11.1.2 Features

Each buffered DAC has the following features:

- 12-bit programmable internal DAC
- Selectable reference voltage source
- Pull-down resistor on output
- Ability to synchronize with EPWMSYNCPER

11.1.3 Block Diagram

The block diagram for the buffered DAC is shown in Figure 11-1.

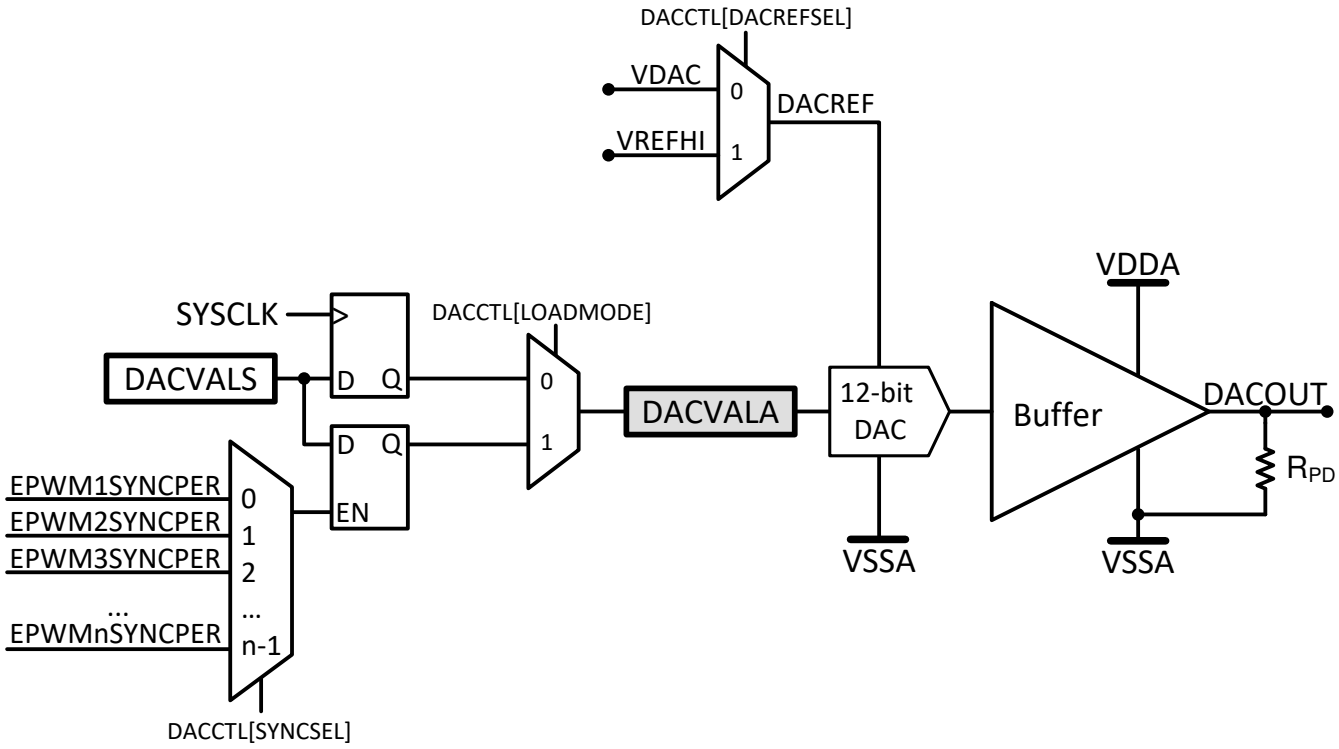

Figure 11-1. DAC Module Block Diagram

11.2 Using the DAC

The internal DAC's reference voltage source, DACREF, is selectable between VDAC and VREFHI.

Two sets of DACVAL registers, DACVALA and DACVALS, are present in the buffered DAC module. DACVALA is a read-only register that actively controls the buffered DAC value. DACVALS is a writable shadow register that loads into DACVALA either immediately or synchronized with the next EPWMSYNCPER event. If the clock to the buffered DAC is disabled while the buffered DAC is outputting a voltage, the output voltage remains unaffected, but DACVALA and DACVALS is no longer updated with register writes. Enabling the clock to the buffered DAC restores the DAC to the state before the clock was disabled.

The output of the internal DAC is calculated with the following equation:

$$DACOUT = \frac{DACVALA * DACREF}{4096} \quad (9)$$

The output buffer of the buffered DAC can exhibit non-linear behavior near the supply rails (VDDA/VSSA). To determine the linear range of the buffered DAC, see the device-specific data sheet.

11.2.1 Initialization Sequence

1. Enable the buffered DAC clock.
2. Set DACREF with DACREFSEL.
3. Power up the buffered DAC with DACOUTEN.
4. Wait for the power-up time to elapse before outputting a voltage. To determine the power-up time of the buffered DAC, see the device data sheet.
5. For predictable behavior of the buffered DAC, consecutive writes to DACVALS must be spaced apart according to the settling time of the buffered DAC. To determine the settling time of the buffered DAC, see the device data sheet.

11.2.2 DAC Offset Adjustment

Zero offset error is defined as the difference between the voltage at midcode (2048) and 1.25V (for 2.5V reference voltage). DAC offset error is calibrated at 2.5V reference voltage and loaded into the DAC offset trim register as part of the Device_cal() function. If the DAC is used at any reference voltage other than 2.5V, the offset trim must be adjusted to make sure the offset error performance stays within the device-specific data sheet limits. The DAC offset register is a 16-bit register that contains the 8-bit signed offset trim in the lower half of the register. Use the function call DAC_tuneOffsetTrim() found in C2000Ware to adjust the offset.

11.2.3 EPWMSYNCPER Signal

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the *Time-Base Submodule* section of the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACVALA when DACCTL [LOADMODE] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at a high level and DACVALA is immediately loaded from DACVALS irrespective of the value of DACCTL [LOADMODE]. Due to this, configure the EPWM first before setting DACCTL [LOADMODE] to 1.

Note

The name of the sync signal that the GPDAC receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

11.3 Lock Registers

A DACLOCK register is provided to prevent spurious writes from modifying the DACCTL, DACVALS, and DACOUTEN registers. Once a register is protected through DACLOCK, write access are locked out until the device is reset.

11.4 Software

11.4.1 DAC Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dac

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

11.4.1.1 Buffered DAC Enable

FILE: buffdac_ex1_enable.c

This example generates a voltage on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

ExternalConnections

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB0.

11.4.1.2 Buffered DAC Random

FILE: buffdac_ex2_random.c

This example generates random voltages on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

ExternalConnections

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can accomplished by connecting a jumper wire from 3.3V to ADCINB0.

11.4.1.3 Buffered DAC Sine (buffdac_sine)

FILE: buffdac_ex3_waveform.c

This example generates a sine wave on the buffered DAC output, DACOUTA/ADCINA0 (HSEC Pin 9) and uses the default DAC reference setting of VDAC.

When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can accomplished by connecting a jumper wire from 3.3V to ADCINB0.

11.5 DAC Registers

This section describes the Buffered Digital to Analog Converter registers.

11.5.1 DAC Base Addresses

Table 11-1. DAC Base Address Table

Chapter 12

Comparator Subsystem (CMPSS)

The Comparator Subsystem (CMPSS) consists of analog comparators and supporting circuits that are useful for power applications such as peak current mode control, switched-mode power, power factor correction, voltage trip monitoring, and so forth.

See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

12.1 Introduction

The comparator subsystem is built around a number of modules. Each subsystem contains two comparators, two reference 12-bit DACs, and two digital filters. The subsystem also includes one ramp generator. The ramp generator ramps down only.Comparators are denoted "H" or "L" within each module where “H” and “L” represent high and low, respectively. Each comparator generates a digital output which indicates whether the voltage on the positive input is greater than the voltage on the negative input. The positive input of the comparator is driven from an external pin. The negative input can be driven by an external pin or by the programmable reference 12-bit DAC . Each comparator output passes through a programmable digital filter that can remove spurious trip signals. An unfiltered output is also available if filtering is not required.

A ramp generator circuit is optionally available to control the reference 12-bit DAC value for the high comparator in the subsystem.

12.1.1 CMPSS Related Collateral

Foundational Materials

- C2000 Academy - CMPSS
- *Real-Time Control Reference Guide*
  - Refer to the Comparator section

Expert Materials

- *Peak Current Control Realization for Boost Circuit Based On C2000™ MCU Application Report*
- *Peak Current Mode Controlled PSFB Converter Reference Design Using C2000™ Real-time MCU*
- *Understanding and Applying Current-Mode Control Theory Application Report*

12.1.2 Features

Each CMPSS includes:

- Two analog comparators
- Two programmable reference 12-bit DACs
- One decrementing ramp generator
- Two digital filters, max filter clock prescale = 2^{10}
- Ability to synchronize submodules with EPWMSYNCPER
- Ability to synchronize output with SYSCLK
- Ability to latch output
- Ability to invert output
- Option to use hysteresis on the input
- Option for negative input of comparator to be driven by an external signal or by the reference DAC
- The DAC reference voltage can be set to VDDA or VDAC

12.1.3 Block Diagram

The block diagram for the CMPSS is shown in Figure 12-1.

- CTRIPx(x= "H" or "L") signals are connected to the ePWM X-BAR for ePWM trip response. See the *Enhanced Pulse Width Modulator (ePWM)* chapter for more details on the ePWM X-BAR mux configuration.
- CTRIPxOUTx(x= "H" or "L") signals are connected to the Output X-BAR for external signaling. See the *General-Purpose Input/Output (GPIO)* chapter for more details on the Output X-BAR mux configuration.

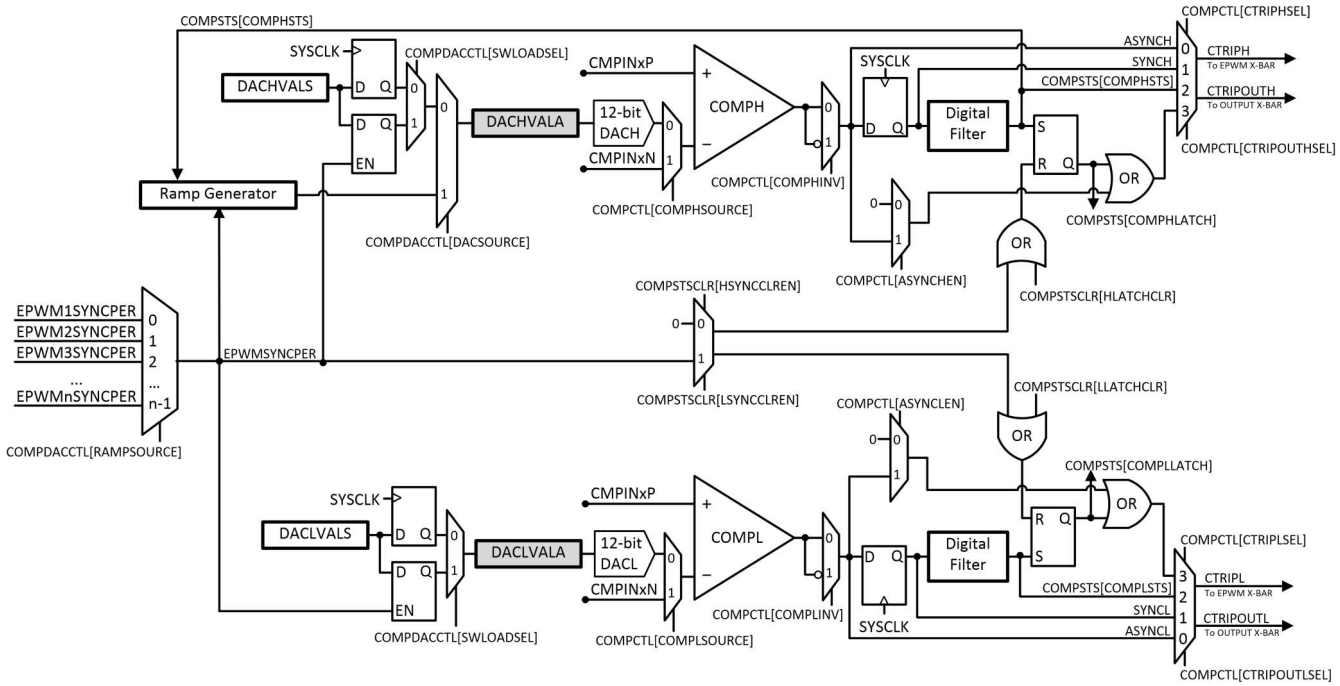

Figure 12-1. CMPSS Module Block Diagram

12.2 Comparator

The comparator generates a high digital output when the voltage on the positive input is greater than the voltage on the negative input, and a low digital output when the voltage on the positive input is less than the voltage on the negative input. The comparator is illustrated in Figure 12-2.

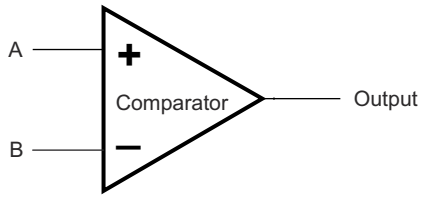

Figure 12-2. Comparator Block Diagram

Voltages	Output
Voltage A > Voltage B	1
Voltage A < Voltage B	0

12.3 Reference DAC

Each reference 12-bit DAC can be configured to drive a reference voltage into the negative input of the respective comparator. The reference 12-bit DAC output is internal only and cannot be observed externally.

Two sets of DACxVAL registers, DACxVALA and DACxVALS, are present for each reference 12-bit DAC. DACxVALA is a read-only register that actively controls the reference 12-bit DAC value. DACxVALS is a writable shadow register that loads into DACxVALA either immediately or synchronized with the next EPWMSYNCPER event. The high and low reference 12-bit DAC (DACx) can optionally source the register DACxVALA value from the ramp generator instead of the register DACxVALS.

The operating range of the reference 12-bit DAC is bounded by DACREF and VSSA. The high-voltage reference is VDDA by default, but the high voltage reference can be configured to be VDAC using the COMPDACCTL register. The reference 12-bit DAC is illustrated in Figure 12-3.

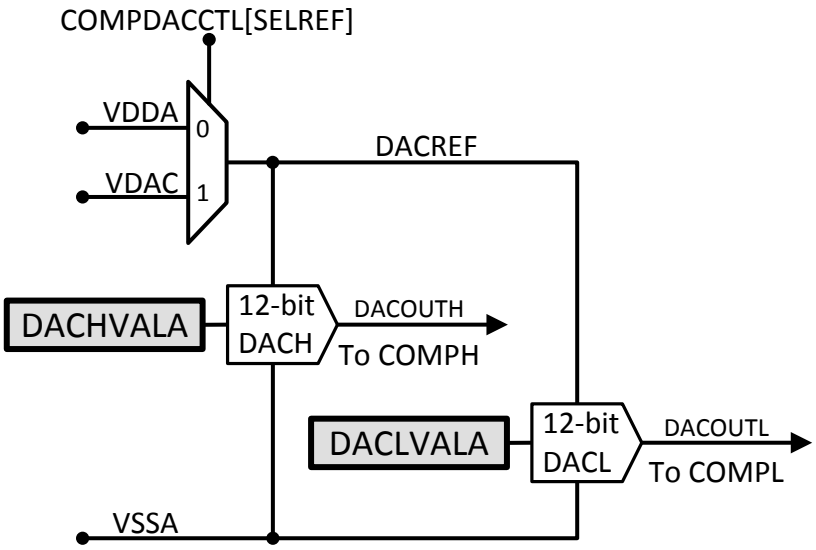

Figure 12-3. Reference DAC Block Diagram

The output of the reference 12-bit DAC can be calculated as:

$$DACOUT = \frac{(1 + DACVALA)*DACREF}{4096} \quad (10)$$

Note

- In the situations where both the DACH and DACL are driving the high and low comparators, a trip on one comparator can temporarily disturb the DAC output of the other comparator. The amount and length of time of this disturbance is specified in the device data sheet as “CMPSS DAC output disturbance” and “CMPSS DAC disturbance time”, respectively.

  Users must design the system carefully so that if the input signal crosses either DACH or DACL and trips the associated comparator, the input signal stays more than a “CMPSS DAC output disturbance” away from the other comparator trip point for “CMPSS DAC disturbance time”.
- The DACH setting must always be higher than the DACL setting. If the user is not using the DACL, the DACLVALS register must be set to 0 to avoid the comparator COMPL from tripping and affecting the DACH. In this case, there is no limitation on the DACHVALS setting. Accordingly, when not using the DACH, the user must set the DACHVALS register to the maximum.
- The CMPSS instance can be enabled before programming the reference DAC values.

12.4 Ramp Generator

This section discusses the characteristics and behavior of the ramp generator.

12.4.1 Ramp Generator Overview

The ramp generator produces a falling ramp input for the high-reference 12-bit DAC when selected. In this mode, the reference 12-bit DAC uses the most-significant 12 bits of the RAMPSTS countdown register as the input. The low 4 bits of the RAMPSTS countdown register effectively act as a prescale for the falling ramp rate configurable with RAMPDECVALA.

The ramp generator is enabled by setting DACSOURCE = 1. When DACSOURCE = 1 is selected, the value of RAMPSTS is loaded from RAMPMAXREFS and the register remains static until the selected EPWMSYNCPER signal is received. After receiving the selected EPWMSYNCPER signal, the value of RAMPDECVALA is subtracted from RAMPSTS on every subsequent SYSCLK cycle.

To prevent the subtraction from commencing a SYSCLK cycle after a EPWMSYNCPER event, the RAMPDLYA register that serves as a delay counter can be used to hold off the RAMPSTS subtraction. On receiving a EPWMSYNCPER event, the value of RAMPDLYA is decremented by one on every SYSCLK cycle until the register reaches zero. So, the RAMPSTS subtraction only begins when RAMPDLYA is zero.

12.4.2 Ramp Generator Behavior

The ramp generator makes state changes on every rising edge of DACSOURCE, EPWMSYNCPER, and COMPHSTS.

On the rising edge of DACSOURCE: RAMPMAXREFA, RAMPDECVALA, and RAMPDLYA are loaded with the shadow registers. RAMPSTS is loaded with RAMPMAXREFS.

On the rising edge of the selected EPWMSYNCPER: RAMPMAXREFA, RAMPDECVALA, and RAMPDLYA are loaded with the shadow registers. RAMPSTS is loaded with RAMPMAXREFS and starts decrementing when RAMPDLYA counter reaches zero.

On the rising edge of COMPHSTS with RAMPLOADSEL = 1: RAMPMAXREFA, RAMPDECVALA, and RAMPDLYA are loaded with the shadow registers. RAMPSTS is loaded with RAMPMAXREFS and stops decrementing.

On the rising edge of COMPHSTS with RAMPLOADSEL = 0: RAMPSTS is loaded with RAMPMAXREFA and stops decrementing.

Additionally, if the value of RAMPSTS reaches zero, the RAMPSTS register remains static at zero until the next EPWMSYNCPER is received. These state changes are illustrated in the ramp generator block diagram in Figure 12-4.

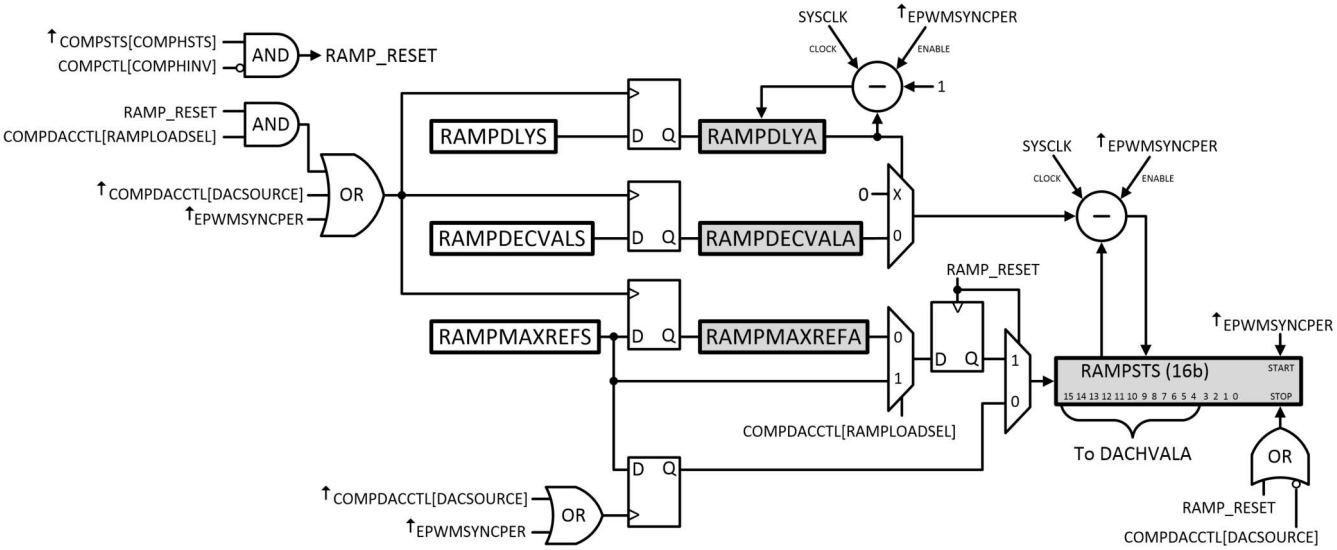

Figure 12-4. Ramp Generator Block Diagram

12.4.3 Ramp Generator Behavior at Corner Cases

Since the ramp generator makes state changes on every rising edge of EPWMSYNCPER and COMPHSTS, the following behavior can be expected on instances when these two events occur simultaneously or very close together.

Case 1: COMPHSTS rising edge occurs one or more cycles before EPWMSYNCPER rising edge.
RAMPSTS stops decrementing on COMPHSTS rising edge event. RAMPSTS starts decrementing on EPWMSYNCPER rising edge event when RAMPDLYA reaches 0.

Case 2: COMPHSTS rising edge occurs simultaneously as EPWMSYNCPER rising edge.
EPWMSYNCPER rising edge event takes precedence and RAMPSTS starts decrementing when RAMPDLYA reaches 0. COMPHSTS rising edge event is ignored and does not halt RAMPSTS.

Case 2: COMPHSTS rising edge occurs simultaneously as EPWMSYNCPER rising edge.
COMPHSTS rising edge event takes precedence and RAMPSTS stops decrementing. EPWMSYNCPER rising edge event is ignored and does not start decrementing RAMPSTS when RAMPDLYA reaches 0.

Case 3: COMPHSTS rising edge occurs one or more cycles after EPWMSYNCPER rising edge but before RAMPDLYA reaches 0.
RAMPSTS does not decrement when RAMPDLYA reaches 0.

Case 4: COMPHSTS rising edge occurs simultaneously as RAMPDLYA reaches 0 from EPWMSYNCPER rising edge.
RAMPSTS does not decrement.

This behavior is also illustrated in Figure 12-5.

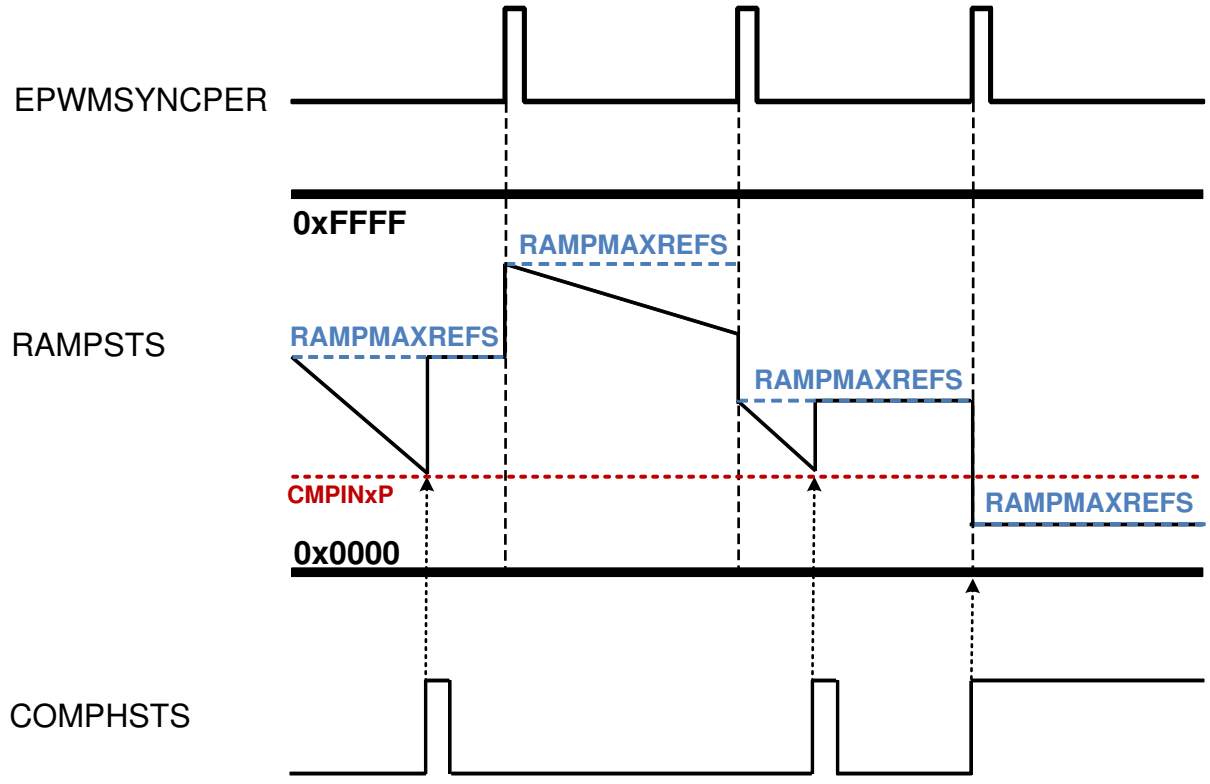

Figure 12-5. Ramp Generator Behavior

12.5 Digital Filter

The digital filter works on a window of FIFO samples (SAMPWIN) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than SAMPWIN / 2 and less than or equal to SAMPWIN.

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every prescale system clocks. Old data from the FIFO is discarded.

Note that for SAMPWIN, THRESH and CLKPRESCALE, the internal number used by the digital filter is + 1 in all cases. In essence, samples = SAMPWIN + 1, threshold = THRESH + 1 and prescale = CLKPRESCALE + 1.

A conceptual model of the digital filter is shown in Figure 12-6.

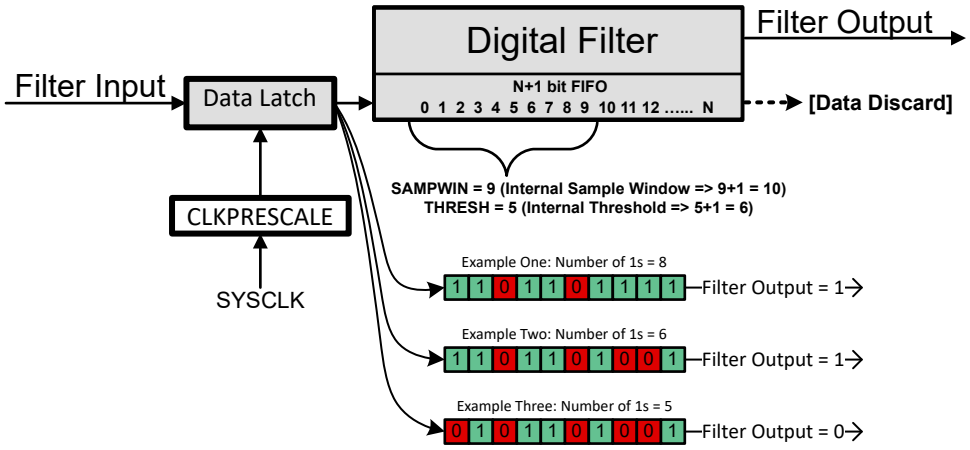

Figure 12-6. Digital Filter Behavior

Equivalent C code of the filter implementation is:

```
if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}
```

12.5.1 Filter Initialization Sequence

For proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure and enable the comparator for operation.
2. Configure the digital filter parameters for operation:
   - Set SAMPWIN for the number of samples to monitor in the FIFO window.
   - Set THRESH for the threshold required for majority qualification.
   - Set CLKPRESCALE for the digital filter clock prescale value.
3. Initialize the sample values in the digital FIFO window by setting FILINIT.
4. Clear COMPSTS latch using COMPSTSCLR, if the latched path is desired.
5. Configure the CTRIP and CTRIPOUT signal paths.
6. If desired, configure the destination module, for example, ePWM, GPIO, and so on to accept the filtered signals.

12.6 Using the CMPSS

12.6.1 LATCHCLR and EPWMSYNCPER Signals

The LATCHCLR signal holds the latch output in reset (0) after the required delays. The LATCHCLR signal is activated in software using xLATCHCLR (x = H or L). The LATCHCLR signal can also be activated by EPWMSYNCPER when xSYNCCLREN (x = H or L) is set.

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the Time-Base submodule section in the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACxVALA when COMPDACCTL[SWLOADSEL] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at level high and DACxVALA is loaded immediately from DACxVALS irrespective of the value of COMPDACCTL[SWLOADSEL]. Due to this, configure the EPWM first before setting COMPDACCTL[SWLOADSEL] to 1.

Note

The name of the sync signal that the CMPSS receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of what are these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

12.6.2 Synchronizer, Digital Filter, and Latch Delays

The synchronization block adds a delay of 1-2 sysclks. If the digital filter is bypassed (all filter settings are 0), the digital filter adds a delay of 2 sysclks. The latch adds 1 sysclk delay.

12.6.3 Calibrating the CMPSS

The CMPSS has two sources of offset errors: comparator offset error and compdac offset error. In the data sheet, the comparator offset error is referred to as ***Input referred offset error*** and compdac offset error is referred to as ***Static offset error***. See the device data sheet for the values.

If both inputs of the comparator are driven from a pin, only the comparator offset error applies. However if the inverting input of the comparator is driven from the compdac, then only the compdac offset error applies. This is because the compdac offset error includes comparator offset error.

Due to the offset errors, the CMPSS must be calibrated to make sure trips happen at the expected levels. The following flow outlines how the calibration can be performed if the inverting input of the comparator is driven from the compdac.

Notes before calibration:

1. A static DC signal is required on the non-inverting input of the comparator.
2. Hysteresis can be disabled for calibration and can be re-enabled after calibration is complete.
3. A noisy input can make calibration difficult, so use the latch with non-zero filter settings depending on how noisy is the signal on the non-inverting input.

This approach sweeps down the compdac:

1. Set the starting compdac value to max, 0xFFF.
   - Optional: Instead of setting the starting compdac value to maximum, set to ***Vtarget*** + ***Static offset error*** + ***Margin***. Where ***Vtarget*** is the approximate DC voltage on the non-inverting input, ***Static offset error*** is the compdac offset error specification and ***Margin*** is some amount of guard band. This can lead to a faster calibration but only works if ***Vtarget*** is known. Alternatively, if ***Vtarget*** is unknown, the ADC can be used to convert ***Vtarget***.
2. Decrement compdac value by 1.
3. Wait for compdac to settle.
4. Clear latch.
5. Wait for possible latch set.
6. If latch is set, trip code is found exit.
   - Optional: The trip code can be double checked by:
     a. Increasing compdac value by 1.
     b. Clear latch.
     c. Wait for possible latch set.
     d. Latch can be unset.
7. If latch is unset, go back to step 2 and repeat.

It is also possible to calibrate the CMPSS, if both inputs of the comparator are driven from a pin. For this case, the flow stays the same but the voltage on the inverting pin of the comparator is swept externally.

12.6.4 Enabling and Disabling the CMPSS Clock

If the clock to the CMPSS module is disabled while the comparator is active, the following behavior can be expected:

- The comparator remains unaffected and continues to trip from voltages on the inputs.
- If the reference 12-bit DAC is driving the negative input of the comparator, the voltage on the negative input remains static and unaffected but DACVALA can no longer be updated from the ramp generator or DACVALS.
- The ramp generator, synchronize block and digital filter freeze on the current states.

Enabling the clock to the CMPSS restores the clock to the state before the clock was disabled.

12.7 Software

12.7.1 CMPSS Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/cmpss

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

12.7.1.1 CMPSS Asynchronous Trip

FILE: cmpss_ex1_asynch.c

This example enables the CMPSS1 COMPH comparator and feeds the asynchronous CTRIPOUTH signal to the GPIO14/OUTPUTXBAR3 pin and CTRIPH to GPIO15/EPWM8B.

CMPSS is configured to generate trip signals to trip the EPWM signals. CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2. An EPWM signal is generated at GPIO15 and is configured to be tripped by CTRIPOUTH.

When a low input(VSS) is provided to CMPIN1P,
- Trip signal(GPIO14) output is low
- PWM8B(GPIO15) gives a PWM signal

When a high input(higher than VDD/2) is provided to CMPIN1P,
- Trip signal(GPIO14) output turns high
- PWM8B(GPIO15) gets tripped and outputs as high

External Connections
- Outputs can be observed on GPIO14 and GPIO15
- Comparator input pin is on ADCINA2

Watch Variables
- None

12.7.1.2 CMPSS Digital Filter Configuration

FILE: cmpss_ex2_digital_filter.c

This example enables the CMPSS1 COMPH comparator and feeds the output through the digital filter to the GPIO14/OUTPUTXBAR3 pin.

CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2.

When a low input(VSS) is provided to CMPIN1P,
- GPIO14 output is low

When a high input(higher than VDD/2) is provided to CMPIN1P,
- GPIO14 output turns high

12.8 CMPSS Registers

This section describes the CMPSS Registers.

12.8.1 CMPSS Base Addresses

Table 12-1. CMPSS Base Address Table

Device Registers	Register Name	Start Address	End Address
Cmpss1Regs	CMPSS_REGS	0x0000_5C80	0x0000_5C9F

Complex bit access types are encoded to fit into small table cells. Table 12-3 shows the codes that are used for access types in this section.

Table 12-3. CMPSS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 12-3. CMPSS_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

12.8.2.1 COMPCTL Register (Offset = 0h) [Reset = 0000h]

COMPCTL is shown in Figure 12-7 and described in Table 12-4.

Return to the Summary Table.

Chapter 13

Sigma Delta Filter Module (SDFM)

The sigma delta filter module (SDFM) is a four-channel digital filter designed specifically for current measurement and resolver position decoding in motor control applications. Each input channel can receive an independent delta-sigma (ΔΣ) modulator bit stream. The bit streams are processed by four individually-programmable digital decimation filters. The filter set includes a fast comparator (secondary filter) for immediate digital threshold comparisons for over-current and under-current monitoring, and zeros crossing detection.

13.1 Introduction

Figure 13-1 shows the SDFM CPU Interface.

13.1.2 Features

SDFM features include:

- Eight external pins per SDFM module
  - Four sigma-delta data input pins per SDFM module (SD-Dx, where x = 1 to 4)
  - Four sigma-delta clock input pins per SDFM module (SD-Cx, where x = 1 to 4)
- Different configurable modulator clock modes supported:
  - Mode 0: Modulator clock rate equals the modulator data rate.
  - Mode 1: Modulator clock rate running at half the modulator data rate.
  - Mode 2: Modulator data is Manchester-encoded. Modulator clock is not required.
  - Mode 3: Modulator clock rate is double that of the modulator data rate
- Four independent, configurable secondary filter (comparator) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
  - Ability to detect over-value condition, under-value condition, and Threshold-crossing conditions
  - OSR value for comparator filter unit (COSR) programmable from 1 to 32
- Four independent configurable primary filter (data filter) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
  - OSR value for data filter unit (DOSR) programmable from 1 to 256
  - Ability to enable or disable (or both) individual filter module
  - Ability to synchronize all four independent filters of an SDFM module by using the Master Filter Enable (MFE) bit or by using PWM signals
- Data filter output can be represented in either 16 bits or 32 bits.
- PWMs can be used to generate a modulator clock for sigma-delta modulators.

13.1.3 Block Diagram

Each SDFM module has four independent filter modules. These filter modules are identical and can be configured independently. Each individual filter module has the following units:

- Input control unit
- Primary filter (data filter) unit
- Secondary filter (comparator filter) unit with 4 independent comparators

Figure 13-2 shows the SDFM module block diagram. The SDFM port operation is configured and controlled by the registers listed in Section 13.11.

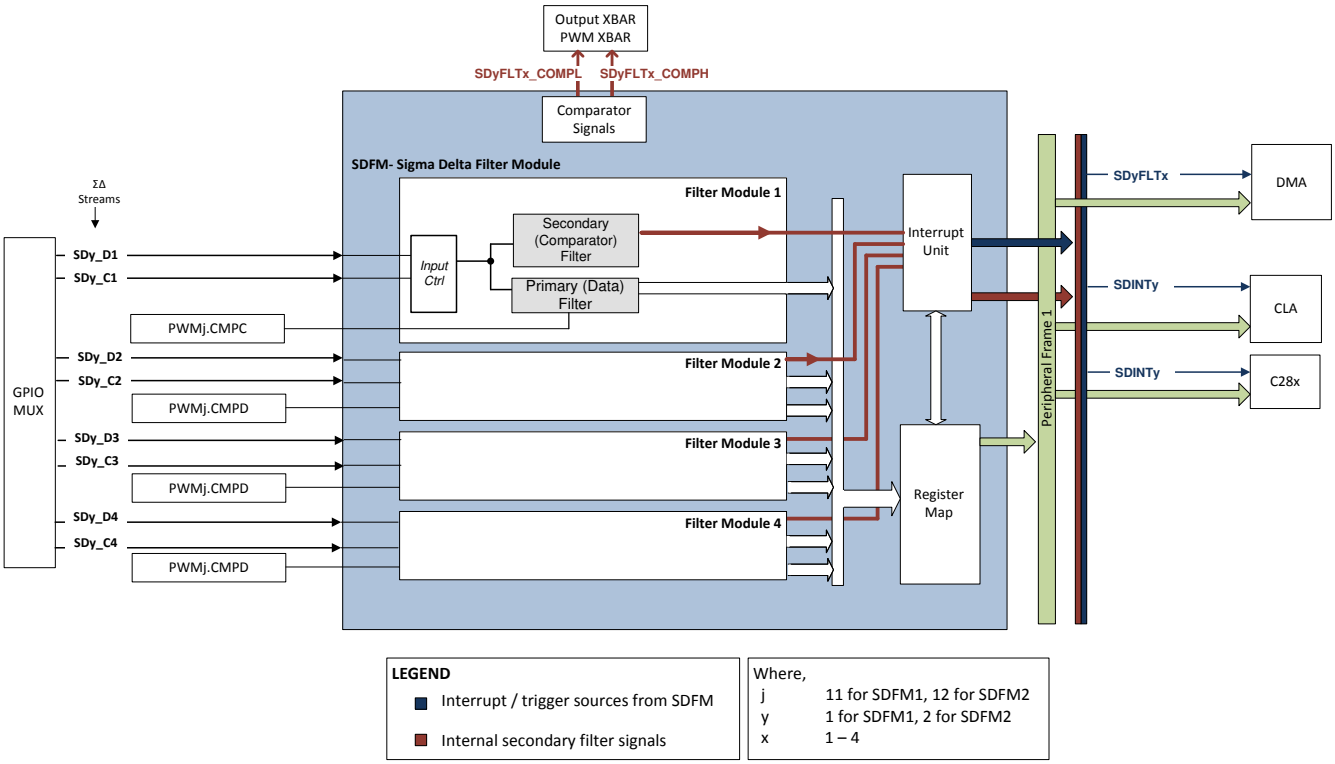

Figure 13-2. Sigma Delta Filter Module (SDFM) Block Diagram

Note

When using PWM11 or PWM12 for SDFM data filter synchronization, you must make sure that only one CMPC or CMPD event is generated per PWM timer period. Using PWM in up-count or down-count mode automatically makes sure that you get only one PWMC or PWMD event. But, if you want to use up-down count mode, then you need to make sure that only one CMPC or CMPD event per PWM cycle is generated; otherwise, the filter synchronizer corrupts the SDFM timing by providing two pulses per PWM cycle.

Each filter module shown in Figure 13-3 has a primary (data) filter and a secondary (comparator) filter pair that receives the same bit stream. Except for the input bit stream, both the primary and secondary filter are completely independent of each other. Each of these filter modules can be independently configured. So, in a SDFM module, there is a total of four primary filters and four secondary filters.

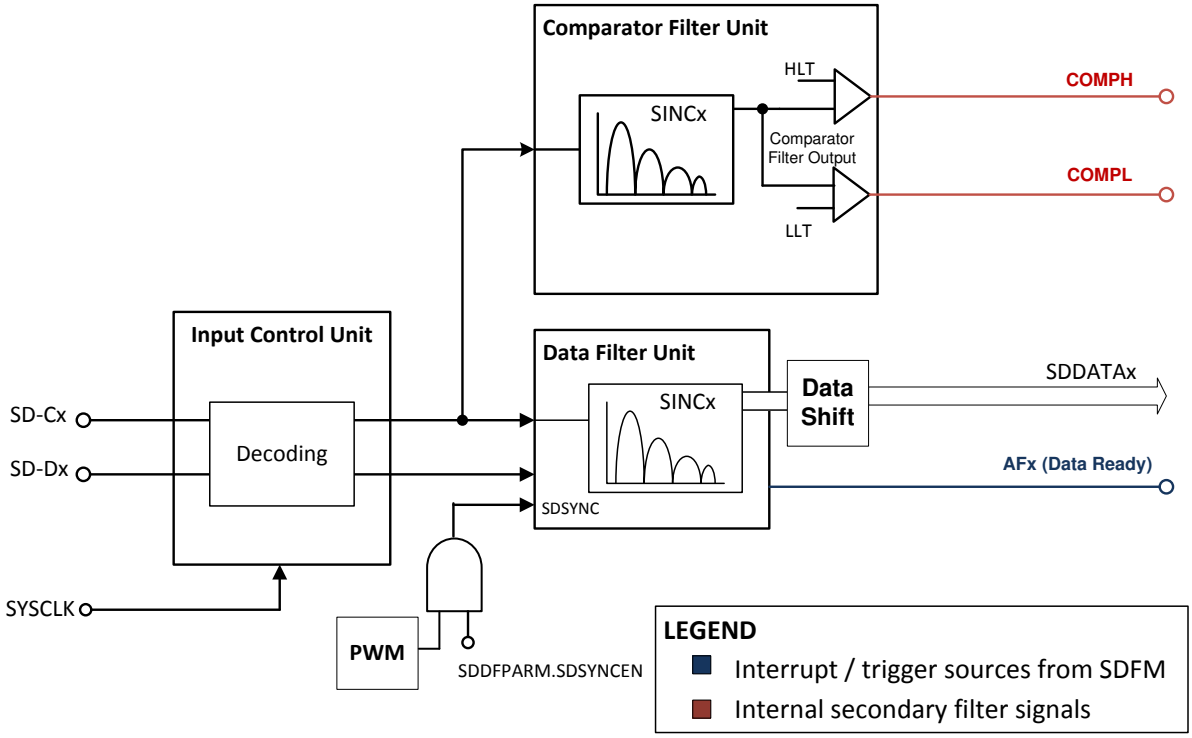

Figure 13-3. Block Diagram of One Filter Module

13.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper SDFM operation, use the following GPIO input qualification. Other GPIO qualifications are not supported.

- **Recommended option:** GPIO Input qualification = 3-sample GPIO Input Qualification. This option provides additional hardware protection against occasional random noise glitches. When GPIO Input qualification is a 3-sample window, make sure to check that the SDFM Electrical Data and Timing (Using 3-Sample GPIO Input Qualification) requirement is met and be aware of the following caution message and note.
- If GPIO Input qualification is ASYNC, make sure to check that the SDFM Electrical Data and Timing (Using ASYNC) requirement is met and be aware that this option is susceptible to random noise glitches.

CAUTION

The SDFM clock inputs (SDx_Cy pins) directly clock the SDFM module. Any glitches or ringing noise on these inputs can corrupt the SDFM module operation. Special precautions must be taken on these signals to make sure of a clean and noise-free signal that meets SDFM timing requirements. Precautions such as series termination for ringing due to any impedance mismatch of the clock driver and spacing of traces from other noisy signals are recommended.

Note

The SDFM module expects SD-Dx to change on the falling edge of SD-Cx and strobes for SD-Dx on the rising edge. But some SD-modulators in the market change SD-Dx on the rising edge and expect SDFM to strobe for data on the falling edge. In such cases, the GPIO inversion feature (GPxINV) is used on SD-Cx pin to change polarity and make it compatible with the SDFM.

The SDFM Qualified GPIO (3-sample) option provides protection against SDFM module corruption due to occasional random noise glitches on the SDx_Cy pin that can result in a false comparator trip and filter output.

The SDFM Qualified GPIO (3-sample) option does not provide protection against persistent violations of the above timing requirements. Timing violations results in data corruption proportional to the number of bits that violate the requirements.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

13.3 Input Control Unit

The input control unit receives sigma delta modulated data and a sigma delta modulated clock. The modulated data received is captured and passed on to the data filter unit and comparator unit. This unit can be configured to receive the modulated data in four different modes. Table 13-1 and Figure 13-4 show how SDCTLPARMx.MOD bits can be configured in these four different modes.

Table 13-1. Modulator Clock Modes

Modulator Mode [MOD]	Description
0	The modulator clock is running with the modulator data rate. The modulator data is strobed at every rising edge of the modulator clock.
1	The modulator clock is running with half of the modulator data rate. The modulator data is strobed at every edge of the modulator clock.
2	The modulator clock is off and the modulator data is Manchester-encoded.
3	The modulator clock is running with double the modulator data rate. The modulator data is strobed at every other positive modulator clock edge.

Note

To achieve the maximum value, the sigma-delta modulator has to be operated at absolute maximum positive or negative full scale, which is outside of the recommended full scale range of 80% of most sigma-delta modulators.

When MOD=2, data and modulated clock signals are encoded into modulated data as shown in Mode 2 of Figure 13-4. In this mode, the clock input SD-Cx pin can be left floating. The input control unit performs continuous automatic calibration to achieve optimum decoding performance.

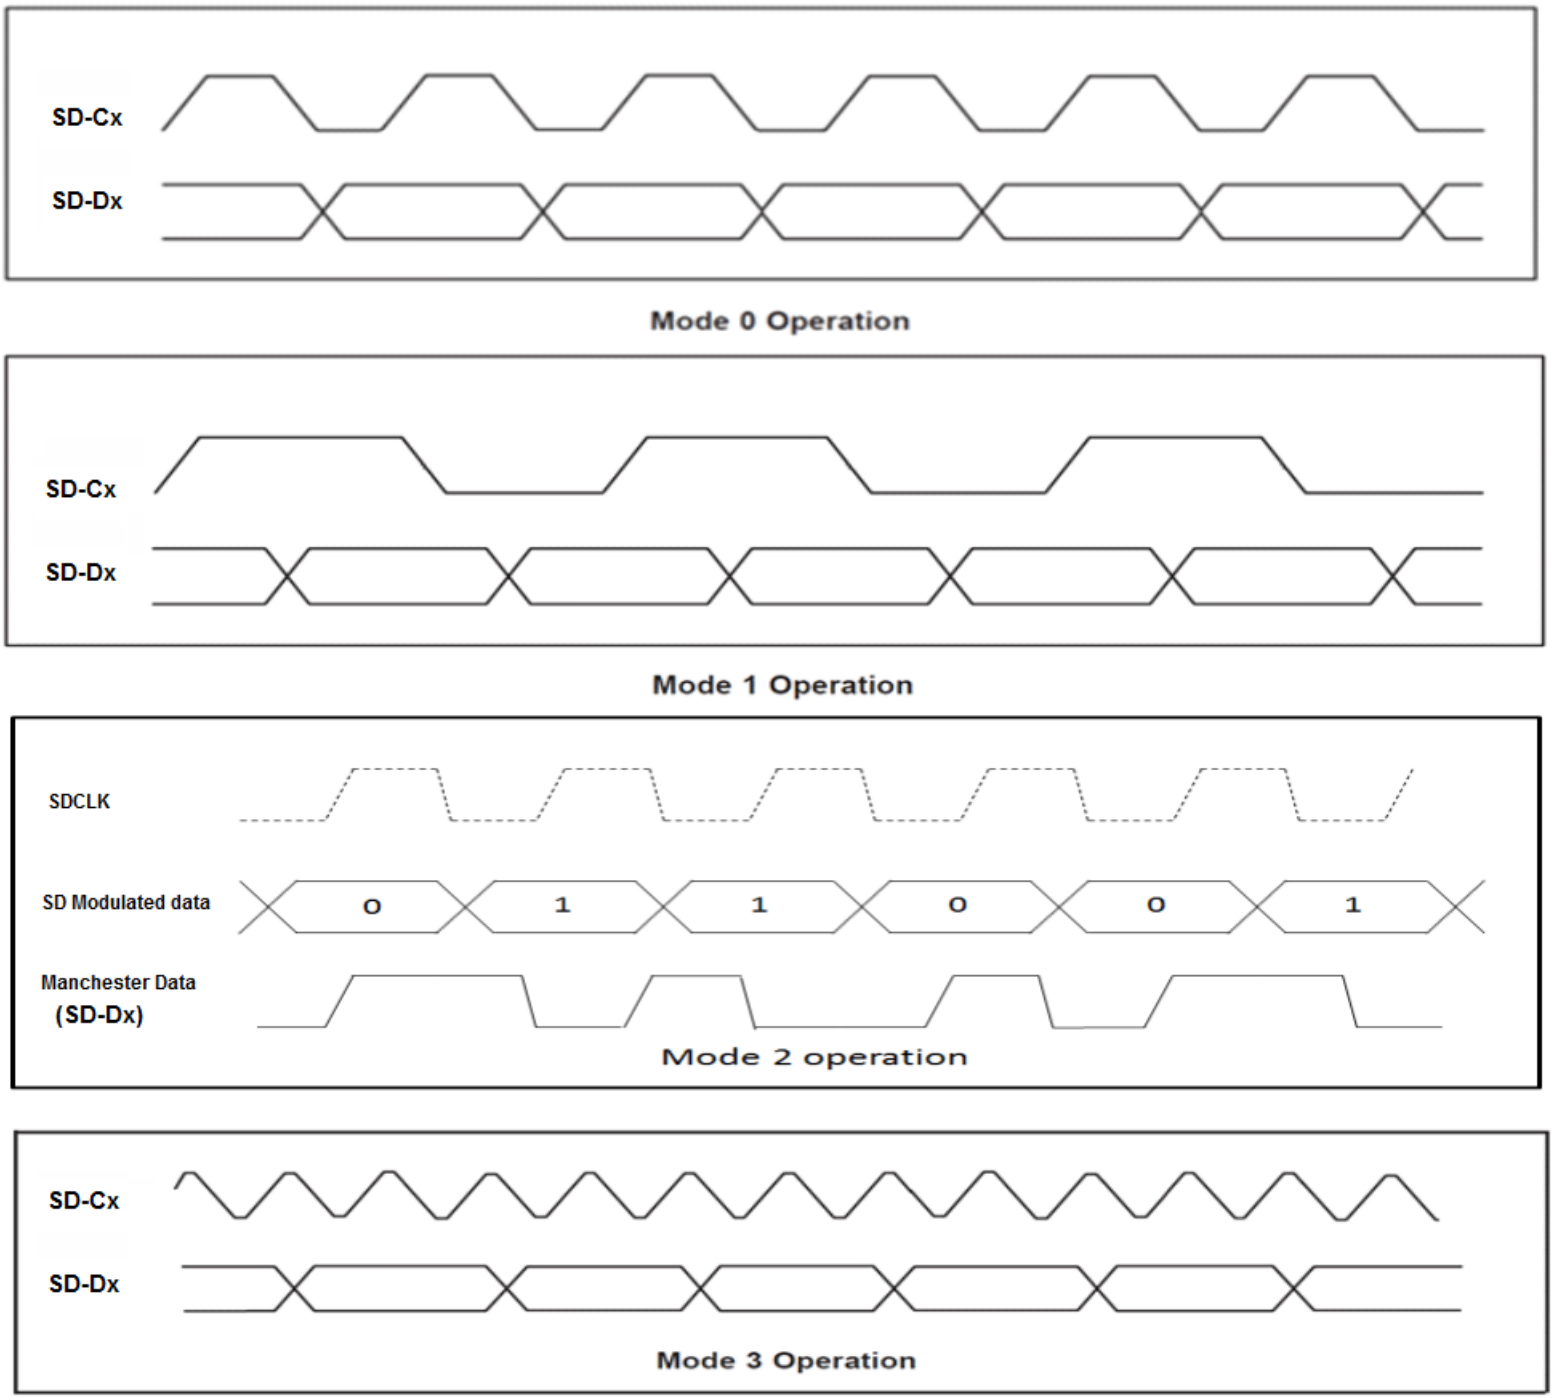

Figure 13-4. Different Modulator Modes Supported

13.4 Sinc Filter

Both the comparator filter and data filter available in SDFM have the Sinc^N filter as the core. The Sinc^N filter is essentially a low-pass filter that converts the input bit stream into digital data by digital filtering and decimation. This filtered digital data represents analog input given to the sigma delta modulator. Simplified Sinc^N architecture

consists of cascaded integrators and differentiators separated by a down-sampler as shown in Figure 13-5. The Z-transfer function of the Sinc filter of order N is shown in Figure 13-6.

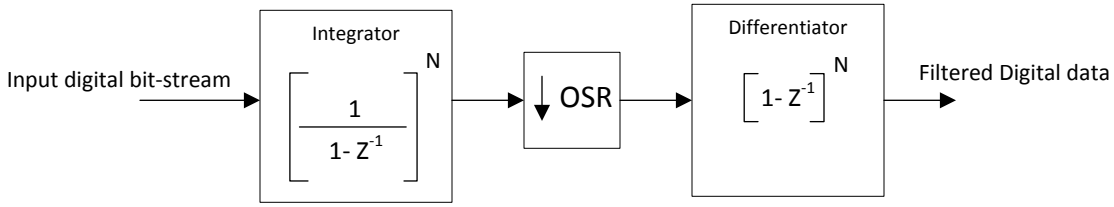

Figure 13-5. Simplified Sinc Filter Architecture

$$H(Z) = \left[\frac{1 - Z^{-OSR}}{1 - Z^{-1}} \right]^{N}$$

N = Order of Sinc filter
OSR = Over Sampling Ratio

Figure 13-6. Z-Transform of Sinc Filter of Order N

Effective resolution of the Sinc filter (ENOB) depends upon filter type, OSR and sigma-delta modulator frequency. Typically, higher resolution or ENOB can be achieved by higher OSR for a given filter type; however, the tradeoff is increased filter delay. It is important to choose the right sigma delta modulator by studying the optimal speed versus resolution tradeoff. Refer to the corresponding sigma delta modulator data sheet to determine the effective resolution for a given Sinc filter configuration. Figure 13-7 shows the frequency response of different filter structures when OSR = 32 and when the sigma delta modulator frequency is 10MHz.

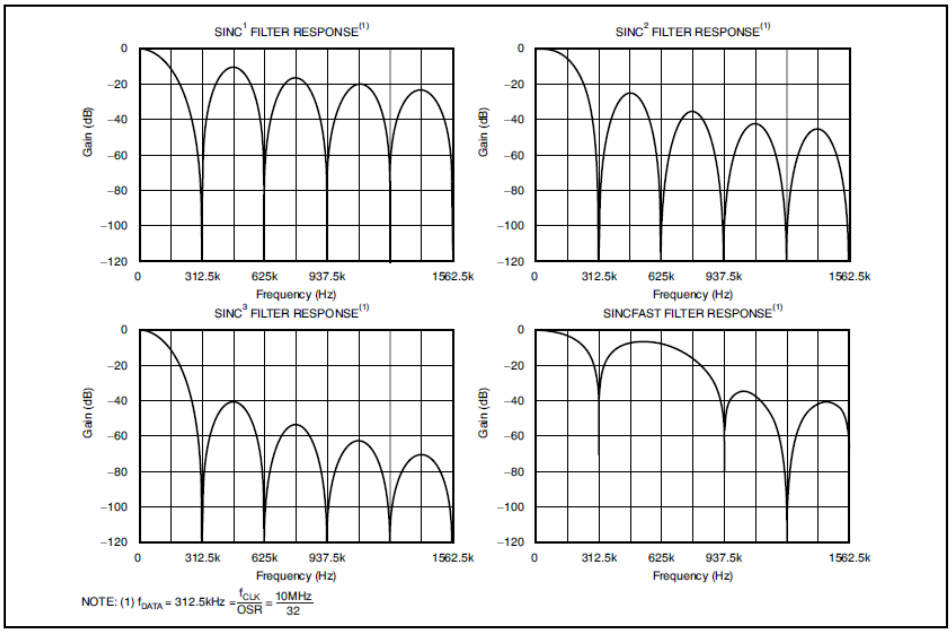

Figure 13-7. Frequency Response of Different Sinc Filters

The order of different sinc filter is shown in Table 13-2.

Table 13-2. Order of Sinc Filter

Filter Type	Order of Sinc Filter
Sinc1	1
Sinc2	2
Sinc3	3
SincFast	3

13.4.1 Data Rate and Latency of the Sinc Filter

The data rate of the sinc filter (filter throughput) represented in samples/sec is calculated by the following formula:

$$Data\ rate\ of\ Sinc\ filter = \frac{Modulator\ data\ rate}{OSR} \tag{11}$$

The latency of the sinc filter represented in secs is defined as the amount of time taken by a sinc filter type to deliver the correct filtered output upon initiation. For a given filter type, latency is calculated by the following formula:

$$Latency\ of\ Sinc\ filter = \frac{Order\ of\ Sinc\ filter}{Data\ rate\ of\ Sinc\ filter} \tag{12}$$

Example configuration:

Sinc filter type	= sinc3
Modulator data rate	= 10MHz
OSR	= 256
Data rate of Sinc Filter	= 10MHz/256 = 39.1K samples/second
Sinc filter latency	= 76.8µs
Sinc filter type	= sinc2
Modulator data rate	= 10MHz
OSR	= 256
Data rate of Sinc Filter	= 10MHz/256 = 39.1K samples/second
Sinc filter latency	=51.2µs

13.5 Data (Primary) Filter Unit

The data filter is a configurable Sinc filter which supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The data filter OSR (DOSR) settings can be configured from 1 to 256 and is independent of the comparator filter. Effective resolution of the data filter (ENOB) depends upon Data filter type, DOSR, and sigma-delta modulator frequency. By default, the data filter is disabled and setting of SDDFPARMx.FEN = 1 enables the data filter. The data filter output is represented in 25-bit signed integer in two's complement format. This filter unit translates a low input signal as '-1' and a high input signal as '1'. The resulting calculation gives both positive and negative values for the output of the data filter. Table 13-3 shows the different full scale values that the data filter can store using different OSRs.

See Section 13.4.1 to understand how to calculate data rate and latency of data filter.

Table 13-3. Peak Data Values for Different DOSR/Filter Combinations

DOSR	Sinc1	Sinc2	Sinc3	SincFast
x	x	x^2	x^3	$2x^2$
4	–4 to 4	–16 to 16	–64 to 64	–32 to 32
8	–8 to 8	–64 to 64	–512 to 512	–128 to 128
16	–16 to 16	–256 to 256	–4096 to 4096	–512 to 512
32	–32 to 32	–1024 to 1024	–32,768 to 32,768	–2048 to 2048
64	–64 to 64	–4096 to 4096	–262,144 to 262,144	–8192 to 8192
128	–128 to 128	–16,384 to 16,384	–2,097,152 to 2,097,152	–32,768 to 32,768
256	–256 to 256	–65,536 to 65,536	–16,777,216 to 16,777,216	–131,072 to 131,072

13.5.1 32-bit or 16-bit Data Filter Output Representation

The data filter output can be represented in either 32-bit or 16-bit format.

32-bit data filter representation:

- When SDDPARMx.DR = 1, data filter output is represented in 32-bit format. Writes to shift control bits do not have any bearing on the output of the data filter in this configuration.

16-bit data filter representation:

- By default, data filter output is represented in 16-bit format
- When SDDPARMx.DR = 0, data filter output is represented in 16-bit format. But it is the responsibility of the user to configure the corresponding shift control bits in the SDDPARMx register to control which 16-bit part of the 32-bit word is sent to the register map.

  For example, for the data filter configuration below:
  - Filter type = Sinc3
  - OSR = 128
  - SDDPARMx.DR = 0

  The data filter with a 25-bit signed output value can be in the range of –2,097,152 to 2,097,152. But, 16-bit signed output supports values only from –32,768 to 32,767. Therefore, it is required to configure shift control bits (SDDPARMx.SH) to 7 to represent the data filter output correctly in 16-bit format. Table 13-4 shows the configuration settings of shift control bits for different OSR and filter types.

Table 13-4. Shift Control Bit Configuration Settings

OSR	Sinc1	Sinc2	SincFast	Sinc3
1 to 31	0	0	0	0
32 to 40	0	0	0	1
41 to 50	0	0	0	2
51 to 63	0	0	0	3
64 to 80	0	0	0	4
81 to 101	0	0	0	5
102 to 127	0	0	0	6
128 to 161	0	0	1	7
162 to 181	0	0	1	8
182 to 203	0	1	2	8
204 to 255	0	1	2	9
256	0	2	3	9

CAUTION

Configuring shift control bits incorrectly results in getting an incorrect 16-bit data filter output.

13.5.2 SDSYNC Event

Primary (data) filters can be synchronized with respect to the PWM event (called SDSYNC event). The SDSYNC signal from the PWM module is used to reset the DOSR counter. This feature is by default disabled and can be enabled by setting SDDFPARMx.SDSYNCEN = 1. Figure 13-8 shows how the PWM signals are connected to the sigma delta module. In this device, PWM11 can be used to reset SDFM1 filter modules and PWM12 can be used to reset SDFM2 modules.

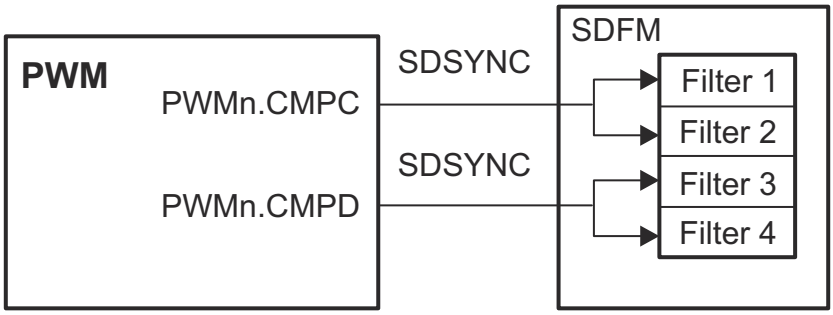

Figure 13-8. SDSYNC Event

Because of the inherent architecture of the Sinc filter (Sinc1, Sinc2, Sinc3, SincFast), the first few samples, depending upon filter type, are incorrect. Table 13-5 shows the number of incorrect samples on the following conditions:

- When Sinc filter is enabled and configured for first time.
- When Sinc filter is disabled and re-enabled or reconfigured in the middle of operation.
- When data filter receives SDSYNC event from PWM.

Table 13-5. Number of Incorrect Samples Tabulated

Filter Type	Number of Incorrect Samples After the Filter is Enabled and Configured
Sinc1	No incorrect sample.
Sinc2	The first sample of the Sinc2 filter is incorrect.
SincFast	The first two samples of the SincFast filter are incorrect.
Sinc3	The first two samples of the Sinc3 filter are incorrect.

CAUTION

SDFM comparator interrupts can be enabled only after providing sufficient settling time to make sure the comparator filter does not trip on these incorrect samples. Therefore, SDFM comparator interrupts (IELx and IEHx) can be enabled only after a sufficient delay is provided after the comparator filter is configured. This sufficient delay is calculated by adding the latency of the comparator filter and 5 SD-Cx clock cycles.

13.6 Comparator (Secondary) Filter Unit

Most control systems require protection of the system by tripping the PWM in case the current or voltage goes out of bounds. The primary purpose of the secondary (comparator) filter is to allow the user to monitor input conditions with a fast settling time. This allows the user to trip PWMs to protect the system from potential damage.

Note

The secondary (comparator) filter cannot be synchronized with respect to the PWM event (SDSYNC event).

The comparator filter is a configurable Sinc filter that supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The comparator OSR (COSR) settings can be configured from 1 to 32 and is independent of the data filter. Effective resolution of the comparator filter (ENOB) depends upon the comparator filter type, COSR, and sigma-delta modulator frequency. By default, the comparator filter is enabled. The comparator filter output is represented in 16-bit unsigned format. This filter unit translates a low input signal as 0 and a high input signal as 1. The resulting calculations give only positive values for the output of the comparator filter. Table 13-6 shows the different full-scale values that the comparator filter can store using different OSRs.

Table 13-6. Peak Data Values for Different OSR/Filter Combinations

OSR	Sinc1	Sinc2	Sinc3	SincFast
x	0 to x	0 to x2	0 to x3	0 to 2x2
4	0 to 4	0 to 16	0 to 64	0 to 32
8	0 to 8	0 to 64	0 to 512	0 to 128
16	0 to 16	0 to 256	0 to 4096	0 to 512
32	0 to 32	0 to 1024	0 to 32,768	0 to 2048

See Section 13.4.1 to understand how to calculate data rate and latency of comparator filter.

The output of the comparator filter is not memory-mapped; instead the output is connected to digital comparators explained below.

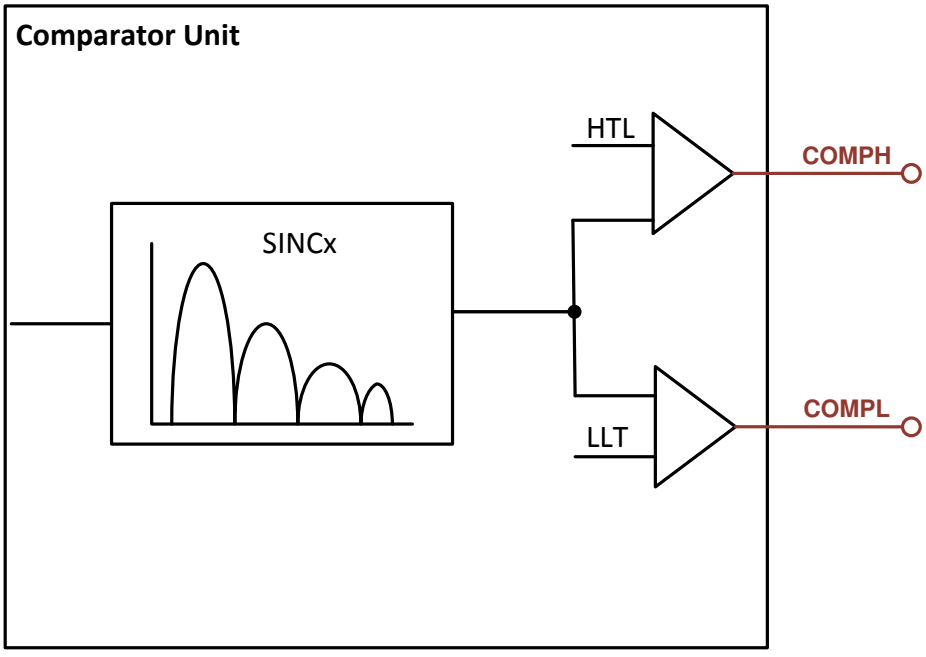

Figure 13-9. Comparator Unit Structure

13.6.1 Higher Threshold (HLT) Comparator

- High threshold comparator can be used to detect over-value condition.
- When comparator data > = higher threshold register, a high threshold event is generated.
- Higher threshold comparator events can be configured to trigger following events: CPU interrupt, CLA task, PWM trip.
- This device has one high threshold comparator:
  - **Higher Threshold (HLT) Comparator**: When SDCTL.MIE = 1 and SDCPARMx.IEH = 1, the high threshold event triggers an SDFM interrupt (SDINT) and sets the SDIFLG.IEHx flag showing the over-value condition is triggered. This SDIFLG.IEHx flag can be reset if the corresponding bit in the SDIFLGCLR register is set and if the interrupt source is no longer active.

13.6.2 Lower Threshold (LLT) Comparator

- The low threshold comparator can be used to detect under-value condition.
- When comparator data < = Lower Threshold register, a low threshold event is generated.
- Lower threshold comparator events can be configured to trigger following events: CPU interrupt, CLA task, PWM trip.
- This device has one low threshold comparator..
  - **Lower Threshold (LLT) Comparator** : When SDCTL.MIE = 1 and SDCPARMx.IEL = 1, the low threshold event triggers an SDFM interrupt (SDINT) and sets the SDIFLG.IELx flag showing an under-value condition is triggered. This SDIFLG.IELx flag can be reset, if the corresponding bit in the SDIFLGCLR register is set and if the interrupt source is no longer active.

13.7 Theoretical SDFM Filter Output

The following equations can be used to derive a theoretical filter output of an SDFM filter output for both a comparator filter and a data filter.

$$\text{Density of ones in bitstream} = \frac{\text{Input Voltage} + \text{Vclipping}}{2 \times \text{Vclipping}} \tag{13}$$

Where:

- Vclipping = maximum differential voltage input range of modulator
- Input voltage = Differential input voltage applied to the modulator

$$\text{Comparator Filter Output (Theoretical)} = \text{Density of ones in bitstream} \times \text{Maximum Filter Output (FilterType, COSR)} \tag{14}$$

$$\text{FilterOutput} = \left\{\frac{\text{absolute(Input voltage)}}{\text{Vclipping}}\right\} \times \text{Maximum Filter Output (FilterType, DOSR)} \tag{15}$$

$$\text{Data Filter Output\_32bit(Theoretical)} = \begin{cases} \text{FilterOutput} & \text{if Input Voltage is +ve voltage} \\ \text{2's complement of FilterOutput} & \text{if input voltage is -ve voltage} \end{cases} \tag{16}$$

$$\text{Data Filter Output\_16bit(Theoretical)} = \text{Data Filter Output\_32bit(Theoretical)} >> \text{Shift value(FilterType, OSR)} \tag{17}$$

For example, when using the AMC1306x25 modulator:

AMC1306x25	Vclipping = Input voltage (AINP - AINN) =	320mV 100mV
SDFM filter settings	Filter type = Comparator OSR (COSR) = Data filter OSR (DOSR) =	3 32 100

Density of 1s in bit stream	Using Equation 13	0.65625
Comparator filter output Filter type = Sinc3 COSR = 32	Using Equation 14	21504
Data filter output (32-bit) Filter type = Sinc3 DOSR = 100	Using Equation 15 and Equation 16	312500
Data filter output (32-bit) Filter type = Sinc3 DOSR = 100 (Right shift by 5)	Using Equation 17	9765

13.8 Interrupt Unit

Each SDFM can generate one CPU interrupt (SDINT).

13.8.1 SDFM (SDINT) Interrupt Sources

Figure 13-10 shows the structure of the interrupt unit. Each SDFM module can generate a CPU interrupt. An SDFM interrupt can be triggered by any of these 16 events.

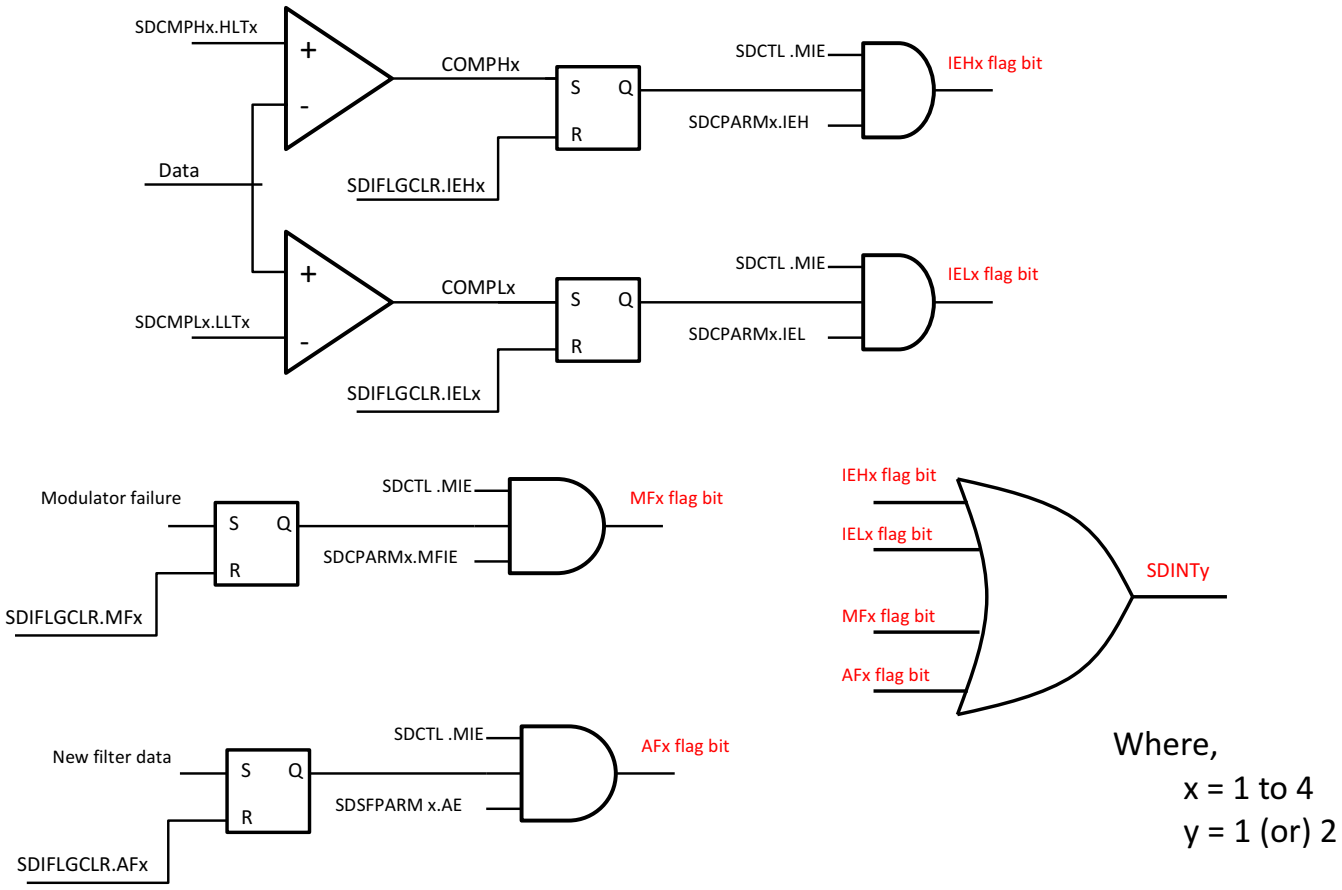

Figure 13-10. SDFM Error (SD_ERR) Interrupt Sources

1. Comparator Lower Threshold events (COMPLx)

COMPL events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDINT interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator filter lower threshold interrupt (SDCPARMx.IEL = 1)

On a COMPL event, SDIFLG.IELx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

2. Comparator High Threshold events (COMPHx)

COMPH events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDINT interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator filter lower threshold interrupt (SDCPARMx.IEH = 1)

On a COMPH event, SDIFLG.IELx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

3. Modulator Failure (MFx) event

Modulator failures (MFx) are generated when SD-Cx goes missing. The modulator clock is considered missing if SD-Cx does not toggle for 64-SYSCLKs. MFx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDINT interrupt only if below configurations are made:

- Enable Main Interrupt Enable (SDCTL.MIE = 1)
- Enable modulator clock failure interrupt source (SDCPARMx.MFIE = 1)

On a MFx event, SDIFLG.MFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

4. New Filter Data Ready (AFx) event

When the primary filter is ready with a new filter data, the AFx event is generated. AFx events from any of the four primary filter modules can be configured to trigger a CPU interrupt. This event can be configured to trigger SDINT interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable data filter acknowledge (SDDFPARMx.AE = 1)

On an AFx event, the SDIFLG.AFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

13.9 Register Descriptions

The register descriptions are shown in the following table and subsections.

Table 13-7. General Registers

Name	SDFM1 address	SDFM2 address	Size (x16)	Description	EALLOW?
SDIFLG	0x5E00	0x5E80	2	Interrupt Flag Register	
SDIFLGCLR	0x5E02	0x5E82	2	Interrupt Flag Clear Register	
SDCTL	0x5E04	0x5E84	1	SD Control Register	YES
SDMFILEN	0x5E06	0x5E86	1	SD Master Filter Enable	YES
Reserved	0x5E07	0x5E87	1	Reserved	

Table 13-8. Filter 1 Registers

Name	SDFM1 address	SDFM2 address	Size (x16)	Description	EALLOW?
SDCTLPARM1	0x5E10	0x5E90	1	Control Parameter Register for Ch1	YES
SDDFPARM1	0x5E11	0x5E91	1	Data Filter Parameter Register for Ch1	YES
SDDPARM1	0x5E12	0x5E92	1	Integer Parameter Register for Ch1	YES
SDCMPH1	0x5E13	0x5E93	1	High-level Threshold Register for Ch1	YES
SDCMPL1	0x5E14	0x5E94	1	Low-level Threshold Register for Ch1	YES
SDCPARM1	0x5E15	0x5E95	1	Comparator Parameter Register for Ch1	YES
SDDATA1	0x5E16	0x5E96	2	Filter Data Register (16- or 32-bit) for Ch1	

Table 13-9. Filter 2 Registers

Name	SDFM1 address	SDFM2 address	Size (x16)	Description	EALLOW?
SDCTLPARM2	0x5E20	0x5EA0	1	Control Parameter Register for Ch2	YES

13.10 Software

13.10.1 SDFM Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/sdfm

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

13.11 SDFM Registers

This section describes the Sigma Delta Filter Module registers.

13.11.1 SDFM Base Addresses

Table 13-12. SDFM Base Address Table

Device Registers	Register Name	Start Address	End Address
Sdfm1Regs	SDFM_REGS	0x0000_5E00	0x0000_5E7F
Sdfm2Regs	SDFM_REGS	0x0000_5E80	0x0000_5EFF

13.11.2 SDFM_REGS Registers

Table 13-13 lists the memory-mapped registers for the SDFM_REGS registers. All register offset addresses not listed in Table 13-13 should be considered as reserved locations and the register contents should not be modified.

Table 13-13. SDFM_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SDIFLG	Interrupt Flag Register		Go
2h	SDIFLGCLR	Interrupt Flag Clear Register		Go
4h	SDCTL	SD Control Register	EALLOW	Go
6h	SDMFILEN	SD Master Filter Enable	EALLOW	Go
10h	SDCTLPARM1	Control Parameter Register for Ch1	EALLOW	Go
11h	SDDFPARM1	Data Filter Parameter Register for Ch1	EALLOW	Go
12h	SDDPARM1	Integer Parameter Register for Ch1	EALLOW	Go
13h	SDCMPH1	High-level Threshold Register for Ch1	EALLOW	Go
14h	SDCMPL1	Low-level Threshold Register for Ch1	EALLOW	Go
15h	SDCPARM1	Comparator Parameter Register for Ch1	EALLOW	Go
16h	SDDATA1	Filter Data Register (16 or 32bit) for Ch1		Go
20h	SDCTLPARM2	Control Parameter Register for Ch2	EALLOW	Go
21h	SDDFPARM2	Data Filter Parameter Register for Ch2	EALLOW	Go
22h	SDDPARM2	Integer Parameter Register for Ch2	EALLOW	Go
23h	SDCMPH2	High-level Threshold Register for Ch2	EALLOW	Go
24h	SDCMPL2	Low-level Threshold Register for Ch2	EALLOW	Go
25h	SDCPARM2	Comparator Parameter Register for Ch2	EALLOW	Go
26h	SDDATA2	Filter Data Register (16 or 32bit) for Ch2		Go
30h	SDCTLPARM3	Control Parameter Register for Ch3	EALLOW	Go
31h	SDDFPARM3	Data Filter Parameter Register for Ch3	EALLOW	Go
32h	SDDPARM3	Integer Parameter Register for Ch3	EALLOW	Go
33h	SDCMPH3	High-level Threshold Register for Ch3	EALLOW	Go
34h	SDCMPL3	Low-level Threshold Register for Ch3	EALLOW	Go
35h	SDCPARM3	Comparator Parameter Register for Ch3	EALLOW	Go
36h	SDDATA3	Filter Data Register (16 or 32bit) for Ch3		Go
40h	SDCTLPARM4	Control Parameter Register for Ch4	EALLOW	Go
41h	SDDFPARM4	Data Filter Parameter Register for Ch4	EALLOW	Go
42h	SDDPARM4	Integer Parameter Register for Ch4	EALLOW	Go
43h	SDCMPH4	High-level Threshold Register for Ch4	EALLOW	Go
44h	SDCMPL4	Low-level Threshold Register for Ch4	EALLOW	Go
45h	SDCPARM4	Comparator Parameter Register for Ch4	EALLOW	Go
46h	SDDATA4	Filter Data Register (16 or 32bit) for Ch4		Go

Complex bit access types are encoded to fit into small table cells. Table 13-14 shows the codes that are used for access types in this section.

Table 13-14. SDFM_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s

Table 13-14. SDFM_REGS Access Type Codes (continued)

Access Type	Code	Description
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

13.11.2.1 SDIFLG Register (Offset = 0h) [Reset = 00000000h]

SDIFLG is shown in Figure 13-11 and described in Table 13-15.

Return to the Summary Table.

Chapter 14

Enhanced Pulse Width Modulator (ePWM)

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipment. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral can also perform a digital-to-analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a power DAC.

This chapter is applicable for ePWM type 4 with added register protection capability. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with an ePWM module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

Further information can be found in the *Flexible PWMs Enable Multi-Axis Drives, Multi-Level Inverters Technical Brief*.

14.1 Introduction

This chapter includes an overview and information about each submodule:

- Time Base (TB) Submodule
- Counter Compare (CC) Submodule
- Action Qualifier (AQ) Submodule
- Dead-Band Generator (DB) Submodule
- PWM Chopper (PC) Submodule
- Trip Zone (TZ) Submodule
- Event Trigger (ET) Submodule
- Digital Compare (DC) Submodule

The ePWM Type 4 is functionally compatible to Type 2 (a Type 3 does not exist). Type 4 has the following enhancements in addition to the Type 2 features:

- **Register Address Map:** Additional registers are required for new features on ePWM Type 4. The ePWM register address space has been remapped for better alignment and easy usage.
- **Delayed Trip Functionality:** Changes have been added to achieve deadband insertion capabilities to support, for example, delayed trip functionality needed for peak current mode control type application scenarios. This has been accomplished by allowing comparator events to go into the Action Qualifier as a trigger event (Events T1 and T2). If comparator T1 / T2 events are used to edit the PWM, changes to the PWM waveform do not take place immediately. Instead, the waveform synchronizes to the next TBCLK.
- **Dead-Band Generator Submodule Enhancements:** Shadowing of the DBCTL register to allow dynamic configuration changes.
- **One Shot and Global Load of Registers:** The ePWM Type 4 allows one shot and global load capability from shadow to active registers to avoid partial loads in, for example, multiphase applications. ePWM Type 4 also allows a programmable prescale of shadow to active load events. ePWM Type 4 Global Load can simplify ePWM software by removing interrupts and making sure that all registers are loaded at the same time.
- **Trip-Zone Submodule Enhancements:** Independent flags have been added to reflect the trip status for each of the TZ sources. Changes have been made to the trip-zone submodule to support certain power converter switching techniques like valley switching.
- **Digital Compare Submodule Enhancements:** Blanking window filter register width has been increased from 8 to 16 bits. DCCAP functionality has been enhanced to provide more programmability.
- **PWM SYNC Related Enhancements:** The ePWM Type 4 allows PWM SYNCOUT generation based on CMPC and CMPD events. These events can also be used for PWMSYNC pulse selection.

The ePWM Type 2 is fully compatible to Type 1. Type 2 has the following enhancements in addition to the Type 1 features:

- **High-Resolution Dead-Band Capability:** High-resolution capability is added to dead-band RED and FED in half-cycle clocking mode.
- **Dead-Band Generator Submodule Enhancements:** The ePWM Type 2 has features to enable both RED and FED on either PWM outputs. Provides increased dead band with 14-bit counters and dead-band / dead-band high-resolution registers are shadowed
- **High-Resolution Extension available on ePWMxB outputs:** Provides the ability to enable high-resolution period and duty cycle control on ePWMxB outputs. This is discussed in more detail in Section 14.14.
- **Counter Compare Submodule Enhancements:** The ePWM Type 2 allows interrupts and SOC events to be generated by additional counter compares CMPC and CMPD.
- **Event Trigger Submodule Enhancements:** Prescaling logic to issue interrupt requests and ADC start of conversion expanded up to every 15 events. This submodule allows software initialization of event counters on SYNC event.
- **Digital Compare Submodule Enhancements:** Digital Compare Trip Select logic [DCTRIPSEL] has up to 12 external trip sources selected by the Input X-BAR logic in addition to an ability to OR all of them (up to 14 [external and internal sources]) to create the respective DCxEVTs.

- **Simultaneous Writes to TBPRD and CMPx Registers:** This feature allows writes to TBPRD, CMPA:CMPAHR, CMPB:CMPBHR, CMPC and CMPD of any ePWM module to be tied to any other ePWM module, and also allows all ePWM modules to be tied to a particular ePWM module if desired.
- **Shadow to Active Load on SYNC of TBPRD and CMP Registers:** This feature supports simultaneous writes of TBPRD and CMPA/B/C/D registers.

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention and must be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel submodules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand the operation quickly.

In this document, the letter x within a signal or submodule name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

Type0 to Type1 Enhancements

- **Increased Dead-Band Resolution:** Dead-band clocking has been enhanced to allow half-cycle clocking to double resolution.
- **Enhanced Interrupt and SOC Generation:** Interrupts and ADC start-of-conversion can now be generated on both the TBCTR == zero and TBCTR == period events. This feature enables dual edge PWM control. Additionally, the ADC start-of-conversion can be generated from an event defined in the digital compare submodule.
- **High-Resolution Period Capability:** Provides the ability to enable high-resolution period. This is discussed in more detail in Section 14.14.
- **Digital Compare Submodule:** The digital compare submodule enhances the event triggering and trip zone submodules by providing filtering, blanking and improved trip functionality to digital compare signals. Such features are essential for peak current mode control and for support of analog comparators.

Note

The name of the sync signal that goes to the CMPSS and GPDAC has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see Table 14-2.

14.1.2 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in Figure 14-1. Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in Section 14.14. See the device data sheet to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

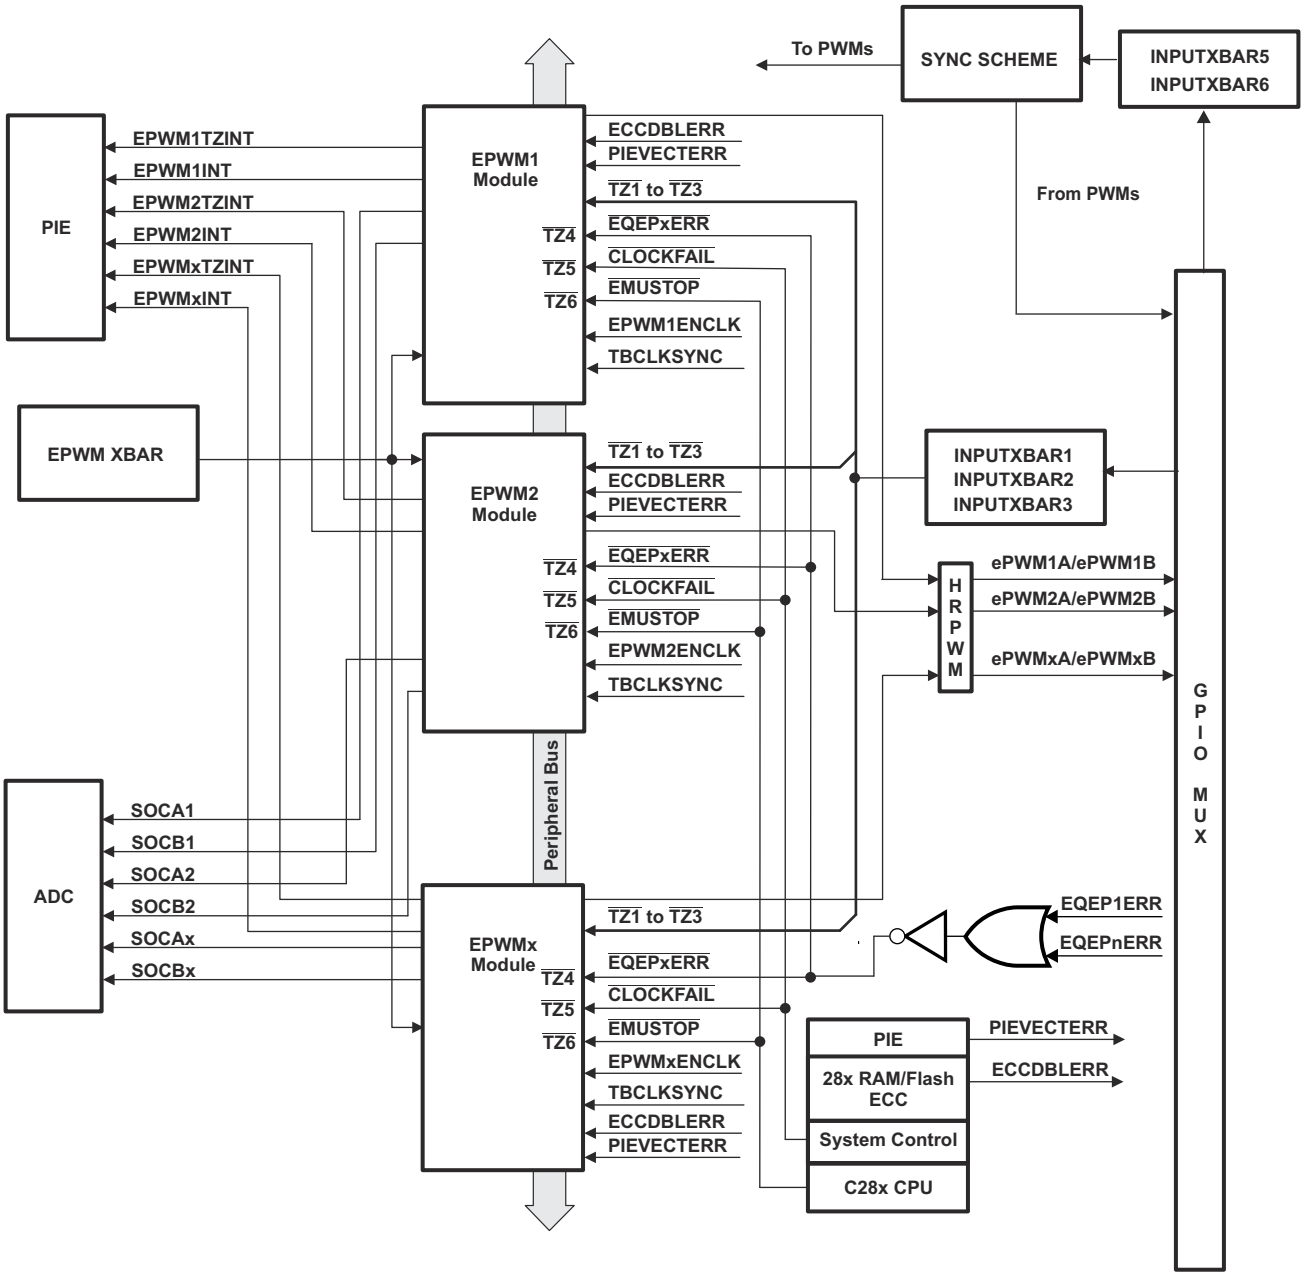
The ePWM modules are chained together by way of a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral submodules (eCAP). The number of submodules is device-dependent and based on target application needs. Submodules can also operate standalone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in Figure 14-1. The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected can differ from what is shown in Figure 14-1. See Section 14.4.3.3 for the synchronization scheme for a particular device. Each ePWM module consists of eight submodules and is connected within a system by way of the signals shown in Figure 14-2.



A. This signal exists only on devices with an eQEP submodule.

Figure 14-1. Multiple ePWM Modules

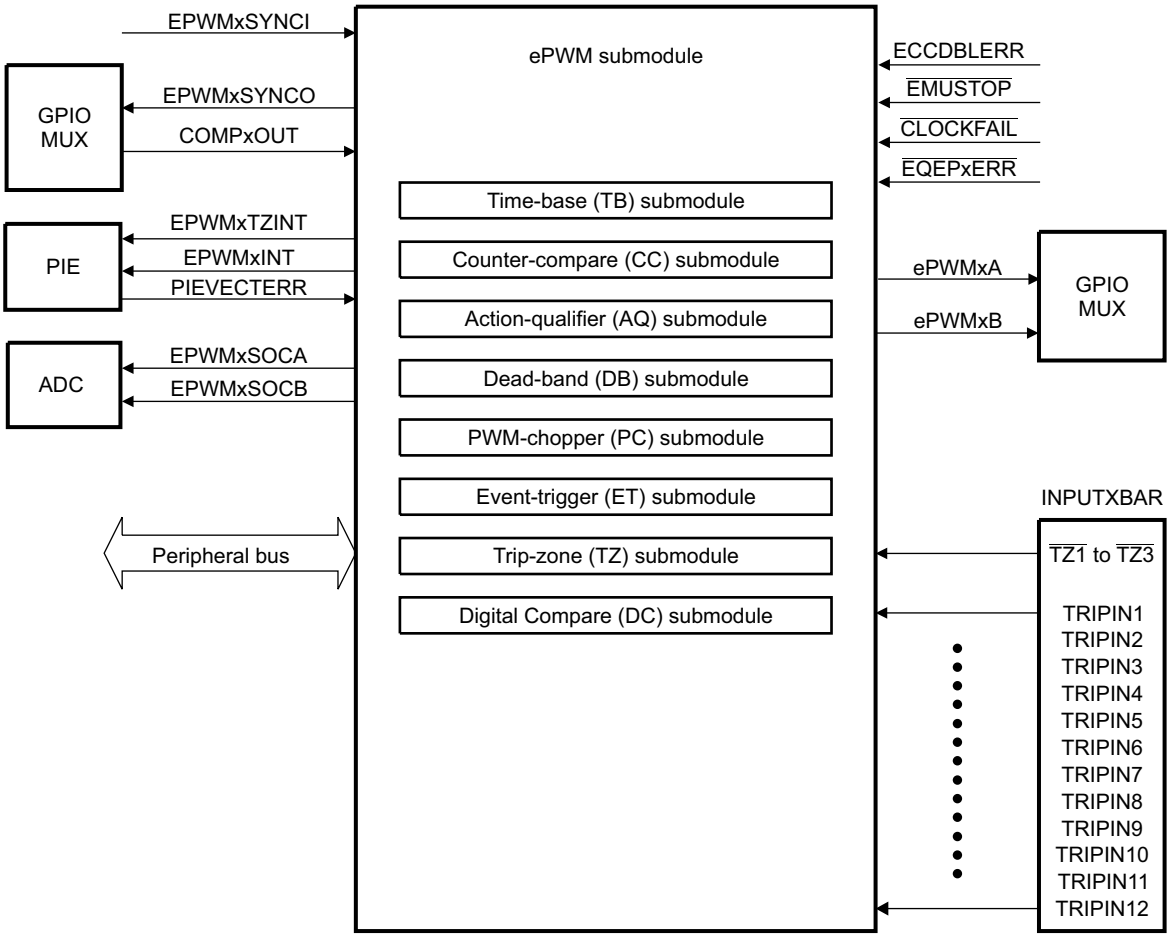


Figure 14-2. Submodules and Signal Connections for an ePWM Module

Figure 14-3 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB)**

  The PWM output signals are made available external to the device.

- **Trip-zone signals ($\overline{TZ1}$ to $\overline{TZ6}$)**

  These input signals alert the ePWM module of fault conditions external to the ePWM module. Each submodule on a device can be configured to either use or ignore any of the trip-zone signals. The $\overline{TZ1}$ to $\overline{TZ3}$ trip-zone signals can be configured as asynchronous inputs through the GPIO peripheral using the Input X-BAR logic, refer to Figure 14-50. $\overline{TZ4}$ is connected to an inverted EQEPx error signal (EQEPxERR), which can be generated from any one of the EQEP submodule (for those devices with an EQEP module). $\overline{TZ5}$ is connected to the system clock fail logic, and $\overline{TZ6}$ is connected to the $\overline{EMUSTOP}$ output from the CPU. This allows configuring a trip action when the clock fails or the CPU halts.

- **Time-base synchronization input (EPWMxSYNCI), output (EPWMxSYNCO), and peripheral (EPWMxSYNCPER) signals**

  The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore the synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The ePWM modules are separated into groups of three for syncing purposes. An external sync signal (EXTSYNCIN1 or EXTSYNCIN2) can be used to issue a sync signal to the first ePWM module in each chain. These same modules can also send the EPWMxSYNCOUT signal to a GPIO. For more information, see Section 14.4.3.3.

  Each ePWM module also generates another PWMSYNC signal called EPWMxSYNCPER. EPWMxSYNCPER goes to the GPDAC and CMPSS for synchronization purposes. Functionality is configured using the HRPCTL register, but has no relation with the HRPWM. For more information on how EPWMxSYNCPER is used by the GPDAC and CMPSS, see the respective chapters.

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB)**

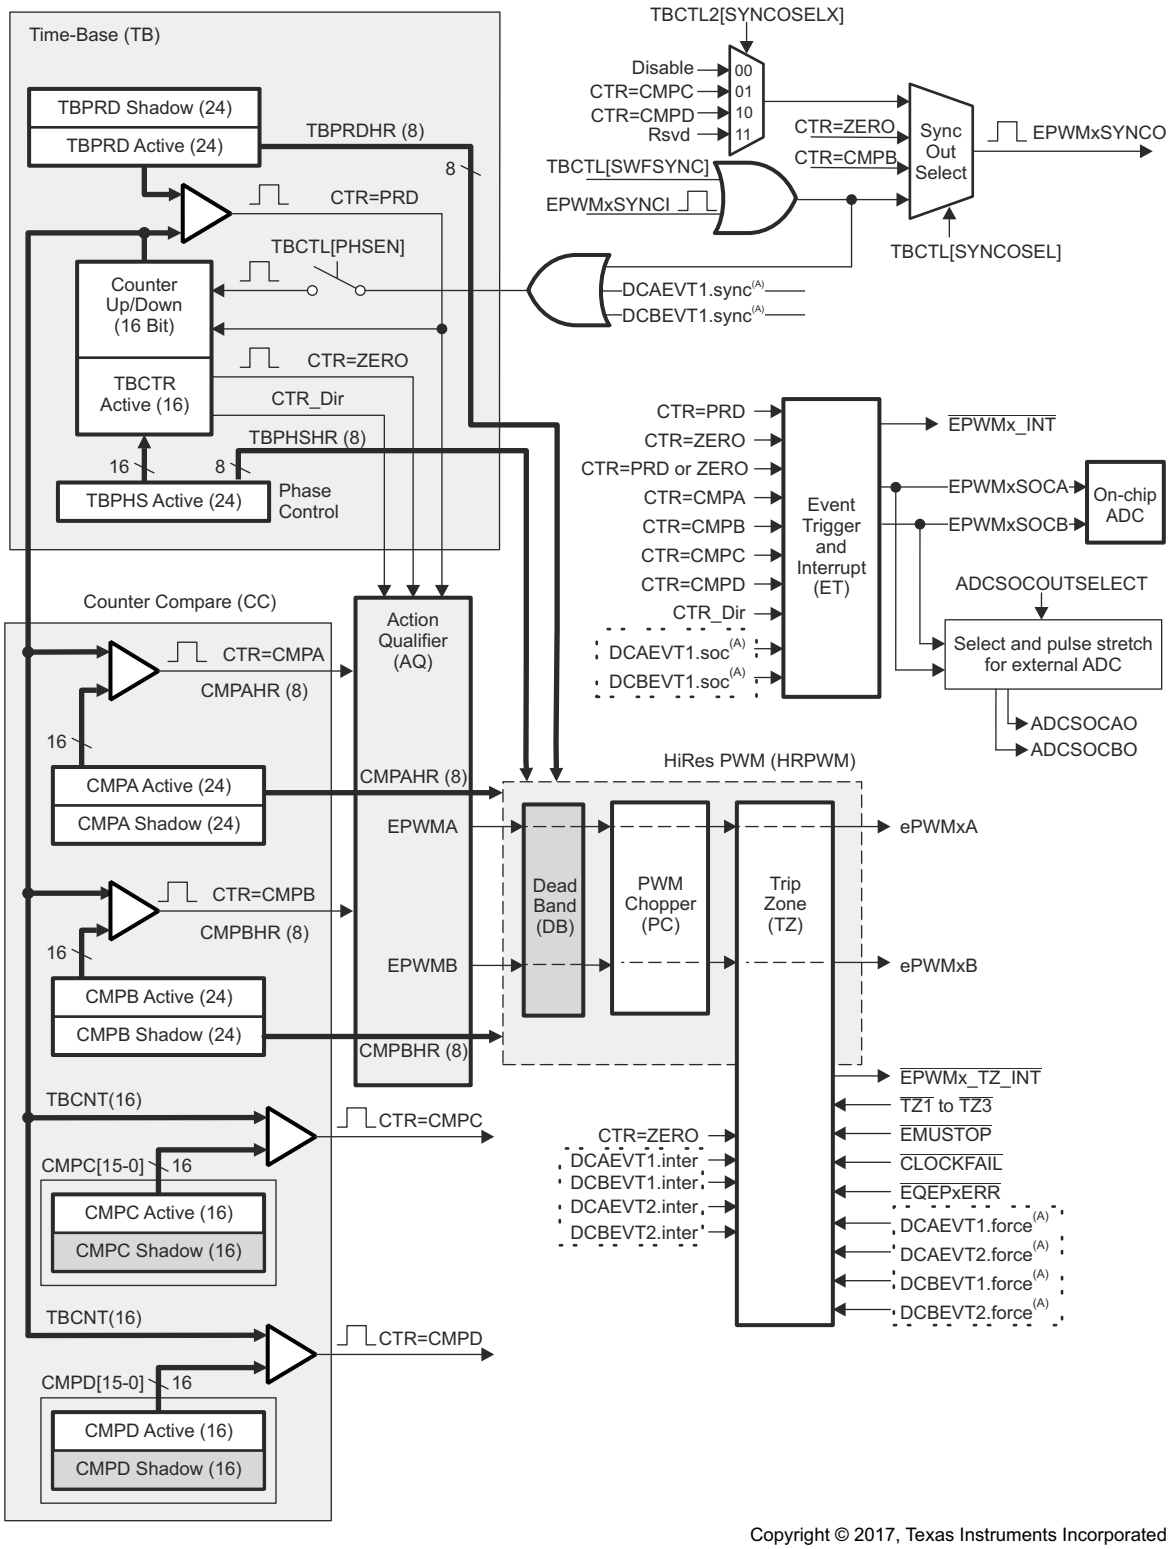
  Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Whichever event triggers the start of conversion is configured in the event-trigger submodule of the ePWM.

- **Comparator output signals (COMPxOUT)**

  Output signals from the comparator module can be fed through the Input X-BAR and EPWM X-BAR to one or all of the 12 trip inputs [TRIPIN1 - TRIPIN12] and in conjunction with the trip zone signals can generate digital compare events.

- **Peripheral bus**

  The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.



A. These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

Figure 14-3. ePWM Modules and Critical Internal Signal Interconnects

14.2 Configuring Device Pins

To connect the device input pins to the module, the Input X-BAR and EPWM X-BAR must be used. Some examples of when an external signal can be needed are TZx, TRIPx, and EXTSYNCIN. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to asynchronous mode by setting the appropriate GPxQSEL register bits to 11b. The internal pullups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals. Additionally, some TRIPx (TRIP4-12 excluding TRIP6) signals must be routed through the ePWM X-Bar in addition to the Input X-Bar.

The GPIO mux registers must be configured for this peripheral. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

14.3 ePWM Modules Overview

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

Table 14-1 lists the key submodules together with a list of the main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, see the counter-compare submodule in Section 14.5 for relevant details.

Table 14-1. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time Base (TB)	• Scale the time-base clock (TBCLK) relative to the ePWM clock (EPWMCLK). • Configure the PWM time-base counter (TBCTR) frequency or period. • Set the mode for the time-base counter: – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Simultaneous writes to the TBPRD registers on all PWM's corresponding to the configuration on EPWMXLINK. • Configure how the time-base counter behaves when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated. • Configure one shot and global load of registers in this module.
Counter Compare (CC)	• Specify the PWM duty cycle for output EPWMxA and output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output • Specify the programmable delay for interrupt and SOC generation with additional comparators • Simultaneous writes to the CMPA, CMPB, CMPC, CMPD registers on all PWM's corresponding to the configuration on EPWMXLINK. • Configure one shot and global load of registers in this module.

Table 14-1. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Action Qualifier (AQ)	• Specify the type of action taken when a time-base counter-compare, trip-zone submodule, or comparator event occurs: – No action taken – Output EPWMxA and EPWMxB switched high – Output EPWMxA and EPWMxB switched low – Output EPWMxA and EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead band through software • Configure one shot and global load of registers in this module.
Dead-Band Generator (DB)	• Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification. • Option to enable half-cycle clocking for double resolution. • Allow ePWMxB phase shifting with respect to the ePWMxA output. • Configure one shot and global load of registers in this module.
PWM Chopper (PC)	• Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM chopper module entirely. In this case the PWM waveform is passed through without modification.
Trip Zone (TZ)	• Configure the ePWM module to react to one, all, or none of the trip-zone signals or digital compare events. • Specify the trip action taken when a fault occurs: – Force EPWMxA and EPWMxB high – Force EPWMxA and EPWMxB low – Force EPWMxA and EPWMxB to a high-impedance state – Configure EPWMxA and EPWMxB to ignore any trip condition. • Configure how often the ePWM reacts to each trip-zone signal: – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely. • Programmable option for cycle-by-cycle trip clear • If desired, independently configure trip actions taken when time-base counter is counting down.
Event Trigger (ET)	• Enable the ePWM events that trigger an interrupt. • Enable ePWM events that trigger an ADC start-of-conversion event. • Specify the rate at which events cause triggers (every occurrence or every 2nd or up to 15th occurrence) • Poll, set, or clear event flags
Digital Compare (DC)	• Enables comparator (COMP) module outputs and trip zone signals which are configured using the Input X-BAR to create events and filtered events • Specify event-filtering options to capture TBCTR counter, generate blanking window, or insert delay in PWM output or time-base counter based on captured value.

14.4 Time-Base (TB) Submodule

Each ePWM module has a time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system.

Figure 14-4 illustrates the time-base submodule within the ePWM.

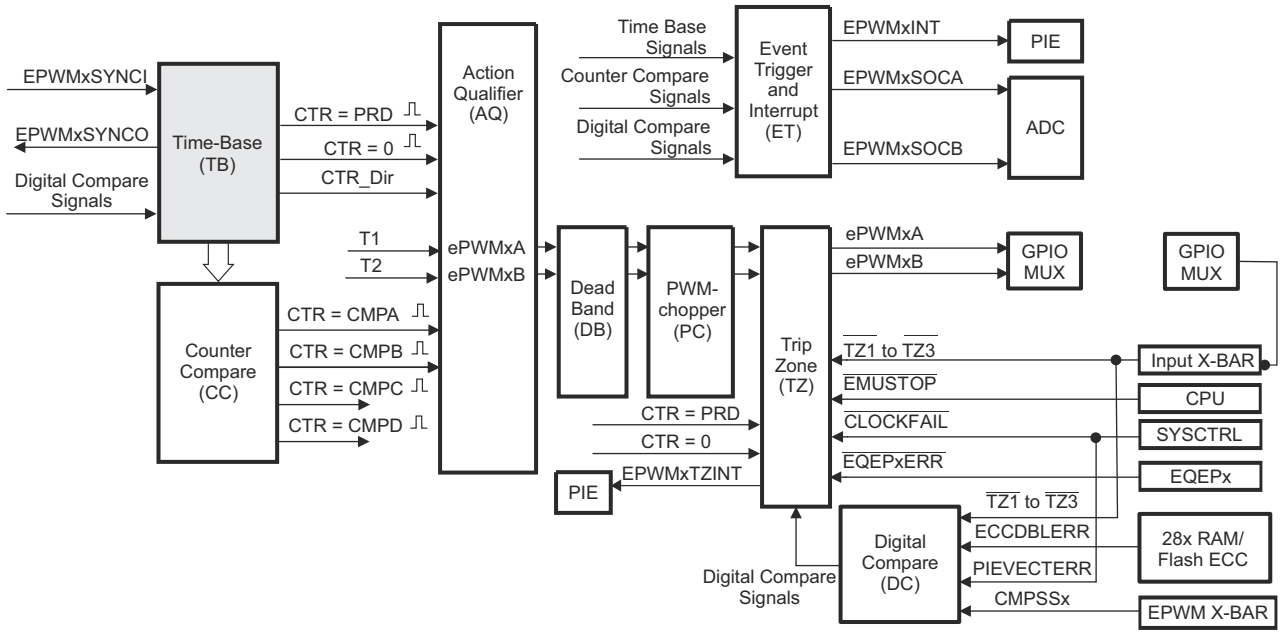


Figure 14-4. Time-Base Submodule

14.4.1 Purpose of the Time-Base Submodule

The time-base submodule can be configured for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00).
- Configure the rate of the time-base clock; a prescaled version of the ePWM clock (EPWMCLK). This allows the time-base counter to increment/decrement at a slower rate.

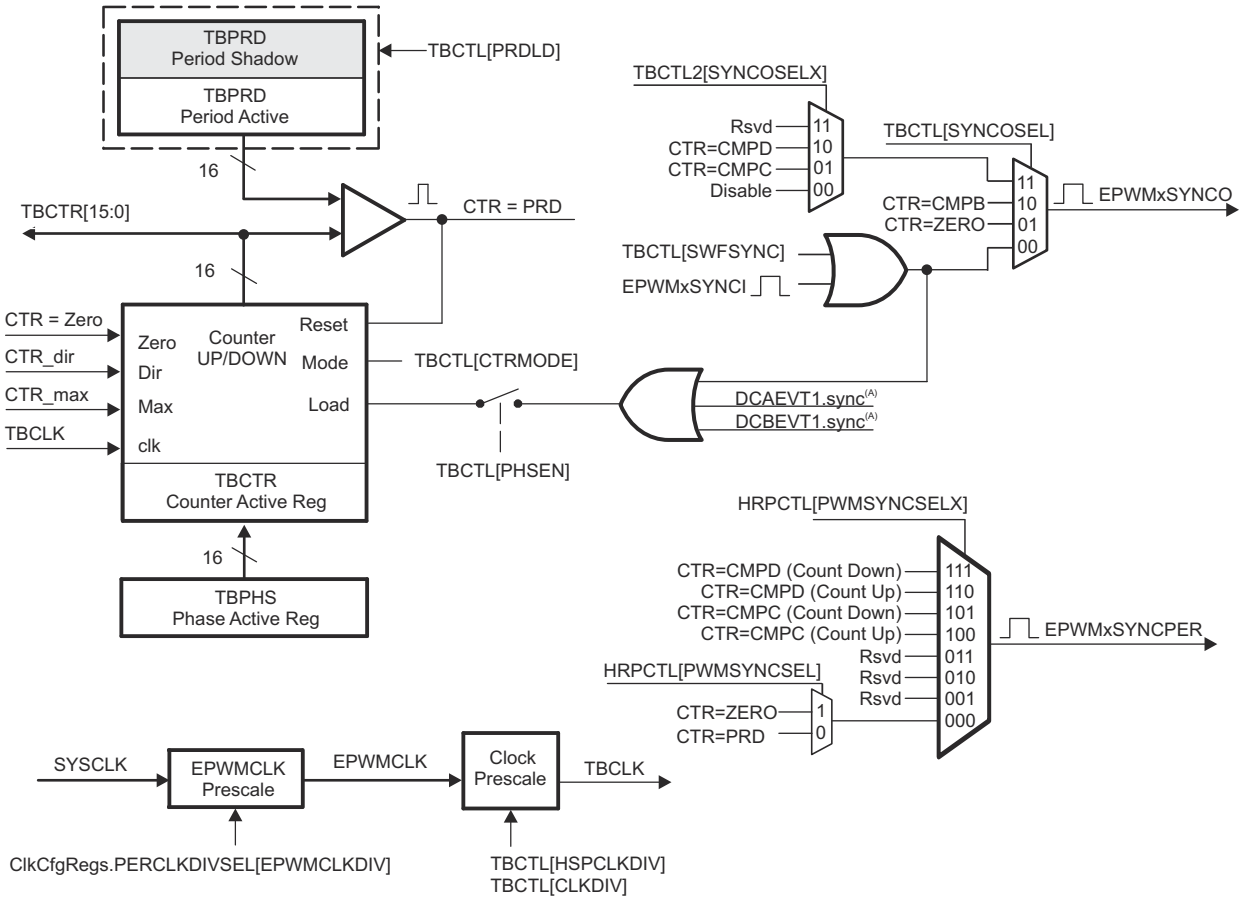
Note

The Type 4 ePWM clocking varies from previous ePWM types. Prior to the Type 4 ePWM, the time-base submodule is clocked directly by the system clock (SYSCLKOUT). On this version of the ePWM, there is a divider (EPWMCLKDIV) of the system clock that defaults to EPWMCLK = SYSCLKOUT/2.

If required by the application code to update the TBCTR value through software while the TBCTR is counting, note that the time-base module needs at least 1 TBCLK cycle for the time-base related events to be realized. Hence, the TBCTR can be written with TBCTR = PRD-1 instead of TBCTR = PRD (in case the counter is counting up) and can be written as TBCTR = 1 instead of TBCTR = 0 (in case the counter is counting down) for the events to be realized.

14.4.2 Controlling and Monitoring the Time-Base Submodule

The block diagram in Figure 14-5 shows the critical signals and registers of the time-base submodule. Table 14-2 provides descriptions of the key signals associated with the time-base submodule.



A. These signals are generated by the digital compare (DC) submodule.

Figure 14-5. Time-Base Submodule Signals and Registers

Table 14-2. Key Time-Base Signals

Signal	Description
EPWMxSYNCI	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module in each synchronization chain, this signal can come from a device pin using INPUT5 or INPUT6 of the Input X-BAR or from a previous ePWM module. For subsequent ePWM modules in each chain, this signal is passed from another ePWM peripheral. For example, EPWM2SYNCI is generated by the ePWM1 peripheral, EPWM3SYNCI is generated by ePWM2 and so forth. For information on the synchronization order of a particular device, see Section 14.4.3.3.
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: 1. EPWMxSYNCI (Synchronization input pulse) 2. CTR = Zero: The time-base counter equal to zero (TBCTR = 0x00). 3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCTR = CMPB) register.
EPWMxSYNCPER	Time-base peripheral synchronization output. This output signal is used to synchronize the GPDAC and CMPSS to the EPWM. The output signal can be configured using the HRPCTL register. Note that this signal has no relation with the HRPWM.
CTR = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.
CTR = Zero	Time-base counter equal to zero This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x00.
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCTR = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic
CTR_dir	Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. The signal is high when the counter is increasing and the signal is low when the counter is decreasing.
CTR_max	Time-base counter equal max value. (TBCTR = 0xFFFF) Generated event when the TBCTR value reaches the maximum value. This signal is only used only as a status bit
TBCLK	Time-base clock. This is a prescaled version of the ePWM clock (EPWMCLK) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

14.4.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 14-6 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the ePWM clock (EPWMCLK).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down Count Mode:** In up-down count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until the counter reaches zero. At this point, the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In up-count mode, the time-base counter starts from zero and increments until the counter reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until the counter reaches zero. When the counter reaches zero, the time-base counter is reset to the period value and begins to decrement once again.

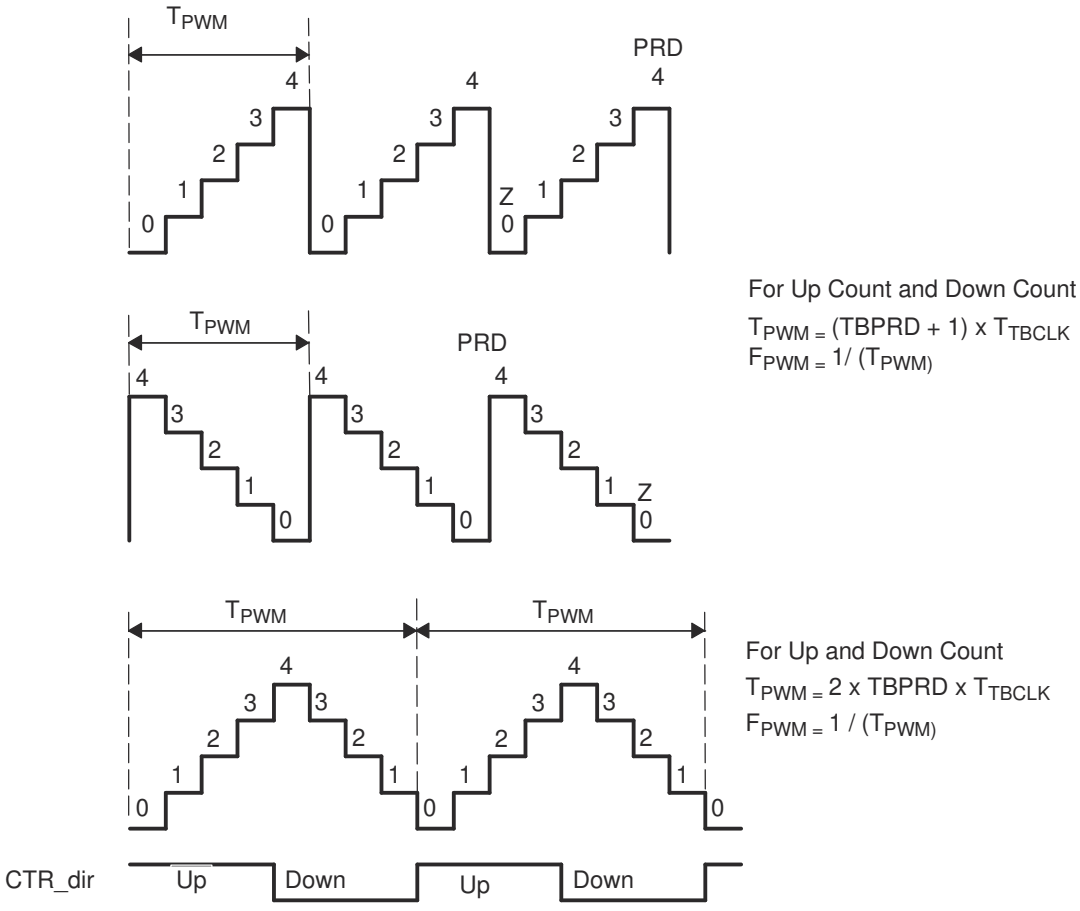


Figure 14-6. Time-Base Frequency and Period

14.4.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers provide a temporary holding location for the active register and have no direct effect on any control hardware. At a strategic point in time, the shadow register content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDLD] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The TBPRD shadow register is enabled when TBCTL[PRDLD] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x00) and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. The PRDLDSYNC bit is valid only if TBCTL[PRDLD] = 0. By default the TBPRD shadow register is enabled. The sources for the SYNC input is explained in Section 14.4.3.3.

  The global load control mechanism can also be used with the time-base period register by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL). Global load control mechanism is explained in Section 14.4.7.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (TBCTL[PRDLD] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

14.4.3.2 Time-Base Clock Synchronization

The TBCLKSYNC bit in the peripheral clock enable registers allows all users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks in the PCLKCRx register
2. Set TBCLKSYNC= 0
3. Configure ePWM modules
4. Set TBCLKSYNC= 1

14.4.3.3 Time-Base Counter Synchronization

The ePWM synchronization scheme allows for increased flexibility of synchronization of the ePWM modules. Each ePWM module has a synchronization input (SYNCI), a synchronization output (SYNCO) and a peripheral synchronization output (SYNCPER). In Figure 14-7, EXTSYNCIN1 is sourced from INPUTXBAR5 and EXTSYNCIN2 is sourced from INPUTXBAR6, which can be configured to select any GPIO as the synchronization input. When configuring the sync chain propagation path using the SYNCSEL registers, make sure that the longest path does not exceed four ePWM/eCAP modules.

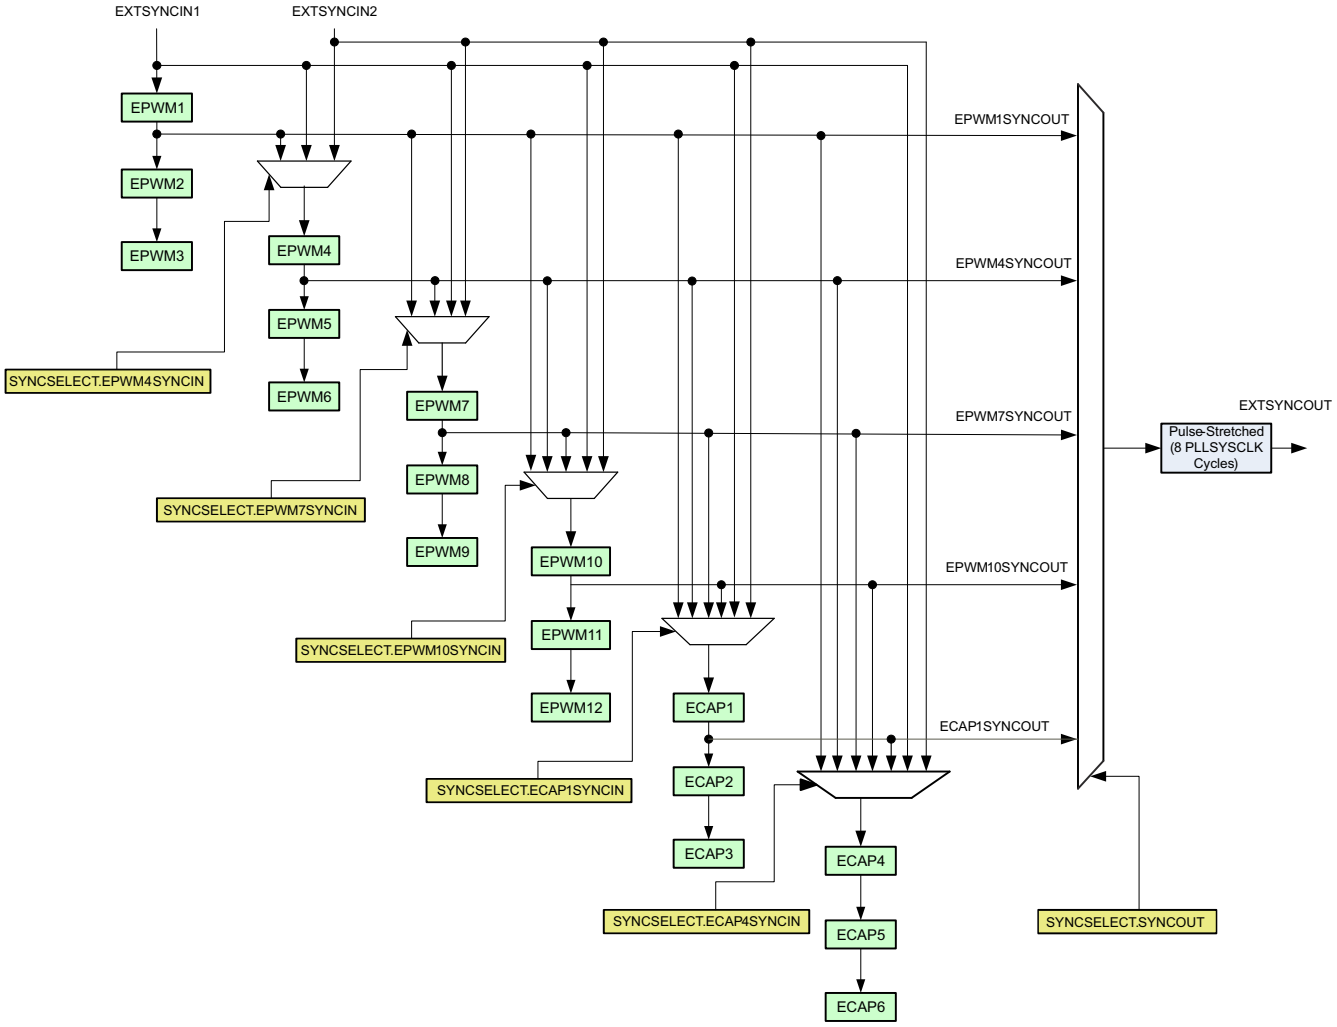

Figure 14-7. Time-Base Counter Synchronization Scheme

Note

See the data sheet for the number of ePWM and eCAP modules available on your specific device.

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module is automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

  The delay from internal control module to target modules is given by:

  - if (TBCLK = EPWMCLK): 2 x EPWMCLK
  - if (TBCLK < EPWMCLK): 1 x TBCLK
- **Software Forced Synchronization Pulse:** Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.
- **Digital Compare Event Synchronization Pulse:** DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCI.

Note

If the EPWMxSYNCI signal is held high, the sync does not continuously occur. The EPWMxSYNCI is rising edge activated.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PHSDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PHSDIR bit is ignored in count-up or count-down modes. See Figure 14-8 through Figure 14-11 for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, a controller time-base (for example, ePWM1) can be set up and downstream modules (ePWM2 - ePWMx) can run in synchronization with the controller. See Section 14.13 for more details on synchronization strategies.

14.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. This bit is part of the device's clock enable registers and is described in the *System Control and Interrupts* section of this manual. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is:

1. Enable the individual ePWM module clocks. This is described in the *System Control and Interrupts* chapter.
2. Set TBCLKSYNC= 0. This stops the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKSYNC = 1.

14.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules

For variable frequency applications, there is a need for simultaneous writes of TBPRD and CMPx registers between ePWM modules. This prevents situations where a CTR = 0 or CTR = PRD pulse forces a shadow to active load of these registers before all registers are updated between ePWM modules (resulting in some registers being loaded from new shadow values while others are loaded from old shadow values). To support this, an ePWM register linking scheme for TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, CMPC, and CMPD registers between PWM modules has been added.

Refer to the register description for EPWMXLINK to see the linked register bit-field values for corresponding ePWM. An example of using the EPWMXLINK is linking ePWM2 CMPA with CMPA of ePWM1 through ePWM2's EPWMXLINK[CMPALINK] register bit-field. In this case, a write to CMPA of ePWM1 also changes the CMPA value for ePWM2.

14.4.6 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode that is asymmetrical
- Down-count mode that is asymmetrical
- Up-down-count that is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

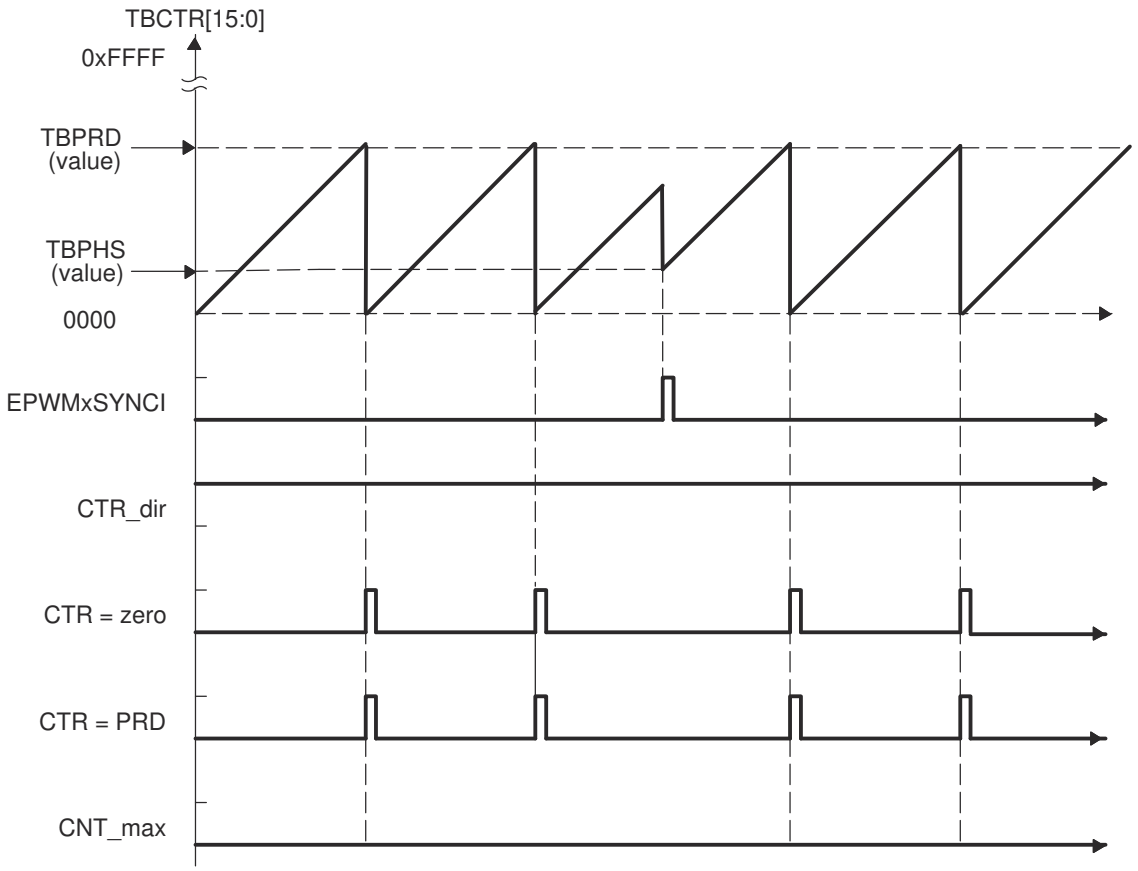

Figure 14-8. Time-Base Up-Count Mode Waveforms

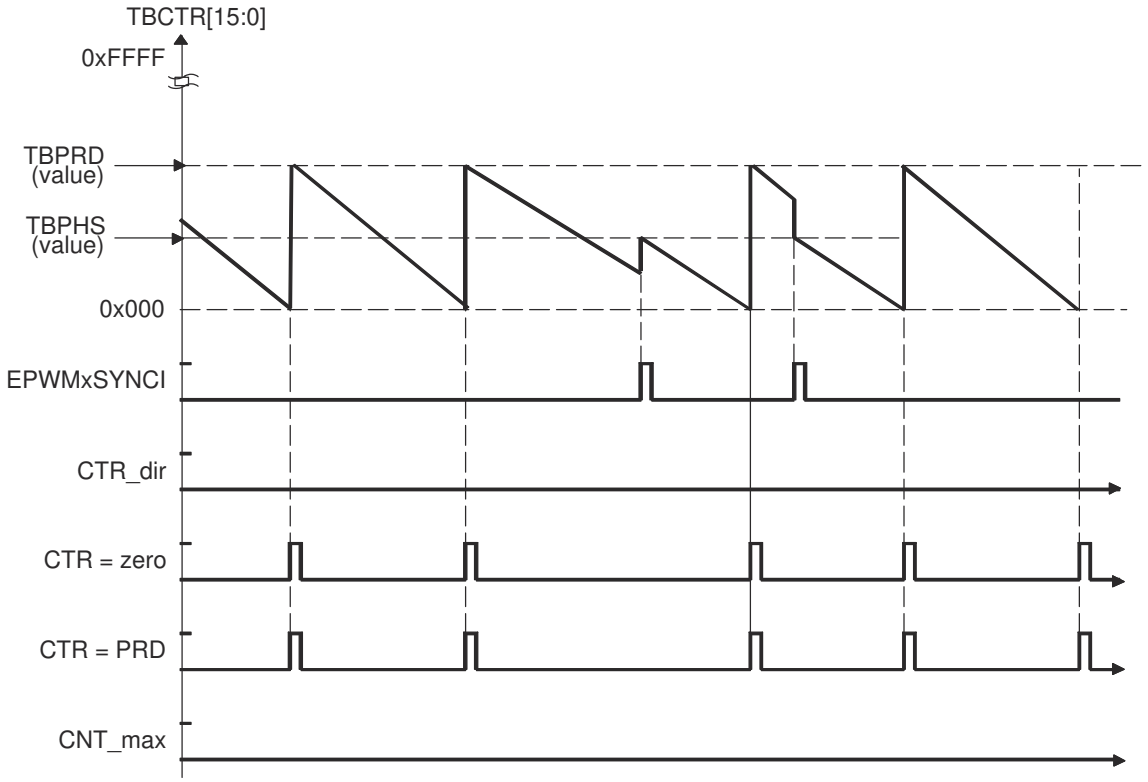

Figure 14-9. Time-Base Down-Count Mode Waveforms

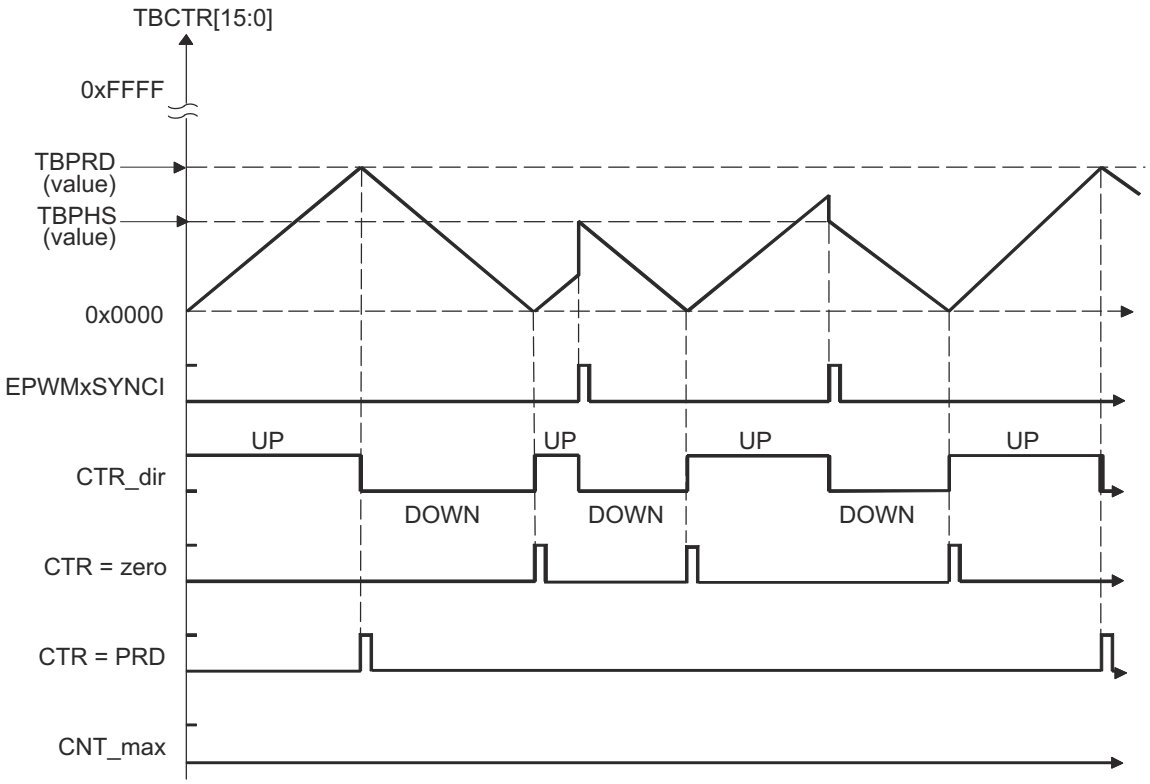

Figure 14-10. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

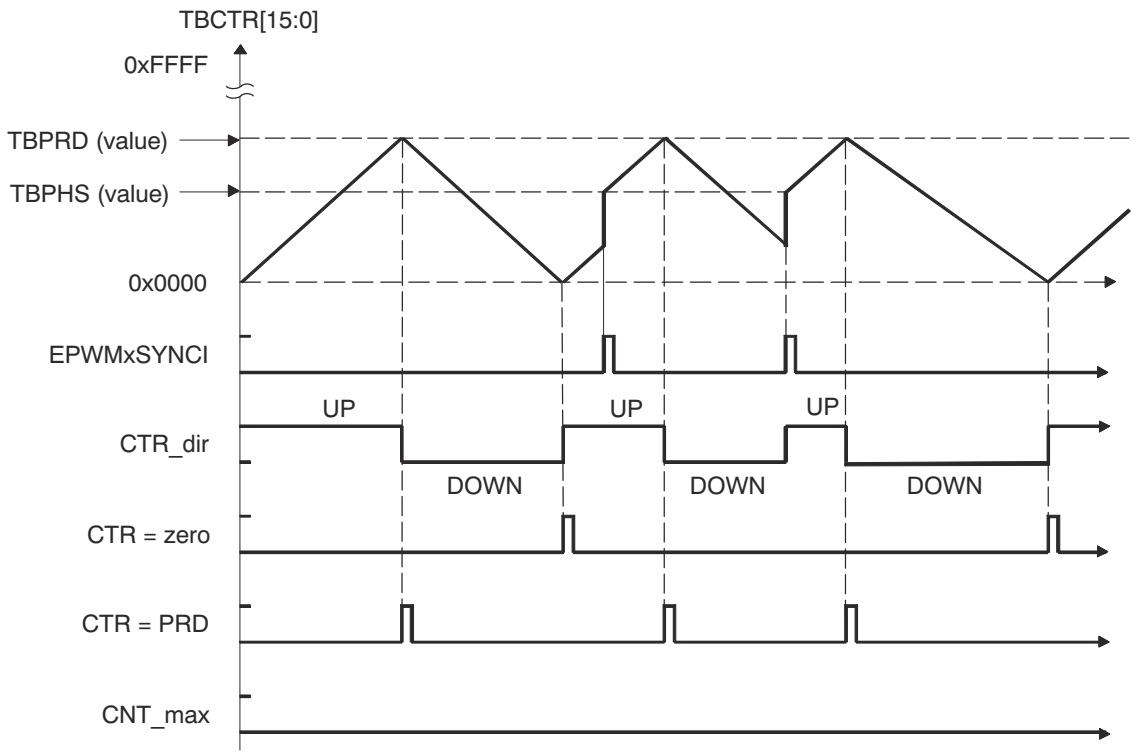

Figure 14-11. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

14.4.7 Global Load

Figure 14-12 shows the signals and registers associated with the global load feature.

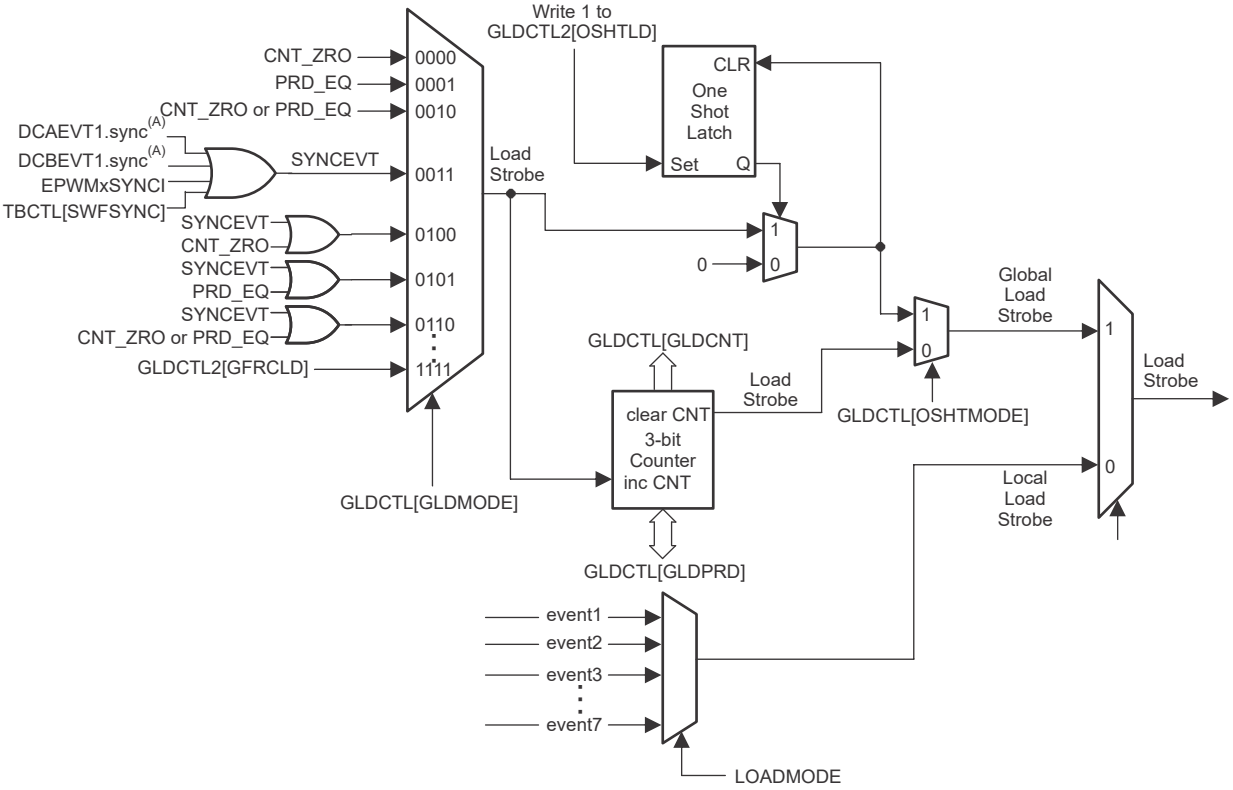

Figure 14-12. Global Load: Signals and Registers

Note

The SYNCEVT signal is only propagated through when PHSEN is SET.

When this feature is enabled, the transfer of contents from the shadow register to the active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL[GLDMODE]). When GLDCTL[GLD] = 1, shadow to active load event selection bits for individual shadowed registers are ignored and global load mode takes effect for the corresponding registers enabled by GLDCFG[REGx].

When GLDCTL[GLD] = 1 and GLDCFG[REGx] = 0, global load mode does not affect the corresponding register (REGx). Shadow to active load event selection bits for individual shadowed registers decide how the transfer of contents from shadow register to active register takes place.

14.4.7.1 Global Load Pulse Pre-Scalar

This feature provides the capability to choose shadow to active transfers to happen once in 'N' occurrences of selected global load pulse (GLDCTL[GLDMODE]). This pre-scale functionality is not available for registers that cannot or are not configured to use the global load mechanism (that is, GLDCTL[GLD] = 0 or GLDCFG[REGx] = 0).

14.4.7.2 One-Shot Load Mode

This feature allows users to cause the shadow register to active register transfers to occur once. When GLDCTL2[OSHTLD] = 1 the shadow to active register transfer, for registers that are configured to use the global load mechanism, takes place on the event selected by GLDCTL[GLDMODE].

Software force loading of contents from shadow register to active register is possible by using GLDCTL2[GFRCLD]. The GLDCTL2 register can also be linked across multiple PWM modules by using EPWMXLINK[GLDCTL2LINK]. This, along with the one-shot load mode feature discussed above, provides a method to correctly update multiple PWM registers in one or more PWM modules at certain PWM events or, if desired, in the same clock cycle. This is very useful in variable frequency applications and/or multi-phase interleaved applications.

Note

One-shot load mode must not be used when high-resolution mode is enabled.

14.4.7.3 One-Shot Sync Mode

To enable the one-shot sync mode to generate a SYNCOUT pulse, configure the TBCTL2[OSHTSYNCMODE] bit and set the TBCTL2[OSHTSYNC] bit as shown in Figure 14-13.

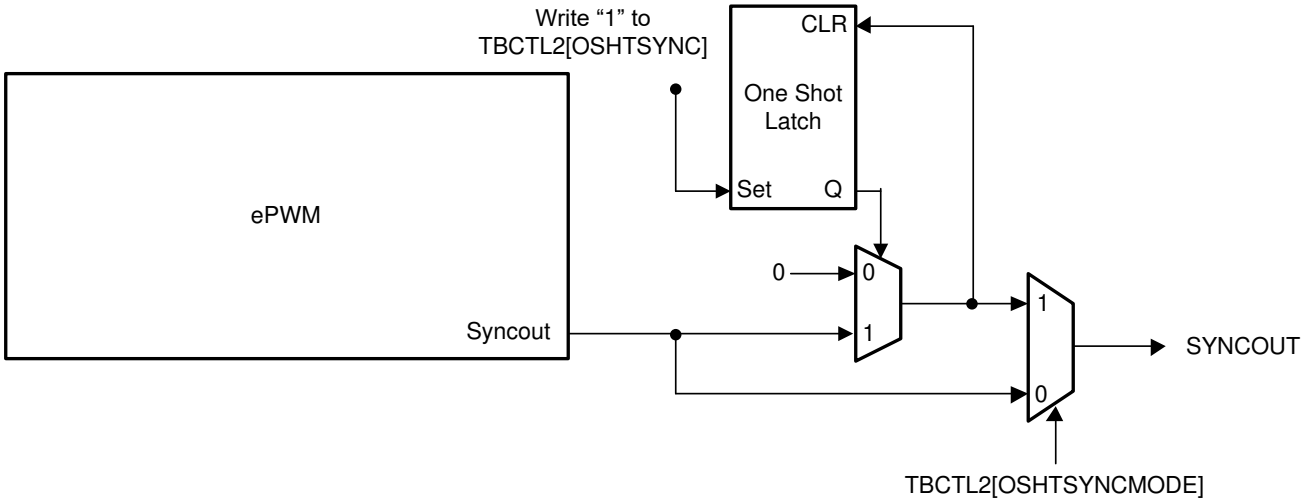

Figure 14-13. One-Shot Sync Mode

14.5 Counter-Compare (CC) Submodule

Figure 14-14 illustrates the counter-compare submodule within the ePWM.

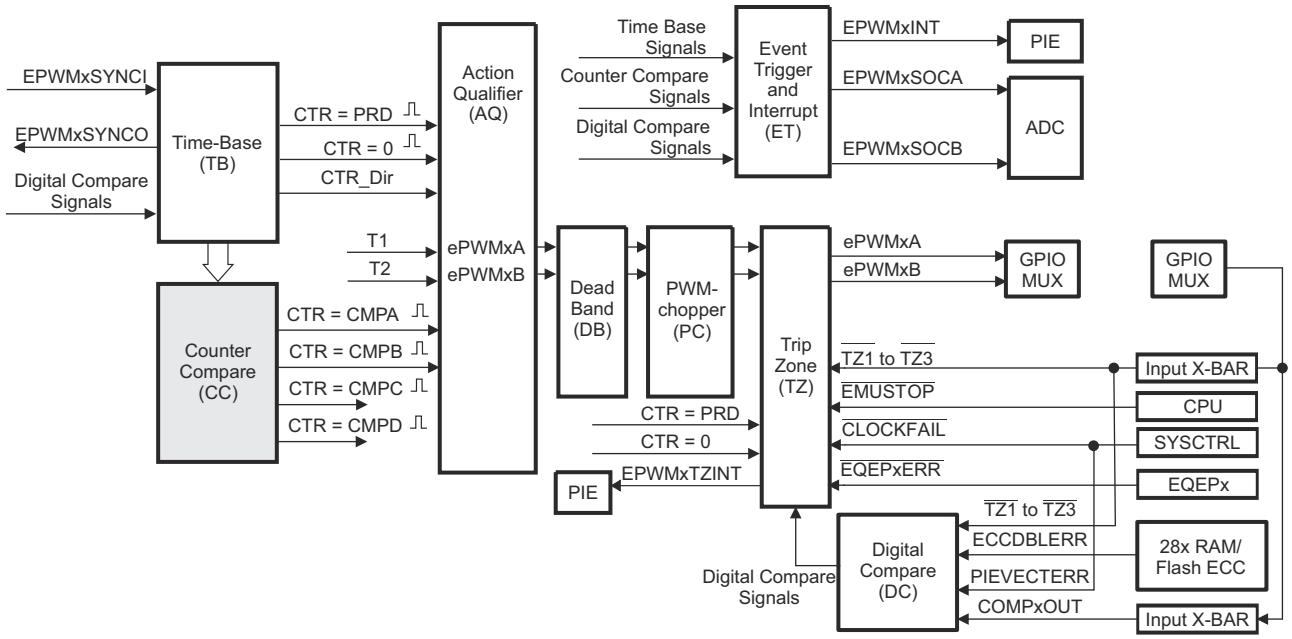

Figure 14-14. Counter-Compare Submodule

14.5.1 Purpose of the Counter-Compare Submodule

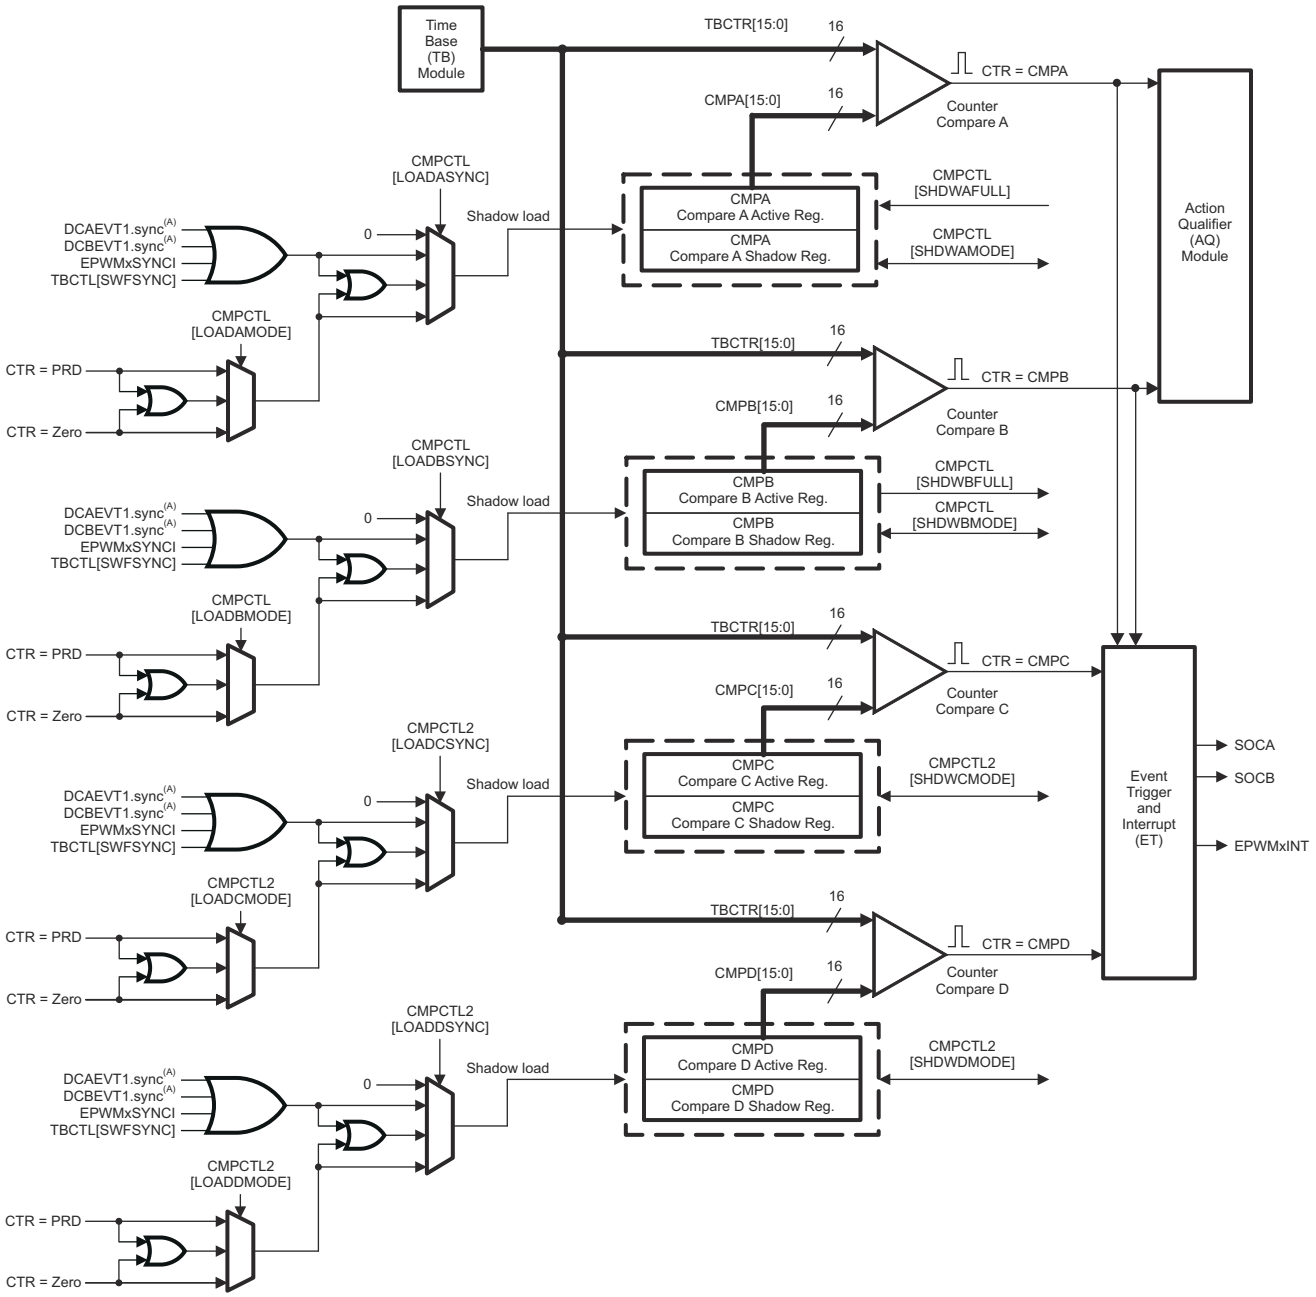
The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA), counter-compare B (CMPB), counter-compare C (CMPC), and counter-compare D (CMPD) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA, CMPB, CMPC, and CMPD registers:
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
  - CTR = CMPC: Time-base counter equals counter-compare C register (TBCTR = CMPC)
  - CTR = CMPD: Time-base counter equals counter-compare D register (TBCTR = CMPD)
- Controls the PWM duty cycle, if the action-qualifier submodule is configured appropriately using counter-compare A (CMPA) and counter-compare B (CMPB)
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

14.5.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is shown in Figure 14-15.



A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and $\overline{TZ}$ signals).

Figure 14-15. Detailed View of the Counter-Compare Submodule

14.5.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating events that can be used in the action-qualifier and event-trigger submodules. There are four independent compare events:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).
3. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC). This event can be used to generate an event in the event trigger submodule only.
4. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD). This event can be used to generate an event in the event trigger submodule only

For up-count or down-count mode, each event occurs only once per cycle. For up-down count mode, each event occurs twice per cycle if the compare value is between 0x00-TBPRD; and once per cycle if the compare value is equal to 0x00 or equal to TBPRD. These events are applies to the action-qualifier submodule where the events are qualified by the counter direction and converted into actions if enabled. Refer to Section 14.6.1 for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. The register that is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPC shadow register and CMPD shadow register, respectively. The behavior of the two load modes is:

Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE], CMPCTL[LOADBMODE], CMPCTL[LOADASYNC], and CMPCTL[LOADBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCI or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADAMODE/LOADBMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Note

Refer to Section 14.6.5 for valid configurations of CMPA/CMPB and LOADAMODE/LOADBMODE.

Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL[SHDWAMODE] = 1 or CMPCTL[SHDWBMODE] = 1), then a read from or a write to the register goes directly to the active register.

Additional Comparators

The counter-compare submodule on ePWMs type 2 and later are responsible for generating two additional independent compare events based on two compare registers, which is fed to Event Trigger submodule:

1. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC).
2. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD).

The counter-compare registers CMPC and CMPD each have an associated shadow register. By default this register is shadowed. The memory address of the active register and the shadow register is identical. The value in the active CMPC and CMPD register is compared to the time-base counter (TBCTR). When the values are equal, the counter compare module generates a “time-base counter equal to counter compare C or counter compare D ” event respectively. Shadowing of this register is enabled and disabled by the CMPCTL2[SHDWCMODE] and CMPCTL2[SHDWDMODE] bit. These bits enable and disable the CMPC shadow register and CMPD shadow register respectively. The behavior of the two load modes is described below:

Shadow Mode:

The shadow mode for the CMPC is enabled by clearing the CMPCTL2[SHDWCMODE] bit and the shadow register for CMPD is enabled by clearing the CMPCTL2[SHDWDMODE] bit. Shadow mode is enabled by default for both CMPC and CMPD.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL2[LOADCMODE], CMPCTL2[LOADDMODE], CMPCTL2[LOADCSYNC], and CMPCTL2[LOADDSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCI or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADCMODE/LOADDMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL2[SHDWCMODE] = 1 or CMPCTL2[SHDWDMODE] = 1), then a read from or a write to the register goes directly to the active register.

Global Load Support

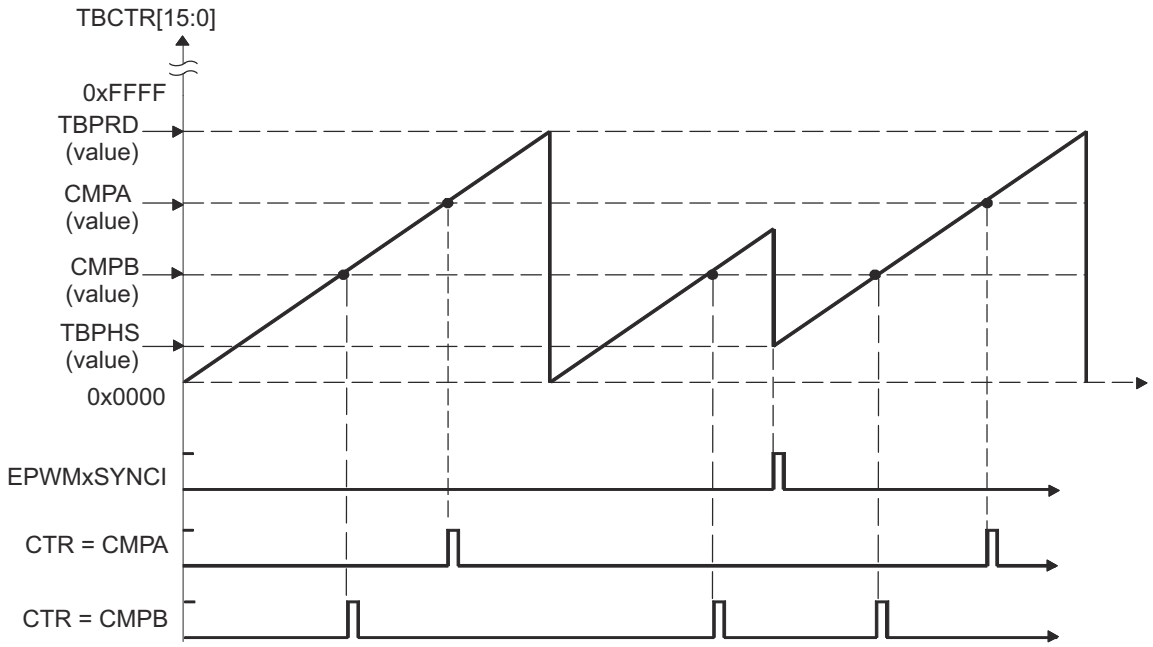
The global load control mechanism can also be used for all counter-compare registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When the global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in Section 14.4.7.

14.5.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in Figure 14-16 through Figure 14-19 show when events are generated and how the EPWMxSYNCI signal interacts.



An EPWMxSYNCI external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

Figure 14-16. Counter-Compare Event Waveforms in Up-Count Mode

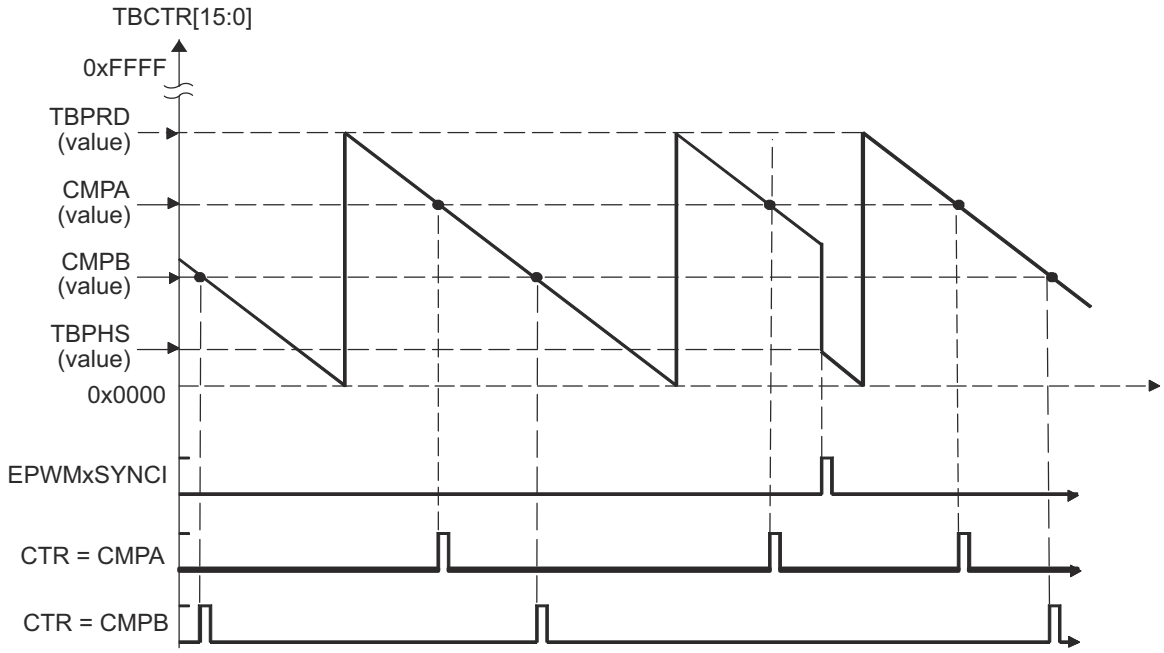


Figure 14-17. Counter-Compare Events in Down-Count Mode

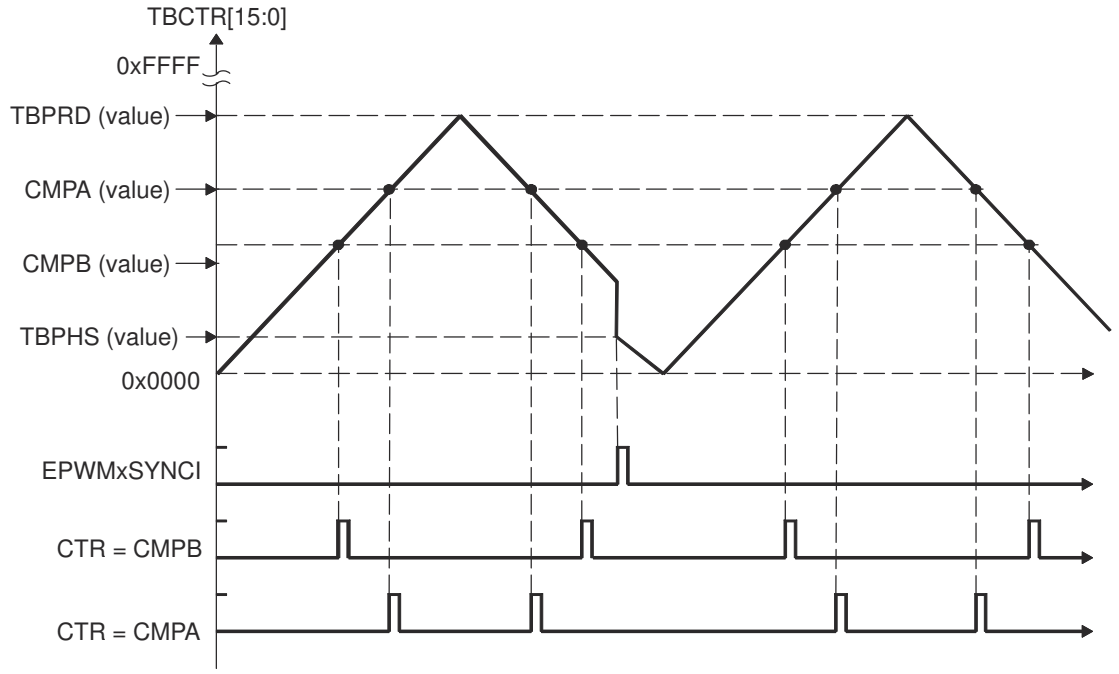

Figure 14-18. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

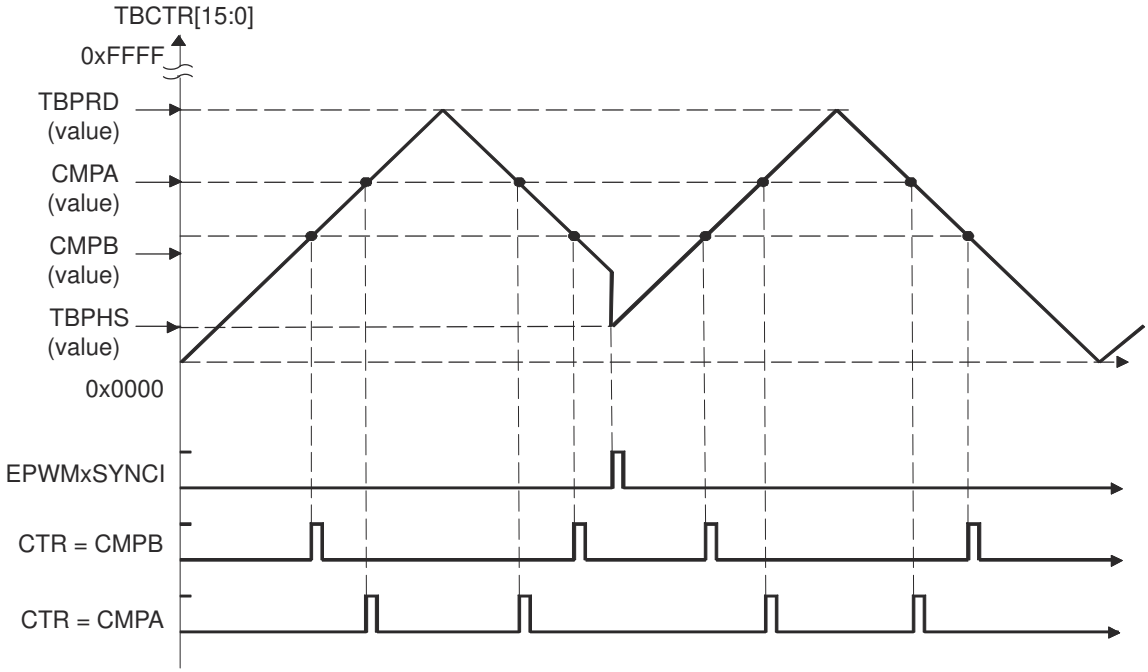

Figure 14-19. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

14.6 Action-Qualifier (AQ) Submodule

The action-qualifier submodule has the most important role in waveform construction and PWM generation. The action-qualifier submodule decides which events are converted into various action types, thereby, producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 14-20 illustrates the action-qualifier submodule within the ePWM.

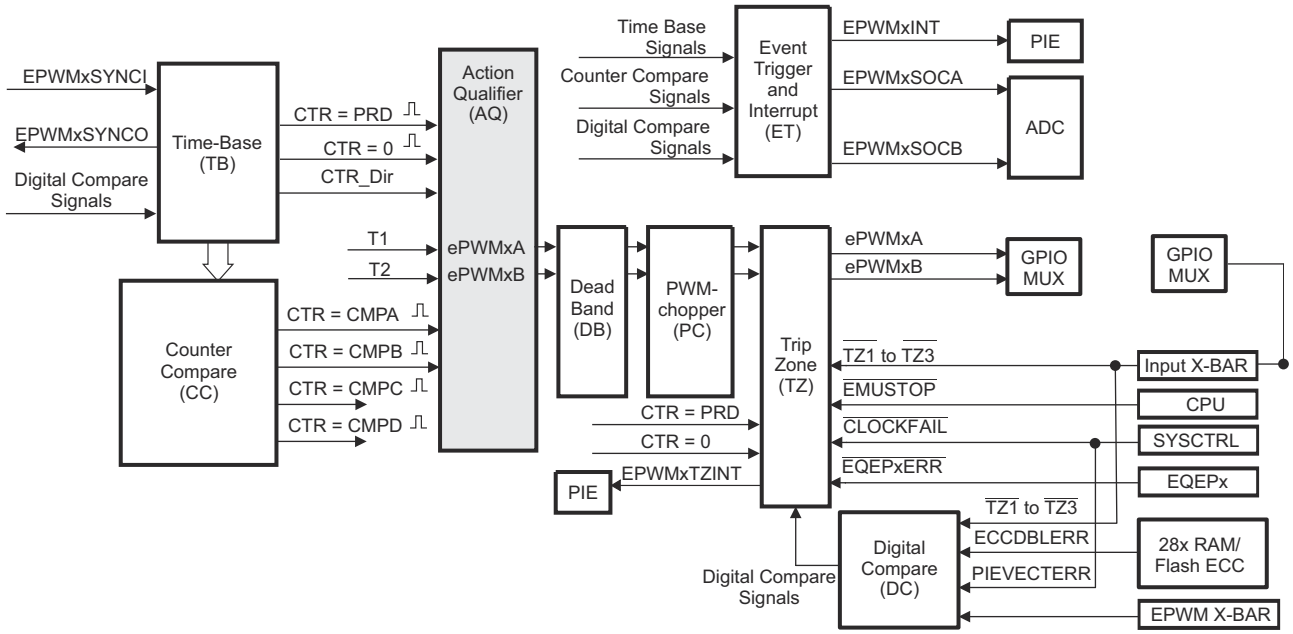

Figure 14-20. Action-Qualifier Submodule

14.6.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- T1, T2 events: Trigger events based on comparator, trip or syncin events
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

14.6.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is shown in Figure 14-21 and monitored by way of the registers in Section 14.15.

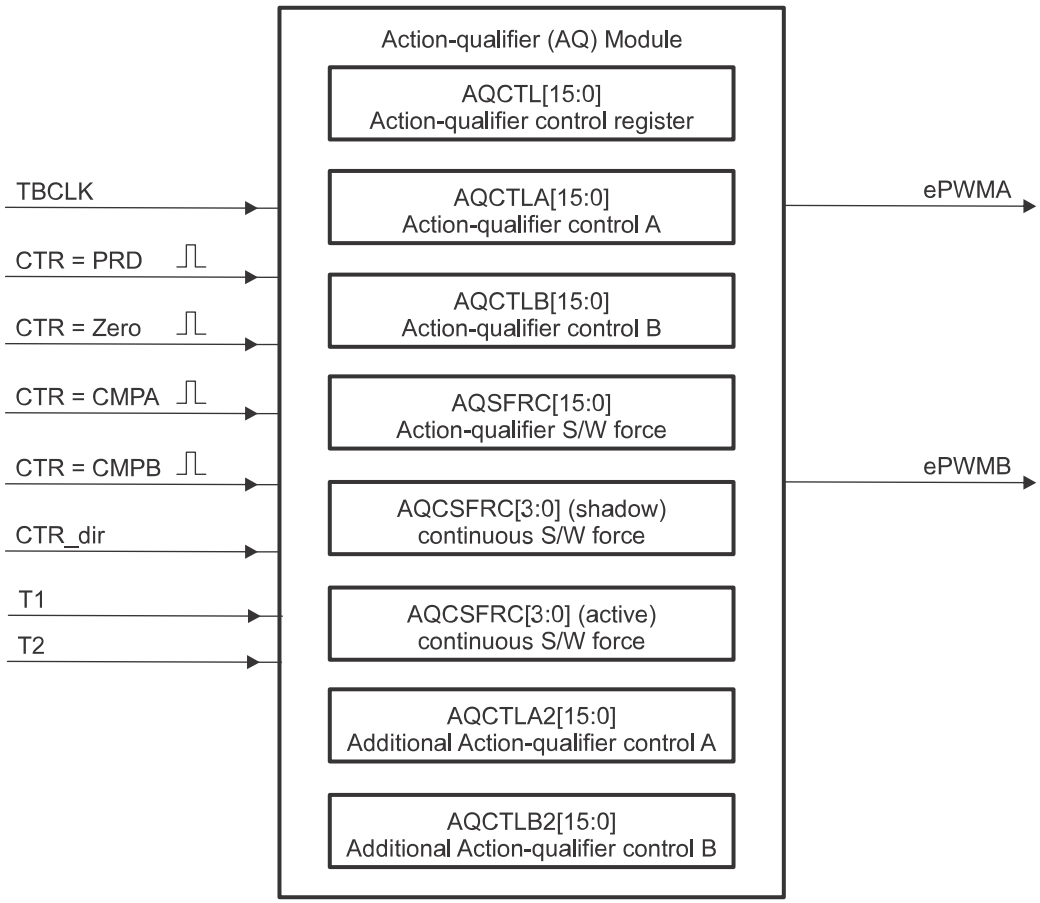

Figure 14-21. Action-Qualifier Submodule Inputs and Outputs

For convenience, the possible input events are summarized again in Table 14-3.

Table 14-3. Action-Qualifier Submodule Possible Input Events

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCTR = TBPRD
CTR = Zero	Time-base counter equal to 0	TBCTR = 0x00
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCTR = CMPB
T1 event	Based on comparator, trip, or syncin events	None
T2 event	Based on comparator, trip, or syncin events	None
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by the AQSFRC and AQCSFRC registers.

Note

If the CSFA is not used in shadow mode, the RLDCSF bit must be configured to disable shadow mode.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the description in Section 14.10 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured using the control registers found in the *ePWM Registers* section.

For clarity, the illustrations in this chapter use a set of symbolic actions. These symbols are summarized in Figure 14-22. Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and the time positions are programmed by way of the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"(the default at reset).

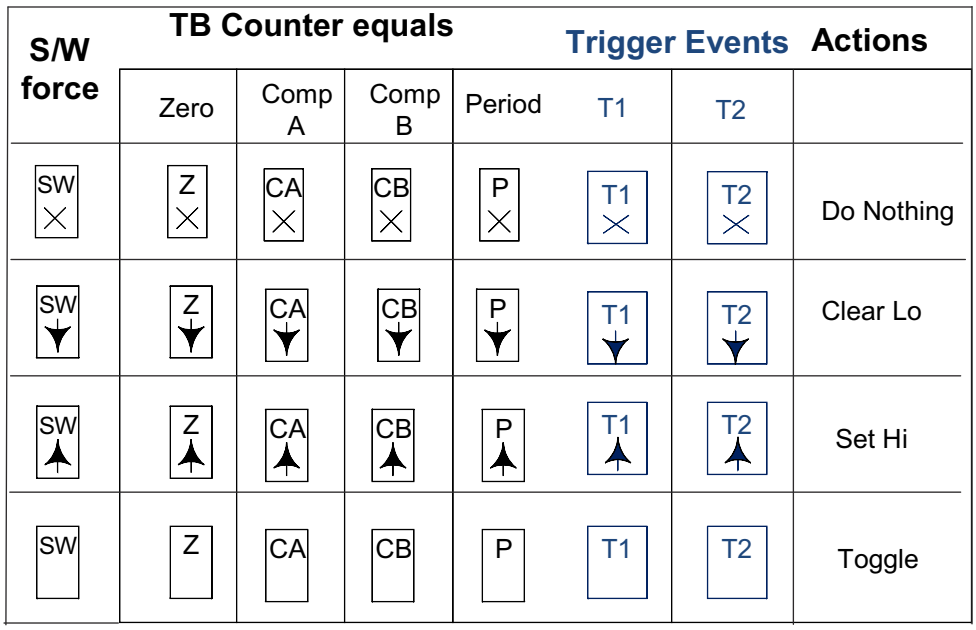

Figure 14-22. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

The Action Qualifier Trigger Event Source Selection register (AQTSRCSEL) is used to select the source for T1 and T2 events. T1/T2 selection and configuration of a trip/digital-compare event in Action Qualifier submodule is independent of the configuration of that event in the Trip-Zone submodule. A particular trip event can or cannot

be configured to cause trip action in the Trip Zone submodule, but the same event can be used by the Action Qualifier to generate T1/T2 for controlling PWM generation.

14.6.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case, events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down count mode are shown in Table 14-4. A priority level of 1 is the highest priority and level 10 is the lowest. The priority changes slightly depending on the direction of TBCTR.

Table 14-4. Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD	Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1
1 (Highest)	Software forced event	Software forced event
2	T1 on up-count (T1U)	T1 on down-count (T1D)
3	T2 on up-count (T2U)	T2 on down-count (T2D)
4	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
5	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
6 (Lowest)	Counter equals zero	Counter equals period (TBPRD)

Table 14-5 shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up; therefore, down-count events never are taken.

Table 14-5. Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	T1 on up-count (T1U)
4	T2 on up-count (T2U)
5	Counter equal to CMPB on up-count (CBU)
6	Counter equal to CMPA on up-count (CAU)
7 (Lowest)	Counter equal to Zero

Table 14-6 shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down; therefore, up-count events never are taken.

Table 14-6. Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	T1 on down-count (T1D)
4	T2 on down-count (T2D)
5	Counter equal to CMPB on down-count (CBD)
6	Counter equal to CMPA on down-count (CAD)
7 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case, the action takes place as shown in Table 14-7.

Table 14-7. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAD/CBD	Compare on Down-Count Event CAD/CBD
Up-Count Mode	If CMPA/CMPB ≤ TBPRD period, then the event occurs on a compare match (TBCTR=CMPA or CMPB).	Never occurs.
	If CMPA/CMPB > TBPRD, then the event does not occur.	
Down-Count Mode	Never occurs.	If CMPA/CMPB < TBPRD, the event occurs on a compare match (TBCTR=CMPA or CMPB).
		If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCTR=TBPRD).
Up-Down Count Mode	If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB).	If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCTR=CMPA or CMPB).
	If CMPA/CMPB is ≥ TBPRD, the event occurs on a period match (TBCTR = TBPRD).	If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCTR=TBPRD).

14.6.4 AQCTLA and AQCTLB Shadow Mode Operations

To enable Action Qualifier mode changes which must occur at the end of a period even when the phase changes, shadowing of the AQCTLA and AQCTLB registers has been added on ePWMs type 2 and later. Additionally, shadow to active load on SYNC of these registers is supported as well. Shadowing of this register is enabled and disabled by the AQCTL[SHDWAQAMODE] and AQCTL[SHDWAQBMODE] bits. These bits enable and disable the AQCTLA shadow register and AQCTLB shadow register, respectively. The behavior of the two load modes is:

Shadow Mode:

The shadow mode for the AQCTLA is enabled by setting the AQCTL[SHDWAQAMODE] bit, and the shadow register for AQCTLB is enabled by setting the AQCTL[SHDWAQBMODE] bit. Shadow mode is disabled by default for both AQCTLA and AQCTLB

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the AQCTL[LDAQAMODE], AQCTL[LDAQBMODE], AQCTL[LDAQASYNC], and AQCTL[LDAQBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCI or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LDAQAMODE/LDAQBMODE

Global Load Support

Global load control mechanism can also be used for AQCTLA:AQCTLA2, AQCTLB:AQCTLB2, and AQCSFRC registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected, the transfer of contents from shadow register to active register for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in Section 14.4.7.

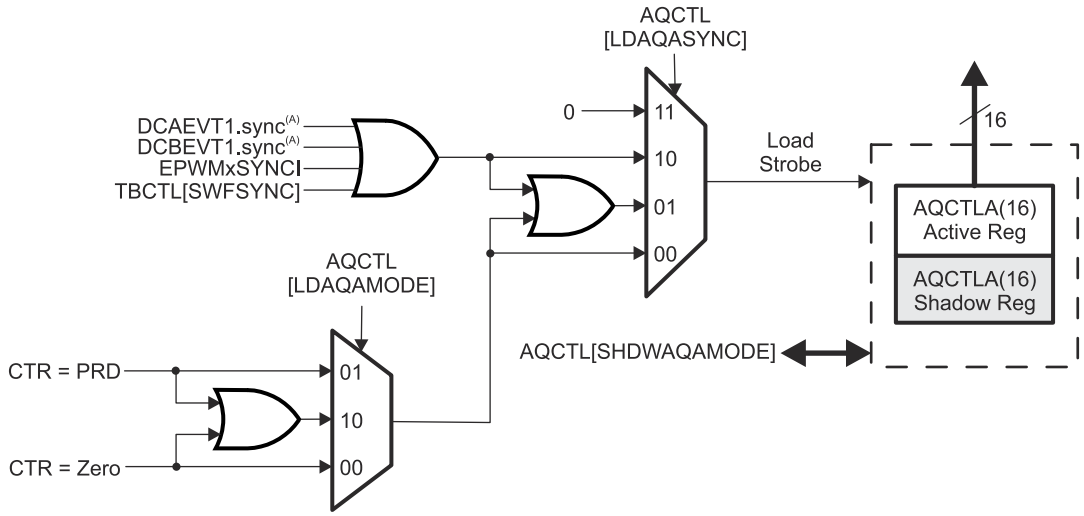
Immediate Load Mode:

If the immediate load mode is selected (that is, AQCTL[SHDWAQAMODE] = 0 or AQCTL[SHDWAQBMODE] = 0), then a read from or a write to the register goes directly to the active register. See Figure 14-23 and Figure 14-24.

Note

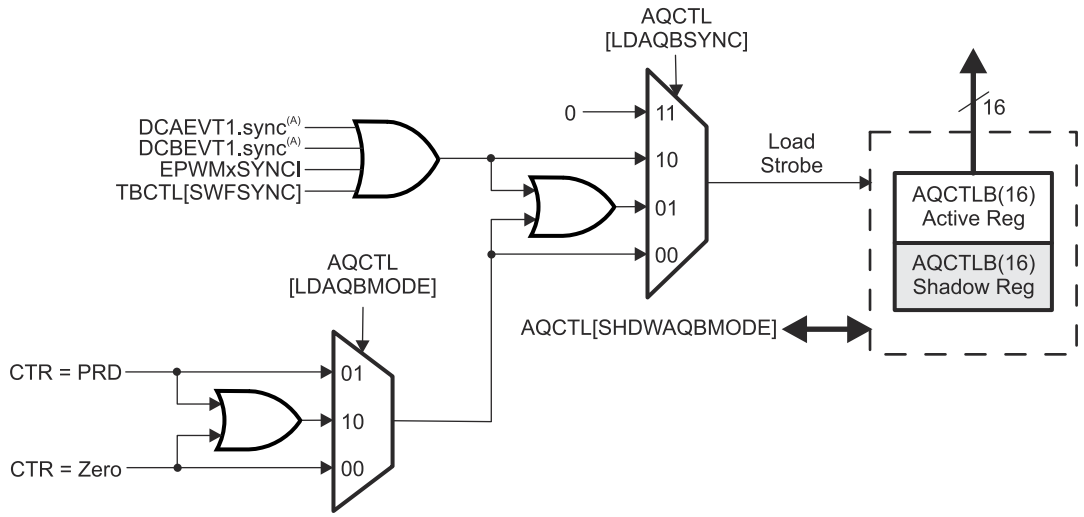
Shadow to Active Load of Action Qualifier Output A/B Control Register [AQCTLA and AQCTLB] on CMPA = 0 or CMPB = 0 boundary

If the Counter-Compare A Register (CMPA) or Counter-Compare B Register (CMPB) is set to a value of 0 and the action qualifier action on AQCTLA and AQCTLB is configured to occur in the same instant as a shadow to active load (that is, CMPA=0 and AQCTLA shadow to active load on TBCTR=0 using AQCTL register LDAQAMODE and LDAQAMODE bits), then both events enter contention. It is recommended to use a Non-Zero Counter-Compare when using Shadow to Active Load of Action Qualifier Output A/B Control Register on TBCTR = 0 boundary.



A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and $\overline{TZ}$ signals).

Figure 14-23. AQCTL[SHDWAQAMODE]



A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and $\overline{TZ}$ signals).

Figure 14-24. AQCTL[SHDWAQBMODE]

14.6.5 Configuration Requirements for Common Waveforms

Note

The waveforms in this chapter show the behavior of the ePWMs for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from the respective shadow registers once every period. Specify when the update takes place: either when the time-base counter reaches zero or when the time-base counter reaches the period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down count mode to generate a symmetric PWM:

- If loading CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If loading CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

  This means there is always a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM, you **must** load CMPA/CMPB on TBPRD. When CMPA/CMPB is not loaded on TBCTR=PRD, boundary conditions can occur depending on the timing of the write and the value written to CMPA/CMPB. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

When using up-count mode to generate an asymmetric PWM with deadband enabled:

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met (CMPX < Deadband) or (CMPX > PRD – Deadband), the actions specified by the AQCTL register for CMPX do not take effect. To avoid this, the AQCTL settings must be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Make sure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

When using up-down count mode to generate an asymmetric PWM with deadband enabled:

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met (CMPX < Deadband/2) or (CMPX > PRD – (Deadband)/2), the actions specified by the AQCTL register for CMPX do not take effect. To avoid this, the AQCTL settings must be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Make sure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

See *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control*.

Figure 14-25 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode, 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing, the CMPA match pulls the PWM output high. Likewise when the counter is decrementing, the compare match pulls the PWM signal low. When CMPA = 0, the PWM signal is high for the entire period giving a 100% duty waveform. When CMPA = TBPRD, the PWM signal is low achieving 0% duty.

When using this configuration in practice, if loading CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If loading CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there is always a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

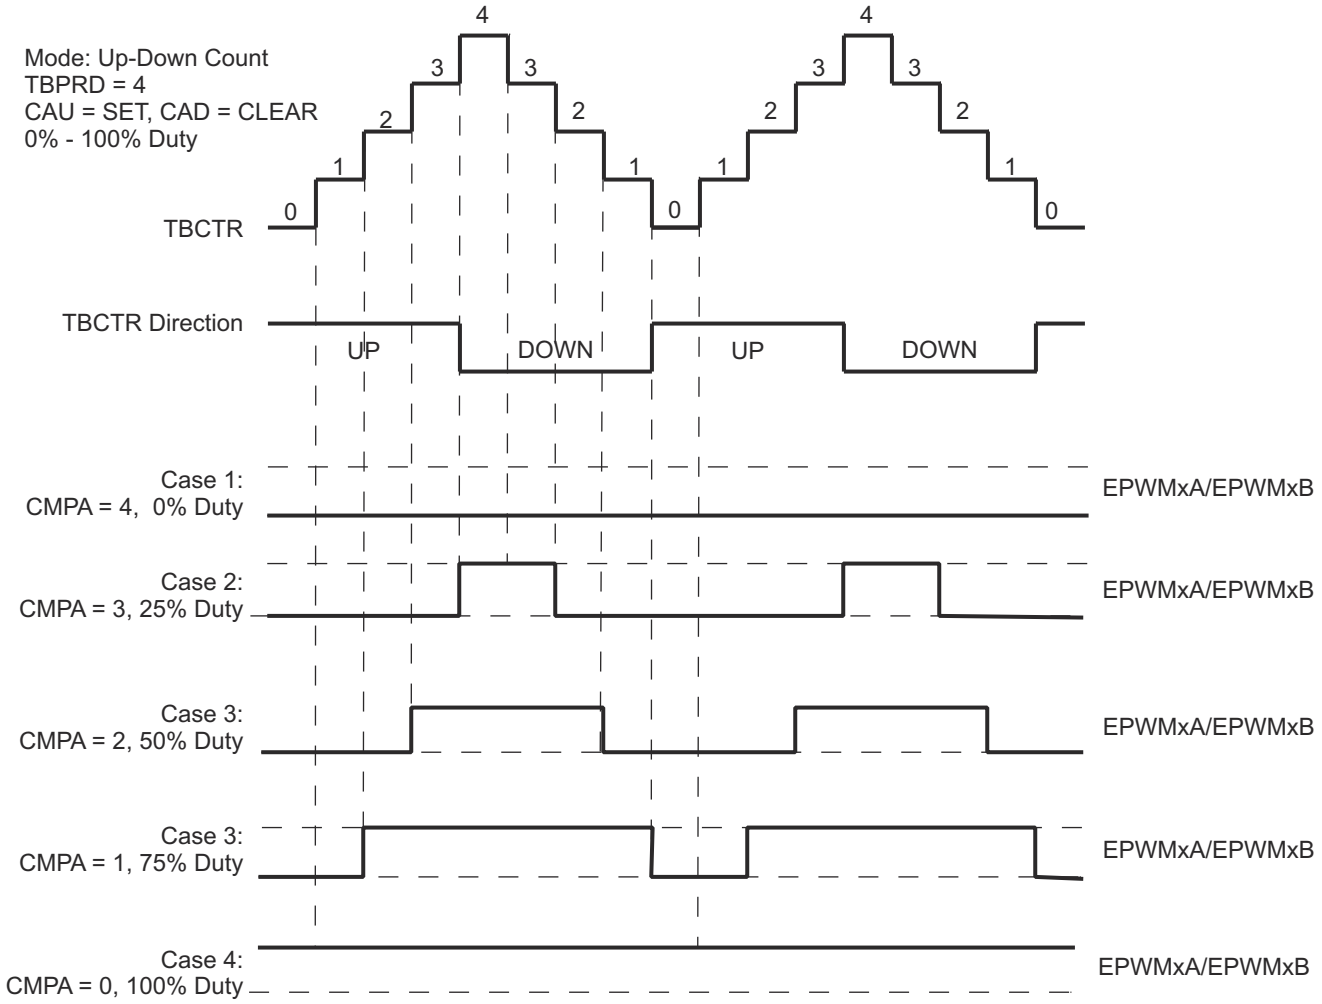


Figure 14-25. Up-Down Count Mode Symmetrical Waveform

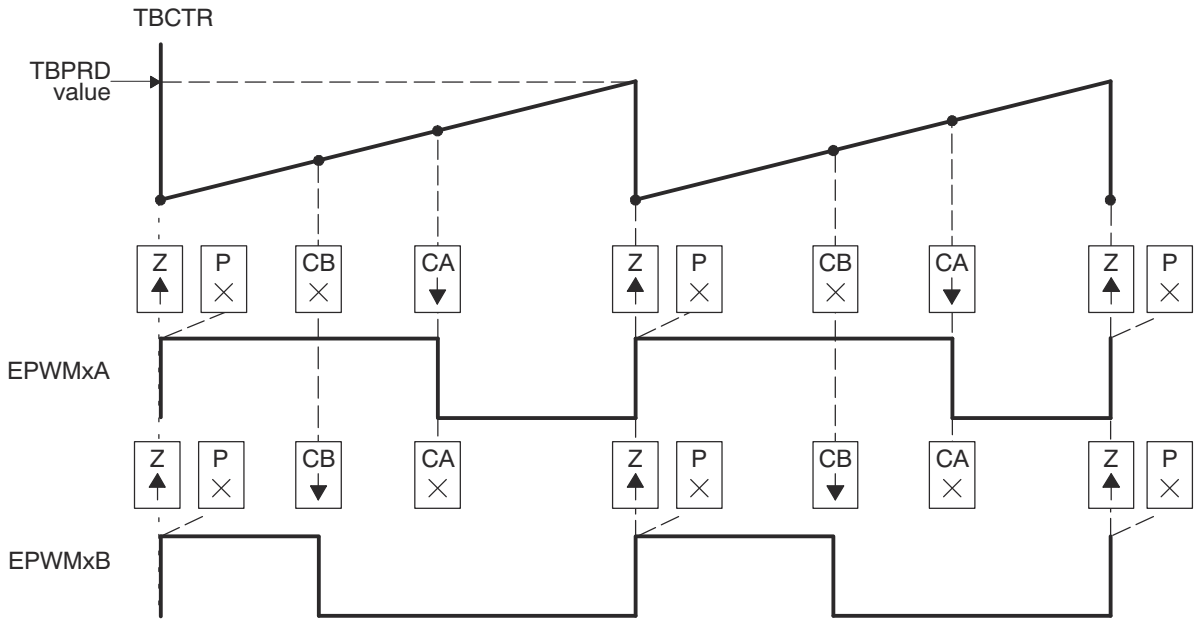
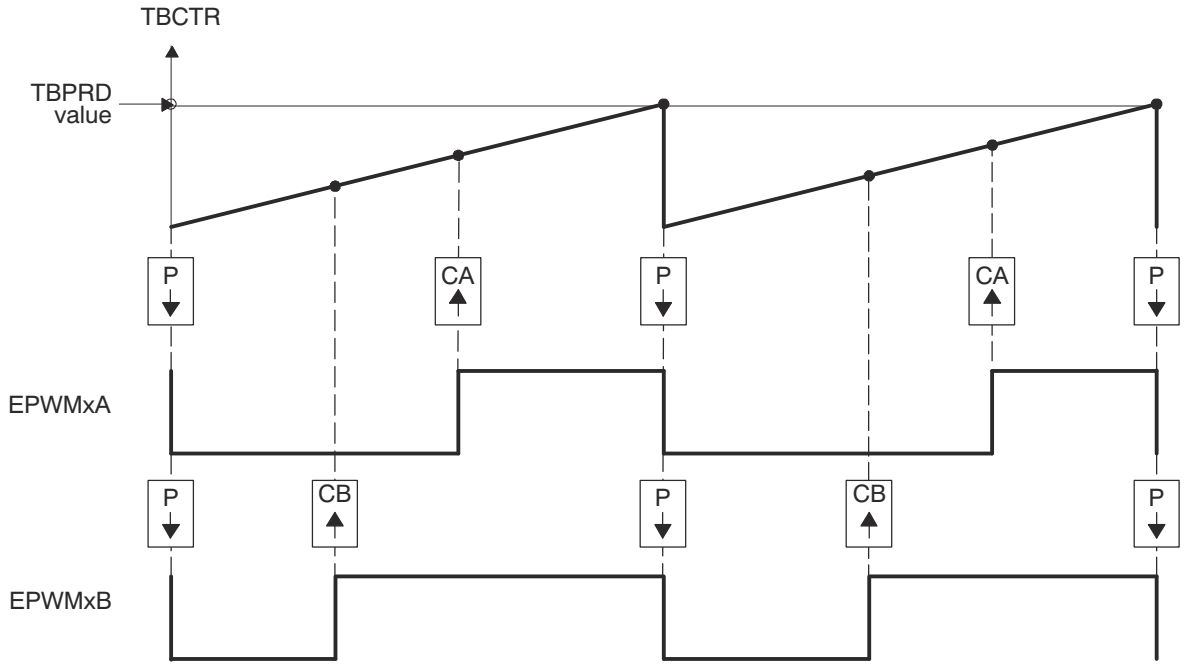
The PWM waveforms in Figure 14-26 through Figure 14-31 show some common action-qualifier configurations. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in the respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means count-up-and count-down mode, Up means up-count mode and Down means down-count mode
- Sym = Symmetric, Asym = Asymmetric



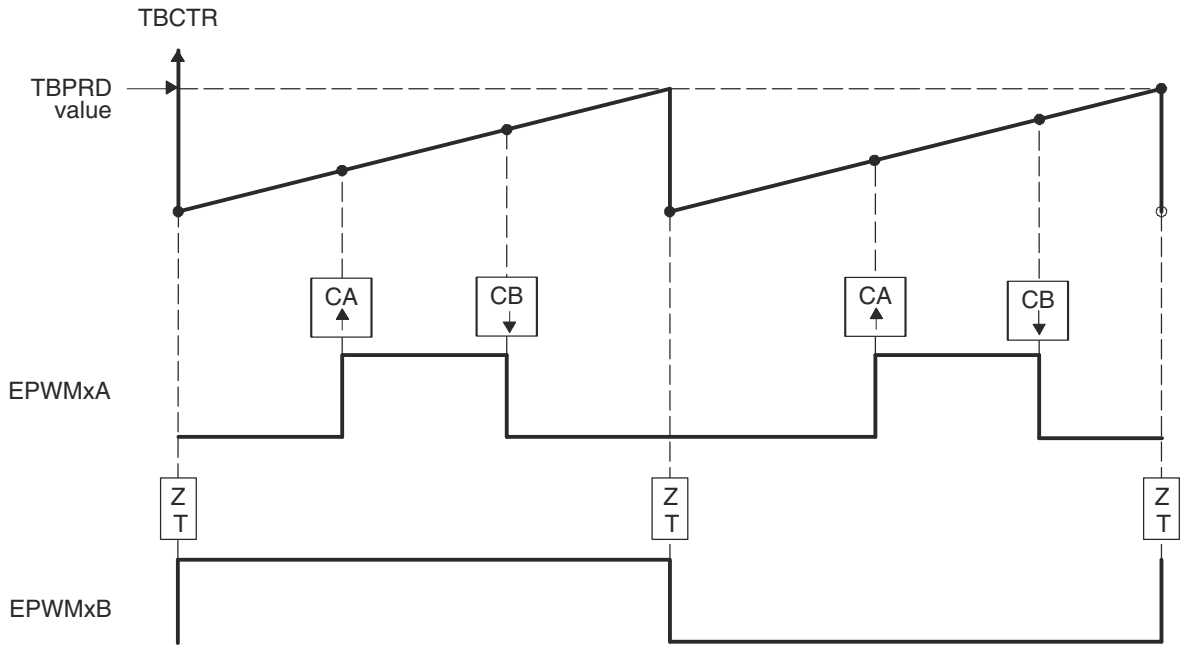
A. PWM period = (TBPRD + 1) × T_{TBCLK}
B. Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
C. Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
D. The "Do Nothing" actions (X) are shown for completeness, but are not shown on subsequent diagrams.
E. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

Figure 14-26. Up, Single Edge Asymmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB—Active High



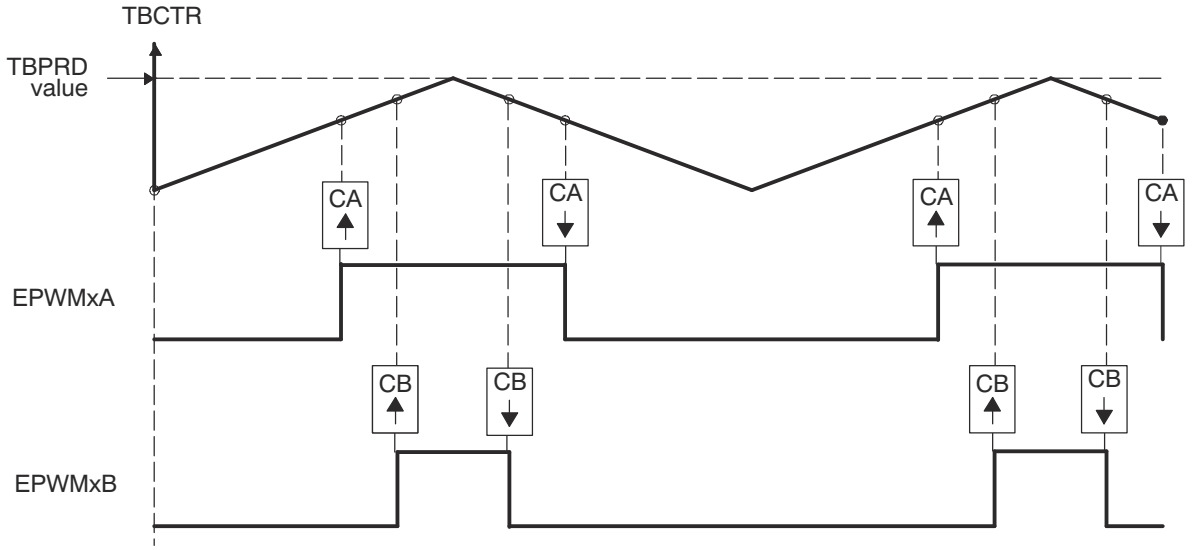
A. PWM period = (TBPRD + 1) × T_{TBCLK}
B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
D. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

Figure 14-27. Up, Single Edge Asymmetric Waveform with Independent Modulation on EPWMxA and EPWMxB—Active Low



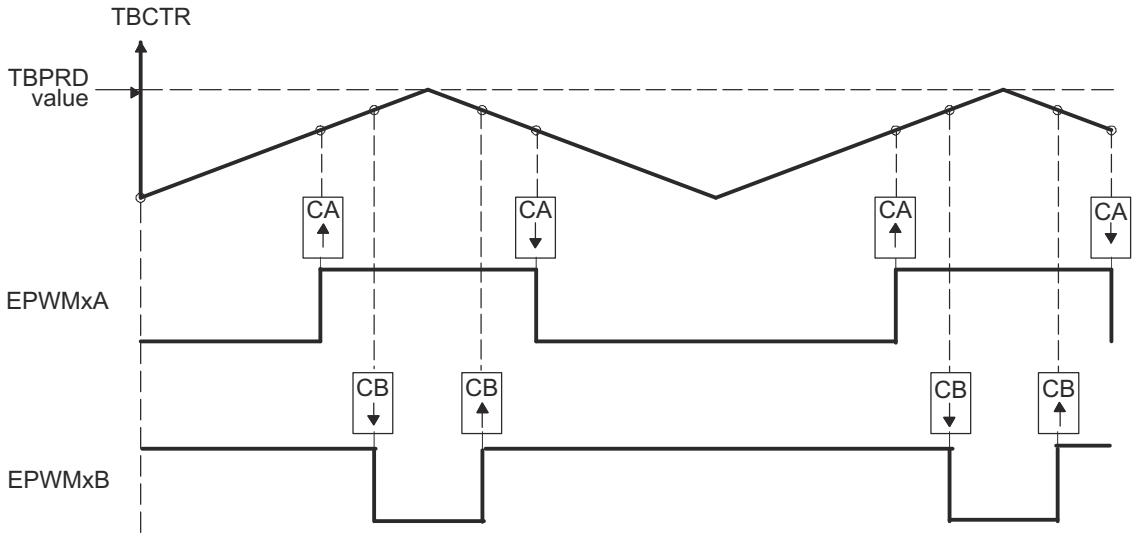
A. PWM frequency = 1/((TBPRD + 1) × T_{TBCLK})
B. Pulse can be placed anywhere within the PWM cycle (0000 - TBPRD)
C. High time duty proportional to (CMPB - CMPA)

Figure 14-28. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA



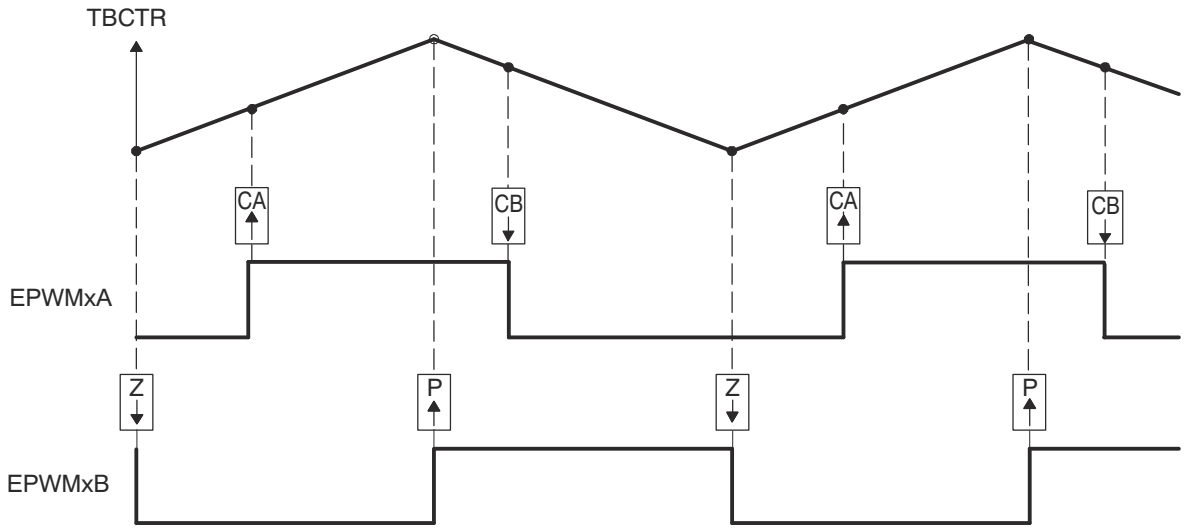
A. PWM period = 2 x TBPRD × T_{TBCLK}
B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
D. Outputs EPWMxA and EPWMxB can drive independent power switches.

Figure 14-29. Up-Down Count, Dual-Edge Symmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB — Active Low



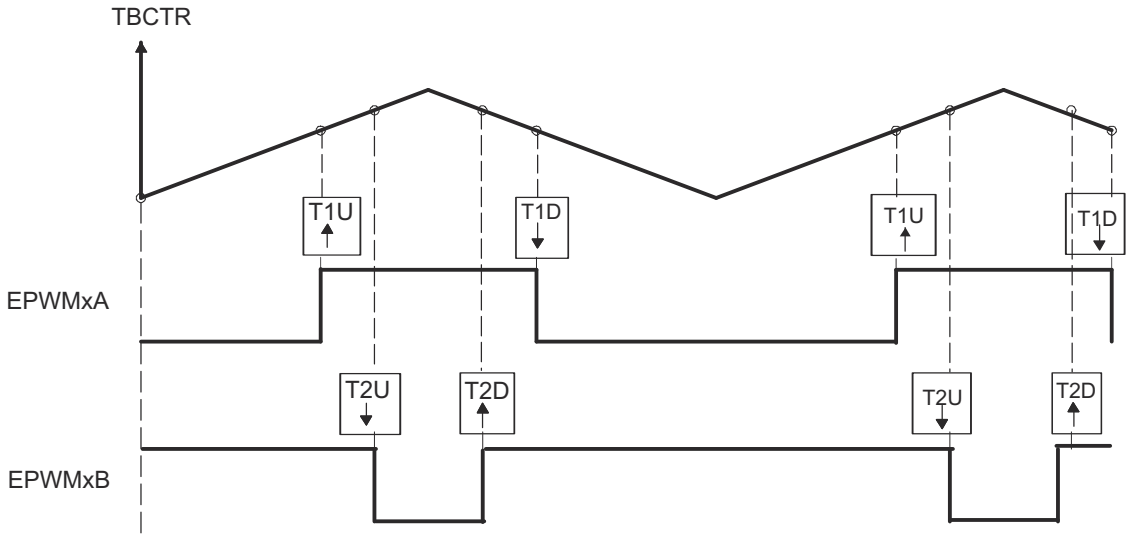
A. PWM period = 2 × TBPRD × T_{TBCLK}
B. Duty modulation for EPWMxA is set by CMPA, and is active low, that is, low time duty proportional to CMPA.
C. Duty modulation for EPWMxB is set by CMPB and is active high, that is, high time duty proportional to CMPB.
D. Outputs EPWMx can drive upper/lower (complementary) power switches.
E. Dead-band = CMPB - CMPA (fully programmable edge placement by software). Note the dead-band module is also available if the more classical edge delay method is required.

Figure 14-30. Up-Down Count, Dual-Edge Symmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB — Complementary



A. PWM period = 2 × TBPRD × TBCLK
B. Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
C. Duty modulation for EPWMxA is set by CMPA and CMPB.
D. Low time duty for EPWMxA is proportional to (CMPA + CMPB).
E. To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Clear on CMPA, Set on CMPB).
F. Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB).

Figure 14-31. Up-Down Count, Dual-Edge Asymmetric Waveform, with Independent Modulation on EPWMxA—Active Low



A. PWM period = 2 × TBPRD × TTBCLK
B. Independent T1 event actions when counter is counting up and when the counter is counting down are used to generate EPWMxA output.
C. Independent T2 event actions when counter is counting up and when the counter is counting down are used to generate EPWMxB output.
D. TZ1 is selected as the source for T1.
E. TZ2 is selected as the source for T2.

Figure 14-32. Up-Down Count, PWM Waveform Generation Utilizing T1 and T2 Events

14.7 Dead-Band Generator (DB) Submodule

Figure 14-33 illustrates the dead-band submodule within the ePWM.

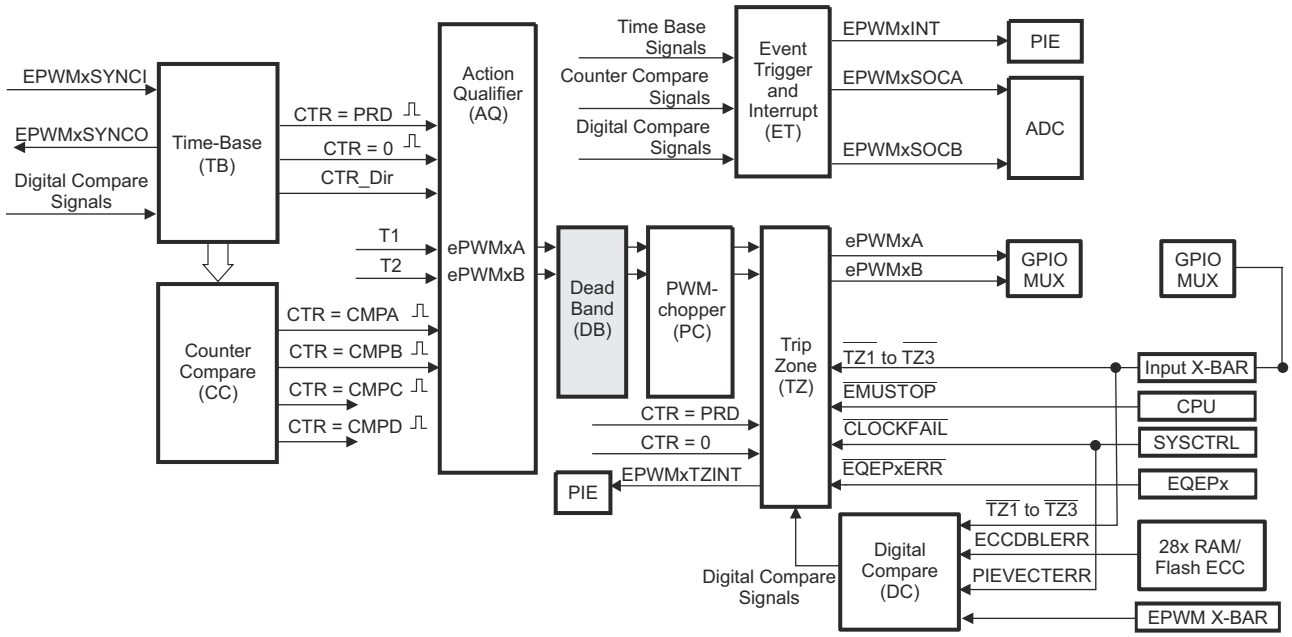


Figure 14-33. Dead_Band Submodule

14.7.1 Purpose of the Dead-Band Submodule

The action-qualifier (AQ) module section discussed how the AQ module can generate the required dead band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead band with polarity control is required, then the dead-band submodule described here must be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

14.7.2 Dead-band Submodule Additional Operating Modes

On type 1 ePWM RED can appear on one channel output and FED can appear on the other channel output.

The following list shows the distinct difference between type 1 and type 4 modules with respect to dead-band operating modes:

- By adding S6, S7, and S8 in Figure 14-34, RED and FED can appear on both the A-channel and B-channel outputs. Additionally, both RED and FED together can be applied to either the A-channel or B-channel outputs to allow B-channel phase shifting with respect to the A-channel.

Note

Phase shifting B-channel with respect to the A-channel using the dead-band submodule additional operating modes has limitations with respect to the choice of RED and FED delay with respect to the operating duty cycle of the ePWMxA and ePWMxB outputs.

- The dead-band counters have also been increased to 14 bits
- Deadband and deadband high-resolution registers are now shadowed
- High-resolution deadband RED and FED have been enabled using the DBREDHR and DBFEDHR registers

Note

The PWM chopper is not enabled when high-resolution deadband is enabled.

High-resolution deadband RED and FED requires half-cycle clocking mode (DBCTL[HALFCYCLE] = 1).

Cannot have both RED and FED together applied to both ePWMxA and ePWMxB. RED and FED together can be applied only to either OutA OR OutB.

Phase shifting B-channel with respect to the A-channel: When PWMxB is derived from PWMxA using the DEDB_MODE bit and by delaying rising edge and falling edge by the phase shift amount. When the duty cycle value on PWMxA is less than this phase shift amount, PWMxA's falling edge has precedence over the delayed rising edge for PWMxB. Make sure the duty cycle value of the current waveform applied to the dead-band module is greater than the required phase shift amount.

The Type 4 action qualifier and dead-band outputs of the ePWM module are delayed by one TBCLK cycle in comparison to the Type 2 ePWM module, although the Type 4 behavior is the same as the Type 3 PWM. Both PWMA and PWMB signals are delayed under all circumstances.

Shadow Mode:

The shadow mode for the DBRED is enabled by setting the DBCTL[SHDWDBREDMODE] bit and the shadow register for DBFED is enabled by setting the DBCTL [SHDWDBFEDMODE] bit. Shadow mode is disabled by default for both DBRED and DBFED

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL [LOADREDMODE] and DBCTL [LOADFEDMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

The DBCTL register can be shadowed. The shadow mode for DBCTL is enabled by setting the DBCTL2[SHDWDBCTLMODE] bit. If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL2[LOADDBCTLMODE] register bit:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

Note

The application software must enable shadow load mode in the DBCTL[SHDWDBREDMODE] and DBCTL[SHDWDBFEDMODE] **before** programming values for the DBRED and DBFED registers. If the shadow register is enabled **after** programming the DBRED and DBFED registers, the DBRED and DBFED registers are loaded with a value of 0.

Global Load Support

Global load control mechanism can also be used for DBRED:DBREDHR, DBFED:DBFEDHR, and DBCTL registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The Global load control mechanism is explained in Section 14.4.7.

Note

When DBRED/DBFED active is loaded with a new shadow value while DB counters are counting, the new DBRED/DBFED value only affects the NEXT PWMx edge and not the current edge.

A Deadband value of zero cannot be used when the Global Shadow to Active Load is set to occur at CTR=ZERO. Similarly, a Deadband value of PRD cannot be used when the Global Shadow to Active Load is set to occur at CTR=PRD.

TBPRDHR cannot be used with Global load. If high-resolution period must be changed in the application, users must write to the individual period registers from an ePWM ISR (The ISR must be synchronous with the PWM switching period), where the Global Load One-Shot bit is also written to.

14.7.3 Operational Highlights for the Dead-Band Submodule

The configuration options for the dead-band submodule are shown in Figure 14-34.

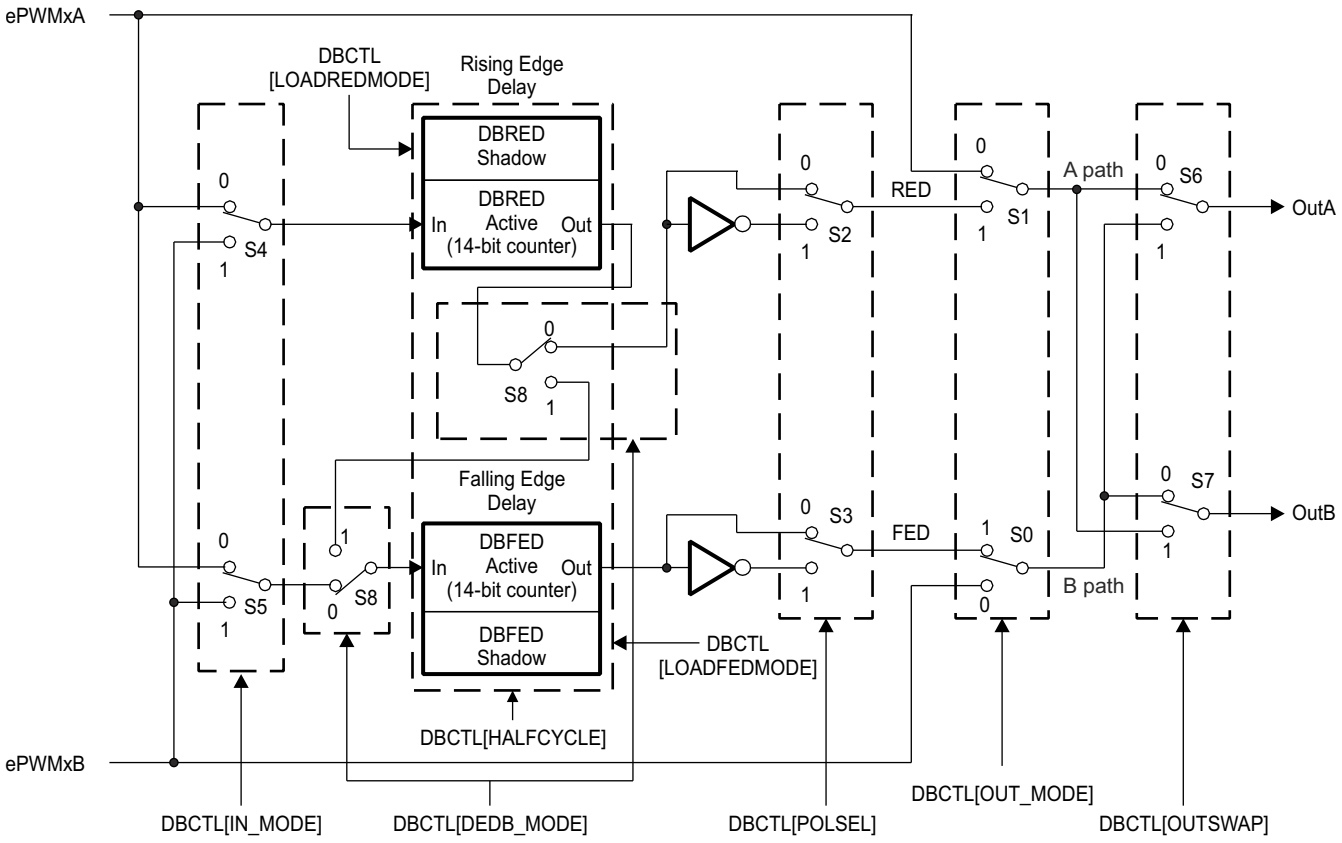

Figure 14-34. Configuration Options for the Dead-Band Submodule

Although all combinations are supported, not all are typical usage modes. Table 14-8 documents some classical dead-band configurations. These modes assume that the DBCTL[IN_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 14-8 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED):** Allows the user to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings:** These represent typical polarity configurations that can address all the active-high and active-low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 14-35. Note that to generate equivalent waveforms to Figure 14-35, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge delay (RED) and Mode 7: Bypass falling-edge delay (FED):** Finally the last two entries in Table 14-8 show combinations where either the falling-edge delay (FED) or rising-edge delay (RED) blocks are bypassed.

Figure 14-35 shows waveforms for typical cases where 0% < duty < 100%.

Table 14-8. Classical Dead-Band Operating Modes

Mode	Mode Description	DBCTL[POLSEL]		DBCTL[OUT_MODE]	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	X	X	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling-Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising-Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

Table 14-9. Additional Dead-Band Operating Modes

Mode Description	DBCTL[DEDB-MODE]	DBCTL[OUTSWAP]	
	S8	S6	S7
EPWMxA and EPWMxB signals are as defined by OUT-MODE bits.	0	0	0
EPWMxA = A-path as defined by OUT-MODE bits. EPWMxB = A-path as defined by OUT-MODE bits (rising-edge delay or delay-bypassed A-signal path)	0	0	1
EPWMxA = B-path as defined by OUT-MODE bits (falling-edge delay or delay-bypassed B-signal path) EPWMxB = B-path as defined by OUT-MODE bits	0	1	0
EPWMxA = B-path as defined by OUT-MODE bits (falling-edge delay or delay-bypassed B-signal path) EPWMxB = A-path as defined by OUT-MODE bits (rising-edge delay or delay-bypassed A-signal path)	0	1	1
Rising-edge delay applied to EPWMxA / EPWMxB as selected by S4 switch (IN-MODE bits) on A signal path only. Falling-edge delay applied to EPWMxA / EPWMxB as selected by S5 switch (IN-MODE bits) on B signal path only.	0	X	X
Rising-edge delay and falling-edge delay applied to source selected by S4 switch (IN-MODE bits) and output to B signal path only.(1)	1	X	X

(1) When this bit is set to 1, the user can always either set OUT_MODE bits such that Apath = InA or set OUTSWAP bits such that EPWMxA=Bpath. Otherwise, EPWMxA is invalid.

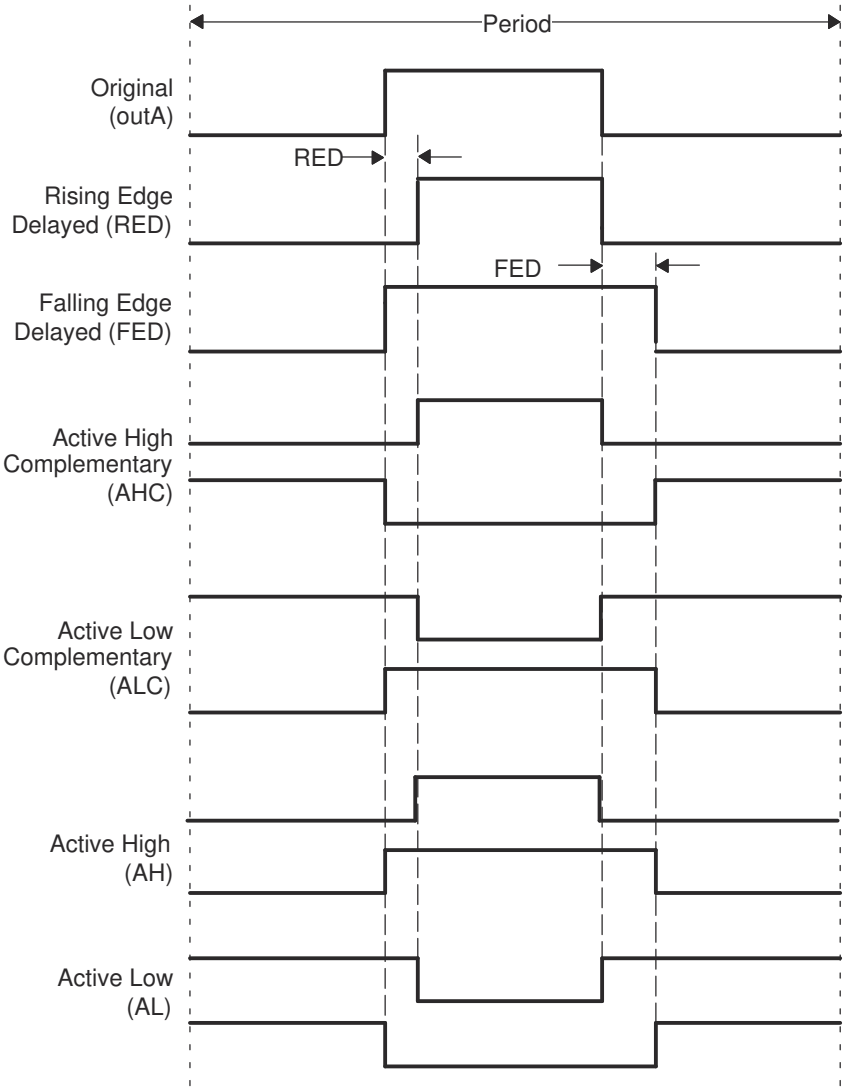

Figure 14-35. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and the value represents the number of TBCLK (time-base clock) pulses by which a signal edge is delayed. For example, the formula to calculate falling-edge-delay and rising-edge-delay is:

$FED = DBFED \times T_{TBCLK}$

$RED = DBRED \times T_{TBCLK}$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of EPWMCLK.

For convenience, delay values for various TBCLK options are shown in Table 14-10. The ePWM input clock frequency that these delay values been computed by is 100MHz.

Table 14-10. Dead-Band Delay Values in µs as a Function of DBFED and DBRED

Dead-Band Value	Dead-Band Delay (µs)		
DBFED, DBRED	TBCLK = EPWMCLK/1	TBCLK = EPWMCLK /2	TBCLK = EPWMCLK/4
1	0.01	0.02	0.04
5	0.05	0.10	0.20
10	0.10	0.20	0.40
100	1.00	2.00	4.00
200	2.00	4.00	8.00
400	4.00	8.00	16.00
500	5.00	10.00	20.00
600	6.00	12.00	24.00
700	7.00	14.00	28.00
800	8.00	16.00	32.00
900	9.00	18.00	36.00
1000	10.00	20.00	40.00

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

FED = DBFED × $T_{TBCLK}/2$

RED = DBRED × $T_{TBCLK}/2$

14.8 PWM Chopper (PC) Submodule

The PWM chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if pulse transformer-based gate drivers to control the power switching elements are needed.

Figure 14-36 illustrates the PWM chopper submodule within the ePWM.

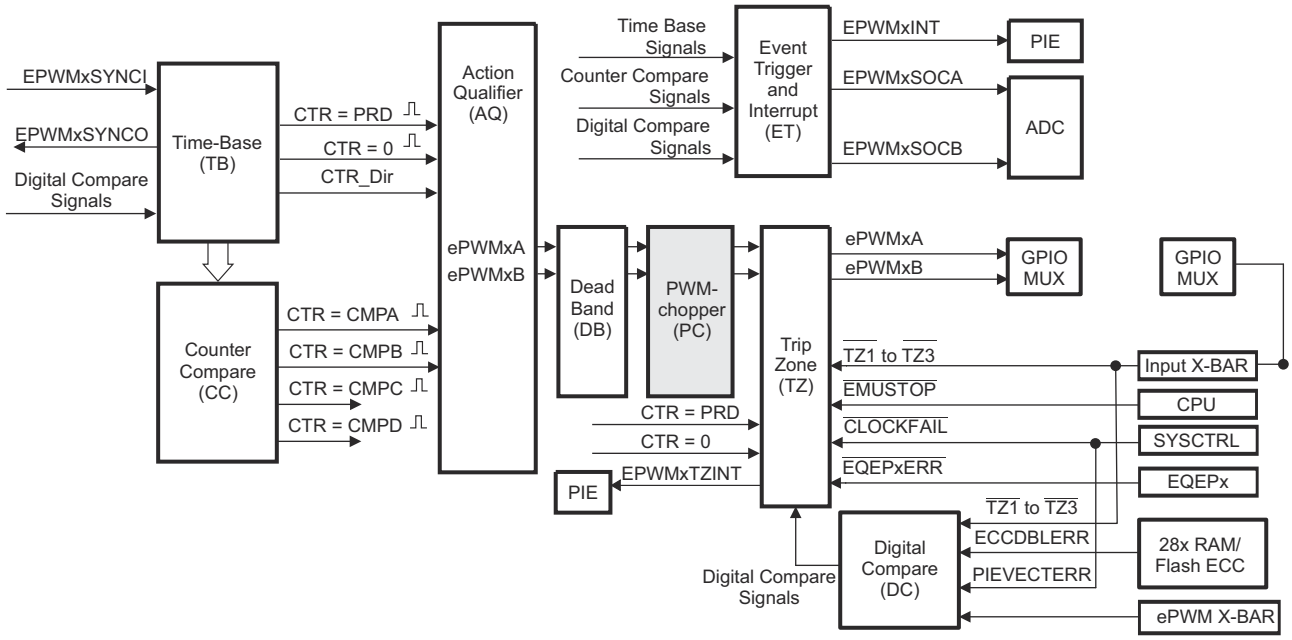

Figure 14-36. PWM Chopper Submodule

14.8.1 Purpose of the PWM Chopper Submodule

The key functions of the PWM chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

14.8.2 Operational Highlights for the PWM Chopper Submodule

Figure 14-37 shows the operational details of the PWM chopper submodule. The carrier clock is derived from EPWMCLK. The clock frequency and duty cycle are controlled using the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to make sure hard and fast power switch turn on, while the subsequent pulses sustain pulses, making sure the power switch remains on. The one-shot width is programmed using the OSHTWTH bits. The PWM chopper submodule can be fully disabled (bypassed) using the CHPEN bit.

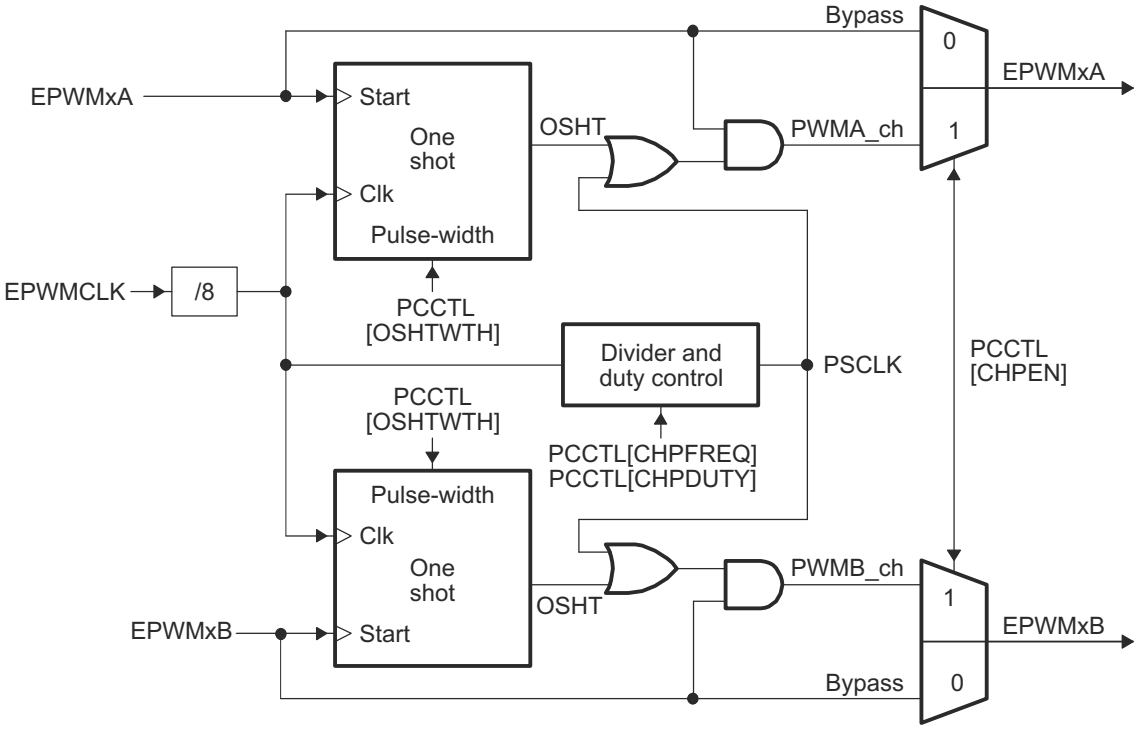

Figure 14-37. PWM Chopper Submodule Operational Details

14.8.3 Waveforms

Figure 14-38 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

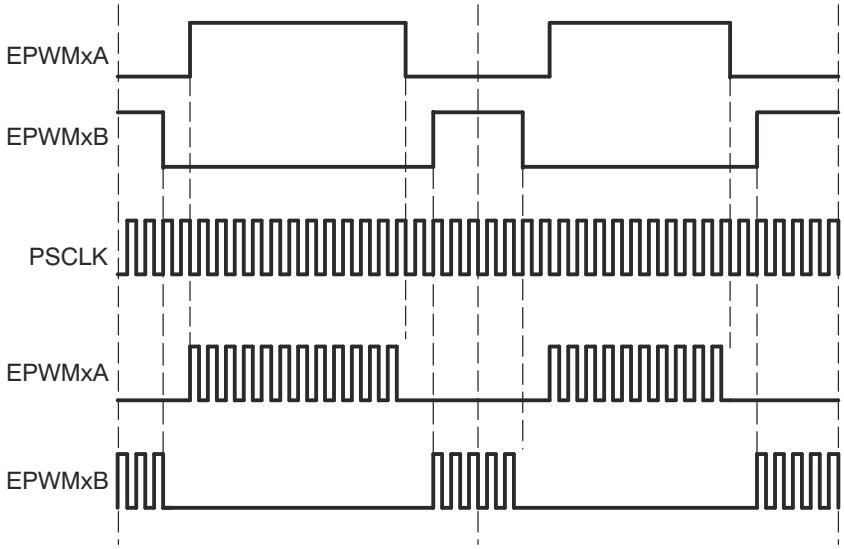

Figure 14-38. Simple PWM Chopper Submodule Waveforms Showing Chopping Action Only

14.8.3.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{EPWMCLK} \times 8 \times OSHTWTH$$

Where $T_{EPWMCLK}$ is the period of the system clock (EPWMCLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 14-39 shows the first and subsequent sustaining pulses and Table 14-11 gives the possible pulse width values for a EPWMCLK = 80MHz.

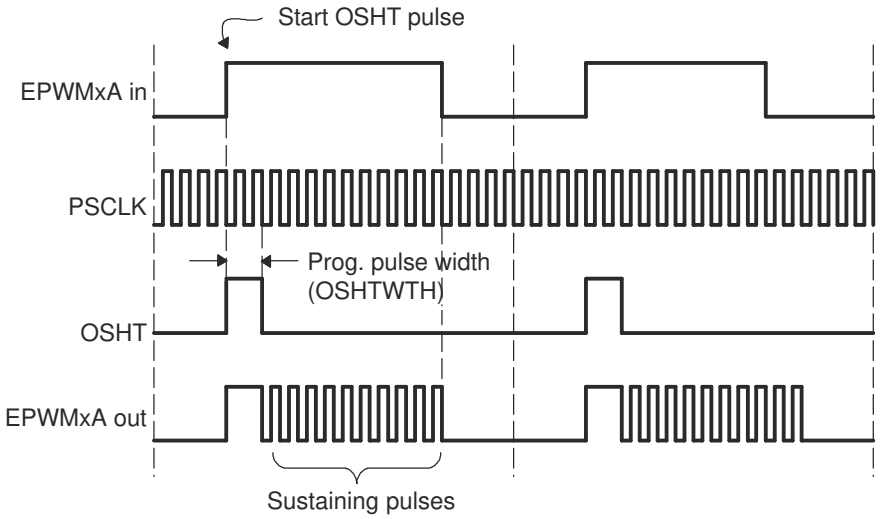

Figure 14-39. PWM Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

Table 14-11. Possible Pulse Width Values for EPWMCLK = 80MHz

OSHTWTH (hex)	Pulse Width (ns)
0	100
1	200
2	300
3	400
4	500
5	600

14.8.3.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses make sure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized using software control.

Figure 14-40 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

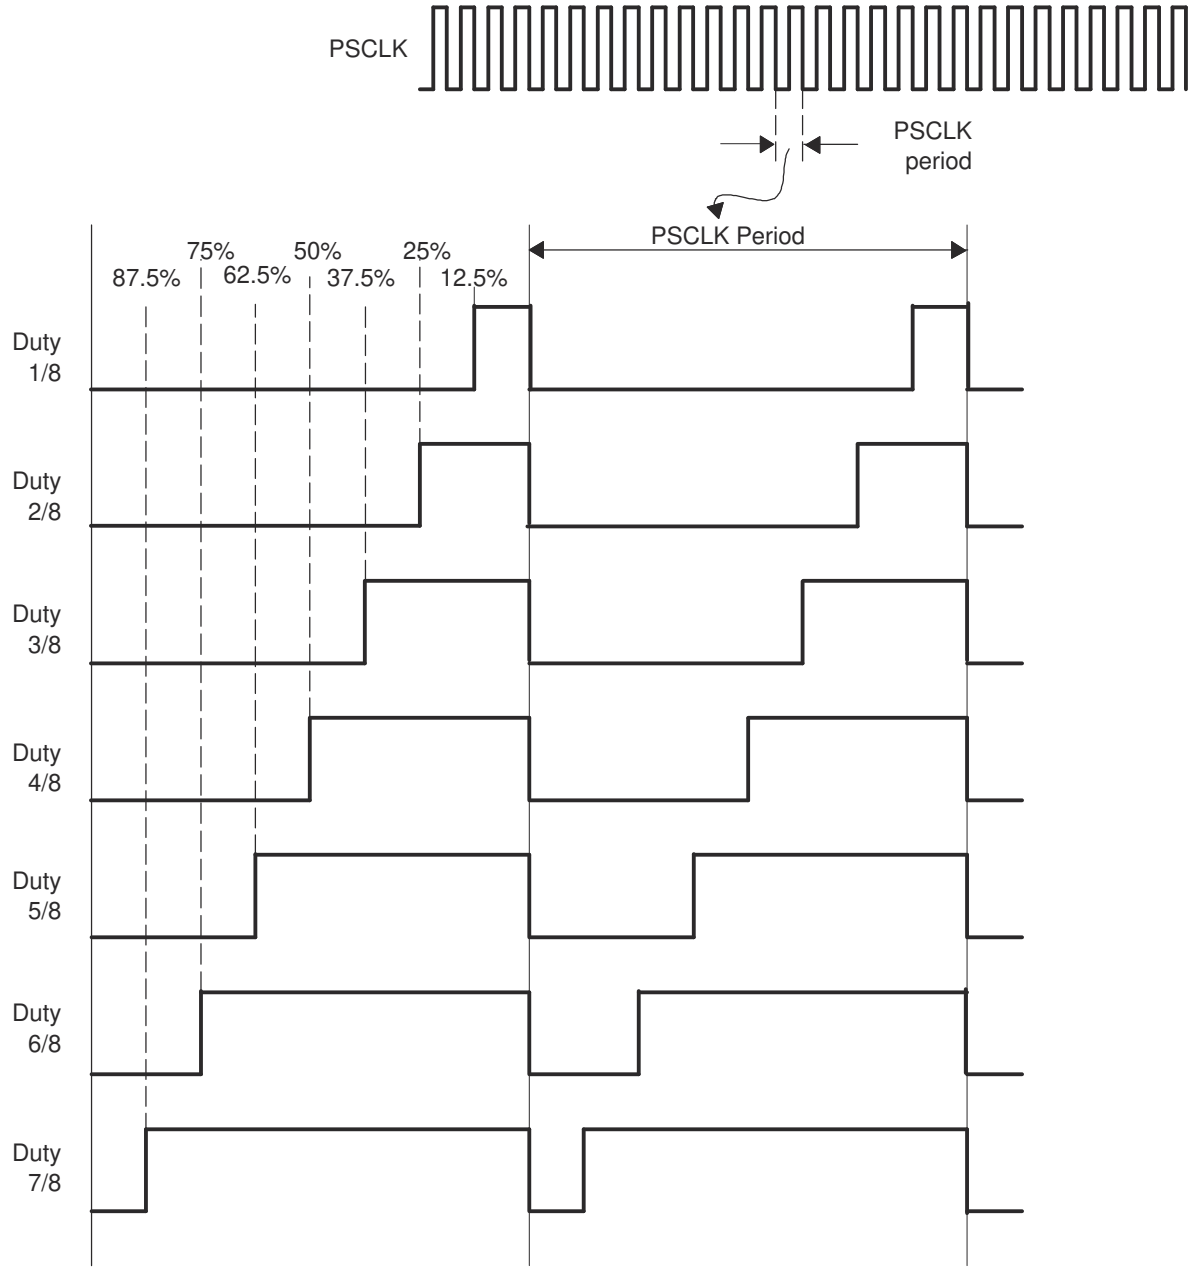

Figure 14-40. PWM Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

14.9 Trip-Zone (TZ) Submodule

Each ePWM module is connected to six $\overline{TZn}$ signals ($\overline{TZ1}$ to $\overline{TZ6}$). $\overline{TZ1}$ to $\overline{TZ3}$ are sourced from the GPIO mux. $\overline{TZ4}$ is sourced from an inverted EQEPxERR signal on those devices with an EQEP module. $\overline{TZ5}$ is connected to the system clock fail logic, and $\overline{TZ6}$ is sourced from the EMUSTOP output from the CPU. These signals indicate external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

Figure 14-41 illustrates the trip-zone submodule within the ePWM.

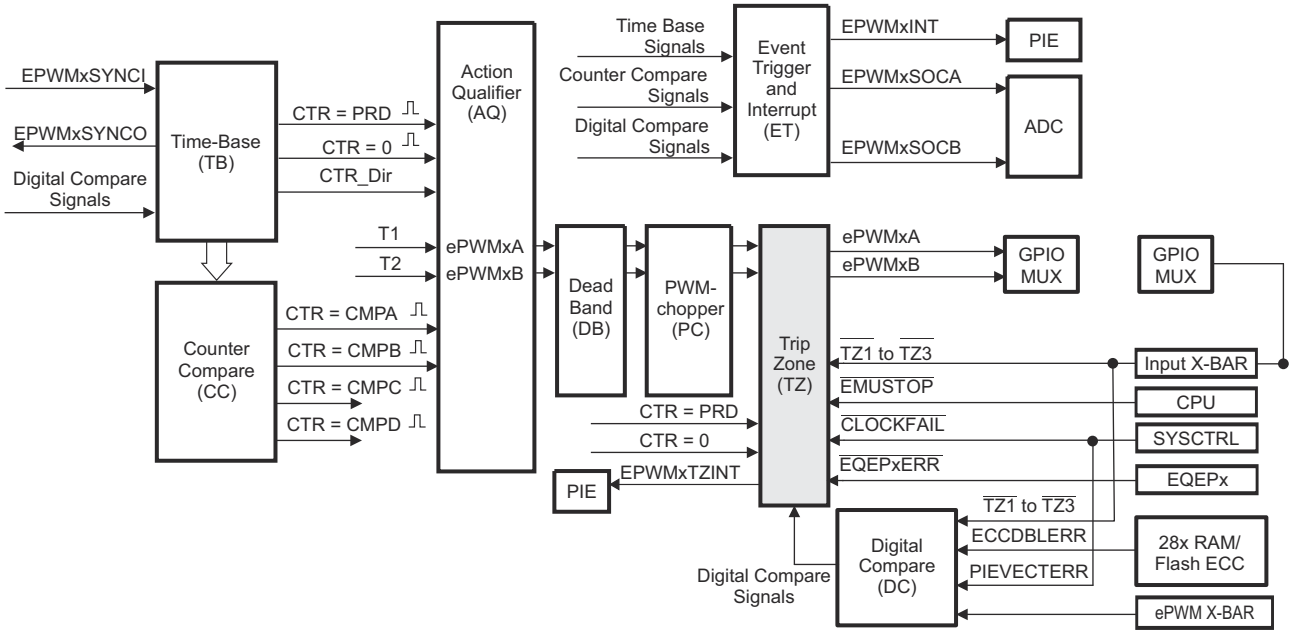

Figure 14-41. Trip-Zone Submodule

14.9.1 Purpose of the Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs $\overline{TZ1}$ to $\overline{TZ6}$ can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and $\overline{TZ1}$ to $\overline{TZ3}$ signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if the trip-zone submodule is not required.

14.9.2 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals $\overline{TZ1}$ to $\overline{TZ6}$ (also collectively referred to as $\overline{TZn}$) are active-low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, the indication is that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals can or cannot be synchronized to the ePWMclock (EPWMCLK) and digitally filtered within the GPIO MUX block. A minimum of 3*TBCLK low pulse width on $\overline{TZn}$ inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition cannot be latched by CBC or OST latches. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on $\overline{TZn}$ inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the *System Control and Interrupts* chapter.

Each $\overline{TZn}$ input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input), respectively.

- **Cycle-by-Cycle (CBC):**

  When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and EPWMxB outputs. Table 14-12 lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up or while the counter is counting down by appropriately configuring bits in the TZCTL2 register. Actions specified in the TZCTL2 register take effect only when the ETZE bit in TZCTL2 is set.

  Additionally, when a cycle-by-cycle trip event occurs, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller. A corresponding flag for the event that caused the CBC event is also set in register TZCBCFLG.

  If the CBC interrupt is enabled using the TZEINT register and DCAEVT2 or DCBEVT2 are selected as CBC trip sources using the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

  The specified condition on the inputs is automatically cleared based on the selection made with TZCLR[CBCPULSE] if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] and TZCBCFLG flag bits remain set until the flag bits are manually cleared by writing to the TZCLR[CBC] and TZCBCCLR flag bits. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] and TZCBCFLG register bits are cleared, then these bits are again immediately set.

- **One-Shot (OSHT):**

  When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and EPWMxB output. Table 14-12 lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and while the counter is counting down by appropriately configuring bits in TZCTL2 register. Actions specified in TZCTL2 register take effect only when ETZE bit in TZCTL2 is set.

  Additionally, when a one-shot trip event occurs, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller. A corresponding flag for the event that caused the OST event is also set in register TZOSTFLG. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit. If desired, the TZOSTFLG register bit can be cleared by manually writing to the corresponding bit in the TZOSTCLR register.

If the one-shot interrupt is enabled using the TZEINT register and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources using the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

Note

Clear the TZFLG and TZOSTFLG flags after making sure that the TRIPIN source of the OST has become inactive. Otherwise, if interrupts are enabled, depending on when the flags are cleared, an OST interrupt can occur and the OST flags are zero.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

  A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected using the DCTRIPSEL register and can be either trip zone input pins or analog comparator CMPSSx signals. For more information on the digital compare submodule signals, see Section 14.11.

  When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and EPWMxB output. Table 14-12 lists the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and while the counter is counting down by appropriately configuring bits in TZCTLDCA and TZCTLDCB register. Actions specified in TZCTLDCA and TZCTLDCB registers take effect only when ETZE bit in TZCTL2 is set.

  In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller.

  The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit remains set until the flag is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then the flag is again immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL, TZCTL2, TZCTLDCA, and TZCTLDCB register bit fields. Some of the possible actions, shown in Table 14-12, can be taken on a trip event.

Table 14-12. Possible Actions On a Trip Event

TZCTL Register Bitfield Settings	EPWMxA and EPWMxB	Comment
0,0	High-Impedance	Tripped
0,1	Force to High State	Tripped
1,0	Force to Low State	Tripped
1,1	No Change	Do Nothing. No change is made to the output.

Example 14-1. Trip-Zone Configurations

Scenario A:
A one-shot trip event on $\overline{TZ1}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A is forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B is forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A is forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B is forced high on a trip event.

Scenario B:
A cycle-by-cycle event on $\overline{TZ5}$ pulls both EPWM1A, EPWM1B low.
A one-shot event on $\overline{TZ1}$ or $\overline{TZ6}$ puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables $\overline{TZ5}$ as a cycle-by-cycle event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A is forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B is forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables $\overline{TZ6}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A is put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B ignores the trip event.

Note

When configuring the GPIOs and INPUT X-BAR/EPWM X-BAR options, be aware that a change in the X-BAR input selections can cause an unwanted event. Therefore, set up the GPIO and X-BAR input configurations before enabling the ePWM Trip-Zone. If a requirement is to change the GPIO/X-BAR configurations while the ePWM Trip-Zone is enabled, the user can turn off the TRIPs by clearing the TZSEL register and reconfiguring the TRIP selection (TZSEL) after the INPUT XBAR selection is changed.

14.9.3 Generating Trip Event Interrupts

Figure 14-42 and Figure 14-43 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 14.11.

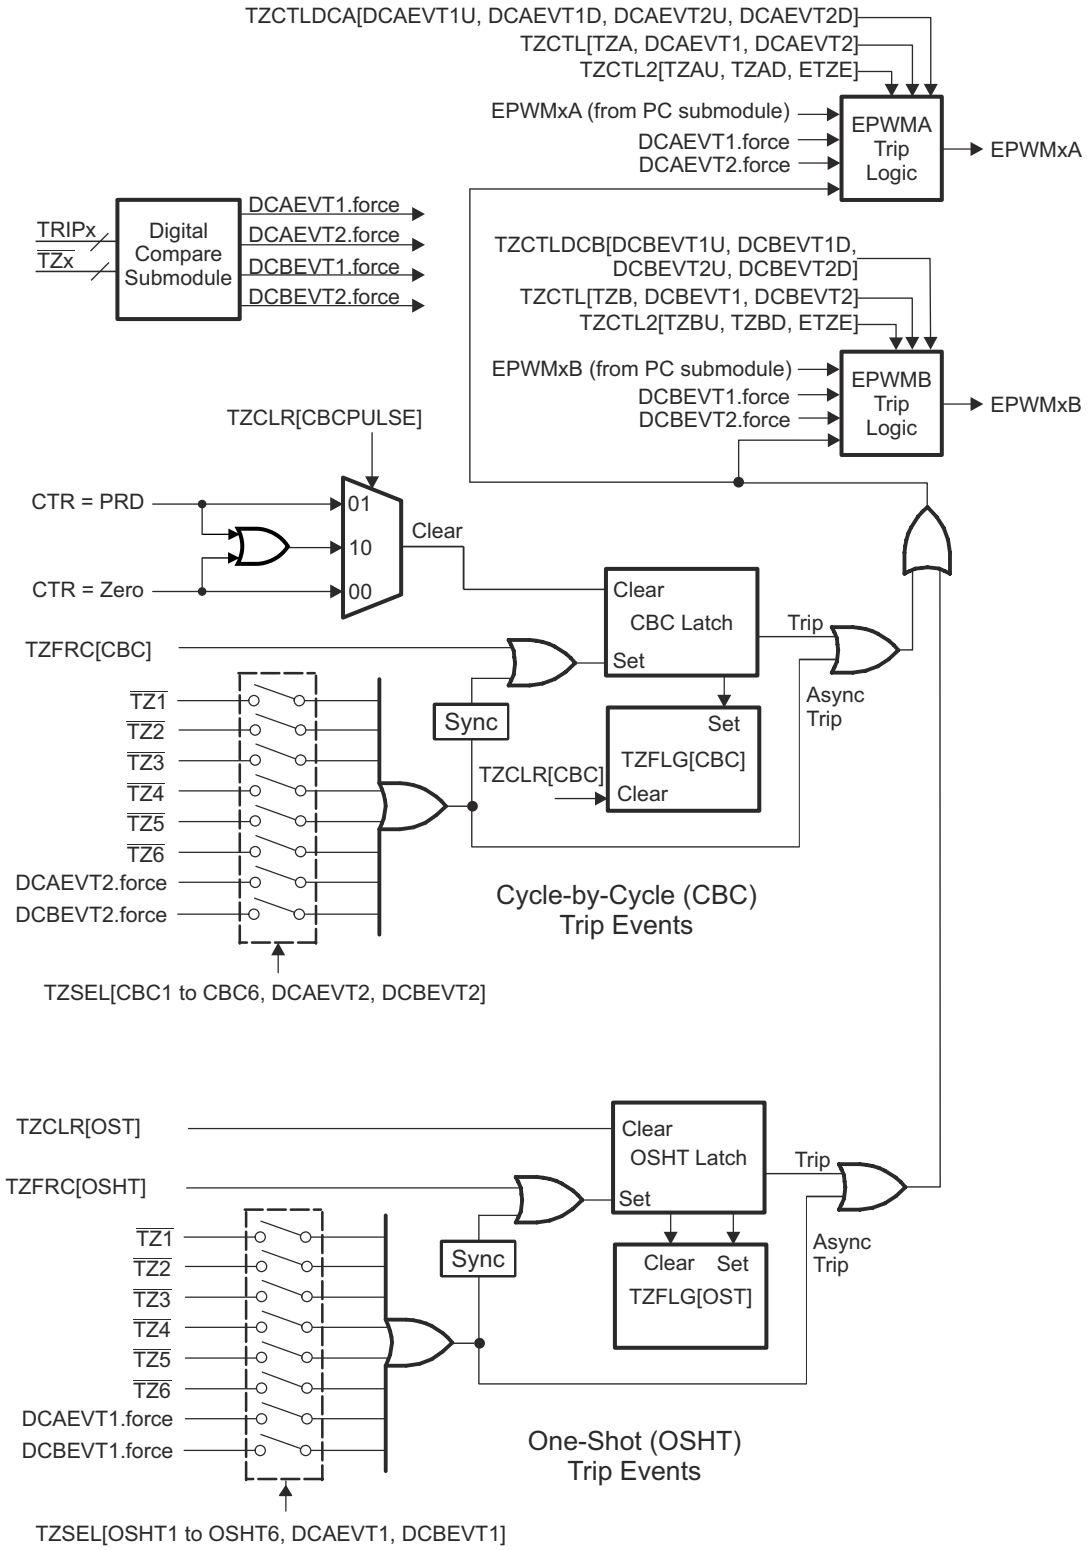

Figure 14-42. Trip-Zone Submodule Mode Control Logic

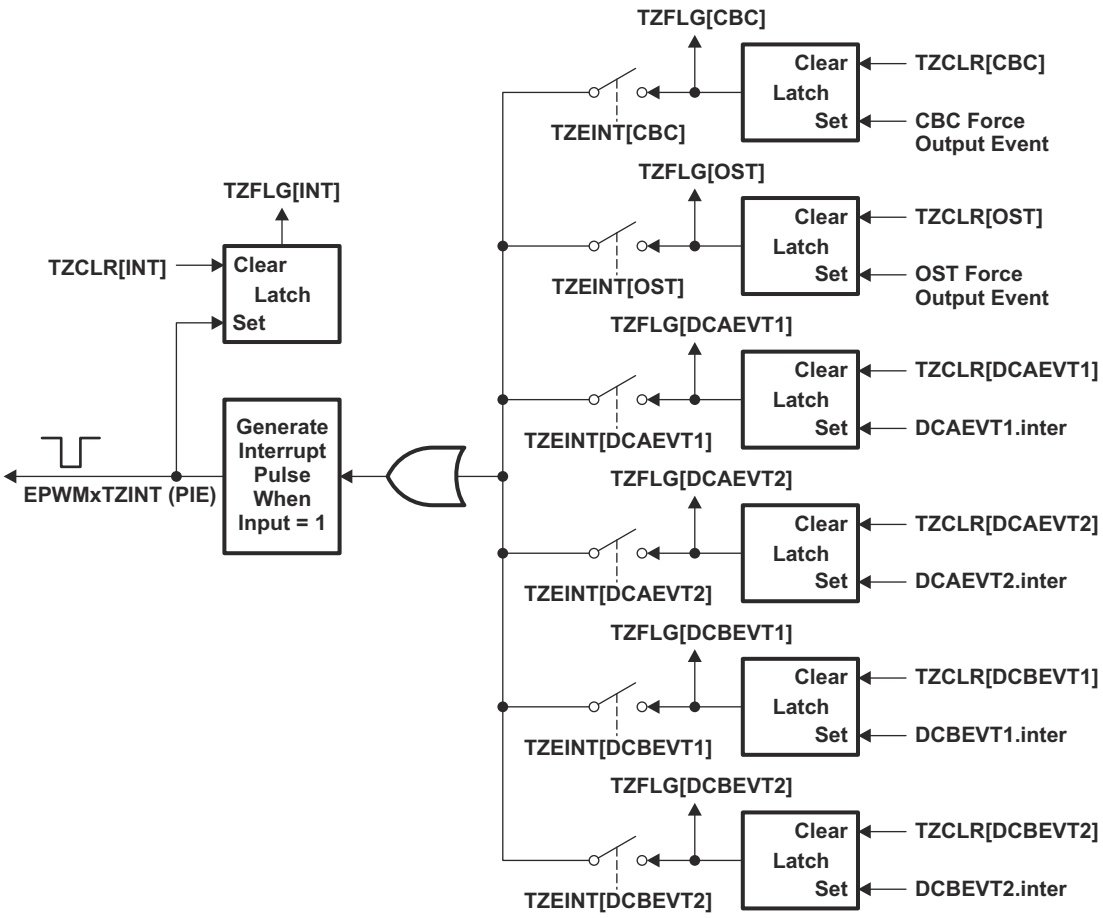

Figure 14-43. Trip-Zone Submodule Interrupt Logic

These individual flags for the CBC, OST and DCxEVTy can be used to detect the source of the EPWMxTZINT Interrupt. When multiple sources are used to generate the EPWMxTZINT interrupt, reading and clearing the flags takes different actions based on the specific event.

14.10 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare, and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Up to every fifteenth event
- Provides full visibility of event generation using event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and a start of conversion pulse to the ADC when a selected event occurs.

Figure 14-44 illustrates the event-trigger submodule within the ePWM.

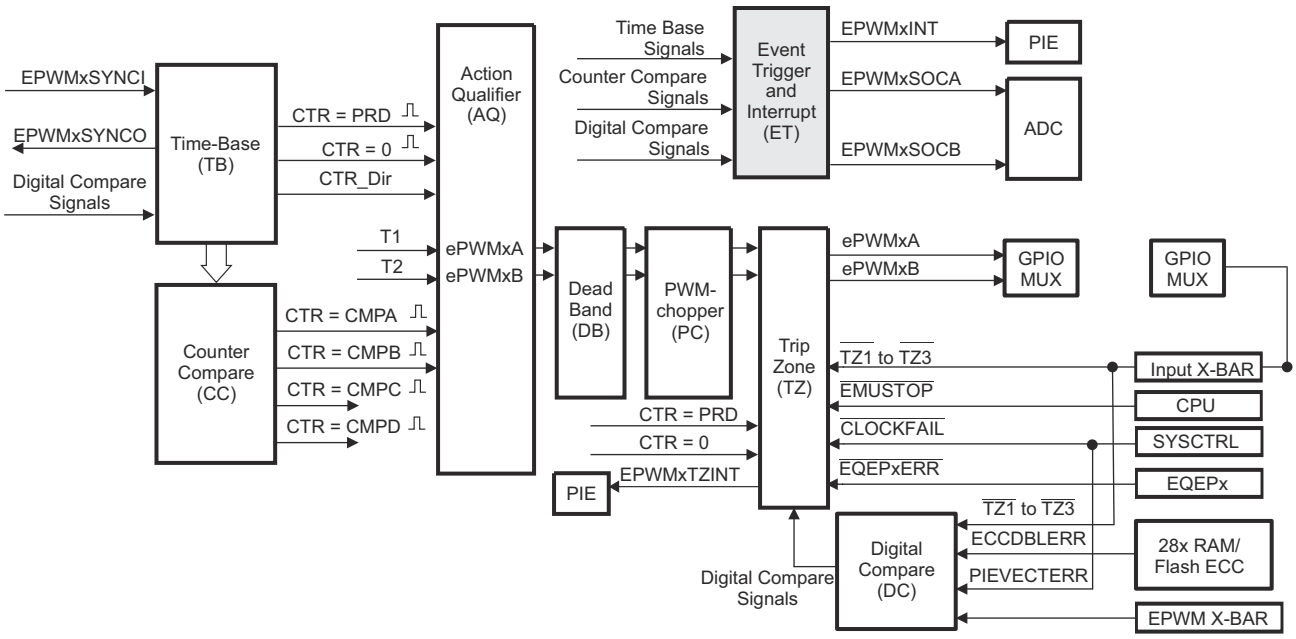

Figure 14-44. Event-Trigger Submodule

14.10.1 Operational Overview of the ePWM Event-Trigger Submodule

The event-trigger submodule monitors various event conditions (shown as inputs on the left side of Figure 14-45) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Up to every fifteenth event

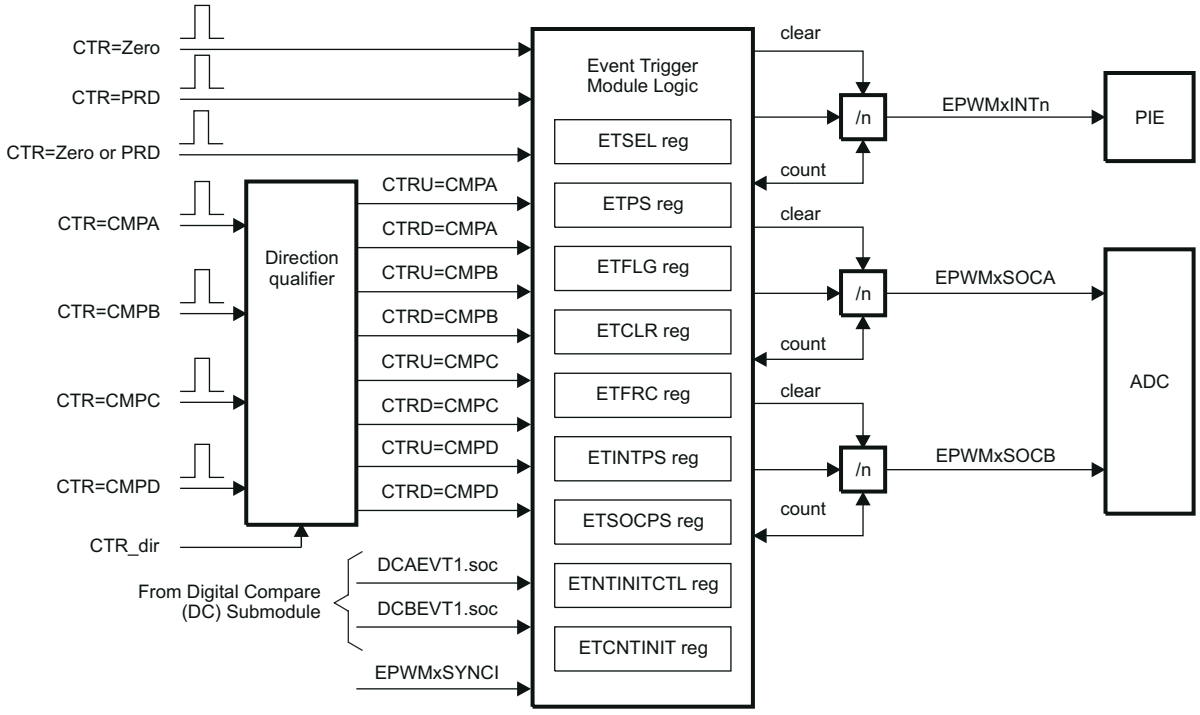

Figure 14-45. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

- ETSEL - This selects which of the possible events trigger an interrupt or start an ADC conversion.
- ETPS - This programs the event prescaling options mentioned above.
- ETFLG - These are flag bits indicating status of the selected and prescaled events.
- ETCLR - These bits allow clearing the flag bits in the ETFLG register using software.
- ETFRC - These bits allow software forcing of an event. Useful for debugging or software intervention.
- ETINTPS - This programs the interrupt event prescaling options, supporting count and period up to 15 events.
- ETSOCPS - This programs the SOC event prescaling options, supporting count and period up to 15 events.
- ETCNTINITCTL - These bits enable ETCNTINIT initialization using SYNC event or using software force.
- ETCNTINIT - These bits allow initializing INT/SOCA/SOCB counters on SYNC events (or software force) with user programmed value.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in Figure 14-46, Figure 14-47, and Figure 14-48.

Figure 14-46 shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event.
- Generate an interrupt on every second event.
- Generate an interrupt on every third event.

The selection made on ETPS[INTPSSEL] bit determines whether ETINTPS register, INTCNT2 and INTPRD2 bit fields determine frequency of events (interrupt once every 0-15 events).

The event that can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) and (ETSEL[INTSELCMP]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x00).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x00 || TBCTR = TBPRD).
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is incrementing.
- Time-base counter equal to the compare C register (CMPC) when the timer is decrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is incrementing.
- Time-base counter equal to the compare D register (CMPD) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter ETPS[INTCNT] or ETINTPS[INTCNT2] register bits based off of the selection made using ETPS[INTPSSEL]. That is, when the specified event occurs the ETPS[INTCNT] or ETINTPS[INTCNT2] bits are incremented until the bits reach the value specified by ETPS[INTPRD] or ETINTPS[INTPRD2] determined again by the selection made in ETPS[INTPSSEL]. When ETPS[INTCNT] = ETPS[INTPRD], the counter stops counting and the counter output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When ETPS[INTCNT] reaches ETPS[INTPRD], the following behavior occurs. [The following behavior is also applicable to ETINTPS[INTCNT2] and ETINTPS[INTPRD2]:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter begins counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when the counter reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter holds the output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing a 0 to the INTPRD bits automatically clears the counter (INTCNT = 0) and the counter output resets (so no interrupts are generated). For all other writes to INTPRD, INTCNT retains the previous value. INTCNT resets when INTCNT overflows. Writing a 1 to the ETFRC[INT] bit increments the event counter INTCNT. The counter behaves as previously described when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events are detected and the ETFRC[INT] bit is also ignored. The same applies to ETINTPS[INTCNT2] and ETINTPS[INTPRD2].

The previous definition means that an interrupt on every event, on every second event, or on every third event if using the INTCNT and INTPRD can be generated. An interrupt on every event up to 15 events if using the INTCNT2 and INTPRD2 can be generated.

The INTCNT2 value can be initialized with the value from ETCNTINIT[INTINIT] based on the selection made in ETCNTINITCTL[INTINITEN]. When ETCNTINITCTL[INTINITEN] is set, then initialization of INTCNT2 counter with contents of ETCNTINIT[INTINIT] on a SYNC event or software force is determined by ETCNTINITCTL[INTINITFRC].

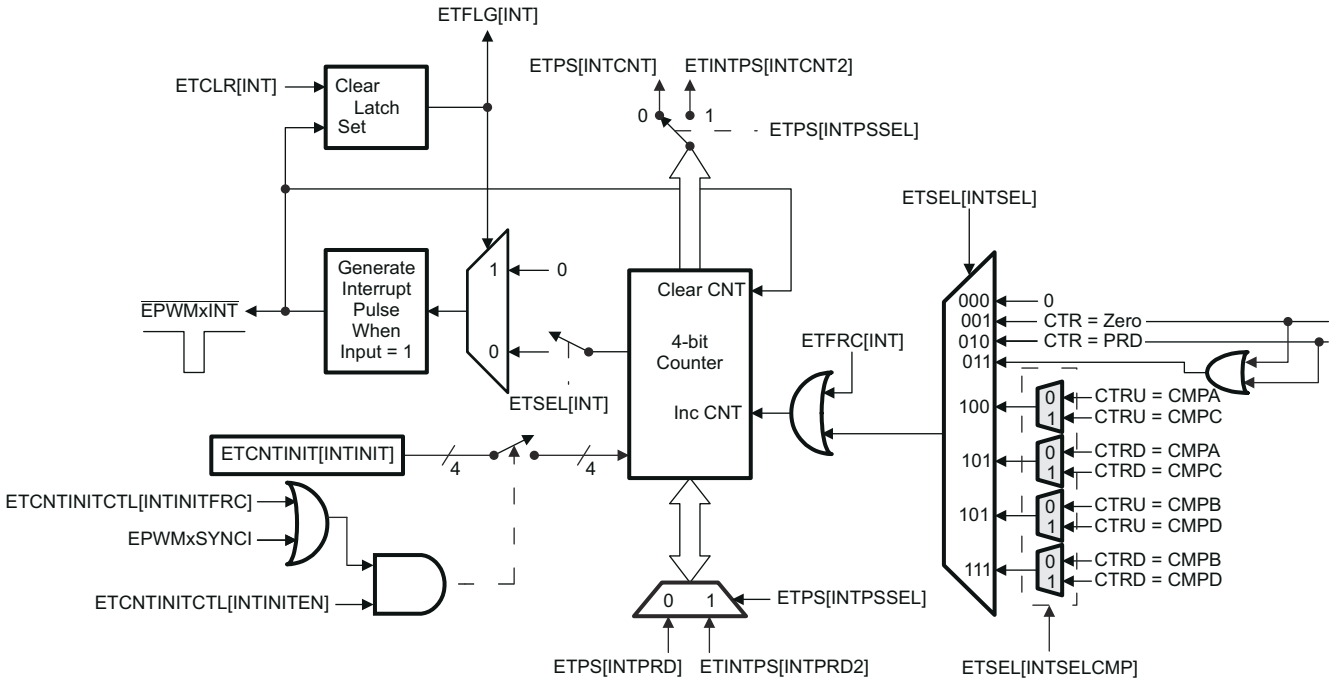

Figure 14-46. Event-Trigger Interrupt Generator

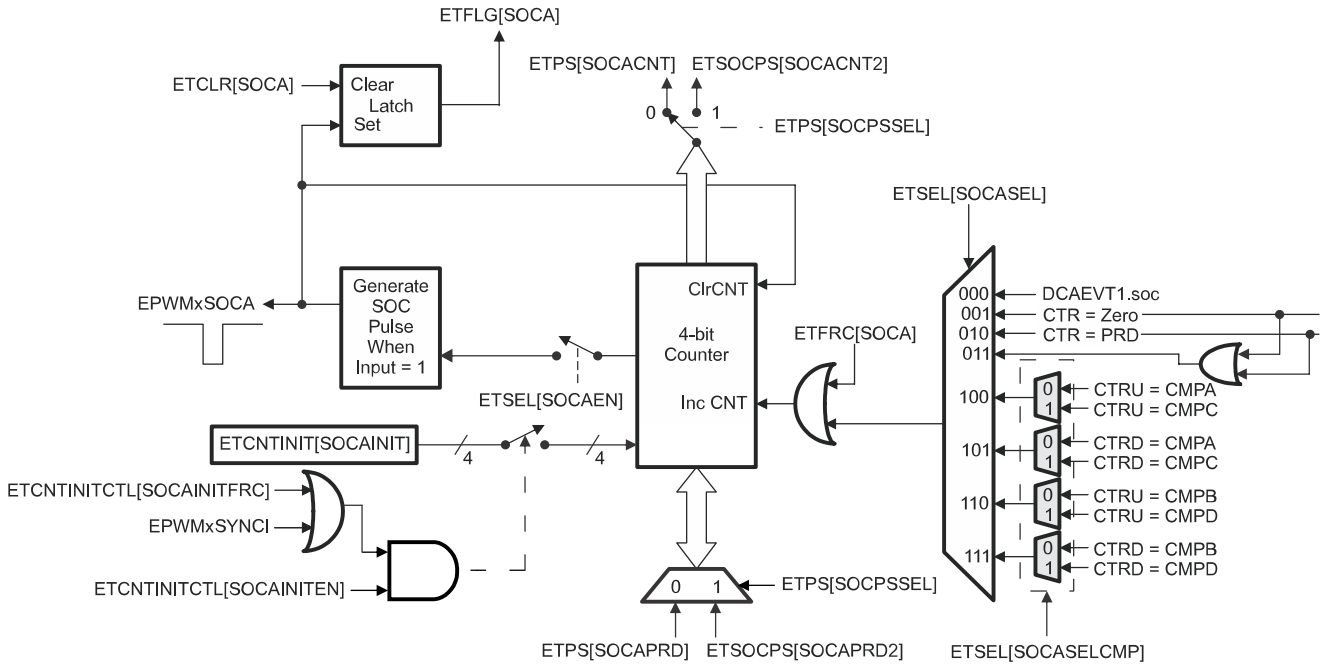
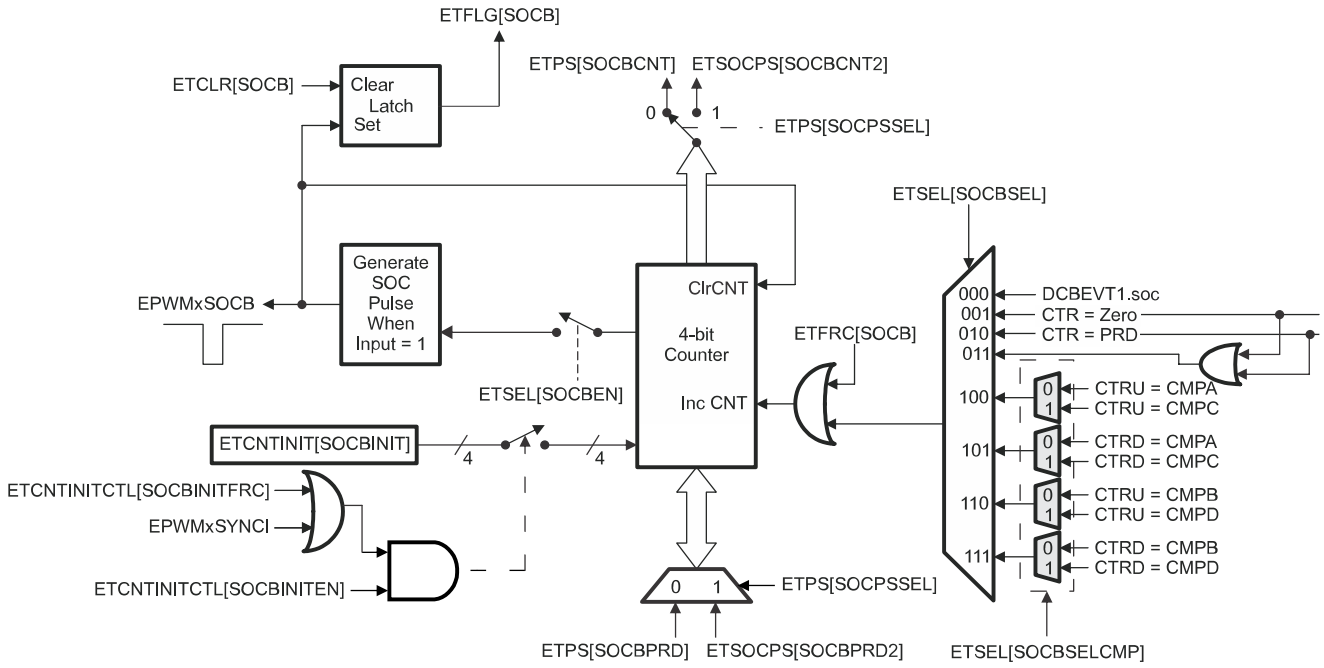
Figure 14-47 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The enhancements include SOCASELCMP and SOCBSELCMP bit fields defined in the ETSEL register enable CMPC and CMPD events respectively to cause a start of conversion. The ETPS[SOCPSSEL] bit field determines whether SOCACNT2 and SOCAPRD2 take control or not. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but the interrupt generator does not stop further pulse generation. The enable and disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that triggers an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule. The SOCACNT2 initialization scheme is very similar to the interrupt generator with respective enable, value initialize and SYNC or software force options.



NOTE: The DCAEVT1.soc signals are generated by the Digital Compare (DC) submodule in Section 14.11.

Figure 14-47. Event-Trigger SOCA Pulse Generator

Figure 14-48 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.



NOTE: The DCBEVT1.soc signals are generated by the Digital Compare (DC) submodule in Section 14.11.

Figure 14-48. Event-Trigger SOCB Pulse Generator

14.11 Digital Compare (DC) Submodule

Figure 14-49 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The eCAP input signals are sourced from the Input X-BAR signals as shown in Figure 14-50.

On this device, any of the GPIO pins can be flexibly mapped to be the trip-zone input and trip inputs to the trip-zone submodule and digital compare submodule. The Input X-BAR Input Select (INPUTxSELECT) register defines which GPIO pins gets assigned to be the trip-zone inputs / trip inputs.

The digital compare (DC) submodule compares signals external to the ePWM module (for instance, CMPSSx signals from the analog comparators) to directly generate PWM events/actions which then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

Note

The user is responsible for driving the correct state on the selected pin before enabling the clock and configuring the trip input for the respective ePWM peripheral to avoid spurious latch of the TRIP signal.

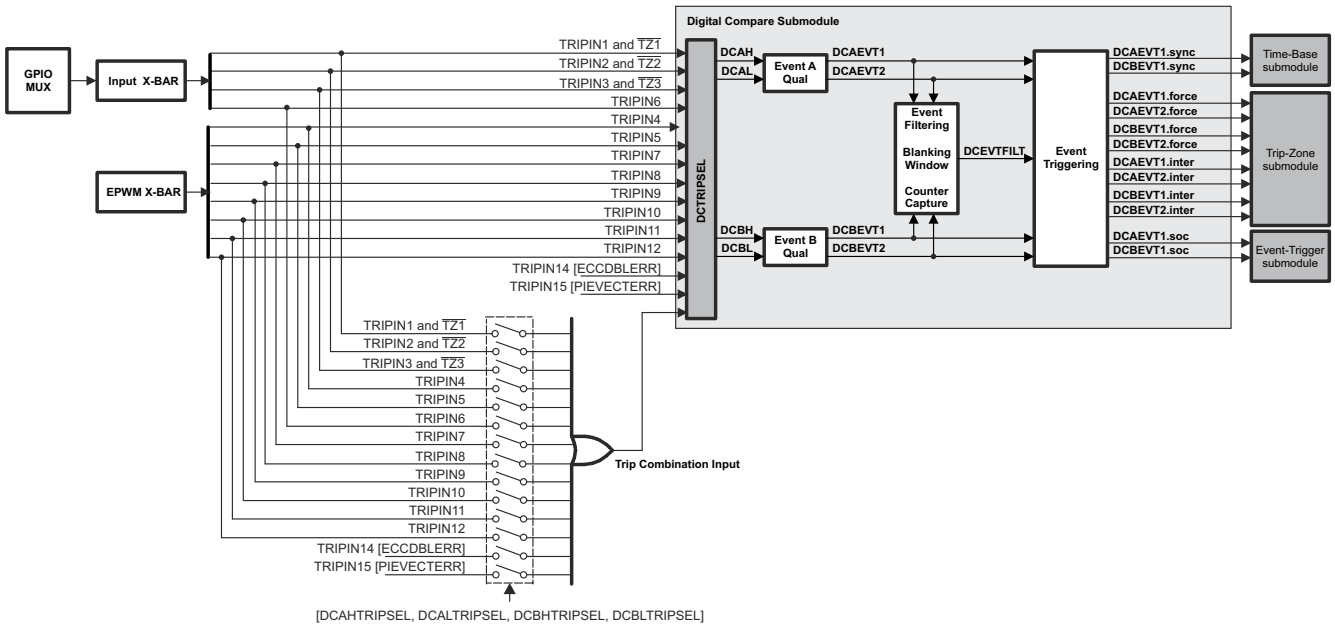


Figure 14-49. Digital-Compare Submodule High-Level Block Diagram

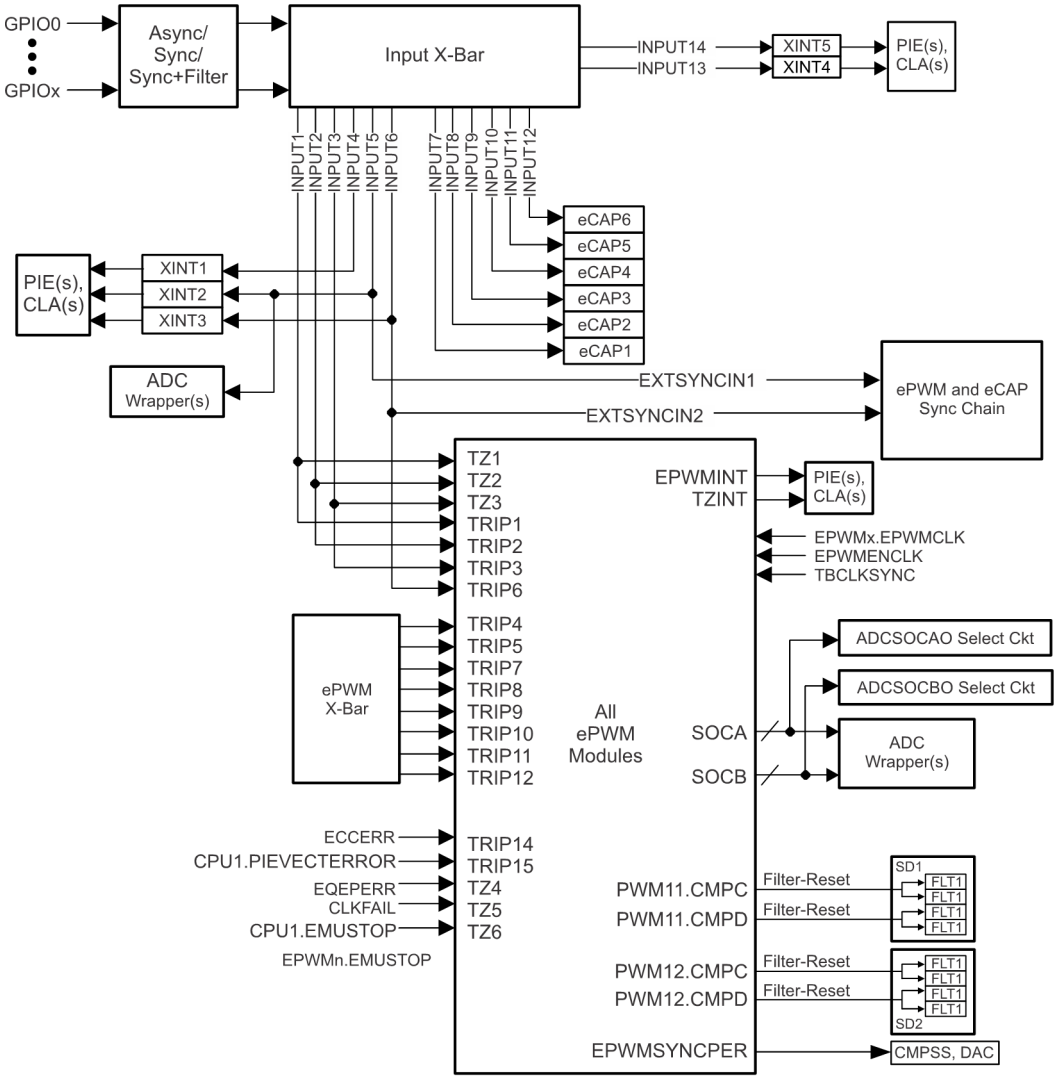

Figure 14-50. GPIO MUX-to-Trip Input Connectivity

14.11.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- Analog comparator (COMP) module outputs fed though the Input X-BAR, EPWM X-BAR, externally using the GPIO peripheral, interrupt controller signals, ECC error signals, TZ1, $\overline{TZ2}$, and $\overline{TZ3}$ inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events that can then either be filtered or applied directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

14.11.2 Enhanced Trip Action Using CMPSS

To allow multiple CMPSS at a time to affect DCA/BEVTx events and trip actions, there is a OR logic to bring together ALL trip inputs (up to 15) from sources external to the ePWM module and feed into DCAH, DCAL, DCBH, and DCBL as a “combinational input” using the DCTRIPSEL register. This is configured by selecting “Trip combination input” (value of 0xF) in the DCTRIPSEL register.

There is a discrete choice of which trip inputs to put through the combinational logic for generating the DCAH, DCAL, DCBH, and DCBL signals. This is achieved using the DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL, and DCBLTRIPSEL register selections. Inputs selected for combinational input are passed through to the DCTRIPSEL register.

14.11.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis

When using the CMPSS to trip the ePWM on a cycle-by-cycle basis, steps can be taken to prevent an asserted comparator trip state in one PWM cycle from extending into the following cycle. The CMPSS can be used to signal a trip condition to the downstream ePWM modules. For applications like peak current mode control, only one trip event per PWM cycle is expected. Under certain conditions, it is possible for a sustained or late trip event (arriving near the end of a PWM cycle) to carry over into the next PWM cycle if precautions are not taken. If either the CMPSS Digital Filter or the ePWM Digital Compare (DC) submodule is configured to qualify the comparator trip signal, “N” number of clock cycles of qualification are introduced before the ePWM trip logic can respond to logic changes of the trip signal. Once an ePWM trip condition is qualified, the trip condition remains active for N clock cycles after the comparator trip signal has de-asserted. If a qualified comparator trip signal remains asserted within N clock cycles prior to the end of a PWM cycle, the trip condition is not cleared until after the following PWM cycle has started. Thus, the new PWM cycle detects a trip condition as soon as the cycle begins.

To avoid this undesired trip condition, the application can take steps to make sure that the qualified trip signal seen by the ePWM trip logic is deasserted prior to the end of each PWM cycle. This can be accomplished through various methods:

- Design the system such that a comparator trip is not asserted within N clock cycles prior to the end of the PWM cycle.
- Activate blanking of the comparator trip signal using the ePWM event filter at least two clock cycles prior to the PWMSYNCPER signal and continue blanking for at least N clock cycles into the next PWM cycle.
- If the CMPSS COMPxLATCH path is used, clear the COMPxLATCH at least N clock cycles prior to the end of the PWM cycle. The latch can be cleared by software (using COMPSTSCLR) or by generating an early PWMSYNCPER signal. The ePWM modules on this device include the ability to generate PWMSYNCPER upon a CMPC or CMPD match (using HRPCTL) for arbitrary PWMSYNCPER placement within the PWM cycle.

14.11.4 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

14.11.4.1 Digital Compare Events

As described in Section 14.11.1, trip zone inputs ($\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$) and CMPSSx signals from the analog comparator (COMP) module can be selected using the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

Note

The $\overline{TZn}$ signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active-high or active-low inputs. ePWM outputs are asynchronously tripped when either the $\overline{TZn}$, DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of 3 * TBCLK sync pulse width is required. If pulse width is < 3*TBCLK sync pulse width, the trip condition can or can not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in Event Filtering. Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:** DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (using TZCTL, TZCTLDCA, TZCTLDCB register configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (using the TZSEL register), the DCAEVT1/2.force signals can effect the trip action using the TZCTL or TZCTL2 register configurations. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

  The priority of conflicting actions on the TZCTL, TZCTL2, TZCTLDCA and TZCTLDCB registers is as follows (highest priority overrides lower priority):

  Output EPWMxA:
  - TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)
  - TZAU (highest) -> DCAEVT1U -> DCAEVT2U (lowest)
  - TZAD (highest) -> DCAEVT1D -> DCAEVT2D (lowest)

  Output EPWMxB:
  - TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)
  - TZBU (highest) -> DCBEVT1U -> DCBEVT2U (lowest)
  - TZBD (highest) -> DCBEVT1D -> DCBEVT2D (lowest)
- **interrupt signal:** DCAEVT1/2.interrupt signals generate trip zone interrupts to the interrupt controller. To enable the interrupt, set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set to clear the interrupt.
- **soc signal:** The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse using the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse using the ETSEL[SOCBSEL] bit.
- **sync signal:** The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCI input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

Figure 14-51 and Figure 14-52 show how the DCAEVT1, DCAEVT2, or DCEVTFLT signals are processed to generate the digital compare A event force, interrupt, soc, and sync signals.

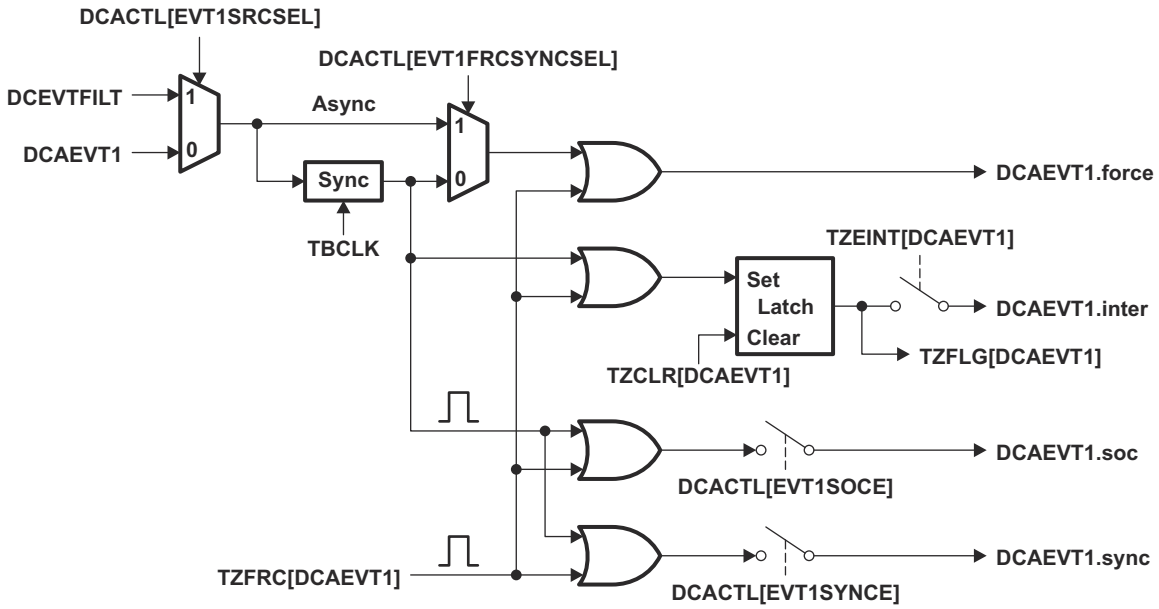

Figure 14-51. DCAEVT1 Event Triggering

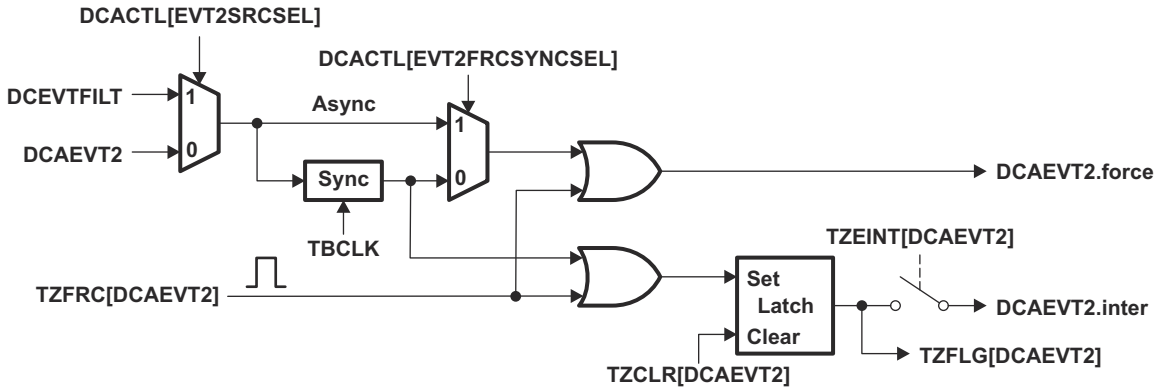

Figure 14-52. DCAEVT2 Event Triggering

Figure 14-53 and Figure 14-54 show how the DCBEVT1, DCBEVT2, or DCEVTFLT signals are processed to generate the digital compare B event force, interrupt, soc, and sync signals.

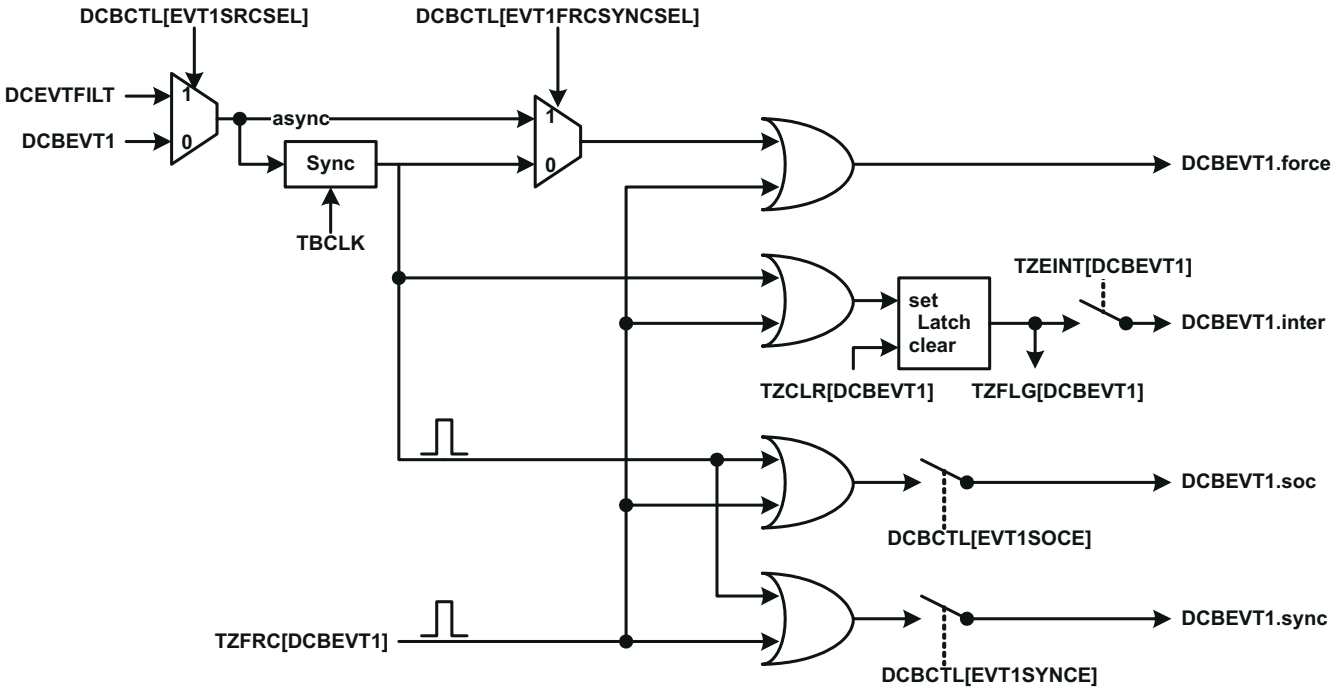

Figure 14-53. DCBEVT1 Event Triggering

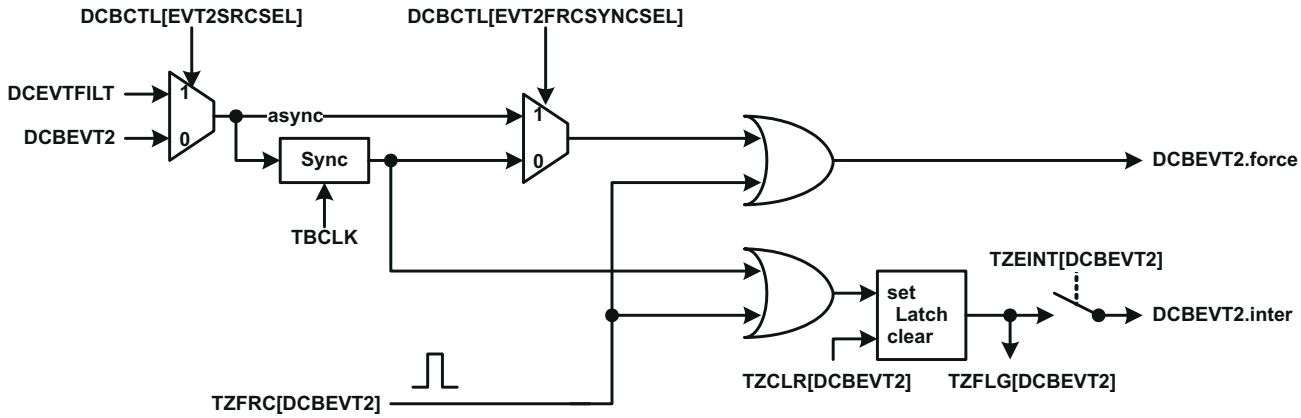

Figure 14-54. DCBEVT2 Event Triggering

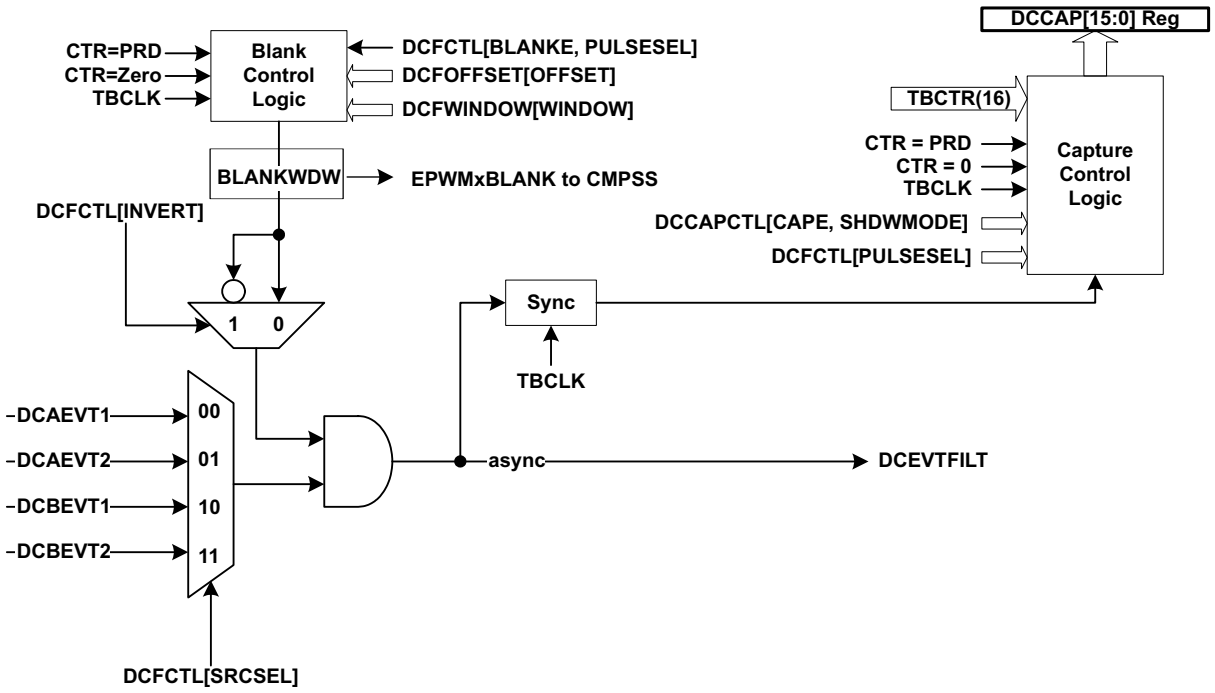
14.11.4.2 Event Filtering

Blank Control Logic: The DCAEVT1/2 and DCBEVT1/2 events can be filtered using event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs can be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blank control logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. Blank control logic is used to define a blanking window, which ignores all event occurrences on the signal while the window is active. The blanking window is configured in the DCFCTL, DCFOFFSET, and DCFWINDOW registers. The DCFCTL register enables the blanking window and aligns the blanking window to either a CTR = PRD pulse or a CTR = 0 pulse or both CTR = PRD and CTR = 0 as specified by DCFCTL[PULSESEL]. DCFCTL[SRCSEL] selects the DCxEVTy event source for the DCEVTFILT signal. An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before. Figure 14-55 shows the details of the event filtering logic.



A. On the F2837x/F2807x family of devices, EPWMxBLANK does not go to the CMPSS

Figure 14-55. Event Filtering

Capture Control Logic: The event filtering can also capture the TBCTR value of the selected DCxEVTy event as configured in the DCCAPCTL register. When capture control logic is enabled, the selected DCxEVTy event triggers capture of the TBCTR to the active register. The CPU reads directly from the active register unless shadow mode is enabled by DCCAPCTL[SHDWMODE]. When shadow mode is enabled, the active register information is copied to shadow register on the event specified by DCFCCTL[PULSESEL], and the CPU reads from the shadow register. After the selected DCxEVTy event, no further capture events occur until the event specified by DCCAPCTL[CAPMODE]. The CAPMODE can be configured two ways: (1) no further capture events occur until the event defined by DCFCTL[PULSESEL] or (2) no further capture events occur until the compare-event flag at DCCAPCTL[CAPSTS] is cleared by DCCAPCTL[CAPCLR].

Figure 14-56 illustrates several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

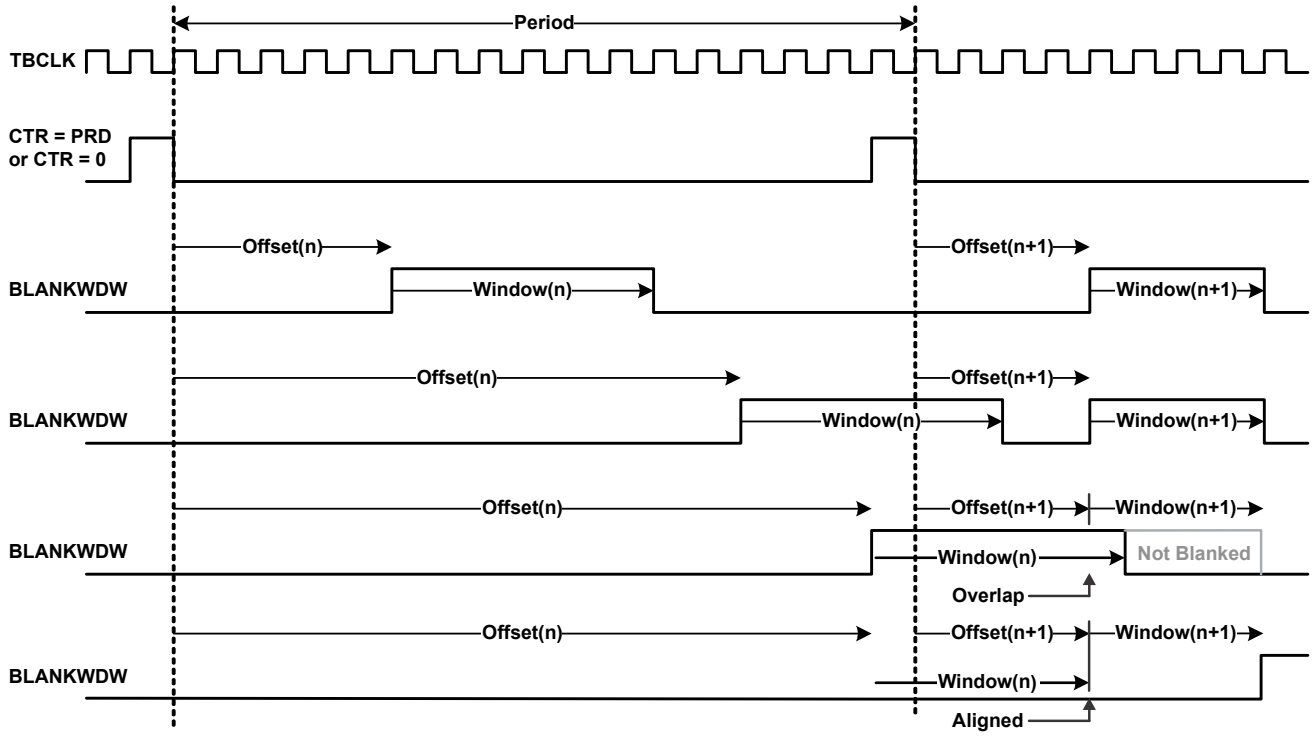


Figure 14-56. Blanking Window Timing Diagram

14.11.4.3 Valley Switching

Event filtering depicts the valley switching function along with the event filtering logic described in Event Filtering. This function can be used to achieve programmable valley switching without any additional external circuitry. This module provides an on-chip hardware mechanism that can:

- Capture the oscillation period
- Accurately delay the PWM switching instant
- Allow a programmable number of edges before the delay takes effect
- Provide multiple choices of triggers and events
- Allow easy adaptability for optimum performance under changing system/operating conditions

The DCxEVTy signal needs further processing to support valley switching. Here is a brief description of how valley switching function is enabled:

1. Select one of the DCxEVTy events as input to the valley switching block (DCFCTL[SRCSEL]) with an option to add the blanking window (Blank Control Logic). This is where the comparator output (or external input) above is selected as an input to the valley switching block.
2. Configure the edge filter to capture 'n' rising, falling or both edges through the edge selection logic (DCFCTL[EDGEMODE, EDGECOUNT]).
3. Select the correct event to reset and restart the edge filter (VCAPCTL[TRIGSEL]). Edge capturing event is triggered or armed by this selected edge.
4. Enable valley capture logic (VCAPCTL[VCAPE]).
5. Select the start edge that indicates the start of capture for oscillation period measurement (VCNTCFG[STARTEDGE]). This is where the 16-bit counter starts counting.
6. Select the stop edge (VCNTCFG[STOPEDGE]) that indicates the edge at which the 16-bit counter stops counting. The captured counter value (CNTVAL) provides oscillation period information.
   - The STOPEDGE value must always be greater than STARTEDGE value.
7. Configure and apply the captured delay (CNTVAL) to the edge filtered DCxEVTy signal. The CNTVAL value can be applied as is or applied in conjunction with a software programmed value (useful for offset adjustment) (SWVDELVAL) or only a fraction of the delay can be applied with or without SWVDELVAL. This is useful to correctly apply a delay corresponding to the valley point. (VCAPCTL[VDELAYDIV])
8. Configure VCAPCTL[EDGEFILTDLYSEL] to apply hardware delay based on the captured value above.

Once the counter is stopped, counter value is copied into CNTVAL register and counter is reset to zero. No further captures are done until the logic is triggered again by occurrence of event selected by VCAPCTL[TRIGSEL]. In this implementation, the software trigger is used as the source for VCAPCTL[TRIGSEL]. Upon occurrence of the trigger event, irrespective of the current status of the counter, the counter is reset and starts counting from zero upon occurrence of the STARTEDGE. Similarly, upon occurrence of the trigger event, the edge filter is reset and starts counting from zero upon occurrence of the STARTEDGE.

Output from the valley switching block (DCEVTFILT) is then used to synchronize the PWM time-base. The process is shown in Figure 14-57.

Note

A specific application example showcasing the usage of valley switching hardware and software is available in C2000Ware.

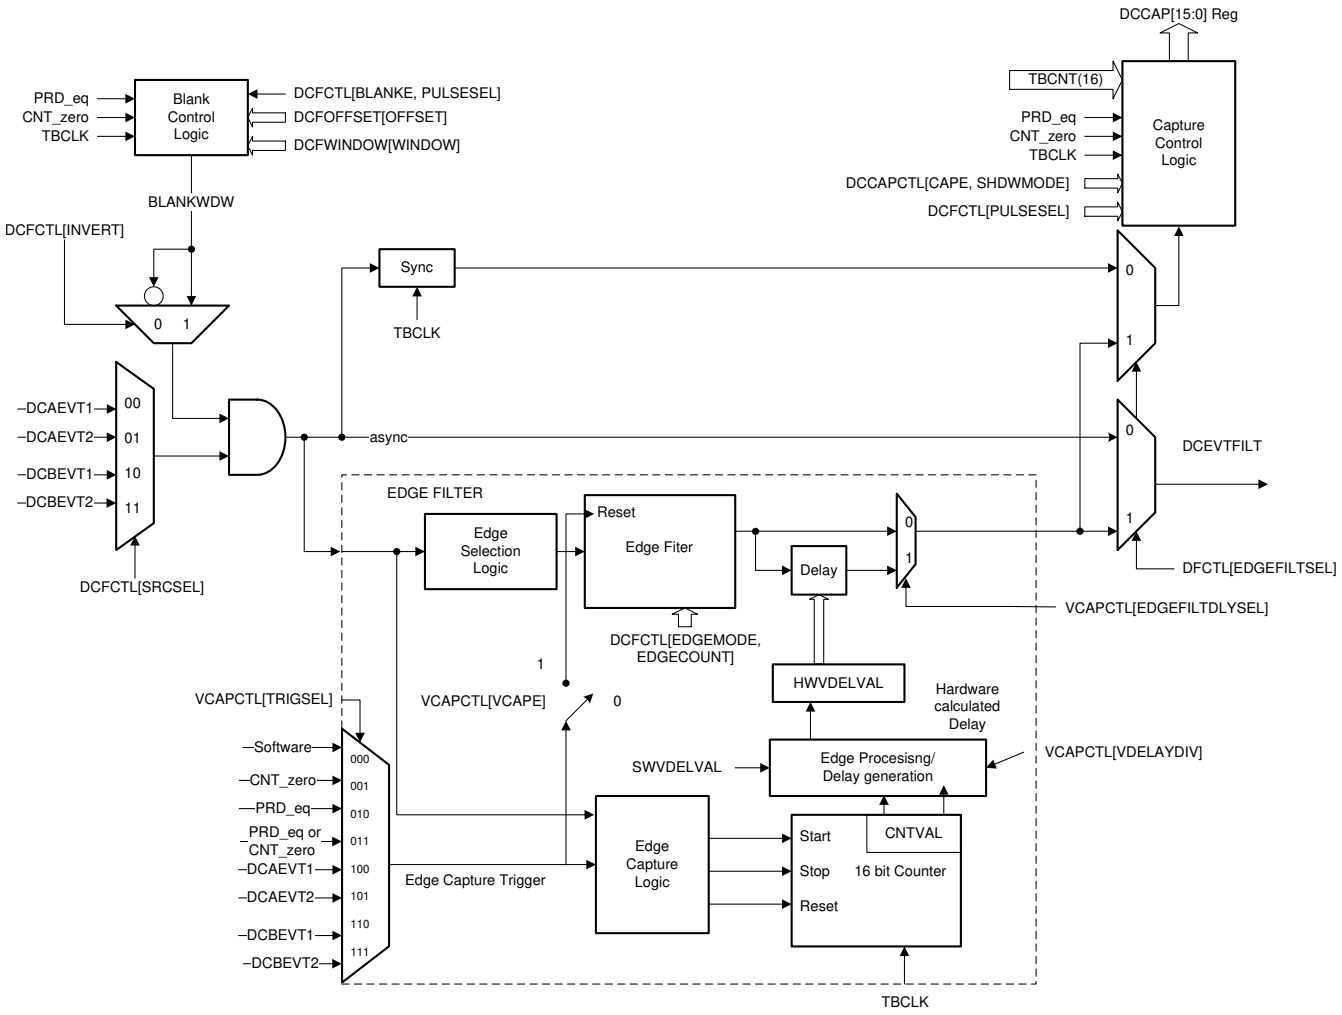

Figure 14-57. Valley Switching

14.12 ePWM Crossbar (X-BAR)

Figure 14-58 shows the architecture of the ePWM Crossbar (X-BAR). This module enables selection of various trigger sources into any of the eight dedicated EPWM trips inputs, namely the TRIP4, TRIP5, TRIP7, TRIP8, TRIP9, TRIP10, TRIP11, and TRIP12.

Note

Refer to the *Crossbar (X-BAR)* chapter for more information on the X-BAR modules, including X-BAR flags.

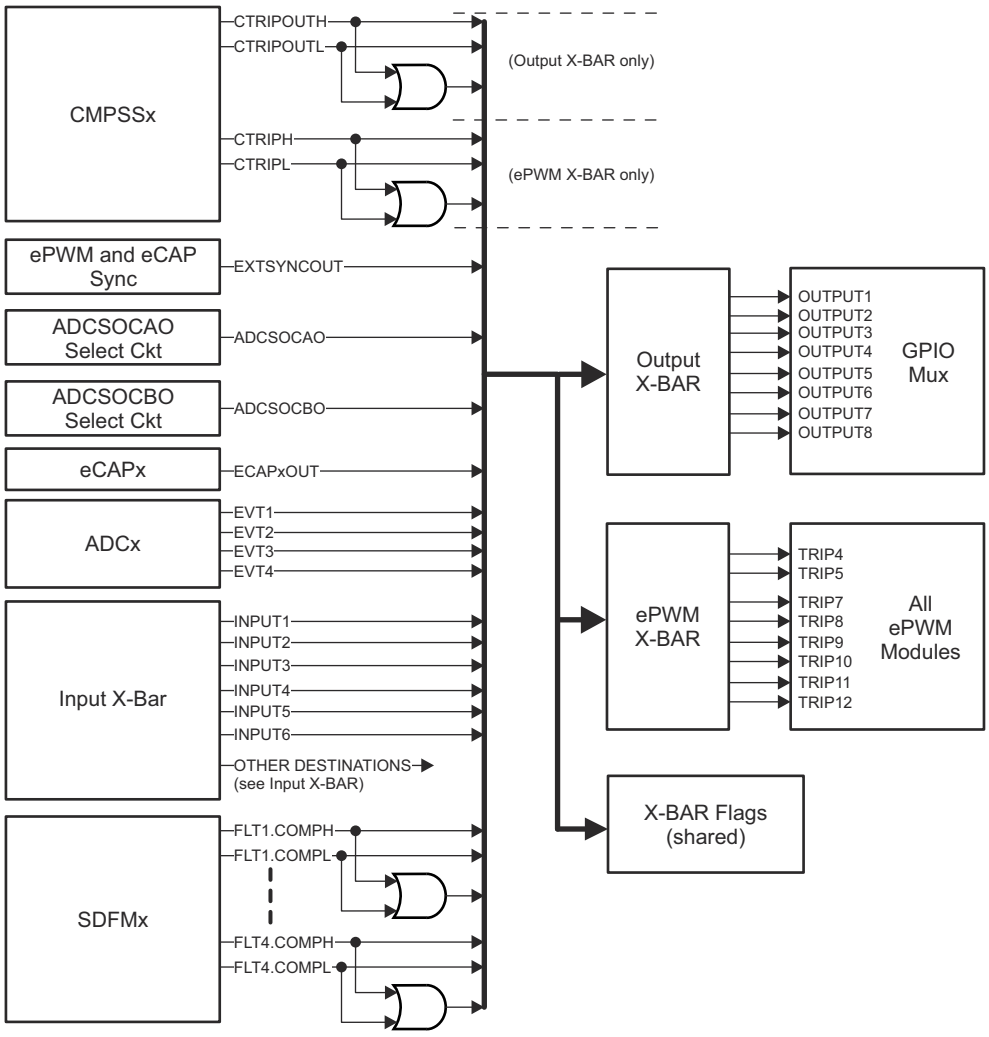

Figure 14-58. ePWM X-BAR

14.13 Applications to Power Topologies

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

14.13.1 Overview of Multiple Modules

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 14-59. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

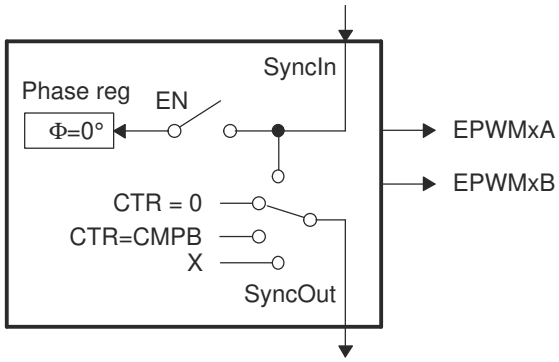

Figure 14-59. Simplified ePWM Module

14.13.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module can also choose to load the counter with a new phase value on a SyncIn strobe input or choose to ignore the value (that is, by the enable switch). Although various combinations are possible, the two most common—Master module and Slave module modes—are shown in Figure 14-60.

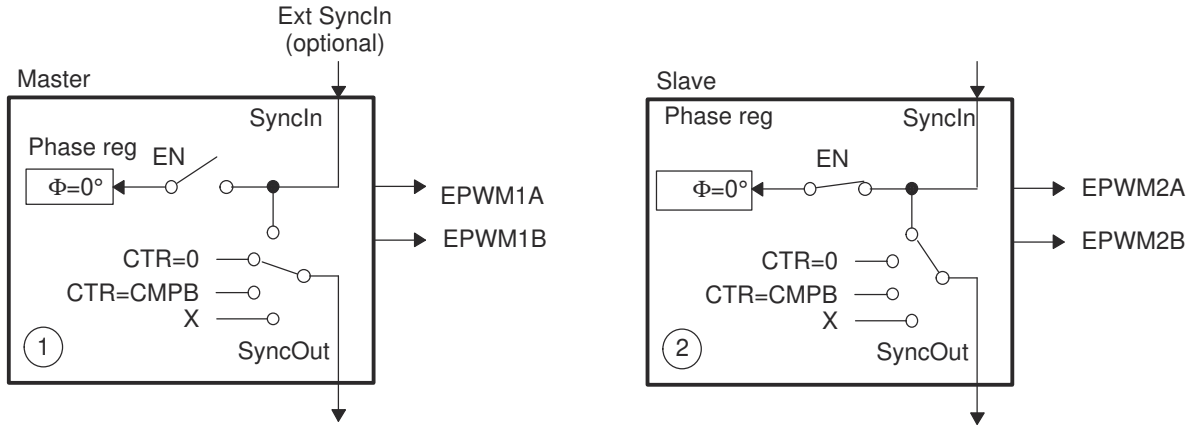

Figure 14-60. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave

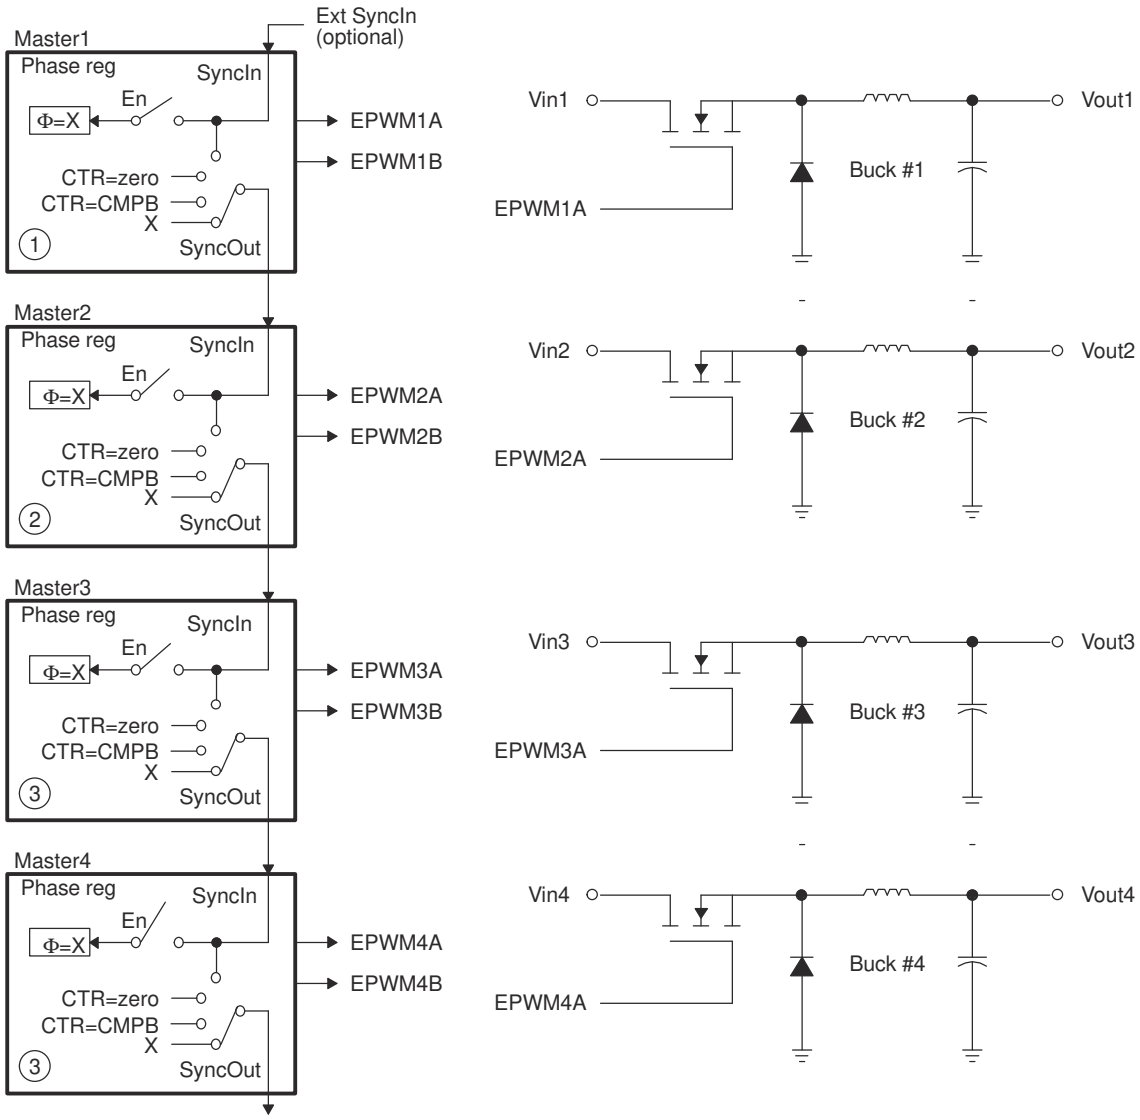
14.13.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 14-61 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 14-62 shows the waveforms generated by the setup shown in Figure 14-61; note that only three waveforms are shown, although there are four stages.



A. φ = X indicates value in phase register is a "don't care"

Figure 14-61. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$

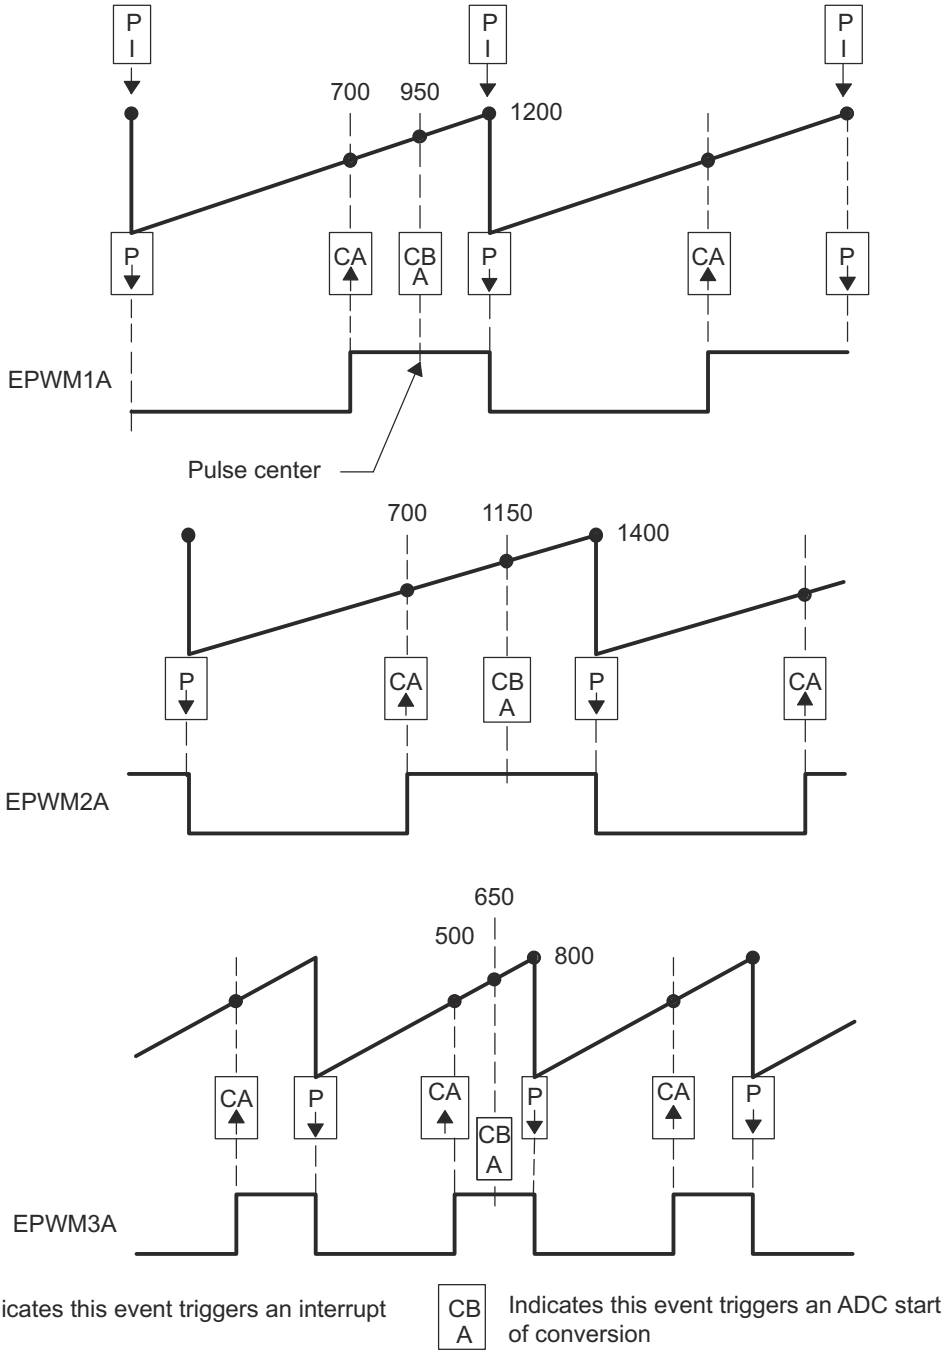


Figure 14-62. Buck Waveforms for Control of Four Buck Stages (Note: Only three bucks shown here)

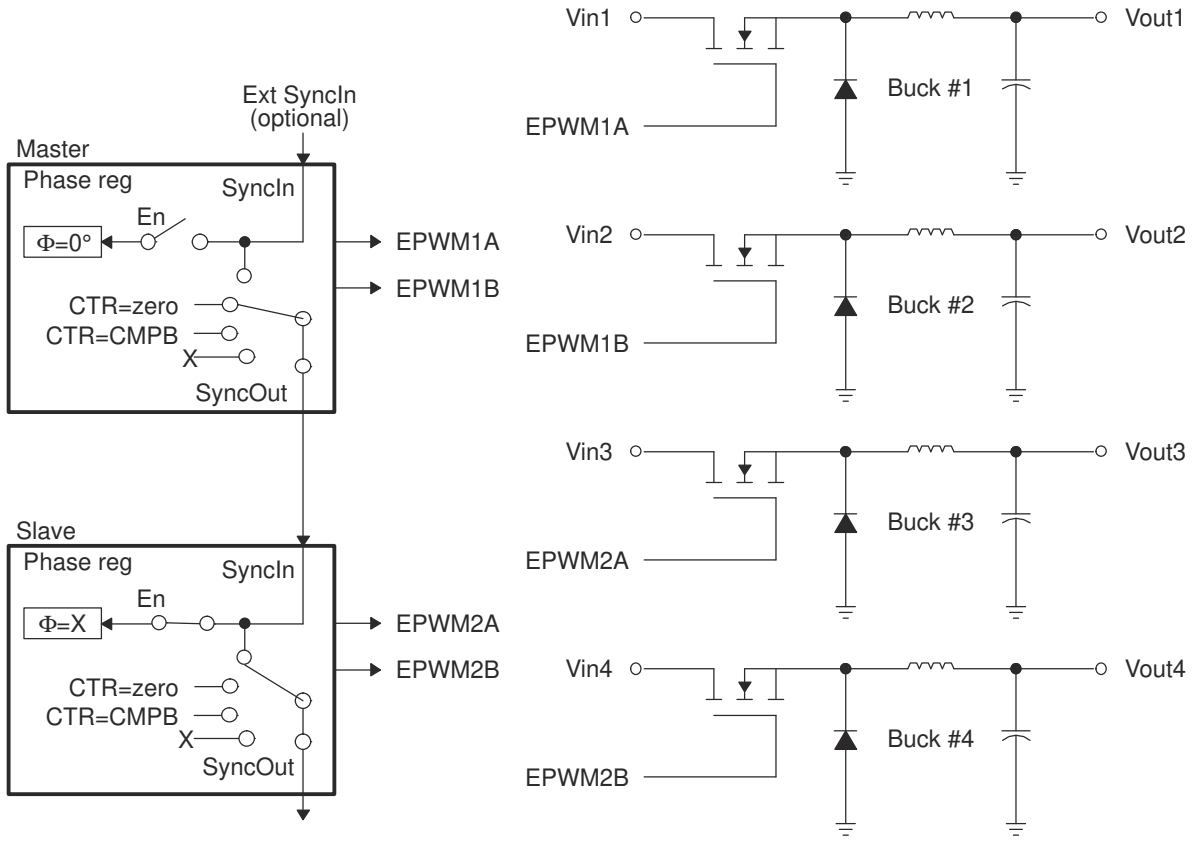
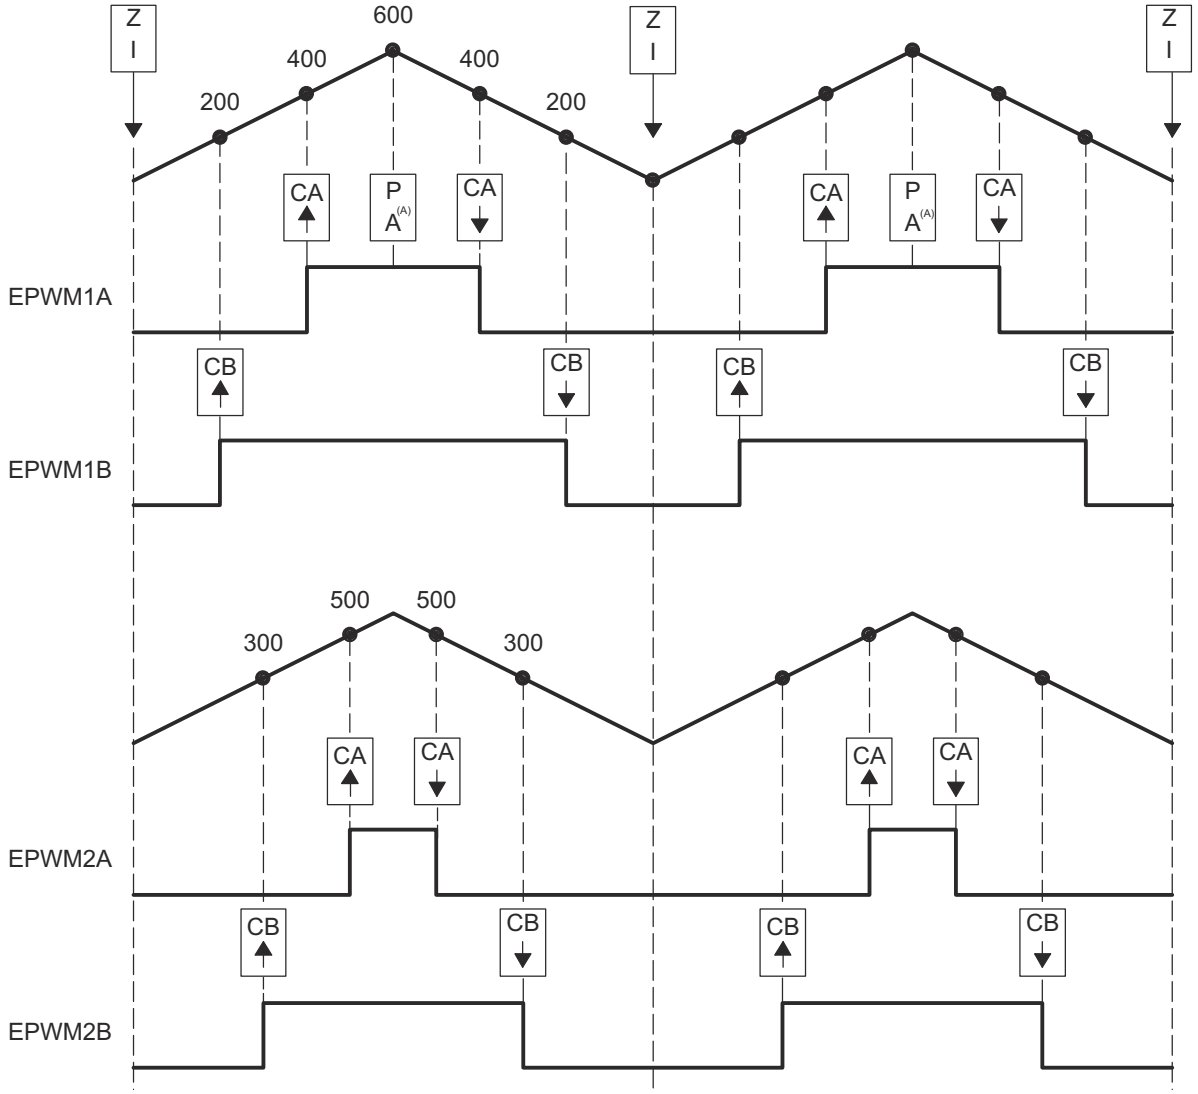
14.13.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 is configured as a slave and operates at integer multiple (N) frequencies of module 1. The sync signal from master to slave makes sure these modules remain locked. Figure 14-63 shows such a configuration; Figure 14-64 shows the waveforms generated by the configuration.



A. φ = X indicates value in phase register is a "don't care"

Figure 14-63. Control of Four Buck Stages. (Note: F_{PWM2} = N x F_{PWM1})



A. Starts ADC conversion.

Figure 14-64. Buck Waveforms for Control of Four Buck Stages (Note: $F_{PWM2} = F_{PWM1}$)

14.13.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 14-65 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 14-66 shows the waveforms generated by the configuration shown in Figure 14-65.

ePWM module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by ePWM module 3 and also, most importantly, to remain in synchronization with master ePWM module 1.

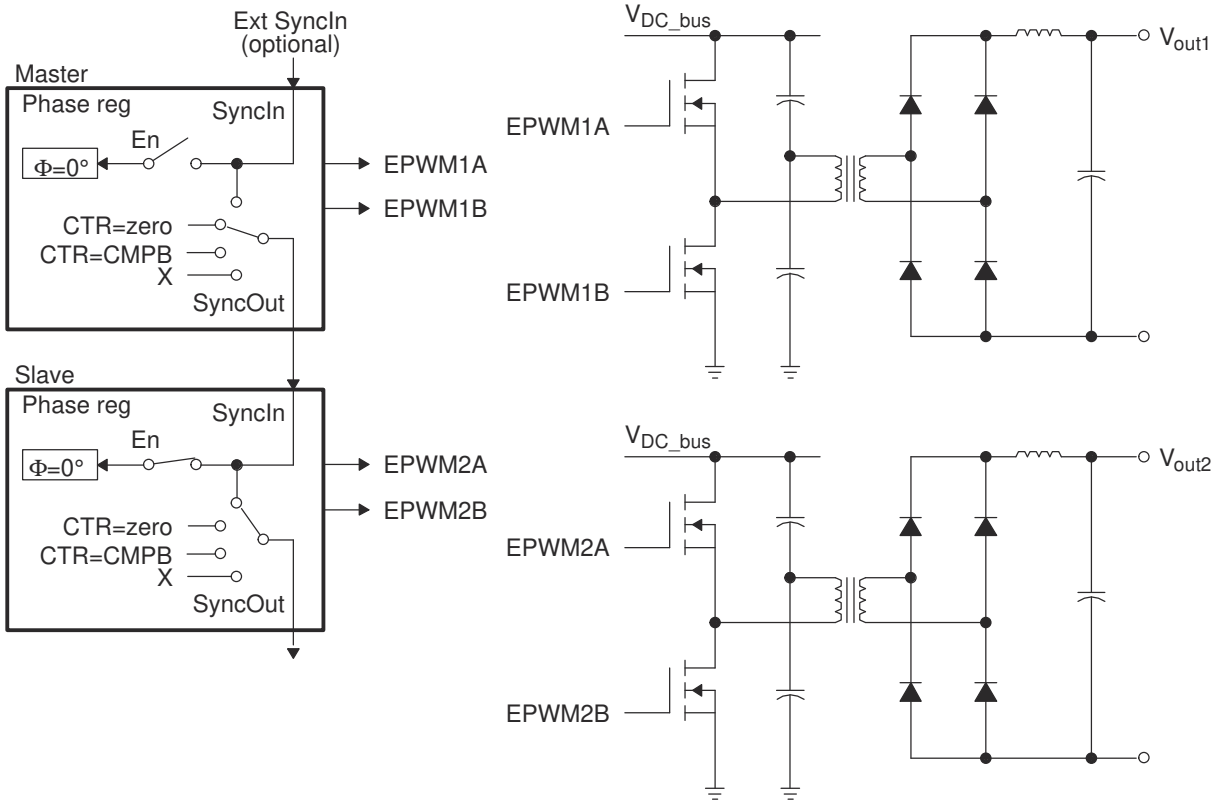


Figure 14-65. Control of Two Half-H Bridge Stages (F_{PWM2} = N x F_{PWM1})

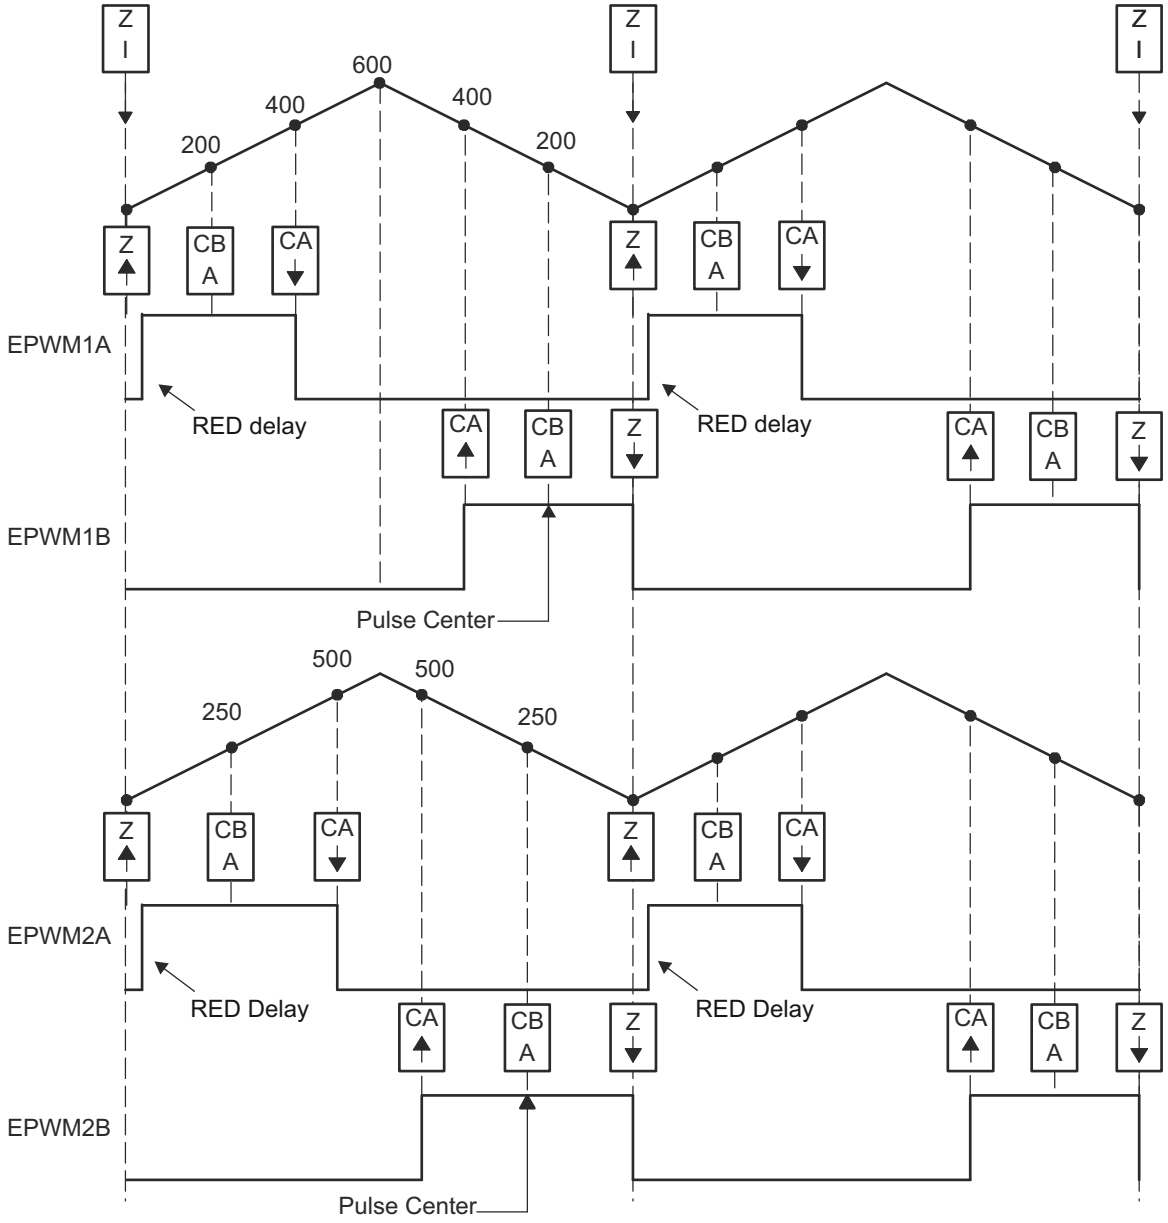

Figure 14-66. Half-H Bridge Waveforms for Control of Two Half-H Bridge Stages (Note: Here $F_{PWM2} = F_{PWM1}$)

14.13.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase inverter case. In such a case, six switching elements are controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master slaves configuration easily addresses this requirement. Figure 14-67 shows how six PWM modules control two independent 3-phase inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 14-67), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, and 3 (also all equal).

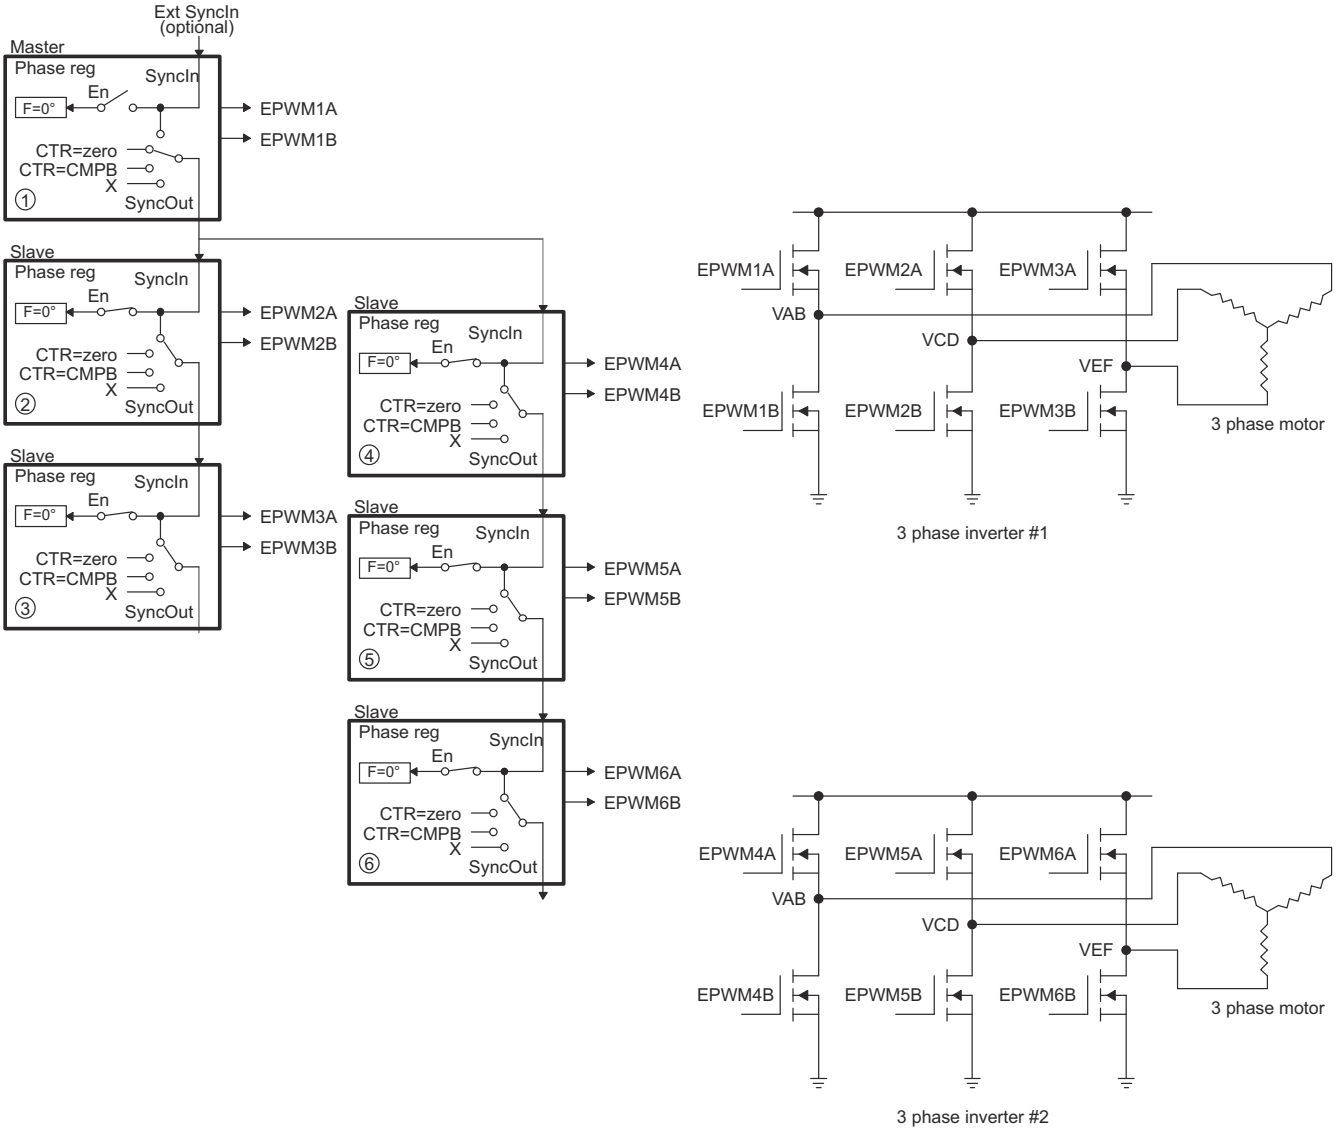

Figure 14-67. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control

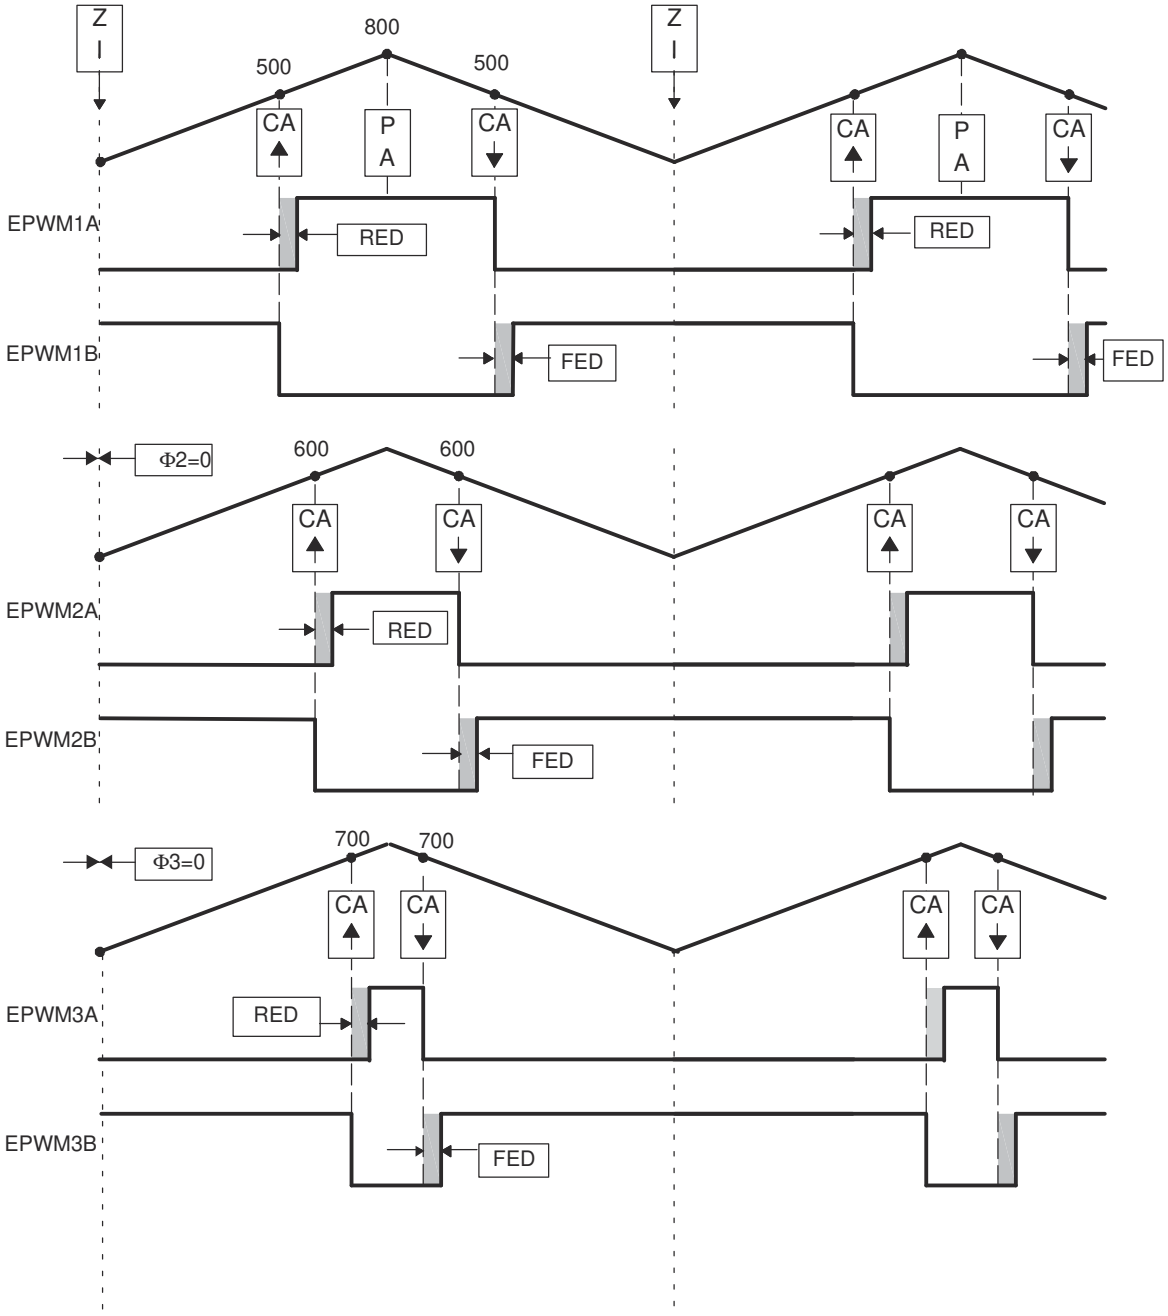

Figure 14-68. 3-Phase Inverter Waveforms for Control of Dual 3-Phase Inverter Stages (Only One Inverter Shown)

14.13.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of power topologies that rely on phase relationship between legs (or stages) for correct operation. As described in the time-base submodule section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, Figure 14-69 shows a master and slave module with a phase relationship of 120° (that is, the slave leads the master).

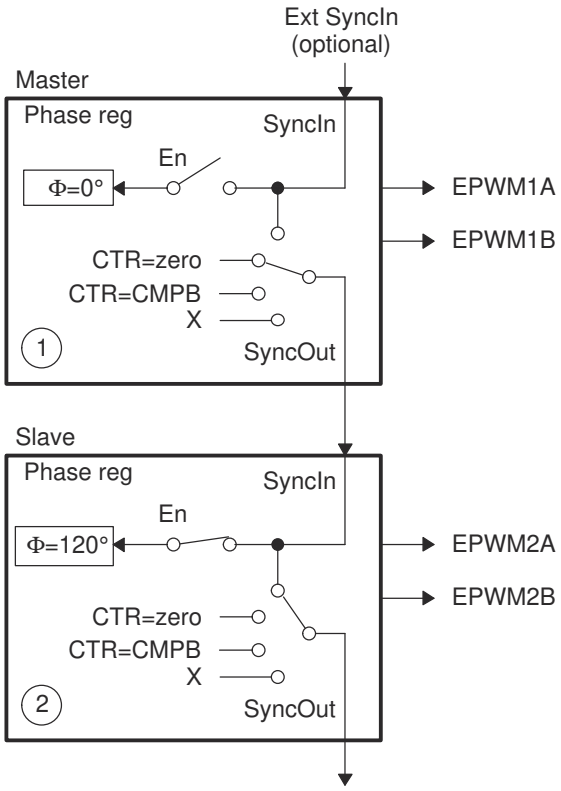

Figure 14-69. Configuring Two PWM Modules for Phase Control

Figure 14-70 shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (that is, 200/600 x 360° = 120°). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCTR register so the slave time-base is always leading the master time-base by 120°.

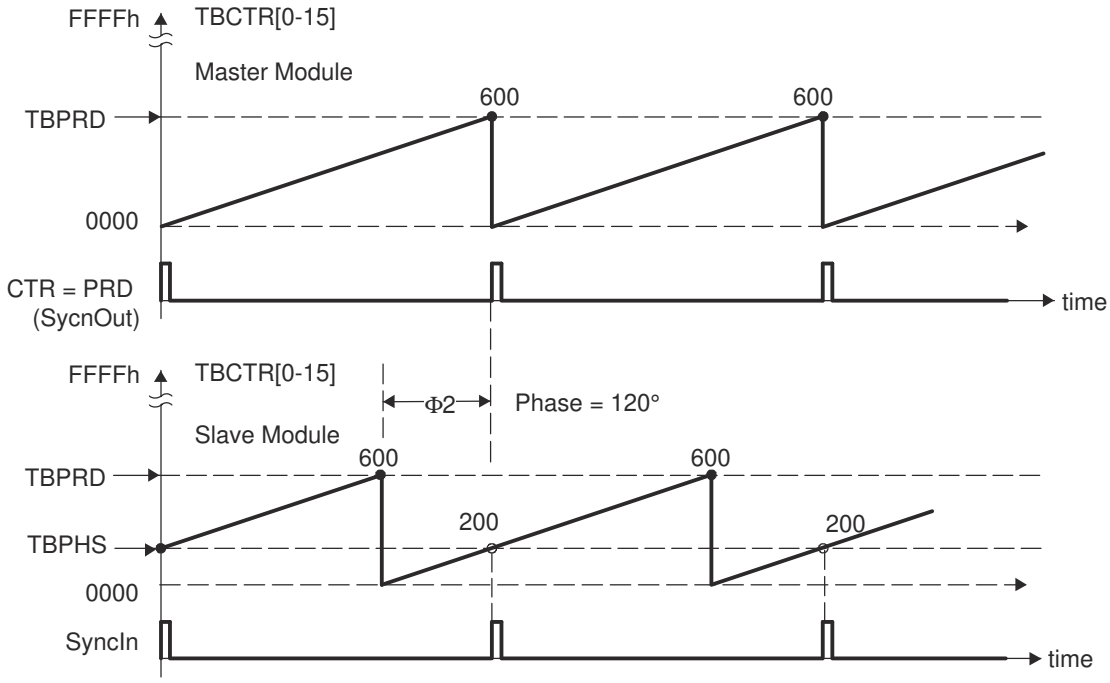

Figure 14-70. Timing Waveforms Associated with Phase Control Between Two Modules

14.13.8 Controlling a 3-Phase Interleaved DC/DC Converter

A popular power topology that makes use of phase-offset between modules is shown in Figure 14-71. This system uses three PWM modules, with module 1 configured as the master. To work, the phase relationship between adjacent modules must be F = 120°. This is achieved by setting the slave TBPHS registers 2 and 3 with values of 1/3 and 2/3 of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then TBPHS (slave 2) = 200 and TBPHS (slave 3) = 400. Both slave modules are synchronized to the master module 1.

This concept can be extended to four or more phases, by setting the TBPHS values appropriately. The following formula gives the TBPHS values for N phases:

TBPHS(N,M) = (TBPRD/N) x (M-1)

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N=3), TBPRD = 600,

TBPHS(3,2) = (600/3) x (2-1) = 200 (that is, Phase value for Slave module 2)

TBPHS(3,3) = 400 (that is, Phase value for Slave module 3)

Figure 14-72 shows the waveforms for the configuration in Figure 14-71.

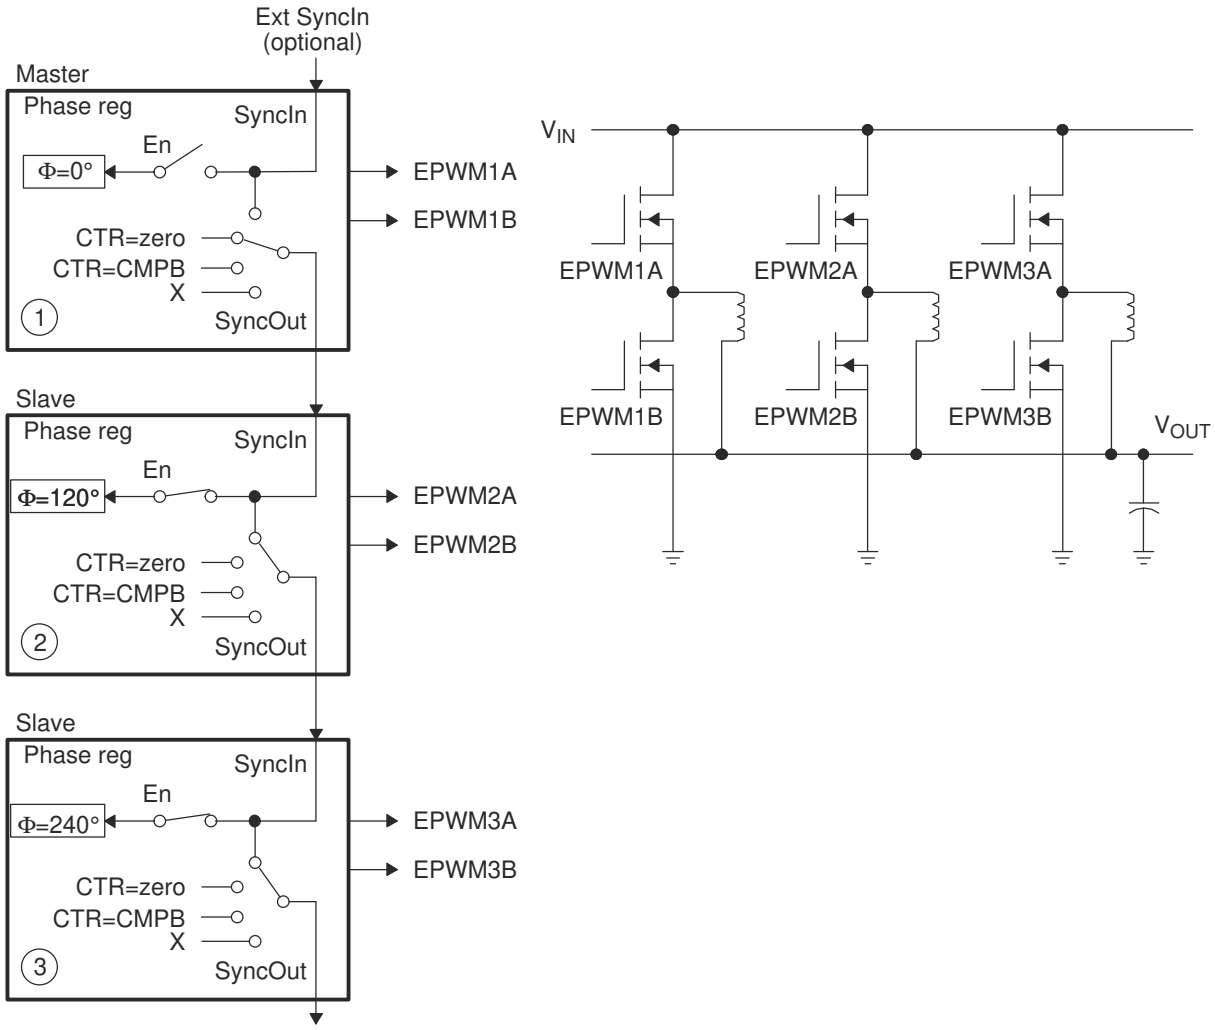

Figure 14-71. Control of 3-Phase Interleaved DC/DC Converter

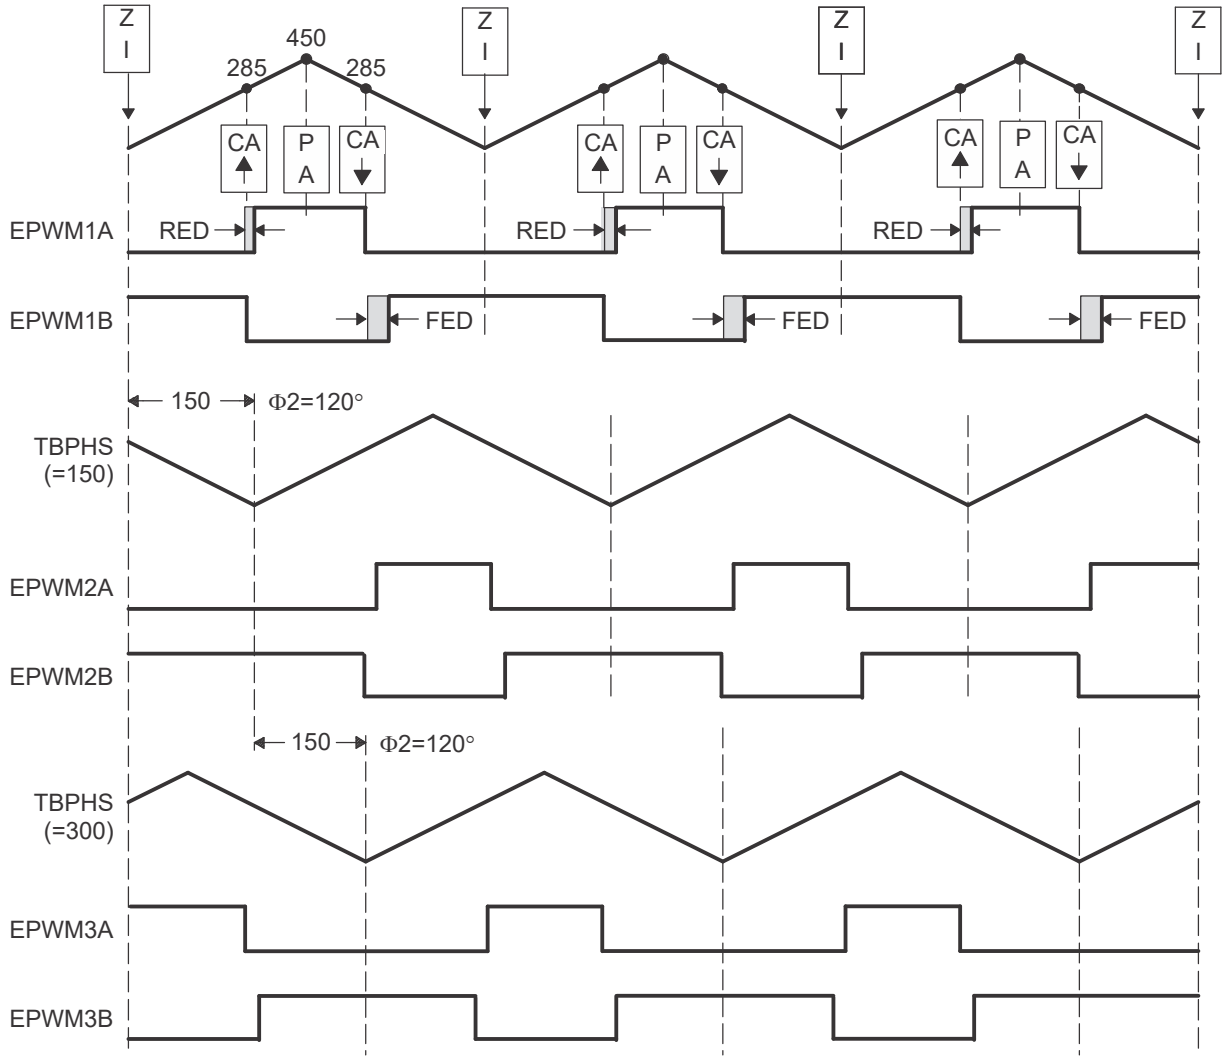

Figure 14-72. 3-Phase Interleaved DC/DC Converter Waveforms for Control of 3-Phase Interleaved DC/DC Converter

14.13.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in Figure 14-73 assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge.* Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. Figure 14-74 shows a master and slave module combination synchronized together to control a full H-bridge. In this case, both master and slave modules are required to switch at the same PWM frequency. The phase is controlled by using the slave phase register (TBPHS). The master phase register is not used and therefore can be initialized to zero.

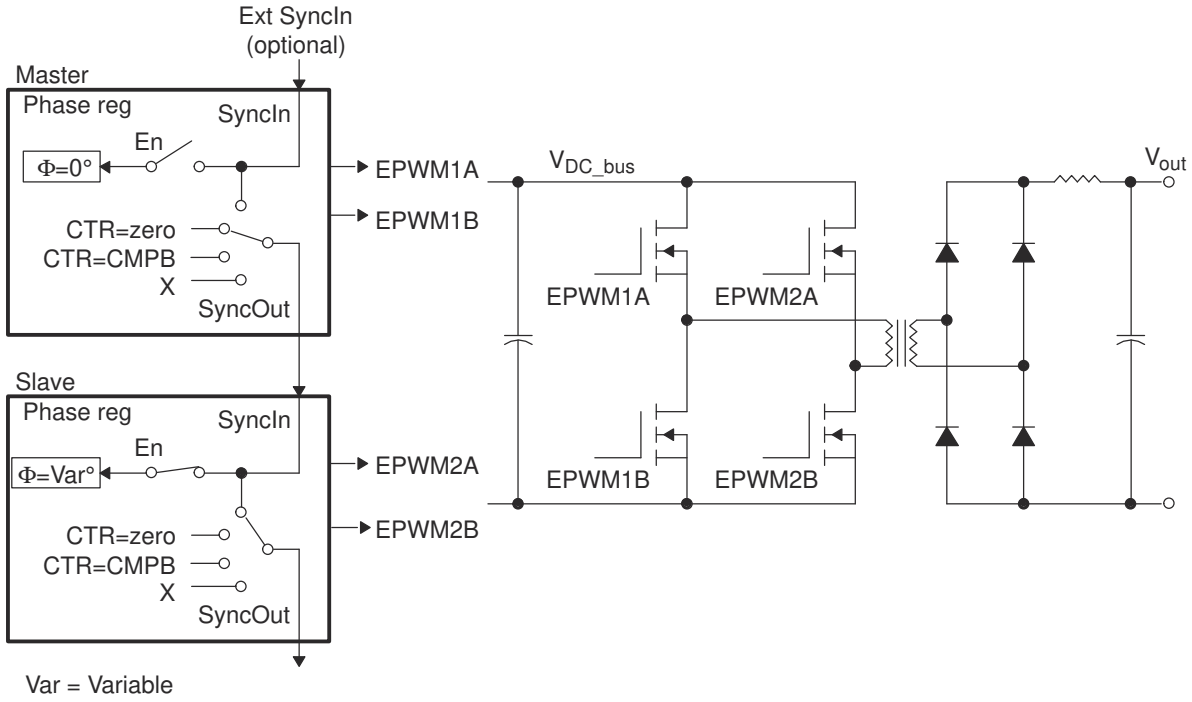

Figure 14-73. Control of Full-H Bridge Stage (F_{PWM2} = F_{PWM1})

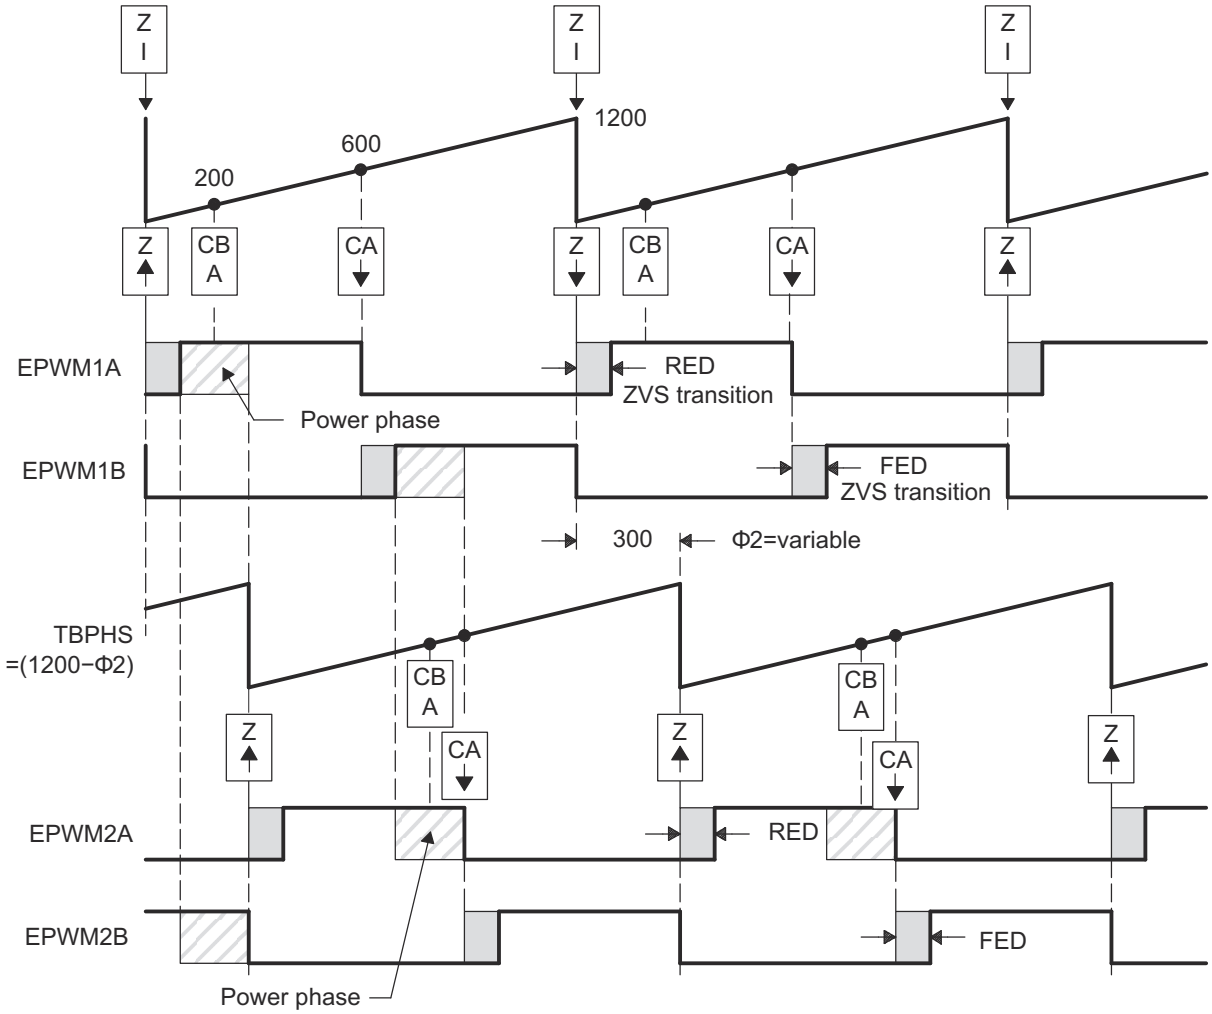

Figure 14-74. ZVS Full-H Bridge Waveforms

14.13.10 Controlling a Peak Current Mode Controlled Buck Module

Peak current control techniques offer a number of benefits like automatic over current limiting, fast correction for input voltage variations and reducing magnetic saturation. Figure 14-75 shows the use of ePWM1A along with the on-chip analog comparator for buck converter topology. The output current is sensed through a current sense resistor and fed to the positive terminal of the on-chip comparator. The internal programmable 12-bit DAC can be used to provide a reference peak current at the negative terminal of the comparator. Alternatively, an external reference can be connected at this input. The comparator output is an input to the Digital compare sub-module. The ePWM module is configured in such a way so as to trip the ePWM1A output as soon as the sensed current reaches the peak reference value. A cycle-by-cycle trip mechanism is used. Figure 14-76 shows the waveforms generated by the configuration.

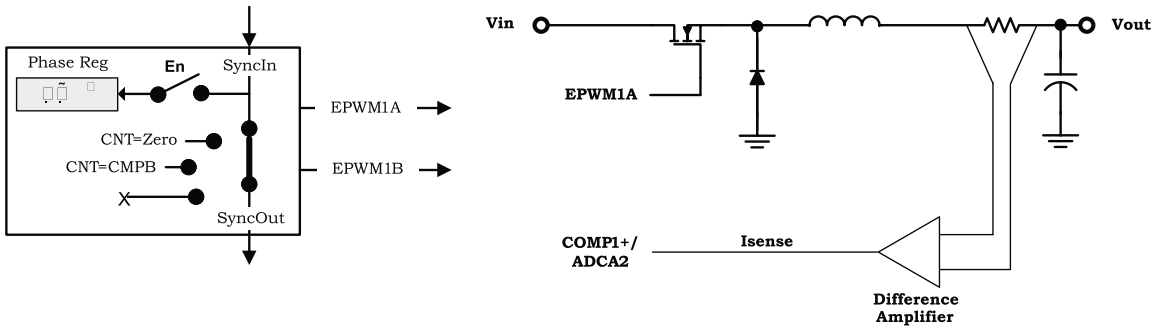

Figure 14-75. Peak Current Mode Control of Buck Converter

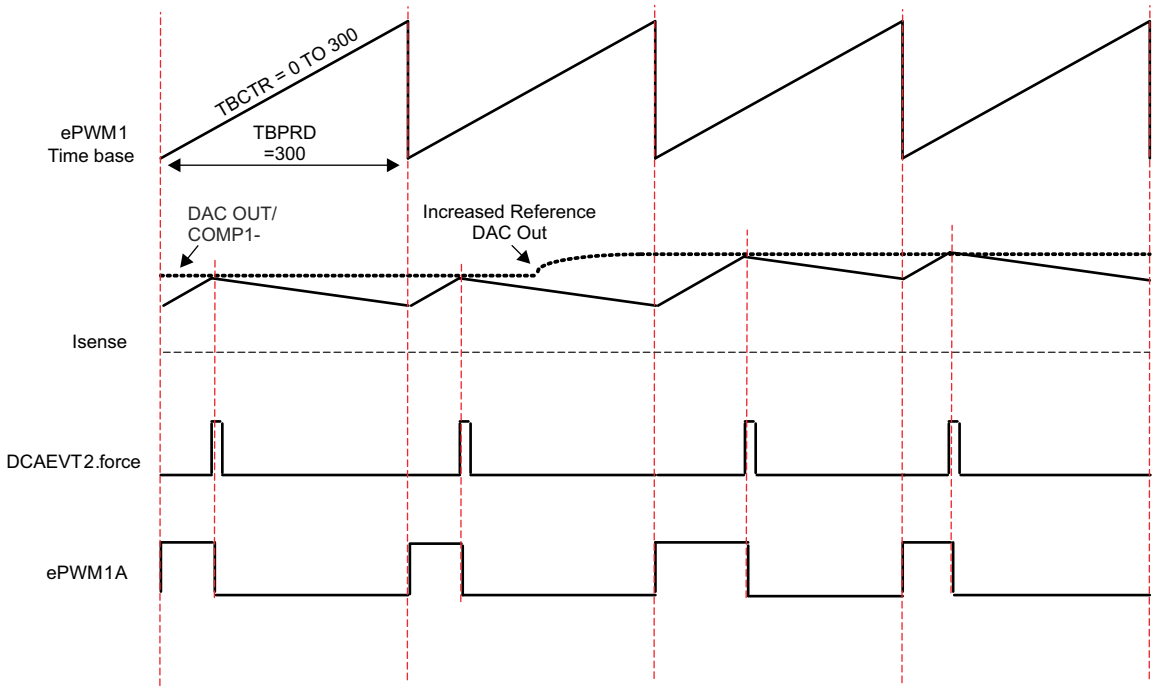

Figure 14-76. Peak Current Mode Control Waveforms for Control of Buck Converter

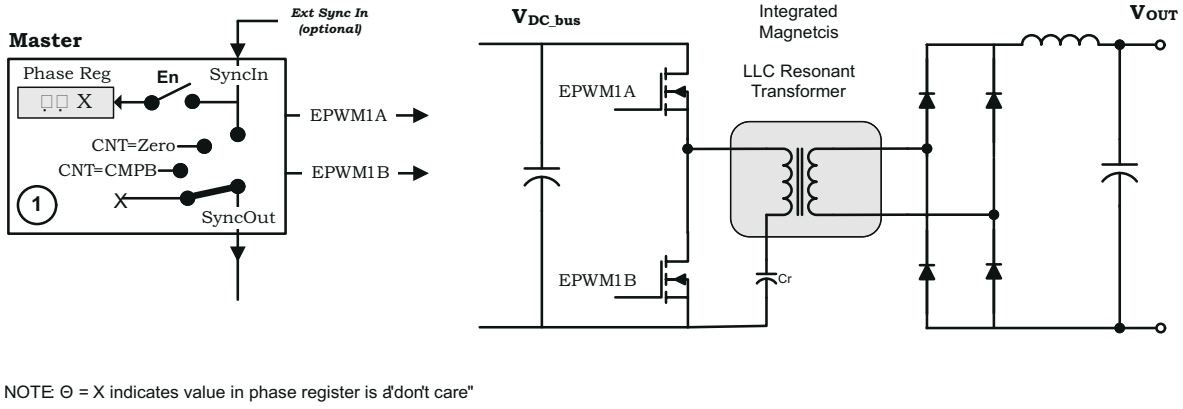
14.13.11 Controlling H-Bridge LLC Resonant Converter

Various topologies of resonant converters are well-known in the field of power electronics for many years. In addition to these, H-bridge LLC resonant converter topology has recently gained popularity in many consumer electronics applications where high efficiency and power density are required. In this example, single channel configuration of ePWM1 is detailed, yet the configuration can easily be extended to multichannel. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead the parameter is frequency. Although the deadband is not controlled and kept constant as 300ns (that is, 30 at 100MHz TBCLK), the user can update the deadband in real time to enhance the efficiency by adjusting enough time delay for soft switching.



NOTE: Θ = X indicates value in phase register is a "don't care"

Figure 14-77. Control of Two Resonant Converter Stages

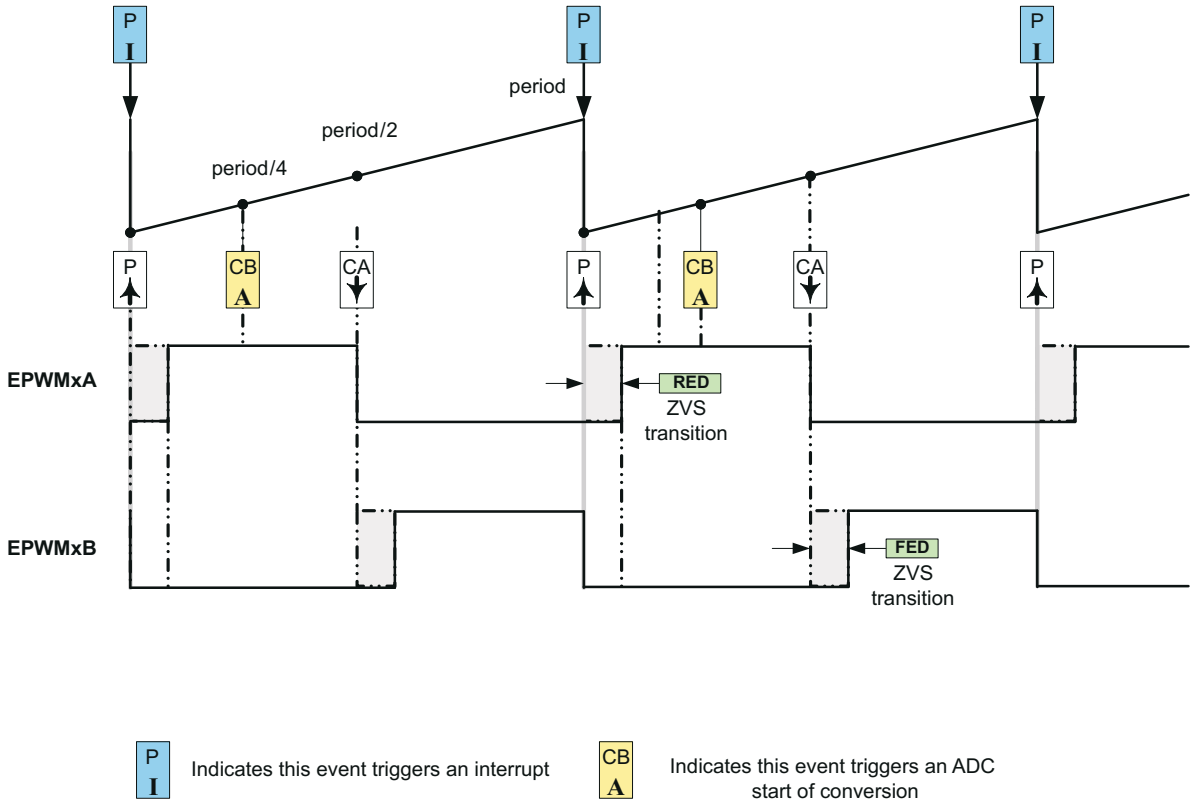


Figure 14-78. H-Bridge LLC Resonant Converter PWM Waveforms

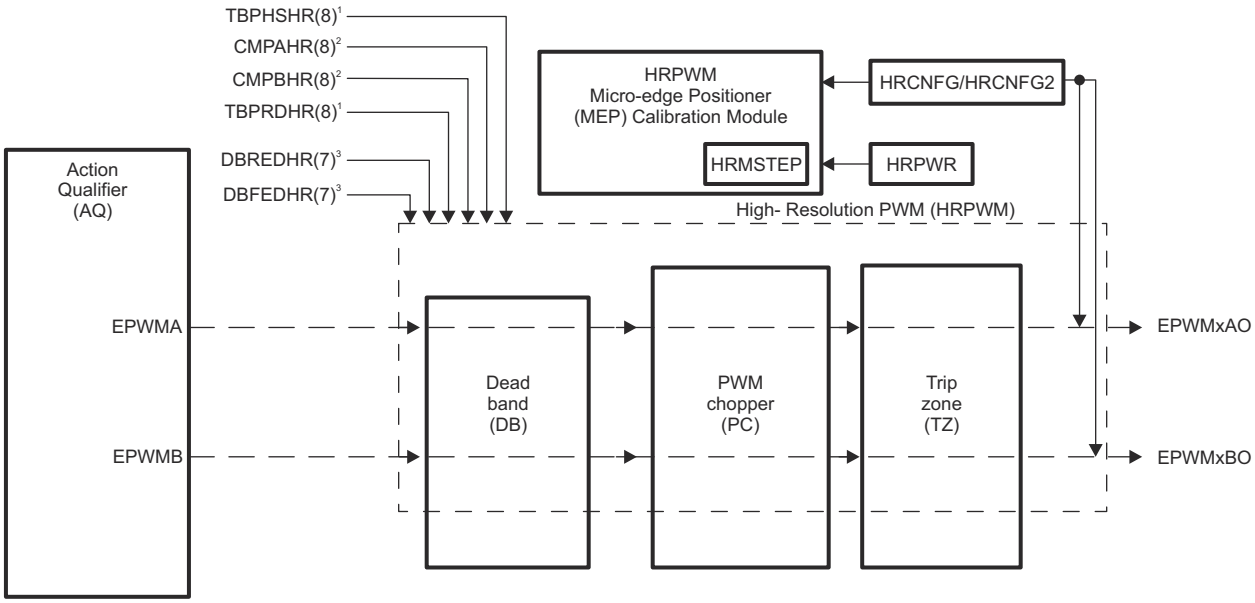
14.14 High-Resolution Pulse Width Modulator (HRPWM)

Figure 14-79 shows a block diagram of the HRPWM. This module extends the time resolution capabilities of the conventionally derived digital pulse width modulator (PWM). HRPWM is typically used when PWM resolution falls below approximately 9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A, Compare B and Phase registers
- Implemented using the A and B signal path of PWM, that is, on the EPWMxA and EPWMxB output
- Dead band high-resolution control for falling and rising edge delay in half cycle clocking operation
- Self-check diagnostics software mode to check if the micro edge positioner (MEP) logic is running how designed
- Enables high-resolution output swapping on the EPWMxA and EPWMxB output
- Enables high-resolution output on EPWMxB signal output using inversion of EPWMxA signal output
- Enables high-resolution period, duty and phase control on the EPWMxA and EPWMxB output on devices with an ePWM module

Note

See the device data sheet to determine if your device has an ePWM module with high-resolution period support.



A. From ePWM Time-base (TB) submodule
B. From ePWM counter-compare (CC) submodule
C. From ePWM Deadband (DB) submodule

Figure 14-79. HRPWM Block Diagram

The ePWM peripheral is used to perform a function mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 14-80, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

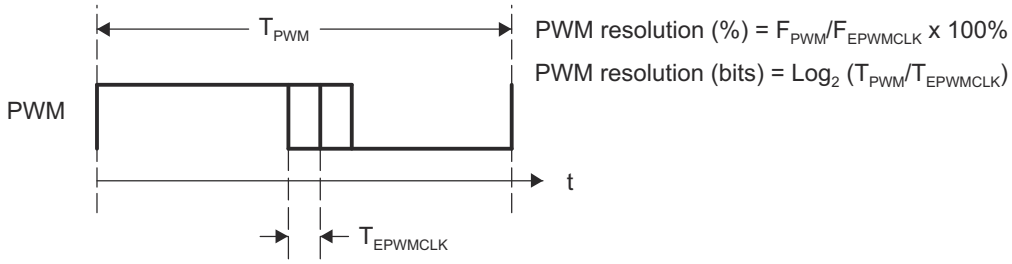


Figure 14-80. Resolution Calculations for Conventionally Generated PWM

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, consider using HRPWM. As an example of improved performance offered by HRPWM, Table 14-13 shows resolution in bits for various PWM frequencies. These values assume a MEP step size of 180ps. See the device data sheet for typical and maximum performance specifications for the MEP.

Table 14-13. Resolution for PWM and HRPWM

PWM Frequency (kHz)	Regular Resolution (PWM) 100MHz EPWMCLK		High Resolution (HRPWM)	
	Bits	%	Bits	%
20	12.3	0.02	18.1	0.000
50	11	0.05	16.8	0.001
100	10	0.1	15.8	0.002
150	9.4	0.15	15.2	0.003
200	9	0.2	14.8	0.004
250	8.6	0.25	14.4	0.005
500	7.6	0.5	13.4	0.009
1000	6.6	1	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2	11.4	0.036

Although each application can differ, typical low-frequency PWM operation (below 250kHz) does not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multiphase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

14.14.1 Operational Description of HRPWM

The HRPWM is based on micro-edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150ps. See the device data sheet for the typical MEP step size on a particular device. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running as designed under all operating conditions. Details on software diagnostics and functions are in Section 14.14.1.7.

Figure 14-81 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled using an 8-bit field in the Compare A extension register (CMPAHR). The same operating logic applies to CMPBHR as well.

To generate an HRPWM waveform, configure the ePWM registers to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the ePWM registers to extend edge resolution. Although many programming combinations are possible, only a few are needed and practical. These methods are described in Section 14.14.1.8.

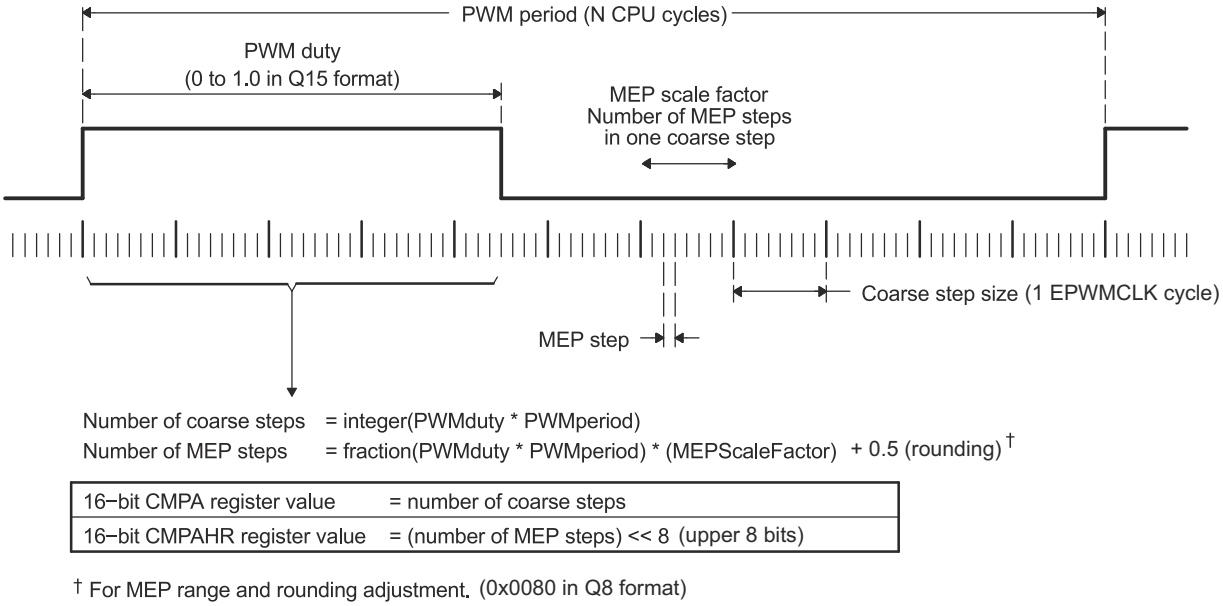

Figure 14-81. Operating Logic Using MEP

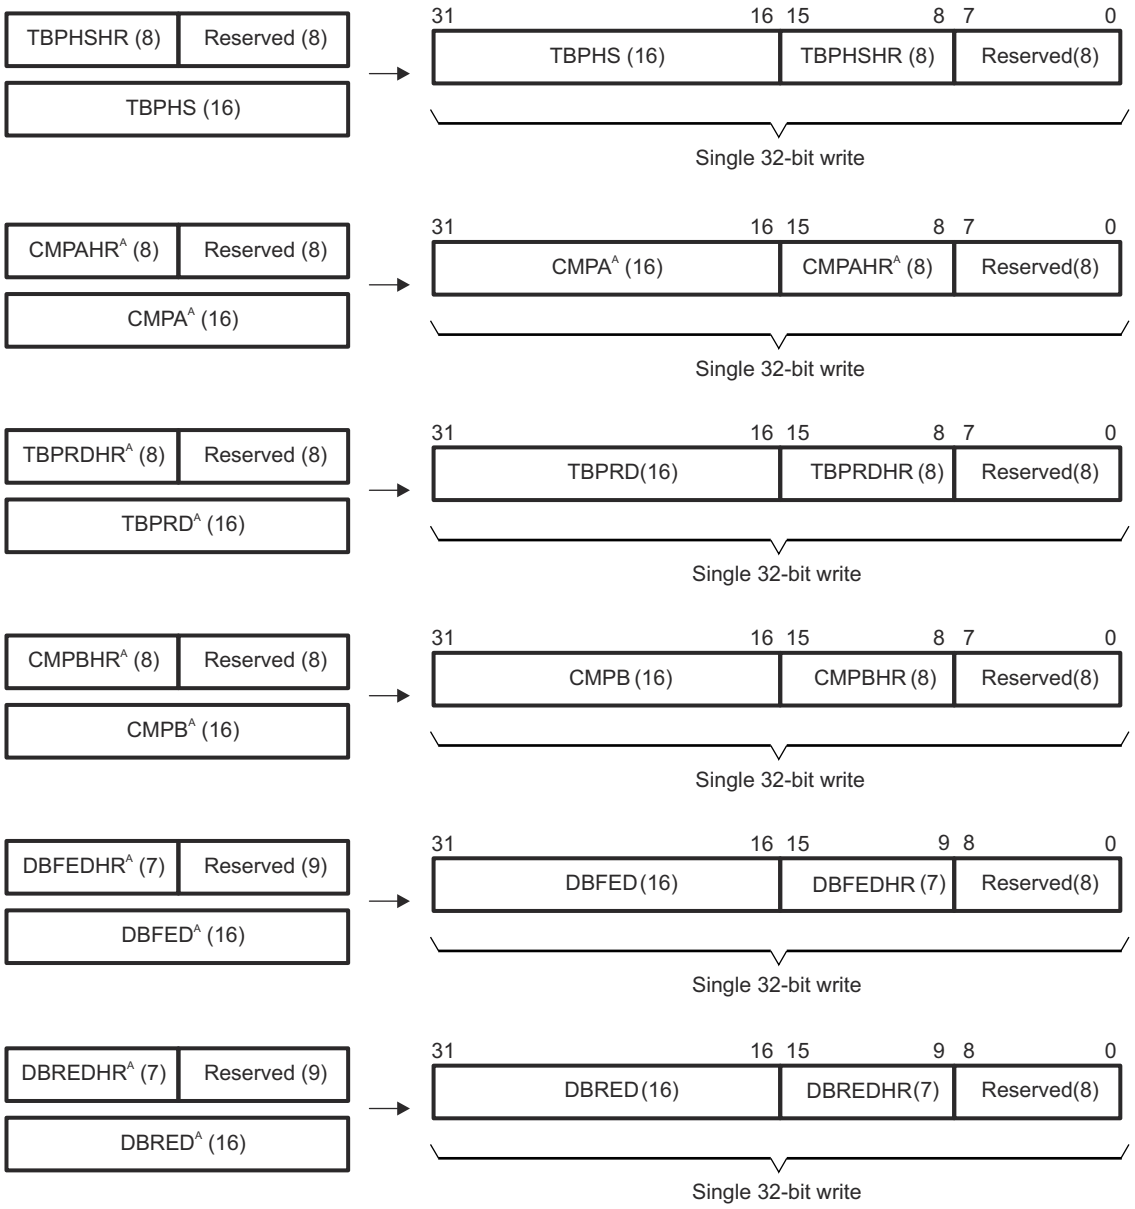
14.14.1.1 Controlling the HRPWM Capabilities

The MEP of the HRPWM is controlled by six extension registers. These HRPWM registers are concatenated with the 16-bit TBPHS, TBPRD, CMPA, CMPBM, DBREDM, and DBFEDM registers used to control PWM operation.

- TBPHSHR - Time Base Phase High Resolution Register
- CMPAHR - Counter Compare A High Resolution Register; CMPAHR is for use with the AQ output of Channel A, and is not related to CMPA
- TBPRDHR - Time Base Period High Resolution Register. (available on some devices)
- CMPBHR - Counter Compare B High Resolution Register; CMPBHR is for use with the AQ output of Channel B, and is not related to CMPB
- DBREDHR - Dead-band Generator Rising Edge Delay High Resolution Register
- DBFEDHR - Dead-band Generator Falling Edge Delay High Resolution Register



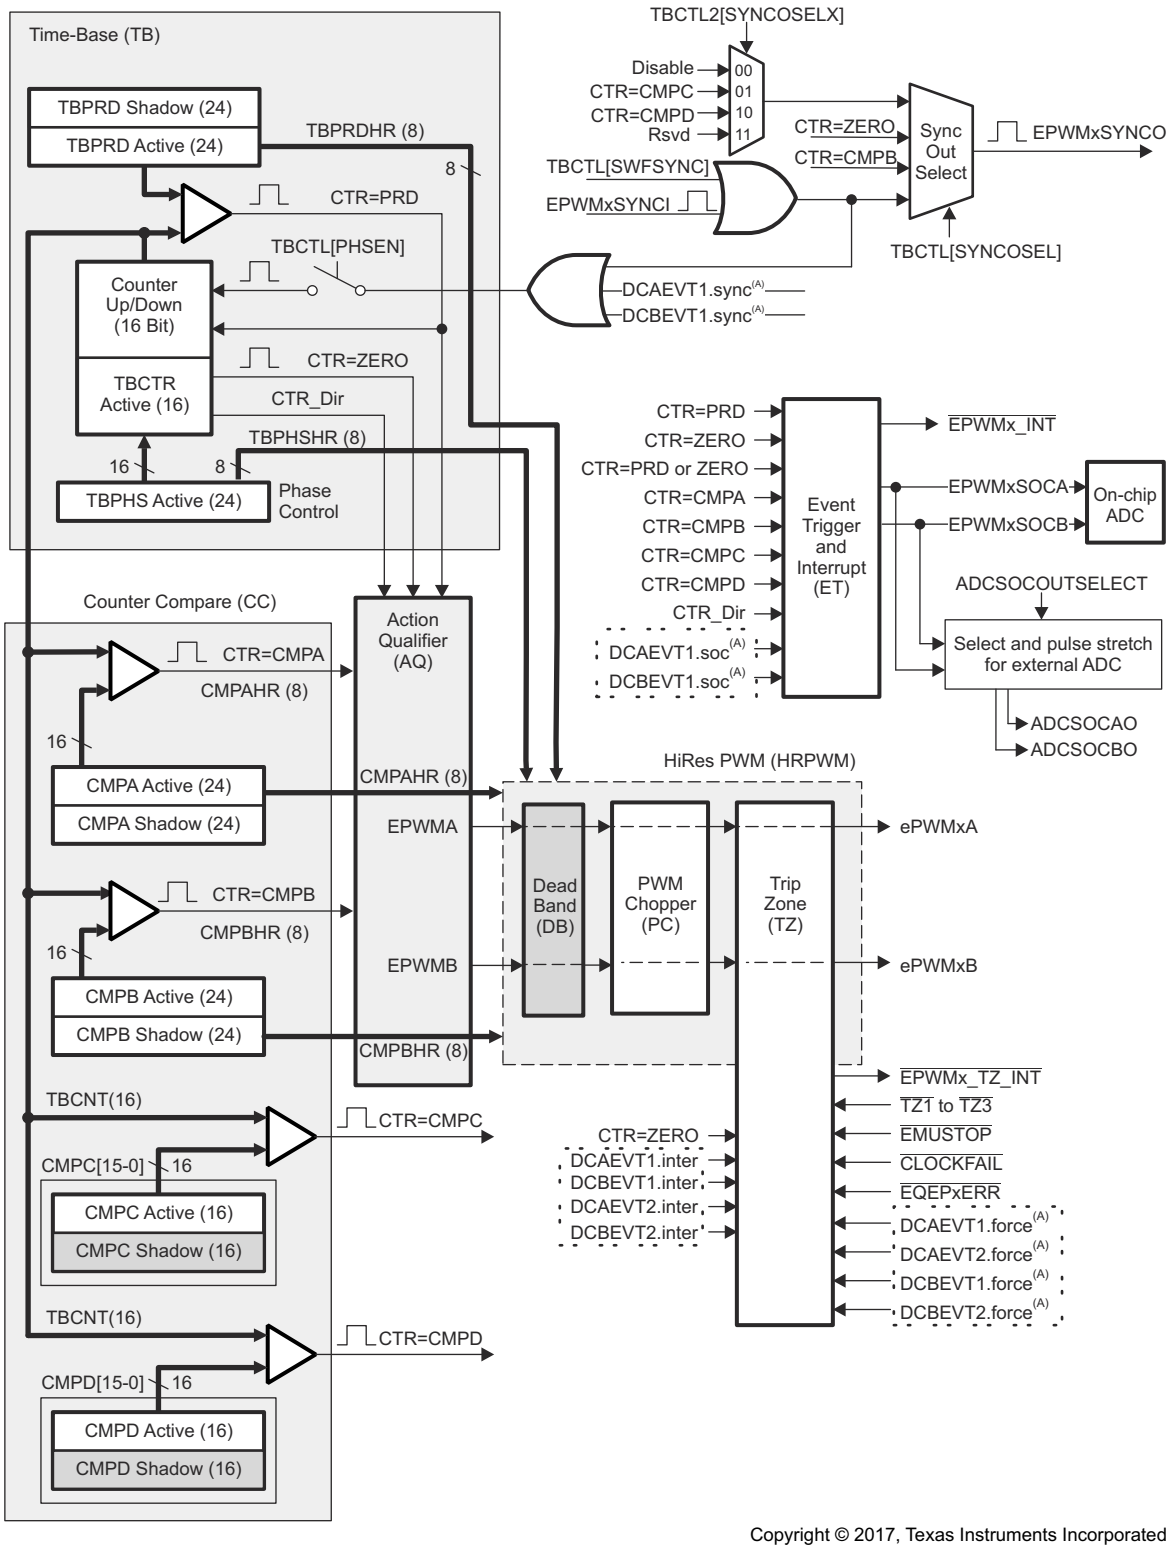
A. Dependent upon your device, these registers can be mirrored and can be written to at two different memory locations.

Figure 14-82. HRPWM Extension Registers and Memory Configuration

Note

HRPWM capabilities on Deadband Rising Edge Delay and Falling Edge Delay is applicable only during dead band half cycle clocking Operation. The number of MEP steps is half in size [bits 15:9] than duty and phase high-resolution registers for the same reason.

HRPWM capabilities are controlled using the Channel A and B PWM signal path. HRPWM support on the Dead band signal path is available by properly configuring the HRCNFG2 register. Figure 14-83 shows how the HRPWM interfaces with the 8-bit extension registers.



A. These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

Figure 14-83. HRPWM System Interface

14.14.1.2 HRPWM Source Clock

The HRPWM module and HRCAL module are clocked from the EPWM1CLK. Therefore, EPWM1CLK must be enabled for the HRCAL or any of the HRPWM modules to be enabled. Figure 14-84 shows the HRCAL and HRPWM modules sourced from the ePWM1 clock source.

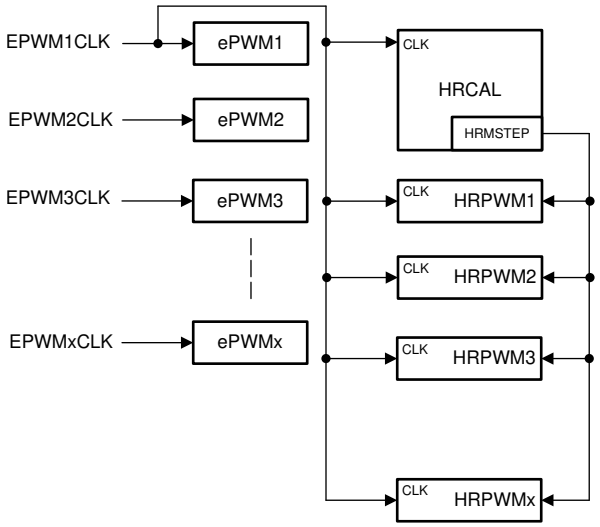


Figure 14-84. HRPWM and HRCAL Source Clock

14.14.1.3 Configuring the HRPWM

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register in that particular ePWM module's register space. This register provides the following configuration options:

Edge Mode	The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE) or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control (CMPA or CMPB high-resolution control), while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge (TBPHS or TBPRD high-resolution control).
Control Mode	The MEP is programmed to be controlled either from the CMPAHR/CMPBHR register in case of duty cycle control or the TBPHSHR register (phase control). RE or FE control mode can be used with the CMPAHR or CMPBHR register. BE control mode can be used with the TBPHSHR register. When the MEP is controlled from the TBPRDHR register (period control), the duty cycle and phase can also be controlled using their respective high-resolution registers.
Shadow Mode	This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR, CMPBHR, and TBPRDHR registers and can be chosen to be the same as the regular load option for the CMPA/CMPB register. If TBPHSHR is used, then this option has no effect.
High-Resolution B Signal Control	The B signal path of an ePWM channel can generate a high-resolution output by outputting an inverted version of the high-resolution ePWMxA signal on the ePWMxB pin. A Type 2 or Type 4 HRPWM module can also enable high-resolution features on the B signal path independently of the A signal path as well.
Swap ePWMxA and ePWMxB Outputs	This mode enables the swapping of the high-resolution A and B outputs. The mode selection allows either A and B Outputs Unchanged or A Output Comes Out On B and B Output Comes Out On A.

Auto-conversion Mode

This mode is used in conjunction with the scale factor optimization (SFO) software only. For a type 4 HRPWM module, below is a description of the Auto-conversion Mode taking CMPAHR as an example. If auto-conversion is enabled, CMPAHR = fraction(PWMduty*PWMperiod)<<8. The scale factor optimization software calculates the MEP scale factor in the background code and automatically updates the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module then uses the values in the HRMSTEP and CMPAHR registers to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle and moves the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, the CMPAHR register behaves like a type 0 HRPWM module and CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor + 0.5)<<8). All calculations need to be performed by your code in this mode, and the HRMSTEP register is ignored. Auto-conversion for high-resolution period has the same behavior as auto-conversion for high-resolution duty cycle. Auto-conversion must always be enabled for high-resolution period mode.

Note

If the HRPWM module is configured in UP-DOWN counter mode, the shadow mode for the HRPWM registers must be set to load on both ZERO AND PERIOD. New values from the user are loaded to the shadow registers only at CTR=ZERO, but the shadow mode of for the registers must be set to both ZERO AND PERIOD. The CTR=PRD event is used for specific internal logic inside the HRPWM module.

Auto-conversion Mode performs the calculation for CMPBHR , DBREDHR, and DBFEDHR. The scale factor optimization software calculates the MEP scale factor in the background code and automatically updates the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module then uses the values in the HRMSTEP and CMPBHR or DBREDHR/DBFEDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional components and moves the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, CMPBHR behaves the same as CMPAHR. CMPBHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor + 0.5)<<8).

14.14.1.4 Configuring High-Resolution in Deadband Rising-Edge and Falling-Edge Delay

Once the ePWM has been configured to provide conventional PWM of a given frequency, polarity, and dead band enabled in half-cycle clocking mode, the high-resolution operation on dead band RED and FED lines are enabled by programming the HRCNFG2 register in that particular ePWM module register space. This register provides the following configuration options:

Edge Mode The MEP can be programmed to provide precise position control on the dead band rising edge (RED), dead band falling edge (FED), or both edges (rising edge of DBRED signal and falling edge of DBFED signal) at the same time.

Control Mode Selects the time event that loads the shadow value in the active register for DBRED and DBFED in high-resolution mode. Select the pulse to match the selection in the ePWM DBCTL[LOADREDMODE] and DBCTL[LOADFEDMODE] bits.

14.14.1.5 Principle of Operation

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps (see the device data sheet for typical MEP step size). The MEP works with the TBM and CCM registers to be certain that time steps are applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies, and other operating conditions. Table 14-14 shows the typical range of operating frequencies supported by the HRPWM.

Table 14-14. Relationship Between MEP Steps, PWM Frequency, and Resolution

System (MHz)	MEP Steps Per EPWMCLK (1) (2) (3)	PWM Minimum (Hz) (4)	PWM Maximum (MHz)	Resolution at Maximum (Bits) (5)
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

(1) TBCLK = EPWMCLK.
(2) Table data based on a MEP time resolution of 180ps (this is an example value. See the device data sheet for MEP limits)
(3) MEP steps applied = $T_{EPWMCLK}$/180ps in this example.
(4) PWM minimum frequency is based on a maximum period value,(TBPRD = 65535). PWM mode is asymmetrical up-count.
(5) Resolution in bits is given for the maximum PWM frequency stated.

14.14.1.5.1 Edge Positioning

Note

The following example is presented using the [CMPA:CMPAHR] register combination. The theory of operation and equations are the same, if intending to use the [CMPBM:CMPBHRM] for duty cycle control.

In a typical power control loop, a digital controller issues a duty command, usually expressed in a per unit or percentage terms. Assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on time and the required converter PWM frequency is 1.25MHz. In conventional PWM generation with a system clock of 100MHz, the duty cycle choices are in the vicinity of 40.5%. As shown in Figure 14-85, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that can be attained. This is equivalent to an edge position of 320ns instead of the desired 324ns. This data is shown in Table 14-15.

By utilizing the MEP, an edge position much closer to the desired point of 324ns can be achieved. Table 14-15 shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) positions the edge at 323.96ns, resulting in almost zero error. In this example, assume that the MEP has a step resolution of 180ps.

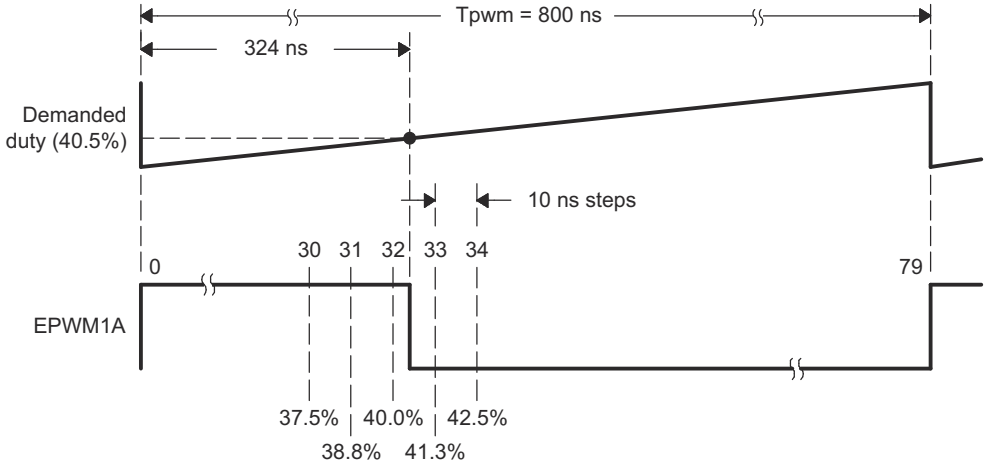

Figure 14-85. Required PWM Waveform for a Requested Duty = 40.5%

Table 14-15. CMPA versus Duty (left), and [CMPA:CMPAHR] versus Duty (right)

CMPA (count)(1) (2) (3)	Duty (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	***35.0***	280	32	18	***40.405***	323.24
29	***36.3***	290	32	19	***40.428***	323.42
30	***37.5***	300	32	20	***40.450***	323.60
31	***38.8***	310	32	21	***40.473***	323.78
32	***40.0***	320	32	22	***40.495***	323.96
33	***41.3***	330	32	23	***40.518***	324.14
34	***42.5***	340	32	24	***40.540***	324.32
			32	25	***40.563***	324.50
Required			32	26	***40.585***	324.68
32.40	***40.5***	324	32	27	***40.608***	324.86

(1) Assumed MEP step size for the above example = 180ps. See the device-specific data sheet for typical and maximum MEP values.
(2) TBCLK = 100MHz, 10ns
(3) For a PWM Period register value of 80 counts, PWM Period = 80 × 10ns = 800ns, PWM frequency = 1/800ns = 1.25MHz

14.14.1.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard CMPA and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in nanoseconds (ns). Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

TBCLK	=	10ns (100MHz)
PWM frequency	=	1.25MHz (1/800ns)
Required PWM duty cycle, **PWMDuty**	=	0.405 (40.5%)
PWM period in terms of coarse steps, **PWMPeriod** (800ns/10ns)	=	80
Number of MEP steps per coarse step at 180ps (10ns/180ps), **MEP_ScaleFactor**	=	55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	=	0.5 (0080h in Q8 format)

Step 1: Percentage Integer Duty value conversion for CMPA register

CMPA register value	=	int(**PWMDuty***PWMPeriod**); int means integer part
	=	int(0.405 * 80)
	=	int(32.4)
CMPA register value	=	32 (20h)

Step 2: Fractional value conversion for CMPAHR register

CMPAHR	=	(frac(**PWMDuty***PWMPeriod**)*MEP_ScaleFactor** + 0.5) <<8); frac means fractional part
	=	(frac(32.4) * 55 + 0.5) <<8; Shifting is to move the value to the high byte of CMPAHR.
	=	(0.4 * 55 + 0.5) <<8
	=	(22 + 0.5) <<8
	=	22.5 * 256; Shifting left by 8 is the same as multiplying by 256.
	=	5760 (1680h)
CMPAHR	=	1680h CMPAHR value = 1600h (lower 8 bits are ignored by hardware).

Note

If the AUTOCONV bit (HRCNFG.6) is set and the MEP_ScaleFactor is in the HRMSTEP register, then CMPAHR / CMPBHR register value = frac (PWMDuty*PWMperiod<<8). The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

The MEP scale factor (MEP_ScaleFactor) varies with the system clock and DSP operating conditions. TI provides an MEP scale factor optimizing (SFO) software C function, which uses the built in diagnostics in each HRPWM and returns the best scale factor for a given operating point.

The scale factor varies slowly over a limited range so the optimizing C function can be run very slowly in a background loop.

The CMPA, CMPB, CMPAHR and CMPBHR registers are configured in memory so that the 32-bit data capability of the CPU can write this as a single concatenated value, that is, [CMPA:CMPAHR], [CMPB:CMPBHR], and so on.

The mapping scheme has been implemented in both C and assembly, as shown in Section 14.14.1.8. The actual implementation takes advantage of the 32-bit CPU architecture and is somewhat different from the steps shown in Section 14.14.1.5.2.

For time-critical control loops where every cycle counts, the assembly version is recommended. This is a cycle optimized function (11 EPWMCLK cycles) that takes a Q15 duty value as input and writes a single [CMPA:CMPAHR] value.

14.14.1.5.3 Duty Cycle Range Limitation

In high-resolution mode, the MEP is not active for 100% of the PWM period and becomes operational:

- Three EPWMCLK cycles after the period starts when high-resolution period (TBPRDHR) control is not enabled.
- When high-resolution period (TBPRDHR) control is enabled using the HRPCTL register:
  - In up-count mode: three EPWMCLK cycles after the period starts until three EPWMCLK cycles before the period ends.
  - In up-down count mode: when counting up, three cycles after CTR = 0 until three cycles before CTR = PRD, and when counting down, three cycles after CTR = PRD until three cycles before CTR = 0.
- When using DBREDHR or DBFEDHR, DBRED or DBFED (the register corresponding to the edge with high-resolution displacement) must be greater than or equal to 7.

Duty cycle range limitations are illustrated in Figure 14-86 to Figure 14-89. This limitation imposes a duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. When high-resolution period control is disabled, regular PWM duty control is fully operational down to 0% duty cycle despite the unavailability of HRPWM features in the first three cycles. In most applications, this cannot be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle. To better understand the useable duty cycle range, see Table 14-16. When high-resolution period control is enabled (HRPCTL[HRPE] = 1), the duty cycle must not fall within the restricted range; otherwise, there can be undefined behavior on the ePWMxA output.

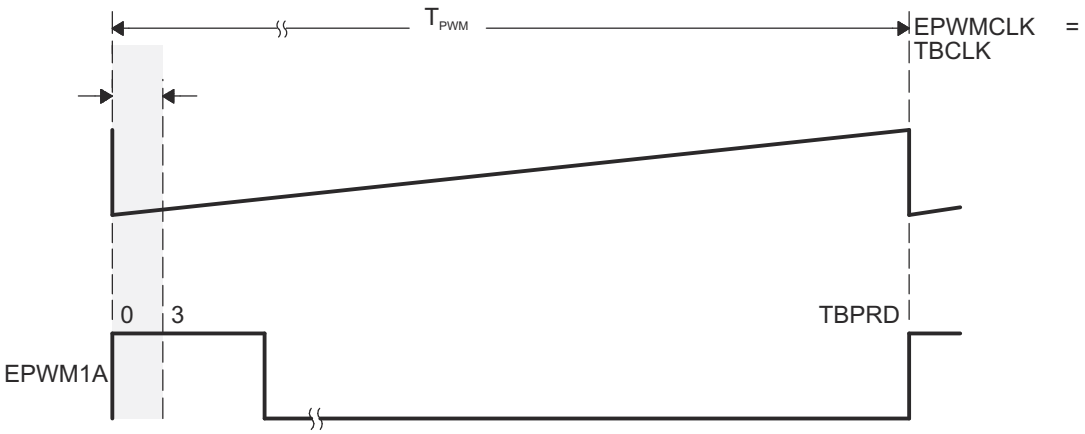

Figure 14-86. Low % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)

Table 14-16. Duty Cycle Range Limitation for Three EPWMCLK/TBCLK Cycles

PWM Frequency(1) (kHz)	3 Cycles Minimum Duty	3 Cycles Maximum Duty(2)
200	0.6%	99.4%
400	1.2%	98.8%
600	1.8%	98.2%
800	2.4%	97.6%
1000	3%	97%
1200	3.6%	96.4%
1400	4.2%	95.8%
1600	4.8%	95.2%
1800	5.4%	94.6%
2000	6%	94%

(1) EPWMCLK = TBCLK = 100MHz
(2) This limitation applies only if high-resolution period (TBPRDHR) control is enabled.

If the application demands HRPWM operation below the minimum duty cycle limitation, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP when high-resolution period is disabled (HRPCTL[HRPE] = 0). This is illustrated in Figure 14-87. In this configuration, the minimum duty cycle limitation is no longer an issue. However, there is a maximum duty limitation with same percent numbers as given in Table 14-16.

CAUTION

If the application has enabled high-resolution period control (HRPCTL[HRPE] = 1), the duty cycle must not fall within the restricted range; otherwise, there can be undefined behavior on the ePWM output.

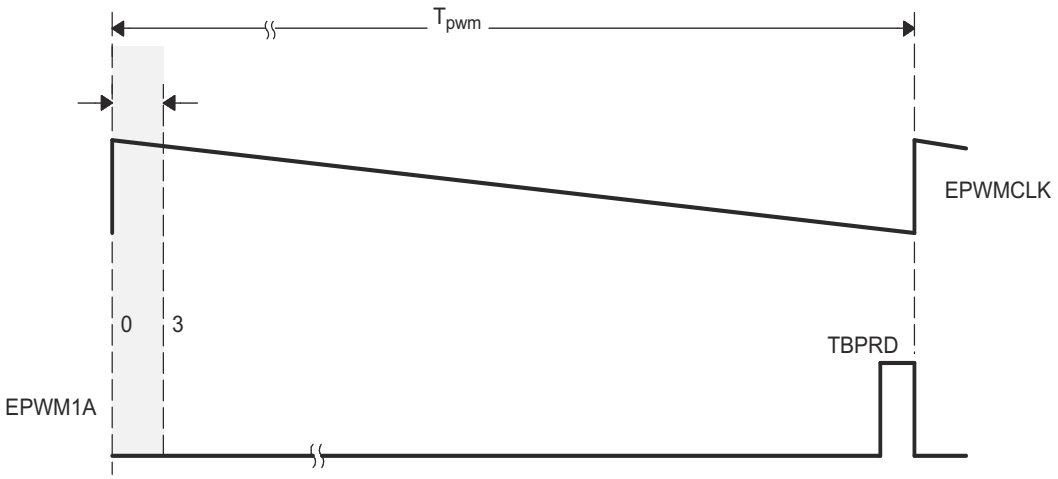

Figure 14-87. High % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)

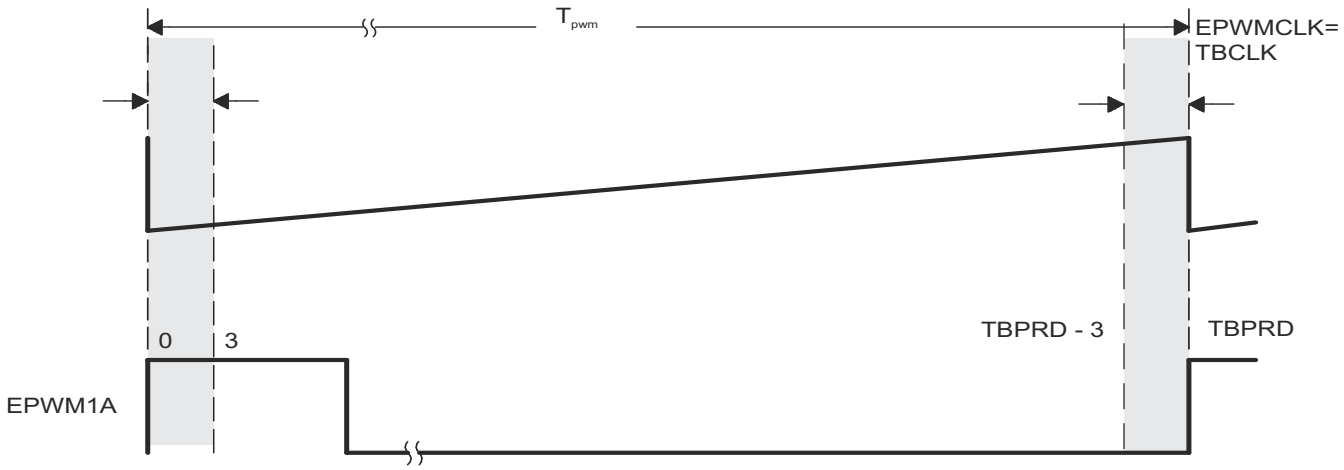

Figure 14-88. Up-Count Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 1)

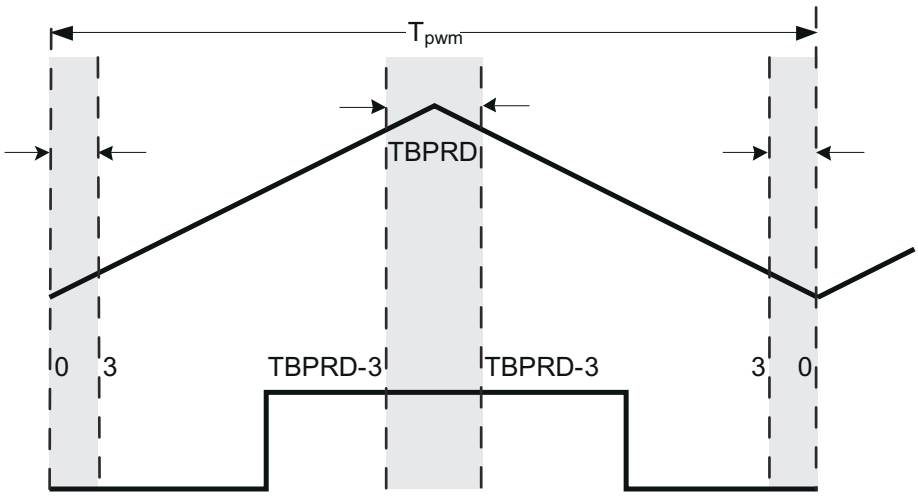

Figure 14-89. Up-Down Count Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 1)

14.14.1.5.4 High-Resolution Period

High-resolution period control using the MEP logic is supported on devices with a Type 1 ePWM module or greater.

Note

When high-resolution period control is enabled, on ePWMxA only, and not ePWMxB output and conversely, the non high-resolution output has ±1 TBCLK cycle jitter in up-count mode and ±2 TBCLK cycle jitter in up-down count mode.

The scaling procedure described for duty cycle in Section 14.14.1.5.2 applies for high-resolution period as well:

Assumptions for this example:

TBCLK	= 10ns (100MHz)
Required PWM frequency	= 175kHz (period of 571.428)
Number of MEP steps per coarse step at 180ps (10ns/180ps), (MEP_ScaleFactor)	= 55
Value to keep TBPRDHR within range of 1-255 and fractional rounding constant (default value)	= 0.5 (0080h in Q8 format)

Problem:

In up-count mode:

- If TBPRD = 571, then PWM frequency = 174.82kHz (period = (571+1)* T_{TBCLK}).
- If TBPRD = 570, then PWM frequency = 175.13kHz (period = (570+1)* T_{TBCLK}).

In up-down count mode:

- If TBPRD = 286, then PWM frequency = 174.82kHz (period = (286*2)* T_{TBCLK}).
- If TBPRD = 285, then PWM frequency = 175.44kHz (period = (285*2)* T_{TBCLK}).

Solution:

With 55 MEP steps per coarse step at 180ps each:

Step 1: Percentage Integer Period value conversion for TBPRD register

Integer period value	= 571 * T_{TBCLK}
	= int (571.428) * T_{TBCLK}
	= int (PWMperiod) * T_{TBCLK}
In up-count mode:	
TBPRD	= 570 (TBPRD = period value - 1)
	= 023Ah
In up-down count mode:	= 285 (TBPRD = period value/2)
TBPRD	= 011Dh

Step 2: Fractional value conversion for TBPRDHR register

In up-count mode:

TBPRDHR register value	= (frac(PWMperiod) * MEP_ScaleFactor + 0.5)
If auto-conversion enabled and HRMSTEP =	
MEP_ScaleFactor value (55):	= frac (PWMperiod) << 8 (Shifting is to move the value to the high byte of TBPRDHR)
TBPRDHR register value	= frac (571.428) << 8
	= 0.428 × 256
	= 6D00h
The auto-conversion then automatically performs the calculation, such that TBPRDHR MEP delay is scaled by hardware to:	= ((TBPRDHR(15:0) >> 8) × HRMSTEP + 80h) << 8
	= (006Dh × 55 + 80h) >> 8
	= (17EBh) >> 8
Period MEP delay	= 0017h MEP Steps

In up-down count mode:

TBPRDHR register value	= (frac(PWMperiod) * MEP_ScaleFactor + 0.5)
If auto-conversion enabled and HRMSTEP =	
MEP_ScaleFactor value (55):	= frac (PWMperiod / 2) << 8 (Shifting is to move the value to the high byte of TBPRDHR)
TBPRDHR register value	= frac (285.714) << 8
	= 0.714 × 256
	= B600h
The auto-conversion then automatically performs the calculation, such that TBPRDHR MEP delay is scaled by hardware to:	= ((TBPRDHR(15:0) >> 8) × HRMSTEP + 80h) << 8
	= (00B6h × 55 + 80h) >> 8
	= (279Ah) >> 8
Period MEP delay	= 0027h MEP Steps

14.14.1.5.4.1 High-Resolution Period Configuration

To use high-resolution period, the ePWMx module must be initialized in the exact order presented.

The following steps use CMPA with shadow registers and the corresponding HRCNFG bits for high-resolution operation on EPWMxA. For high-resolution operation on EPWMxB, make the appropriate substitutions with the B channel fields.

1. Enable ePWMx clock
2. Enable HRPWM clock
3. Disable TBCLKSYNC
4. Configure ePWMx registers - AQ, TBPRD, CC, and so on.
   - ePWMx can only be configured for up-count or up-down count modes. High-resolution period is not compatible with down-count mode.
   - TBPRD and CC registers must be configured for shadow loads.
   - CMPCTL[LOADAMODE]
     - In up-count mode: CMPCTL[LOADAMODE] = 1 (load on CTR = PRD)
     - In up-down count mode: CMPCTL[LOADAMODE] = 2 (load on CTR=0 or CTR=PRD)
5. Configure the HRCNFG register such that:
   - HRCNFG[HRLOAD] = 2 (load on either CTR = 0 or CTR = PRD)
   - HRCNFG[AUTOCONV] = 1 (Enable auto-conversion)
   - HRCNFG[EDGMODE] = 3 (MEP control on both edges)
6. For TBPHS:TBPHSHR synchronization with high-resolution period, set both HRPCTL[TBPSHRLOADE] = 1 and TBCTL[PHSEN] = 1. In up-down count mode these bits must be set to 1 regardless of the contents of TBPHSHR.
7. Enable high-resolution period control (HRPCTL[HRPE] = 1)
8. Enable TBCLKSYNC
9. TBCTL[SWFSYNC] = 1
10. HRMSTEP must contain an accurate MEP scale factor (# of MEP steps per EPWMCLK coarse step) because auto-conversion is enabled. The MEP scale factor can be acquired using the SFO() function described in Section 14.14.2.
11. To control high-resolution period, write to the TBPRDHR(M) registers.

Note

When high-resolution period mode is enabled, an EPWMxSYNC pulse introduces ±1-2 cycle jitter to the PWM (±1 cycle in up-count mode and ±2 cycle in up-down count mode). For this reason, TBCTL[SYNCOSEL] cannot be set to 1 (CTR = 0 is EPWMxSYNCO source) or 2 (CTR = CMPB is EPWMxSYNCO source). Otherwise, the jitter occurs on every PWM cycle with the synchronization pulse.

When TBCTL[SYNCOSEL] = 0 (EPWMxSYNCI is EPWMxSYNCO source), a software synchronization pulse can be issued only once during high-resolution period initialization. If a software sync pulse is applied while the PWM is running, the jitter appears on the PWM output at the time of the sync pulse.

14.14.1.6 Deadband High-Resolution Operation

Note

In up-count mode, the dead-band module is not available when any high-resolution mode is enabled.

Assumptions for this example:

System clock	= 10ns (100MHz)
Deadband enabled in half-cycle mode, TBCLK = EPWMCLK	
Required PWM frequency	1.33MHz (1/750ns)
Required PWM duty cycle	0.5 (50%)
Required Deadband Rising-Edge Delay	5% over duty
Required Deadband Rising-Edge Delay in ns	(0.05 * 375ns) = 18.75ns

Note

Similar to the duty cycle restrictions when using HRPWM, the DBRED and DBFED values must be greater than 3 to use high-resolution deadband.

Deadband delay values as a function of DBFED and DBRED:

When half-cycle clocking is enabled, the formula to calculate the falling-edge delay (FED) and rising-edge delay (RED) becomes:

FED = DBFED * TBCLK / 2

RED = DBRED * TBCLK / 2

DBRED and DBFED calculated values:

Required Deadband Rising-Edge Delay in ns = 18.75ns

DBRED = RED / (TBCLK / 2)

DBRED = 18.75ns/5ns

DBRED Required = 3.75ns

With 55 MEP steps per coarse step at 180ps each:

Step 1: Integer Deadband value conversion for DBREDM register

Integer DBRED value	= int (RED / (TBCLK / 2))
	= int (3.75)
DBRED	= 3

Step 2: Fractional value conversion for Deadband high-resolution register DBREDHR

DBREDHR register value	= (frac(DBRED Required) * MEP_ScaleFactor + 0.5) << 8 (Shifting is to move the value to the high byte of DBREDHR)
	= (frac (3.75) * 55 + 0.5) << 8
	= (0.75 * 55 + 0.5) << 8
	= (41.75) * 256 Shifting left by 8 is the same as multiplying by 256.
DBREDHR value	= 29C0h MEP Steps
	Hardware ignores lower 9 bits in the above calculated DBREDHR value

Note

If the AUTOCONV bit (HRCNFG.6) is set and the MEP_ScaleFactor is in the HRMSTEP register, then DBREDHR:DBRED = frac((required DB value) < <8). The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

14.14.1.7 Scale Factor Optimizing Software (SFO)

The micro edge positioner (MEP) logic is capable of placing an edge in one of 255 discrete time steps. As previously mentioned, the size of these steps is on the order of 150ps (see the device data sheet for typical MEP step size on your device). The MEP step size varies based on worst-case process parameters, operating temperature, and voltage. MEP step size increases with decreasing voltage and increasing temperature and decreases with increasing voltage and decreasing temperature. Applications that use the HRPWM feature can use the TI-supplied MEP scale factor optimization (SFO) software function. The SFO function helps to dynamically determine the number of MEP steps per EPWMCLK period while the HRPWM is in operation.

To utilize the MEP capabilities effectively, the correct value for the MEP scaling factor needs to be known by the software. To accomplish this, the HRPWM module has built in self-check and diagnostic capabilities that can be used to determine the optimum MEP scale factor value for any operating condition. TI provides a C-callable library containing one SFO function that utilizes this hardware and determines the optimum MEP scale factor. As such, MEP control and diagnostics registers are reserved for TI use.

A detailed description of the SFO library - SFO_TI_Build_V8.lib software can be found in SFO Library Software - SFO TI_Build_V8.lib.

14.14.1.8 HRPWM Examples Using Optimized Assembly Code

The best way to understand how to use the HRPWM capabilities is through two real examples:

1. Simple buck converter using asymmetrical PWM (count-up) with active high polarity.
2. DAC function using simple R+C reconstruction filter.

The following examples all have initialization and configuration code written in C. To make these easier to understand, the #defines shown below are used.

Example 14-2 assumes MEP step size of 150ps and does not use the SFO library.

Example 14-2. #Defines for HRPWM Header Files

```
// HRPWM (High Resolution PWM) //
================================
// HRCNFG
#define HR_Disable 0x0
#define HR_REP 0x1          // Rising Edge position
#define HR_FEP 0x2          // Falling Edge position
#define HR_BEP 0x3          // Both Edge position #define HR_CMP 0x0 // CMPAHR controlled
#define HR_PHS 0x1          // TBPHSHR controlled #define HR_CTR_ZERO 0x0 // CTR = Zero event
#define HR_CTR_PRD 0x1      // CTR = Period event
#define HR_CTR_ZERO_PRD 0x2 // CTR = ZERO or Period event
#define HR_NORM_B  0x0      // Normal ePWMxB output
#define HR_INVERT_B 0x1     // ePWMxB is inverted ePWMxA output
```

14.14.1.8.1 Implementing a Simple Buck Converter

In this example, the PWM requirements are:

- PWM frequency = 1MHz (that is, TBPRD = 100)
- PWM mode = asymmetrical, up-count
- Resolution = 12.7 bits (with a MEP step size of 150ps)

Figure 14-90 and Figure 14-91 show the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

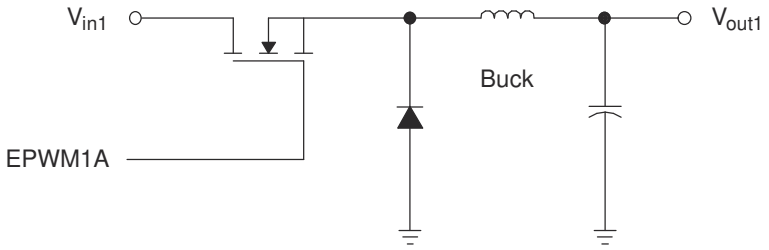

Figure 14-90. Simple Buck Controlled Converter Using a Single PWM

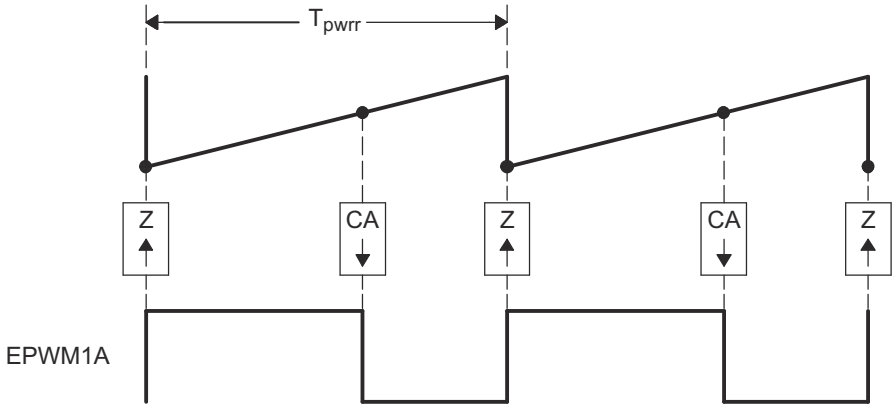

Figure 14-91. PWM Waveform Generated for Simple Buck Controlled Converter

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

Example 14-3 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

This example assumes MEP step size of 150ps and does not use the SFO library.

Example 14-4 shows an assembly example of run-time code for the HRPWM buck converter.

Example 14-3. HRPWM Buck Converter Initialization Code

```
void HrBuckDrvCnf(void)
 {
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDLD = TB_IMMEDIATE;         // set Immediate load
EPwm1Regs.TBPRD = 100;                            // Period set for 1000kHz PWM
hrbuck_period = 200;                              // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;           // EPWM1 is the Master
EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;     // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;       // optional
EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;                // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;              // optional
// Now configure the HRPWM resources
EALLOW;                                           // Note these registers are protected
                                                  // and act only on ChA
EPwm1Regs.HRCNFG.all = 0x0;                       // clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;            // Control Falling Edge Position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;            // CMPAHR controls the MEP
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;        // Shadow load on CTR=Zero
EDIS;
MEP_ScaleFactor = 66*256;                         // Start with typical Scale Factor
                                                  // value for 100MHz
                                                  // Note: Use SFO functions to update
                                                     MEP_ScaleFactor dynamically
}
```

Example 14-4. HRPWM Buck Converter Run-Time Code

```
EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;=============================================
HRBUCK_DRV; (can execute within an ISR or loop)
;=============================================
     MOVW DP, #_HRBUCK_In
     MOVL XAR2,@_HRBUCK_In       ; Pointer to Input Q15 Duty (XAR2)
     MOVL XAR3,#CMPAHR1          ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM)
     MOV T,*XAR2 ; T <= Duty
     MPYU ACC,T,@_hrbuck_period  ; Q15 to Q0 scaling based on Period
     MOV T,@_MEP_ScaleFactor     ; MEP scale factor (from optimizer s/w)
     MPYU P,T,@AL                ; P <= T * AL, Optimizer scaling
     MOVH @AL,P                  ; AL <= P, move result back to ACC
     ADD ACC, #0x080             ; MEP range and rounding adjustment
     MOVL *XAR3,ACC              ; CMPA:CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
     MOV *+XAR3[2],AH            ; Store ACCH to regular CMPB
```

14.14.1.8.2 Implementing a DAC Function Using an R+C Reconstruction Filter

In this example, the PWM requirements are:

- PWM frequency = 400kHz (that is, TBPRD = 250)
- PWM mode = Asymmetrical, Up-count
- Resolution = 14 bits (MEP step size = 150ps)

Figure 14-92 and Figure 14-93 show the DAC function and the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

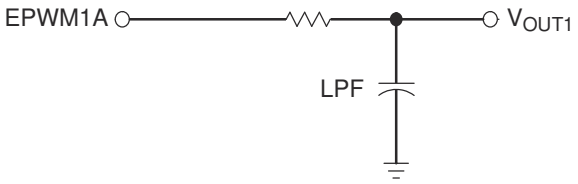

Figure 14-92. Simple Reconstruction Filter for a PWM-based DAC

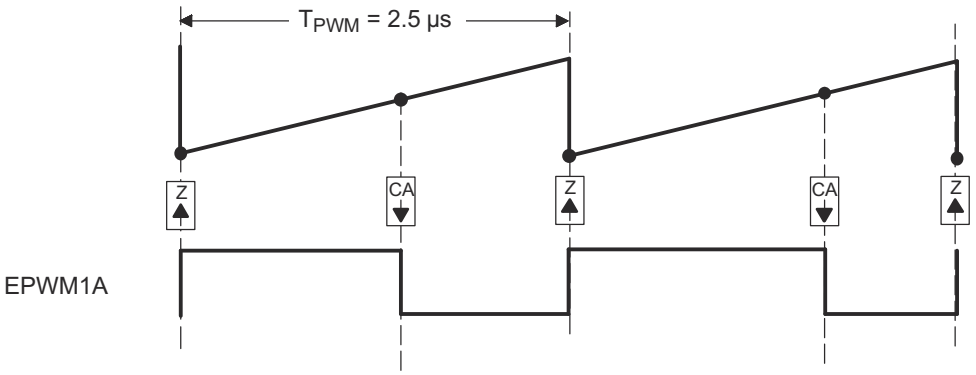

Figure 14-93. PWM Waveform Generated for the PWM DAC Function

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

This example assumes a typical MEP_SP and does not use the SFO library.

Example 14-5 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

Example 14-6 shows an assembly example of run-time code that can execute in a high-speed ISR loop.

Example 14-5. PWM DAC Function Initialization Code

```
void HrPwmDacDrvCnf(void)
{
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDLD = TB_IMMEDIATE;      // Set Immediate load
EPwm1Regs.TBPRD = 250;                         // Period set for 400kHz PWM
hrDAC_period = 250;                            // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;        // EPWM1 is the Master
EPwm1Regs.TBCTL.bit.SYNCOSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;  // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;    // optional

EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;             // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;           // optional
// Now configure the HRPWM resources
EALLOW;                                        // Note these registers are protected
                                               // and act only on ChA.
EPwm1Regs.HRCNFG.all = 0x0;                    // Clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;         // Control falling edge position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;         // CMPAHR controls the MEP.
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;     // Shadow load on CTR=Zero.
EDIS;
MEP_ScaleFactor = 66*256;                      // Start with typical Scale Factor
                                               // value for 100MHz.
                                               // Use SFO functions to update MEP_ScaleFactor
                                               // dynamically.
}
```

Example 14-6. PWM DAC Function Run-Time Code

```
EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;================================================
HRPWM_DAC_DRV; (can execute within an ISR or loop)
;================================================
      MOVW DP, #_HRDAC_In
      MOVL XAR2,@_HRDAC_In             ; Pointer to input Q15 duty (XAR2)
      MOVL XAR3,#CMPAHR1               ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM
      MOV T,*XAR2                      ; T <= duty
      MPY ACC,T,@_hrDAC_period         ; Q15 to Q0 scaling based on period
      ADD ACC,@_HrDAC_period<<15       ; Offset for bipolar operation
      MOV T,@_MEP_ScaleFactor          ; MEP scale factor (from optimizer s/w)
      MPYU P,T,@AL                     ; P <= T * AL, optimizer scaling
      MOVH @AL,P                       ; AL <= P, move result back to ACC
      ADD ACC, #0x080                  ; MEP range and rounding adjustment
      MOVL *XAR3,ACC                   ; CMPA:CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
      MOV *+XAR3[2],AH                 ; Store ACCH to regular CMPB
```

14.14.2 SFO Library Software - SFO_TI_Build_V8.lib

Table 14-17 lists several features of the SFO_TI_Build_V8.lib library.

Table 14-17. SFO Library Features

	SFO_TI_Build_V8.lib	Unit
Completion-checking?	Yes	Function return value
Typical cycles required for SFO() to update MEP_ScaleFactor if called repetitively without interrupts	130,000	EPWMCLK cycles

14.14.2.1 Scale Factor Optimizer Function - int SFO()

This routine drives the micro-edge positioner (MEP) calibration module to run SFO diagnostics and determine the appropriate MEP scale factor (number of MEP steps per coarse EPWMCLK step) for a device at any given time.

If EPWMCLK = TBCLK = 100MHz and assuming the MEP step size is 150ps, the typical scale factor value at 100MHz = 66 MEP steps per TBCLK unit (10ns)

The function returns a MEP scale factor value:

MEP_ScaleFactor = Number of MEP steps per EPWMCLK

Constraints when using this function:

- SFO() can be used with a minimum EPWMCLK = TBCLK = 50MHz. MEP diagnostics logic uses EPWMCLK and not TBCLK, so the EPWMCLK restriction is an important constraint. Below 50MHz with device process variation, the MEP step size can decrease under cold temperature and high core voltage conditions to such a point that 255 MEP steps do not span an entire EPWMCLK cycle.
- At any time, SFO() can be called to run SFO diagnostics on the MEP calibration module.

Usage:

- SFO() can be called at any time in the background while the ePWM channels are running in HRPWM mode. The scale factor result obtained can be applied to all ePWM channels running in HRPWM mode because the function makes use of the diagnostics logic in the MEP calibration module (which runs independently of ePWM channels).
- This routine returns a 1 when calibration is finished and a new scale factor has been calculated or returns a 0 if calibration is still running. The routine returns a 2 if there is an error, and the MEP_ScaleFactor is greater than the maximum 255 fine steps per coarse EPWMCLK cycle. In this case, the HRMSTEP register maintains the last MEP scale factor value less than 256 for auto conversion.
- All ePWM modules operating in HRPWM incur only a 3 EPWMCLK cycle minimum duty cycle limitation when high-resolution period control is not used. If high-resolution period control is enabled, there is an additional duty cycle limitation 3-EPWMCLK cycles before the end of the PWM period (see Section 14.14.1.5.3).
- The SFO() function also updates the HRMSTEP register with the scale factor result. If the HRCNFG[AUTOCONV] bit is set, the application software is responsible only for setting CMPAHR = fraction(PWMduty*PWMperiod) << 8 or CMPBHR = fraction(PWMduty*PWMperiod) << 8 or TBPRDHR = fraction (PWMperiod) while running SFO() in the background. The MEP Calibration Module then uses the values in the HRMSTEP and CMPAHR/CMPBHR/TBPRDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle or period and move the high-resolution ePWM signal edge accordingly.
- If the HRCNFG[AUTOCONV] bit is clear, the HRMSTEP register is ignored. The application software needs to perform the necessary calculations manually so that:
  - CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor) << 8 + 0x080.
  - Similar behavior applies for TBPHSHR, CMPBHR, DBREDHR, and DBFEDHR. Auto-conversion must be enabled when using TBPRDHR.

The following code snippet shows how to use the HRPWM DUTY using driverlib functions.

```
float32_t dutyFine = 85.62;
float32_t count = (dutyFine * (float32_t)(EPWM_TIMER_TBPRD << 8))/100;
uint32_t compCount = (count);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_A, compCount);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_B, compCount);
```

The routine can be run as a background task in a slow loop requiring negligible CPU cycles. The repetition rate at which an SFO function needs to be executed depends on the application's operating environment. As with all digital CMOS devices, temperature and supply voltage variations have an effect on MEP operation. However, in most applications these parameters vary slowly and therefore is often sufficient to execute the SFO function once every 5 to 10 seconds. If more rapid variations are expected, then execution can be performed more frequently to match the application. Note there is no high limit restriction on the SFO function repetition rate; hence, the SFO function can execute as quickly as the background loop is capable.

While using the HRPWM feature, HRPWM logic is not active for the first 3 EPWMCLK cycles of the PWM period (and the last 3 EPWMCLK cycles of the PWM period if TBPRDHR is used). While running the application in this configuration, if high-resolution period control is disabled (HRPCTL[HRPE=0]) and the CMPA/CMPB register value is less than three cycles, then the CMPAHR/CMPBHR register must be cleared to zero. If high-resolution period control is enabled (HRPCTL[HRPE=1]), the CMPA register value must not fall below 3 or above TBPRD-3.This can avoid any unexpected transitions on the PWM signal.

14.14.2.2 Software Usage

The software library function SFO(), calculates the MEP scale factor for the HRPWM-supported ePWM modules. The scale factor is an integer value in the range 1-255, and represents the number of micro step edge positions available for a system clock period. The scale factor value is returned in an integer variable called MEP_ScaleFactor. For example, see Table 14-18.

Table 14-18. Factor Values

Software Function call	Functional Description	Updated Variables
SFO()	Returns MEP scale factor in the HRMSTEP register	MEP_ScaleFactor and HRMSTEP register.

To use the HRPWM feature of the ePWMs, it is recommended that the SFO function be used as described here.

Step 1. Add "Include" Files

The SFO_V8.h file needs to be included as follows. This include file is mandatory while using the SFO library function. For the SFO() to operate, the appropriate (Device)_Device.h and (Device)_Epwm_defines.h must be included in the project. These include files are optional if customized header files are used in the end applications.

Example 14-7. A Sample of How to Add "Include" Files

```
#include "F28x7x_Device.h"         // F28x7x Headerfile
#include "F28x7x_EPwm_defines.h"   // init defines
#include "SFO_V8.h"                // SFO lib functions (needed for HRPWM)
```

Step 2. Element Declaration

Declare an integer variable for the scale factor value as shown below.

Example 14-8. Declaring an Element

```
int MEP_ScaleFactor = 0;   //scale factor value
volatile struct EPWM_REGS *ePWM[] = {0, &EPwm1Regs, &EPwm2Regs, &EPwm3Regs,
&EPwm4Regs};
```

Step 3. MEP_ScaleFactor Initialization

The SFO() function does not require a starting scale factor value in MEP_ScaleFactor. Prior to using the MEP_ScaleFactor variable in application code, SFO() can be called to drive the MEP calibration module to calculate an MEP_ScaleFactor value.

As part of the one-time initialization code prior to using MEP_ScaleFactor, include the following:

Example 14-9. Initializing With a Scale Factor Value

```
MEP_ScaleFactor initialized using function SFO ()
while (SFO() == 0) {} // MEP_ScaleFactor calculated by MEP Cal Module
```

Step 4. Application Code

While the application is running, fluctuations in both device temperature and supply voltage can be expected. To be sure that good Scale Factors are used for each ePWM module, the SFO function can be re-run periodically as part of a slower back-ground loop. Some examples of this are shown here.

Note

See the HRPWM_SFO example in the device-specific C/C++ header files and peripheral examples available from the TI website.

Example 14-10. SFO Function Calls

```
main ()
 {
 int status;
    // User code
    // ePWM1, 2, 3, 4 are running in HRPWM mode
    // The status variable returns 1 once a new MEP_ScaleFactor has been
    // calculated by the MEP Calibration Module running SFO
    // diagnostics.
status = SFO();
if(status==2) {ESTOP0;}   // The function returns a 2 if MEP_ScaleFactor is greater
                          // than the maximum 255 allowed (error condition)
 }
```

14.15 ePWM Registers

This section describes the Enhanced Pulse Width Modulator registers.

14.15.1 ePWM Base Addresses

Table 14-19. ePWM Base Address Table

Device Register	Register Name	Start Address	End Address
EPwm1Regs	EPWM_REGS	0x0000_4000	0x0000_40FF
EPwm2Regs	EPWM_REGS	0x0000_4100	0x0000_41FF
EPwm3Regs	EPWM_REGS	0x0000_4200	0x0000_42FF
EPwm4Regs	EPWM_REGS	0x0000_4300	0x0000_43FF
EPwm5Regs	EPWM_REGS	0x0000_4400	0x0000_44FF
EPwm6Regs	EPWM_REGS	0x0000_4500	0x0000_45FF
EPwm7Regs	EPWM_REGS	0x0000_4600	0x0000_46FF
EPwm8Regs	EPWM_REGS	0x0000_4700	0x0000_47FF
EPwm9Regs	EPWM_REGS	0x0000_4800	0x0000_48FF

Complex bit access types are encoded to fit into small table cells. Table 14-21 shows the codes that are used for access types in this section.

Table 14-21. EPWM_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

14.15.2.1 TBCTL Register (Offset = 0h) [Reset = 0083h]

TBCTL is shown in Figure 14-94 and described in Table 14-22.

Return to the Summary Table.

Time Base Control Register

Figure 14-94. TBCTL Register

15	14	13	12	11	10	9	8
FREE_SOFT		PHSDIR	CLKDIV			HSPCLKDIV	
R/W-0h		R/W-0h	R/W-0h			R/W-1h	
7	6	5	4	3	2	1	0

R/W-1h	R-0/W1S-0h	R/W-0h		R/W-0h	R/W-0h	R/W-3h	

Table 14-22. TBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events 00: Stop after the next time-base counter increment or decrement 01: Stop when counter completes a whole cycle: - Up-count mode: stop when the time-base counter = period (TBCTR = TBPRD) - Down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) - Up-down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) 1x: Free run Reset type: SYSRSn
13	PHSDIR	R/W	0h	Phase Direction Bit This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event.. In the up-count and down-count modes this bit is ignored. 0: Count down after the synchronization event. 1: Count up after the synchronization event. Reset type: SYSRSn
12-10	CLKDIV	R/W	0h	Time Base Clock Pre-Scale Bits These bits select the time base clock pre-scale value (TBCLK = EPWMCLK/(HSPCLKDIV * CLKDIV): 000: /1 (default on reset) 001: /2 010: /4 011: /8 100: /16 101: /32 110: /64 111: /128 Reset type: SYSRSn

Table 14-22. TBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-7	HSPCLKDIV	R/W	1h	High Speed Time Base Clock Pre-Scale Bits These bits determine part of the time-base clock prescale value. TBCLK = EPWMCLK / (HSPCLKDIV x CLKDIV). This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral. 000: /1 001: /2 (default on reset) 010: /4 011: /6 100: /8 101: /10 110: /12 111: /14 Reset type: SYSRSn
6	SWFSYNC	R-0/W1S	0h	Software Forced Sync Pulse 0: Writing a 0 has no effect and reads always return a 0. 1: Writing a 1 forces a one-time synchronization pulse to be generated. SWFSYNC affects EPWMxSYNCO only when SYNCOSEL = 00. Reset type: SYSRSn
5-4	SYNCOSEL	R/W	0h	Sync Output Select 00: EPWMxSYNCI / SWFSYNC 01: CTR = zero: Time-base counter equal to zero (TBCTR = 0x00) 10: CTR = CMPB : Time-base counter equal to counter-compare B (TBCTR = CMPB) 11: EPWMXSYNCO is defined by TBCTL2[SYNCOSELX] Reset type: SYSRSn
3	PRDLD	R/W	0h	Active Period Reg Load from Shadow Select 0: The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to zero and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. A write/read to the TBPRD register accesses the shadow register. 1: Immediate Mode (Shadow register bypassed): A write or read to the TBPRD register accesses the active register. Reset type: SYSRSn
2	PHSEN	R/W	0h	Counter Reg Load from Phase Reg Enable 0: Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS). 1: Allow Counter to be loaded from the Phase register (TBPHS) and shadow to active load events when an EPWMxSYNCI input signal occurs or a software-forced sync signal, see bit 6. Reset type: SYSRSn
1-0	CTRMODE	R/W	3h	Counter Mode The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 00: Up-count mode 01: Down-count mode 10: Up-down count mode 11: Freeze counter operation (default on reset) Reset type: SYSRSn

14.15.2.2 TBCTL2 Register (Offset = 1h) [Reset = 0000h]

TBCTL2 is shown in Figure 14-95 and described in Table 14-23.

Return to the Summary Table.

7	6	5	4	3	2	1	0
LOADREDMODE		IN_MODE		POLSEL		OUT_MODE	
R/W-0h		R/W-0h		R/W-0h		R/W-0h	

Table 14-28. DBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	HALFCYCLE	R/W	0h	Half Cycle Clocking Enable Bit 0: Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate. 1: Half cycle clocking enabled. The dead-band counters are clocked at TBCLK*2. Reset type: SYSRSn
14	DEDB_MODE	R/W	0h	Dead Band Dual-Edge B Mode Control (S8 switch) 0: Rising edge delay applied to InA/InB as selected by S4 switch (IN-MODE bits) on A signal path only. Falling edge delay applied to InA/InB as selected by S5 switch (INMODE bits) on B signal path only. 1: Rising edge delay and falling edge delay applied to source selected by S4 switch (INMODE bits) and output to B signal path only. Note: When this bit is set to 1, user should always either set OUT_MODE bits such that Apath = InA OR OUTSWAP bits such that OutA=Bpath otherwise, OutA will be invalid. Reset type: SYSRSn
13-12	OUTSWAP	R/W	0h	Dead Band Output Swap Control Bit 13 controls the S6 switch and bit 12 controls the S7 switch. 00: OutA and OutB signals are as defined by OUT-MODE bits. 01: OutA = A-path as defined by OUT-MODE bits. OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). 10: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = B-path as defined by OUT-MODE bits. 11: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). Reset type: SYSRSn
11	SHDWDBFEDMODE	R/W	0h	FED Dead-Band Load Mode 0: Immediate mode. Only the active DBFED register is used. All writes/reads via the CPU directly access the active register for immediate 'FED dead-band action.' 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn

Table 14-28. DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	SHDWDBREDMODE	R/W	0h	RED Dead-Band Load Mode 0: Immediate mode. Only the active DBRED register is used. All writes/reads via the CPU directly access the active register for immediate 'RED dead-band action.' 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn
9-8	LOADFEDMODE	R/W	0h	Active DBFED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
7-6	LOADREDMODE	R/W	0h	Active DBRED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
5-4	IN_MODE	R/W	0h	Dead-Band Input Mode Control Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays. 00: EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 01: EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 10: EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 11: EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal. Reset type: SYSRSn
3-2	POLSEL	R/W	0h	Polarity Select Control Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0x0. Other enhanced modes are also possible, but not regarded as typical usage modes. 00: Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 01: Active low complementary (ALC) mode. EPWMxA is inverted. 10: Active high complementary (AHC). EPWMxB is inverted. 11: Active low (AL) mode. Both EPWMxA and EPWMxB are inverted. Reset type: SYSRSn

Table 14-28. DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OUT_MODE	R/W	0h	Dead-Band Output Mode Control Bit 1 controls the S1 switch and bit 0 controls the S0 switch. 00: DBM is fully disabled or by-passed. In this mode the POLSEL and IN-MODE bits have no effect. 01: Apath = InA (delay is by-passed for A signal path) Bpath = FED (Falling Edge Delay in B signal path) 10: Apath = RED (Rising Edge Delay in A signal path) Bpath = InB (delay is by-passed for B signal path) 11: DBM is fully enabled (i.e. both RED and FED active) Reset type: SYSRSn

14.15.2.8 DBCTL2 Register (Offset = Dh) [Reset = 0000h]

DBCTL2 is shown in Figure 14-101 and described in Table 14-29.

Return to the Summary Table.

13	RESERVED	R-0	0h	Reserved
12-11	HRLOADB	R/W	0h	Shadow Mode Bit Selects the time event that loads the CMPBHR shadow value into the active register. 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Reserved Reset type: SYSRSn
10	CTLMODEB	R/W	0h	Control Mode Bits Selects the register (CMP/TBPRD or TBPHS) that controls the MEP: 0: CMPBHR(8) or TBPRDHR(8) Register controls the edge position (i.e., this is duty or period control mode). (Default on Reset) 1: TBPHSHR(8) Register controls the edge position (i.e., this is phase control mode). Reset type: SYSRSn
9-8	EDGMODEB	R/W	0h	Edge Mode Bits Selects the edge of the PWM that is controlled by the micro-edge position (MEP) logic: 00: HRPWM capability is disabled (default on reset) 01: MEP control of rising edge (CMPBHR) 10: MEP control of falling edge (CMPBHR) 11: MEP control of both edges (TBPHSHR or TBPRDHR) Reset type: SYSRSn
7	SWAPAB	R/W	0h	Swap ePWM A & B Output Signals This bit enables the swapping of the A & B signal outputs. The selection is as follows: 0: ePWMxA and ePWMxB outputs are unchanged. 1: ePWMxA signal appears on ePWMxB output and ePWMxB signal appears on ePWMxA output. Reset type: SYSRSn

Table 14-35. HRCNFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	AUTOCONV	R/W	0h	Auto Convert Delay Line Value Selects whether the fractional duty cycle/period/phase in the CMPAHR/TBPRDHR/TBPHSHR register is automatically scaled by the MEP scale factor in the HRMSTEP register or manually scaled by calculations in application software. The SFO library function automatically updates the HRMSTEP register with the appropriate MEP scale factor. 0: Automatic HRMSTEP scaling is disabled. 1: Automatic HRMSTEP scaling is enabled. If application software is manually scaling the fractional duty cycle, or phase (i.e. software sets CMPAHR = (fraction(PWMduty * PWMperiod) * MEP Scale Factor)<<8 + 0x080 for duty cycle), then this mode must be disabled. Reset type: SYSRSn
5	SELOUTB	R/W	0h	EPWMxB Output Select Bit This bit selects which signal is output on the ePWMxB channel output. The inversion will take the high resolution mode into account and the inverted signal will contain any high resolution modification. The inversion takes place as the last step in modifying the ePWMxB signal. 0: ePWMxB output is normal. 1: ePWMxB output is inverted version of ePWMxA signal. Reset type: SYSRSn
4-3	HRLOAD	R/W	0h	Shadow Mode Bit Selects the time event that loads the CMPAHR shadow value into the active register. 00: Load on CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000) 01: Load on CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 10: Load on either CTR = Zero or CTR = PRD 11: Reserved Reset type: SYSRSn
2	CTLMODE	R/W	0h	Control Mode Bits Selects the register (CMP/TBPRD or TBPHS) that controls the MEP: 0: CMPAHR(8) or TBPRDHR(8) Register controls the edge position (i.e., this is duty or period control mode). (Default on Reset) 1: TBPHSHR(8) Register controls the edge position (i.e., this is phase control mode). Reset type: SYSRSn
1-0	EDGMODE	R/W	0h	Edge Mode Bits Selects the edge of the PWM that is controlled by the micro-edge position (MEP) logic: 00: HRPWM capability is disabled (default on reset) 01: MEP control of rising edge (CMPAHR) 10: MEP control of falling edge (CMPAHR) 11: MEP control of both edges (TBPHSHR or TBPRDHR) Reset type: SYSRSn

14.15.2.15 HRPWR Register (Offset = 21h) [Reset = 0000h]

HRPWR is shown in Figure 14-108 and described in Table 14-36.

Return to the Summary Table.

HRPWM Power Register
This register is only accessible on EPWM modules with HRPWM capabilities.

Bit	Field	Type	Reset	Description
15-7	RESERVED	R-0	0h	Reserved
6-4	PWMSYNCSELX	R/W	0h	Extended selection bits for EPWMSYNCPER 000: EPWMSYNCPER is defined by PWMSYNCSEL - > default condition (compatible with previous EPWM versions) 001: Reserved 010: Reserved 011: Reserved 100: CTR = CMPC, Count direction Up 101: CTR = CMPC, Count direction Down 110: CTR = CMPD, Count direction Up 111: CTR = CMPD, Count direction Down Reset type: SYSRSn
3	RESERVED	R/W	0h	Reserved
2	TBPHSHRLOADE	R/W	0h	TBPHSHR Load Enable This bit allows you to synchronize ePWM modules with a high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event. This allows for multiple ePWM modules operating at the same frequency to be phase aligned with high-resolution. 0: Disables synchronization of high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event: 1: Synchronize the high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital comparator synchronization event. The phase is synchronized using the contents of the high-resolution phase TBPHSHR register. The TBCTL[PHSEN] bit which enables the loading of the TBCTR register with TBPHS register value on a SYNCIN or TBCTL[SWFSYNC] event works independently. However, users need to enable this bit also if they want to control phase in conjunction with the high-resolution period feature. This bit and the TBCTL[PHSEN] bit must be set to 1 when high-resolution period is enabled for up-down count mode even if TBPHSHR = 0x0000. This bit does not need to be set when only high-resolution duty is enabled. Reset type: SYSRSn
1	PWMSYNCSEL	R/W	0h	PWMSYNC Source Select Bit: This bit selects the source for the EPWMSYNCPER signal that goes to the CMPSS and GPDAC: 0 CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 1 CTR = zero: Time-base counter equal to zero (TBCTR = 0x00) Reset type: SYSRSn

Table 14-39. HRPCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	HRPE	R/W	0h	High Resolution Period Enable Bit 0: High resolution period feature disabled. In this mode the ePWM behaves as a Type 4 ePWM. 1: High resolution period enabled. In this mode the HRPWM module can control high-resolution of both the duty and frequency. When high-resolution period is enabled, TBCTL[CTRMODE] = 0,1 (down-count mode) is not supported. Reset type: SYSRSn

14.15.2.19 TRREM Register (Offset = 2Eh) [Reset = 0000h]

TRREM is shown in Figure 14-112 and described in Table 14-40.

Return to the Summary Table.

HRPWM High Resolution Remainder Register
This register is only accessible on EPWM modules with HRPWM capabilities.

14.15.2.22 EPWMXLINK Register (Offset = 38h) [Reset = 000XXXXXh]

EPWMXLINK is shown in Figure 14-115 and described in Table 14-43.

Return to the Summary Table.

EPWMx Link Register
This register controls which EPWMs are linked to other EPWM modules. The default reset value will vary for each module. The reset value will link each EPWM module to itself to prevent unintentional linking of modules.

14.15.2.33 TBPHS Register (Offset = 60h) [Reset = 00000000h]

TBPHS is shown in Figure 14-126 and described in Table 14-54.

Return to the Summary Table.

Time Base Phase Register

Figure 14-126. TBPHS Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TBPHS																TBPHSHR															
R/W-0h																R/W-0h															

Table 14-54. TBPHS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	TBPHS	R/W	0h	Phase Offset Register These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. - If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase. - If TBCTL[PHSEN] = 1, then the time-base counter (TBCTR) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization. Reset type: SYSRSn
15-0	TBPHSHR	R/W	0h	Phase Offset (High Resolution) Register. TBPHSHR must not be used. Instead TRREM (HRPWM remainder register) must be used to mimic the functionality of TBPHSHR. The lower 8 bits in this register are ignored - writes are ignored and reads return zero Reset type: SYSRSn

14.15.2.34 TBPRDHR Register (Offset = 62h) [Reset = 0000h]

TBPRDHR is shown in Figure 14-127 and described in Table 14-55.

Return to the Summary Table.

7	6	5	4	3	2	1	0
TBPRDHR							
R/W-0h							

Table 14-55. TBPRDHR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TBPRDHR	R/W	0h	Period High Resolution Bits The upper 8-bits contain the high-resolution portion of the period value. The TBPRDHR register is not affected by the TBCTL[PRDLD] bit. Reads from this register always reflect the shadow register. Likewise writes are also to the shadow register. The TBPRDHR register is only used when the high resolution period feature is enabled. This register is only available with ePWM modules which support high-resolution period control. The lower 8 bits in this register are ignored - writes are ignored and reads return zero Reset type: SYSRSn

14.15.2.35 TBPRD Register (Offset = 63h) [Reset = 0000h]

TBPRD is shown in Figure 14-128 and described in Table 14-56.

Return to the Summary Table.

7	6	5	4	3	2	1	0
TBPRD							
R/W-0h							

Table 14-56. TBPRD Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TBPRD	R/W	0h	Time Base Period Register These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDLD] bit. By default this register is shadowed. - If TBCTL[PRDLD] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero. - If TBCTL[PRDLD] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. - The active and shadow registers share the same memory map address. Reset type: SYSRSn

14.15.2.36 CMPA Register (Offset = 6Ah) [Reset = 00000000h]

CMPA is shown in Figure 14-129 and described in Table 14-57.

Return to the Summary Table.

Counter Compare A Register

Figure 14-129. CMPA Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMPA																CMPAHR															
R/W-0h																R/W-0h															

Table 14-57. CMPA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	CMPA	R/W	0h	Compare A Register The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a 'time-base counter equal to counter compare A' event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include: - Do nothing the event is ignored. - Clear: Pull the EPWMxA and/or EPWMxB signal low - Set: Pull the EPWMxA and/or EPWMxB signal high - Toggle the EPWMxA and/or EPWMxB signal Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed. - If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register. - Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full. - If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. - In either mode, the active and shadow registers share the same memory map address. Reset type: SYSRSn
15-0	CMPAHR	R/W	0h	Compare A HRPWM Extension Register The UPPER 8-bits contain the high-resolution portion (most significant 8-bits) of the counter-compare A value. CMPA:CMPAHR can be accessed in a single 32-bit read/write. Shadowing is enabled and disabled by the CMPCTL[SHDWAMODE] bit as described for the CMPA register. The lower 8 bits in this register are ignored Reset type: SYSRSn

14.15.2.37 CMPB Register (Offset = 6Ch) [Reset = 00000000h]

CMPB is shown in Figure 14-130 and described in Table 14-58.

Return to the Summary Table.

Compare B Register

Figure 14-130. CMPB Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

2	OST	R	0h	Latched Status Flag for A One-Shot Trip Event 0: No one-shot trip event has occurred. 1: Indicates a trip event has occurred on a pin selected as a one-shot trip source. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

Table 14-70. TZFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	CBC	R	0h	Latched Status Flag for Cycle-By-Cycle Trip Event 0: No cycle-by-cycle trip event has occurred. 1: Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x00) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x00 no matter where in the cycle the CBC flag is cleared. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn
0	INT	R	0h	Latched Trip Interrupt Status Flag 0: Indicates no interrupt has been generated. 1: Indicates an EPWMx_TZINT PIE interrupt was generated because of a trip condition. No further EPWMx_TZINT PIE interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

14.15.2.50 TZCBCFLG Register (Offset = 94h) [Reset = 0000h]

TZCBCFLG is shown in Figure 14-143 and described in Table 14-71.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
15-14	SOCBCNT	R	0h	ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Counter Register These bits indicate how many selected ETSEL[SOCBSEL] events have occurred: 00: No events have occurred. 01: 1 event has occurred. 10: 2 events have occurred. 11: 3 events have occurred. Reset type: SYSRSn
13-12	SOCBPRD	R/W	0h	ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Period Select These bits determine how many selected ETSEL[SOCBSEL] events need to occur before an EPWMxSOCB pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCBEN] = 1). The SOCB pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCB] = 1). Once the SOCB pulse is generated, the ETPS[SOCBCNT] bits will automatically be cleared. 00: Disable the SOCB event counter. No EPWMxSOCB pulse will be generated 01: Generate the EPWMxSOCB pulse on the first event: ETPS[SOCBCNT] = 0,1 10: Generate the EPWMxSOCB pulse on the second event: ETPS[SOCBCNT] = 1,0 11: Generate the EPWMxSOCB pulse on the third event: ETPS[SOCBCNT] = 1,1 Reset type: SYSRSn
11-10	SOCACNT	R	0h	ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Counter Register These bits indicate how many selected ETSEL[SOCASEL] events have occurred: 00: No events have occurred. 01: 1 event has occurred. 10: 2 events have occurred. 11: 3 events have occurred. Reset type: SYSRSn

Table 14-78. ETPS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-8	SOCAPRD	R/W	0h	ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Period Select These bits determine how many selected ETSEL[SOCASEL] events need to occur before an EPWMxSOCA pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCAEN] = 1). The SOCA pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCA] = 1). Once the SOCA pulse is generated, the ETPS[SOCACNT] bits will automatically be cleared. 00: Disable the SOCA event counter. No EPWMxSOCA pulse will be generated 01: Generate the EPWMxSOCA pulse on the first event: ETPS[SOCACNT] = 0,1 10: Generate the EPWMxSOCA pulse on the second event: ETPS[SOCACNT] = 1,0 11: Generate the EPWMxSOCA pulse on the third event: ETPS[SOCACNT] = 1,1 Reset type: SYSRSn
7-6	RESERVED	R-0	0h	Reserved
5	SOCPSSEL	R/W	0h	EPWMxSOC A/B Pre-Scale Selection Bits 0: Selects ETPS [SOCACNT/SOCBCNT] and [SOCAPRD/SOCBPRD] registers to determine frequency of events (SOC pulse once every 0-3 events). 1: Selects ETSOCPS [SOCACNT2/SOCBCNT2] and [SOCAPRD2/SOCBPRD2] registers to determine frequency of events (SOC pulse once every 0-15 events). Reset type: SYSRSn
4	INTPSSEL	R/W	0h	EPWMxINTn Pre-Scale Selection Bits 0: Selects ETPS [INTCNT, and INTPRD] registers to determine frequency of events (interrupt once every 0-3 events). 1: Selects ETINTPS [INTCNT2, and INTPRD2] registers to determine frequency of events (interrupt once every 0-15 events). Reset type: SYSRSn
3-2	INTCNT	R	0h	ePWM Interrupt Event (EPWMx_INT) Counter Register These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD]. 00: No events have occurred. 01: 1 event has occurred. 10: 2 events have occurred. 11: 3 events have occurred. Reset type: SYSRSn

Table 14-78. ETPS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	INTPRD	R/W	0h	ePWM Interrupt (EPWMx_INT) Period Select These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented. 00: Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored. 01: Generate an interrupt on the first event INTCNT = 01 (first event) 10: Generate interrupt on ETPS[INTCNT] = 1,0 (second event) 11: Generate interrupt on ETPS[INTCNT] = 1,1 (third event) Reset type: SYSRSn

RESERVED						SHDWMODE	CAPE
R-0-0h						R/W-0h	R/W-0h

Table 14-90. DCCAPCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	CAPMODE	R/W	0h	Counter Capture Mode 0: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs, further trip (capture) events are ignored until the next PRD_eq or CNT_zero event (as selected by the PULSESEL bit in the DCFCTL register) re-triggers the capture mechanism. If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value. If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value. 1: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs - it will set the CAPSTS flag and further trip (capture) events are ignored until this bit is cleared. CAPSTS can be cleared by writing to CAPCLR bit in DCCAPCTL register and it re-triggers the capture mechanism. If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value. If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value. Reset type: SYSRSn
14	CAPCLR	R-0/W1S	0h	DC Capture Latched Status Clear Flag 0: Writing a 0 has no effect. 1: Writing a 1 will clear this CAPSTS (set) condition. Reset type: SYSRSn
13	CAPSTS	R	0h	Latched Status Flag for Capture Event 0: No DC capture event occurred. 1: A DC capture event has occurred. Reset type: SYSRSn
12-2	RESERVED	R-0	0h	Reserved

Table 14-90. DCCAPCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SHDWMODE	R/W	0h	TBCTR Counter Capture Shadow Select Mode 0: Enable shadow mode. The DCCAP active register is copied to shadow register on a TBCTR = TBPRD or TBCTR = zero event as defined by the DCFCTL[PULSESEL] bit. CPU reads of the DCCAP register will return the shadow register contents. 1: Active Mode. In this mode the shadow register is disabled. CPU reads from the DCCAP register will always return the active register contents. Reset type: SYSRSn
0	CAPE	R/W	0h	TBCTR Counter Capture Enable/Disable 0: Disable the time-base counter capture. 1: Enable the time-base counter capture. Reset type: SYSRSn

14.15.2.70 DCFOFFSET Register (Offset = C9h) [Reset = 0000h]

DCFOFFSET is shown in Figure 14-163 and described in Table 14-91.

Return to the Summary Table.

DCFOFFSET							
R/W-0h							

Table 14-91. DCFOFFSET Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	DCFOFFSET	R/W	0h	Blanking Window Offset These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted. Reset type: SYSRSn

14.15.2.71 DCFOFFSETCNT Register (Offset = CAh) [Reset = 0000h]

DCFOFFSETCNT is shown in Figure 14-164 and described in Table 14-92.

Return to the Summary Table.

DCCAP							
R-0h							

Table 14-95. DCCAP Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	DCCAP	R	0h	Digital Compare Time-Base Counter Capture To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low to high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed. - If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value. - If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory map address. Reset type: SYSRSn

14.15.2.75 DCAHTRIPSEL Register (Offset = D2h) [Reset = 0000h]

DCAHTRIPSEL is shown in Figure 14-168 and described in Table 14-96.

Return to the Summary Table.

Chapter 15

Enhanced Capture (eCAP)

This chapter describes the enhanced capture (eCAP) module, which is used in systems where accurate timing of external events is important.

The enhanced capture (eCAP) module is a Type 0 eCAP. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with an eCAP module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

15.1 Introduction

15.1.1 Features

The features of the eCAP module include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed by way of Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module features described in this chapter include:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single-shot capture of up to four event time-stamps
- Continuous mode capture of time stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources are dedicated to a single input pin
- When not used in capture mode, the eCAP module can be configured as a single-channel PWM output

15.1.2 ECAP Related Collateral

Foundational Materials

- C2000 Academy - ECAP

Getting Started Materials

- *Leveraging High Resolution Capture (HRCAP) for Single Wire Data Transfer Application Report*

15.2 Description

The eCAP module represents one complete capture channel that can be instantiated multiple times, depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- Output X-BAR is used to configure output in APWM mode
- 32-bit time base (counter)
- 4 x 32-bit time-stamp capture registers (CAP1-CAP4)
- Four-stage sequencer (modulo4 counter) that is synchronized to external events, eCAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all four events
- Input capture signal prescaling (from 2-62 or bypass)
- One-shot compare register (two bits) to freeze captures after 1-4 time-stamp events
- Control for continuous time-stamp captures using a four-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the four capture events

15.3 Configuring Device Pins for the eCAP

The Input X-BAR connects the device pins to the module as input. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to synchronous or asynchronous mode by setting the GPxQSELn register bits. Using synchronized inputs can help with noise immunity but affects the eCAP accuracy by ±2 cycles. The internal pull-ups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals.

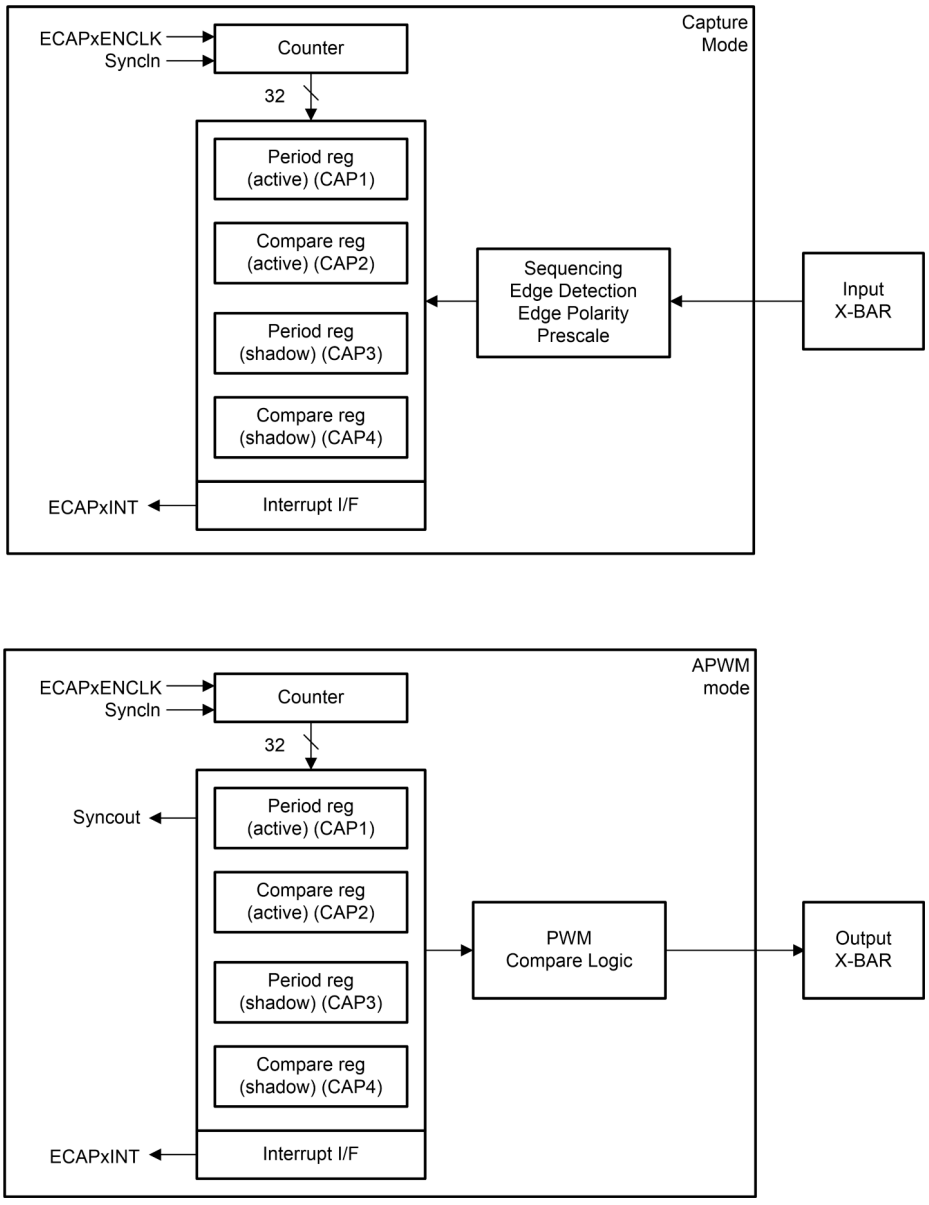
The Output X-BAR must be used to connect output signals to the OUTPUTXBARx output locations. The GPIO mux must then be configured to connect the OUTPUTXBARx lines to any of several IO pins with the GPIO mux. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

15.4 Capture and APWM Operating Mode

Use the eCAP module resources to implement a single-channel PWM generator (with 32-bit capabilities) when the eCAP module is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and compare shadow registers, respectively. Figure 15-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 15-2 further descries the output of the eCAP in APWM mode based on the CMP and PRD values.



A. A single pin is shared between CAP and APWM functions. In capture mode, the pin is an input; in APWM mode, the pin is an output.

B. In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

Figure 15-1. Capture and APWM Modes of Operation

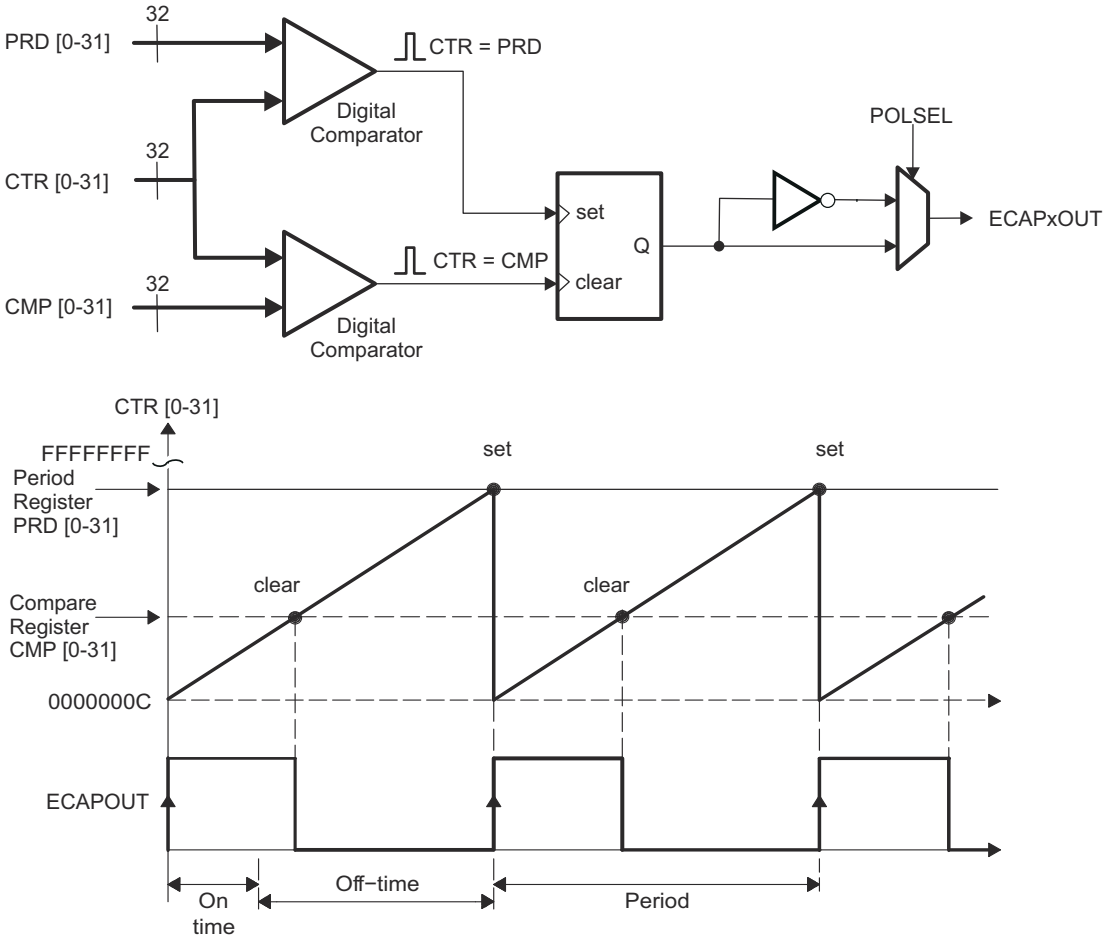


Figure 15-2. Counter Compare and PRD Effects on the eCAP Output in APWM Mode

15.5 Capture Mode Description

Figure 15-3 shows the various components that implement the capture function.

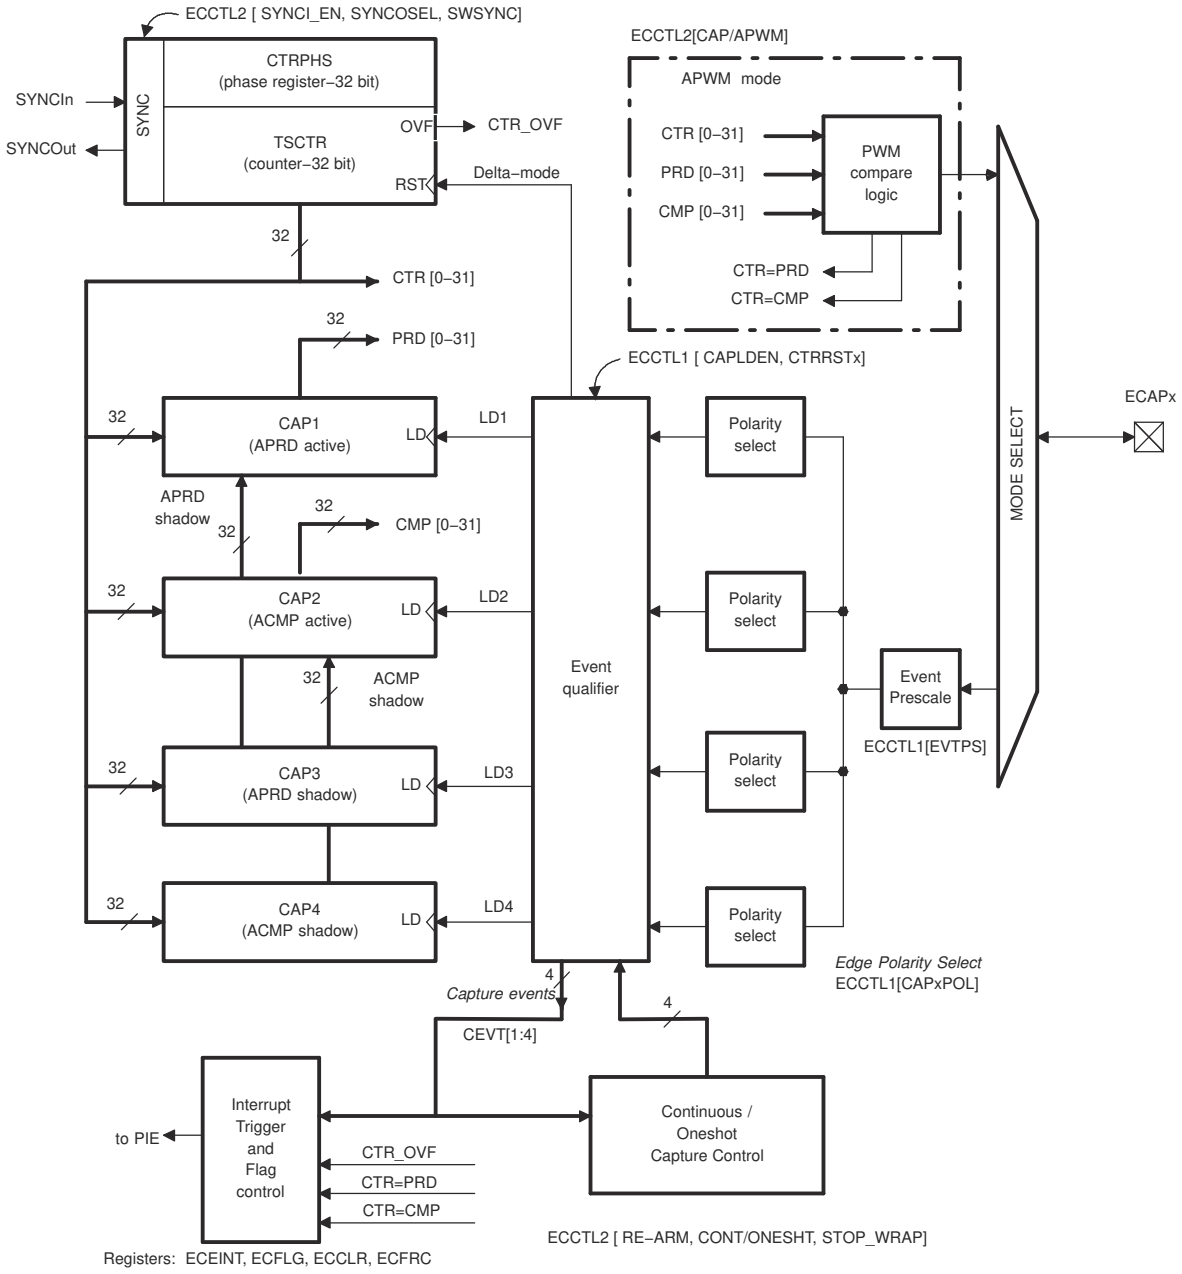

Figure 15-3. eCAP Block Diagram

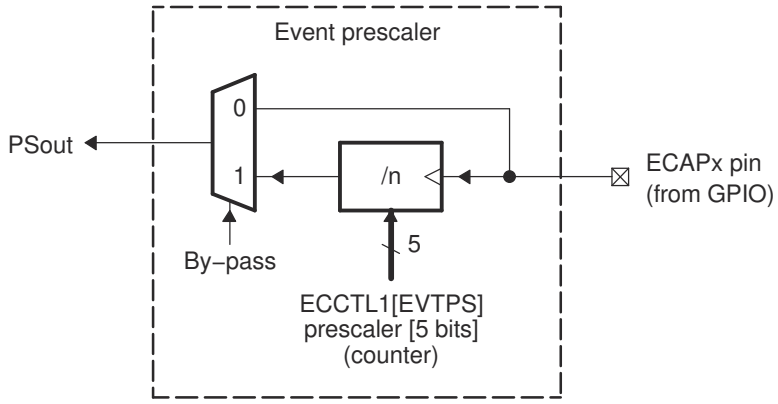
15.5.1 Event Prescaler

An input capture signal (pulse train) can be prescaled by N = 2-62 (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 15-4 shows a functional diagram and Figure 15-5 shows the operation of the prescale function.



A. When a prescale value of 1 is chosen (ECCTL1[13:9] = 0,0,0,0,0), the input capture signal bypasses the prescale logic completely.
B. The first Rise edge after Prescale configuration change is not passed to Capture logic, prescaler value takes into effect on the second rising edge after the configuration.

Figure 15-4. Event Prescale Control

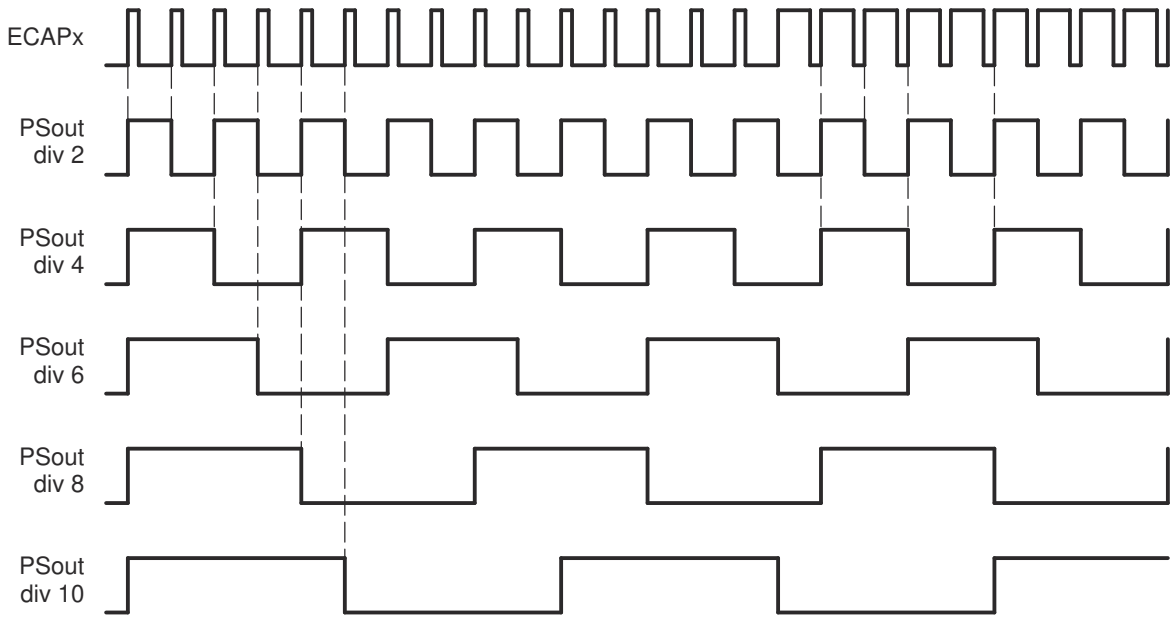


Figure 15-5. Prescale Function Waveforms

15.5.2 Edge Polarity Select and Qualifier

Functionality and features include:

- Four independent edge polarity (rising edge/falling edge) selection muxes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.

- The edge event is gated to the respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

15.5.3 Continuous/One-Shot Control

Operation of eCAP in Continuous/One-Shot mode:

- The Mod4 (2-bit) counter is incremented using edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- During one-shot operation, a 2-bit stop register (STOP_WRAP) is used to compare the Mod4 counter output, and when equal, stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. In this mode, if TSCCTR counter is configured to reset on capture event (CEVTx) by configuring ECCTL1.CTRRSTx bit, the operation still keeps resetting the TSCCTR counter on capture event (CEVTx) after the STOP_WRAP value is reached and re-arm (REARM) has not occurred.

The continuous/one-shot block controls the start, stop and reset (zero) functions of the Mod4 counter, using a mono-shot type of action that can be triggered by the stop-value comparator and re-armed using software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time stamps).

Re-arming prepares the eCAP module for another capture sequence. Also, re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

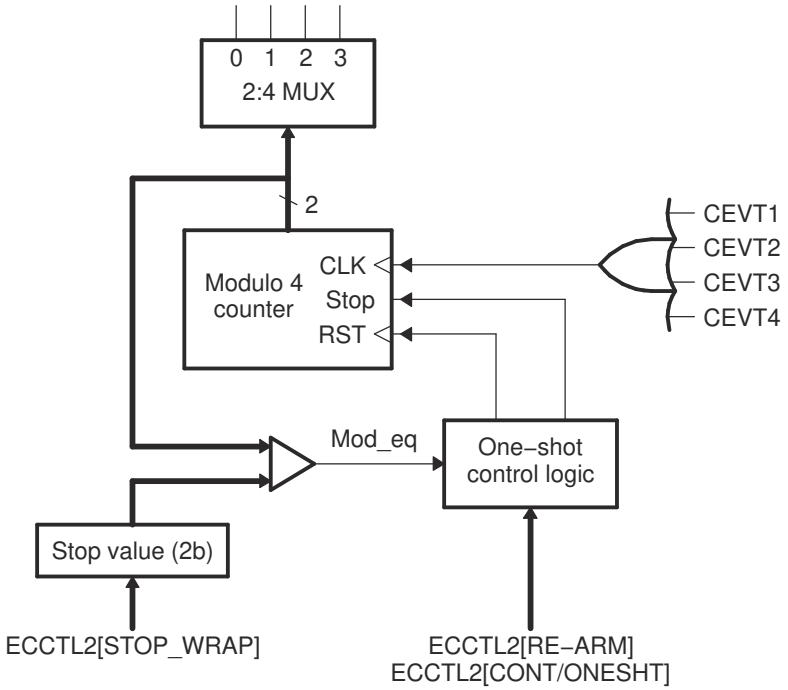

Figure 15-6. Details of the Continuous/One-shot Block

15.5.4 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked using the system clock.

A phase register is provided to achieve synchronization with other counters using a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then the counter value is reset to 0 by any of the LD1-LD4 signals.

15.5.5 CAP1-CAP4 Registers

These 32-bit registers are supplied by the 32-bit counter timer bus, CTR[0-31], and are loaded (capture a time-stamp) when the respective LD inputs are strobed.

Control bit CAPLDEN can inhibit loading of the capture registers. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

15.5.6 eCAP Synchronization

eCAP modules can be synchronized with each other by selecting a common SYNCIN source. SYNCIN source for eCAP can be either software sync-in or external sync-in. The external sync-in signal can come from EPWM, eCAP, or X-Bar. The SWSYNC of the eCAP module is logical ORed with the SYNC signal as shown in Figure 15-7. The SYNC signal is defined by the selection of SYNCSELECT[ECAPxSYNCIN] as shown in Figure 15-8.

Note

If SWSYNC is forced from ECAPx, then the Sync pulse is delayed by one clock cycle for sync pulse receiving ECAPs . This cycle delay/lag for the sync pulse receiving ECAPs can be corrected with the CTRPHS register. If there is an external SYNC signal, then all ECAPs see the signal at the same time.

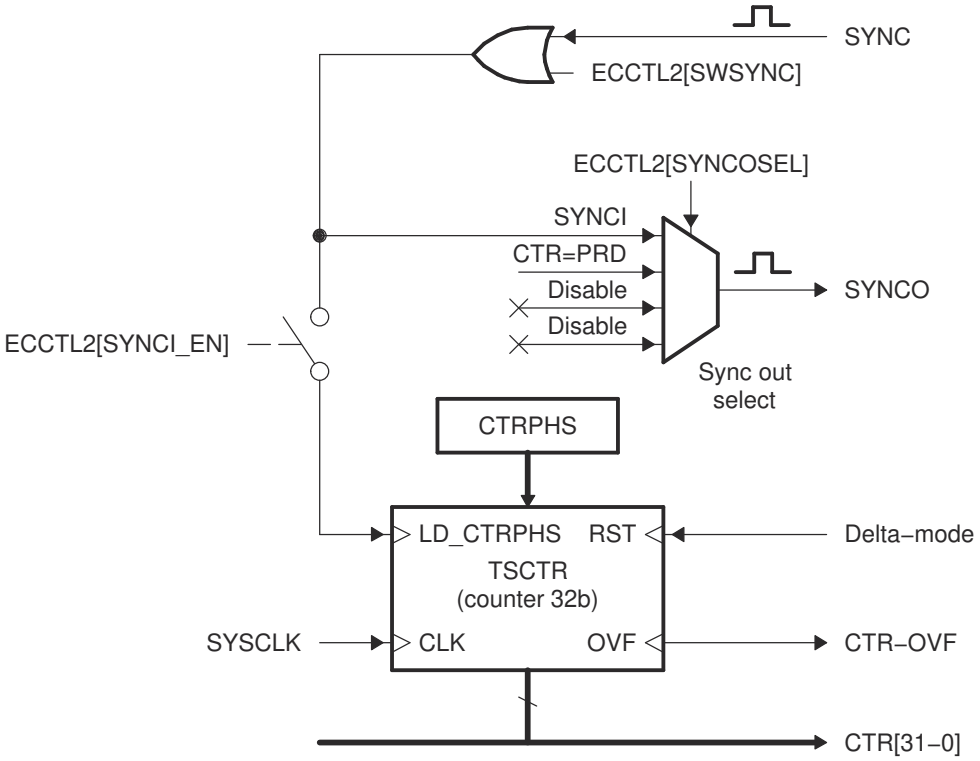

Figure 15-7. Details of the Counter and Synchronization Block

15.5.6.1 Example 1 - Using SWSYNC with ECAP Module

Implement the following steps to use SWSYNC with ECAP1 and ECAP3.

- Configure ECAP[1..3].ECCTL2.SYNCO_SEL = 0x0, to allow the sync-in event to be the sync-out signal pass through.
- Configure ECAP[2..3].ECCTL2.SWSYNC = 0x0, to disable software synchronization for eCAP2 through eCAP3.
- The default sync signal comes from ePWM1, if TBCTL[SYNCOSEL] is not correctly configured this can cause undesired resets of the time-stamp register (TSCTR). Select an unused GPIO in InputXbarRegs.INPUT5SELECT. Configure this GPIO in output mode and write 0 to the GPIO DAT register. By default, this is programmed to GPIO0 so any activity on this pin can cause problems with the SWSYNC.
- Program SYNCSEL[ECAP1SYNCIN] = 0x5. This takes ECAPx.EXTSYNCIN to an inactive state.
- Configure ECAP1.ECCTL2.SWSYNC=0x1, this forces Software Synchronization of TSCTR counter

To use SWSYNC with other eCAP modules, make sure that the previous eCAP chain is not generating a SYNCOUT signal that interferes with the software synchronization.

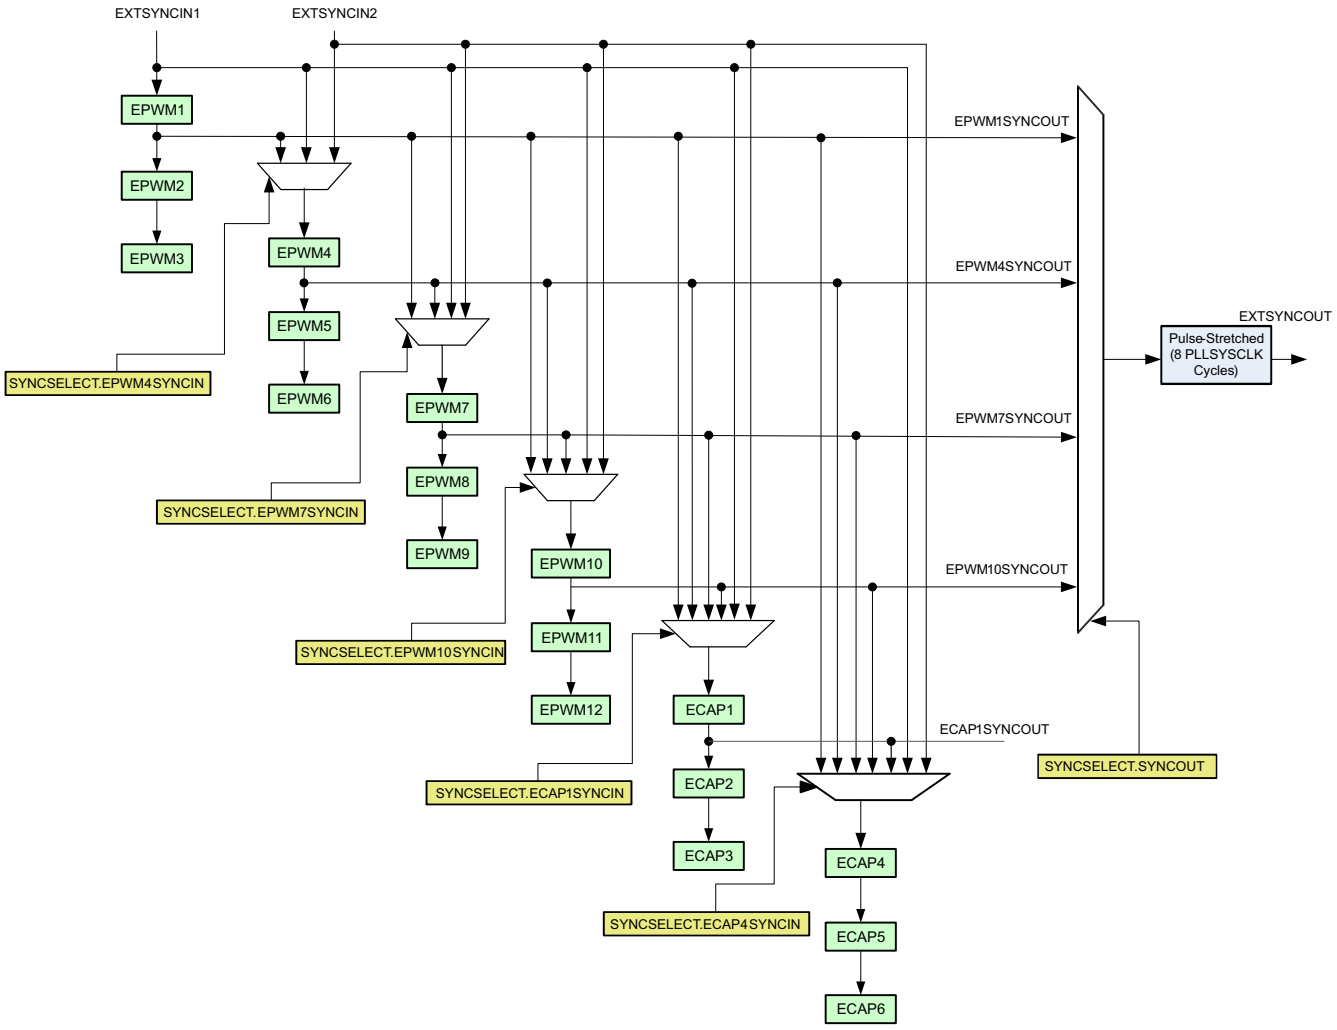

Figure 15-8. Time-Base Counter Synchronization Scheme

15.5.7 Interrupt Control

Operation and features of the eCAP interrupt control include (see Figure 15-9):

- An interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).
- A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).
- The capture events are edge and sequencer-qualified (ordered in time) by the polarity select and Mod4 gating, respectively.
- One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE and CLA.
- Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR=PRD, CTR=CMP) can be generated.
- The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event using the interrupt clear register (ECCLR) before any other interrupt pulses are generated. To force an interrupt event, use the interrupt force register (ECFRC). This is useful for test purposes.

Note

The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR=PRD, CTR=CMP flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

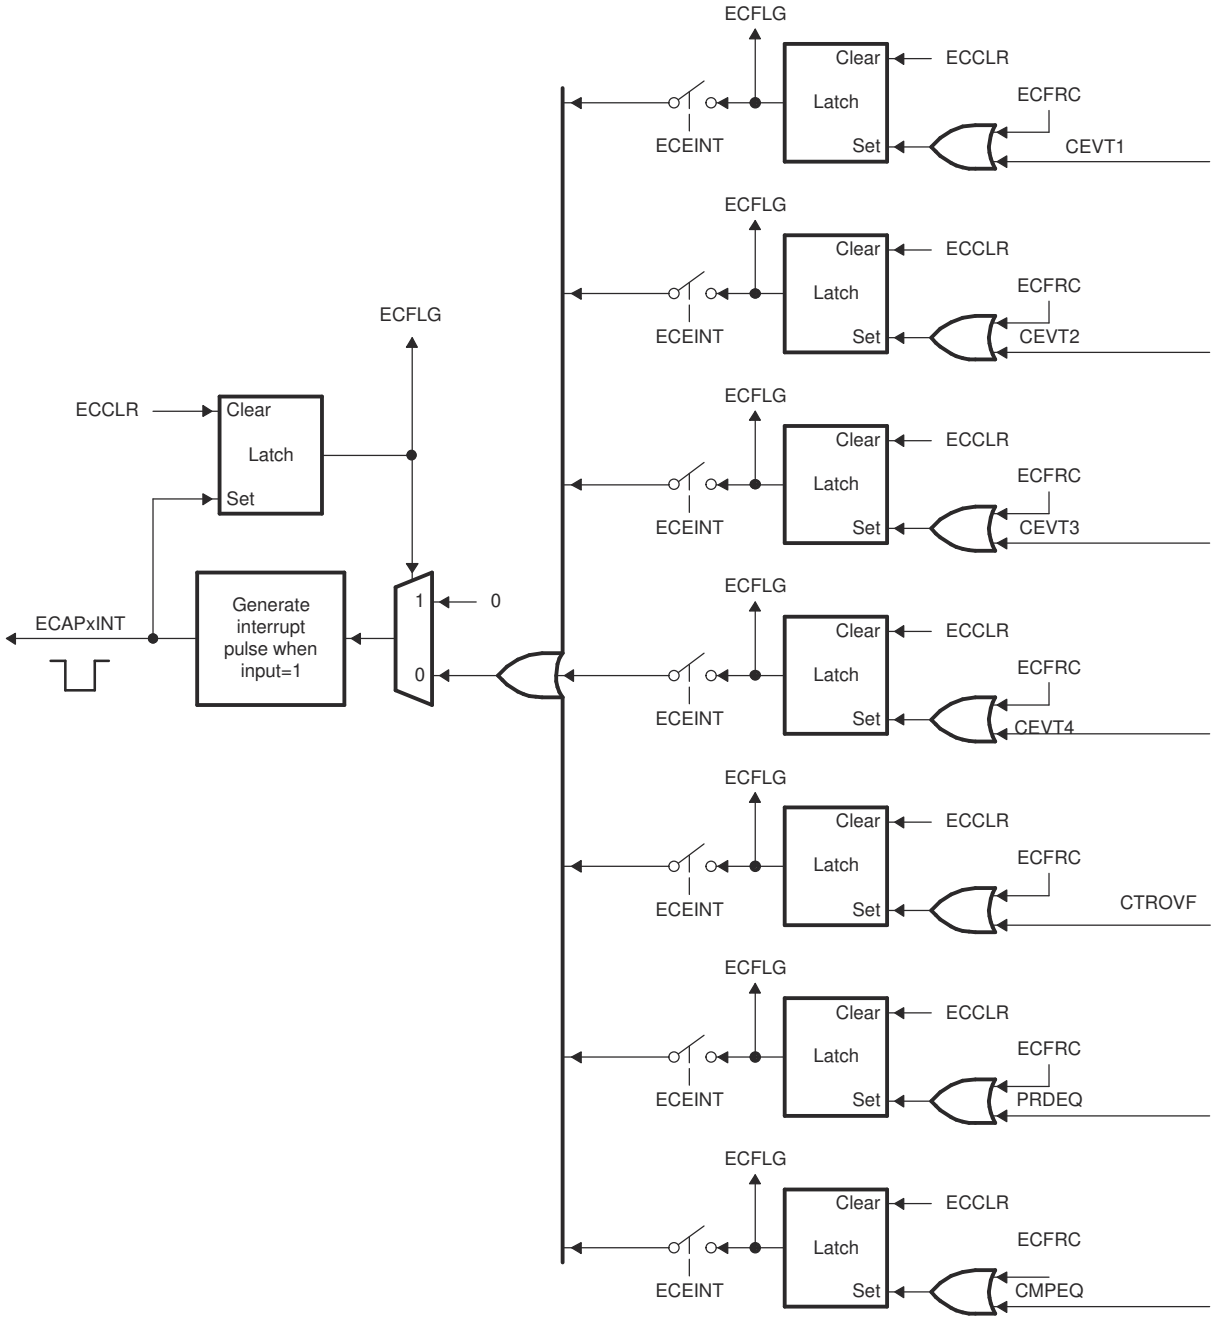

Figure 15-9. Interrupts in eCAP Module

15.5.8 DMA Interrupt

On Type 0 eCAP modules, the CPU was required to begin data transfers using DMA. New to the Type 1 eCAP, a separate DMA Trigger (ECAP_DMA_INT) enables continuous transfer of capture data from eCAP registers to on-chip memory using DMA. Any one of the four available interrupt events () can be selected as the trigger source for ECAP_DMA_INT using ECCTL2 [DMAEVTSEL].

15.5.9 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0].

15.5.10 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison by way of 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, the contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved using shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers, either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.
- During initialization, write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates during run-time, use the shadow registers.

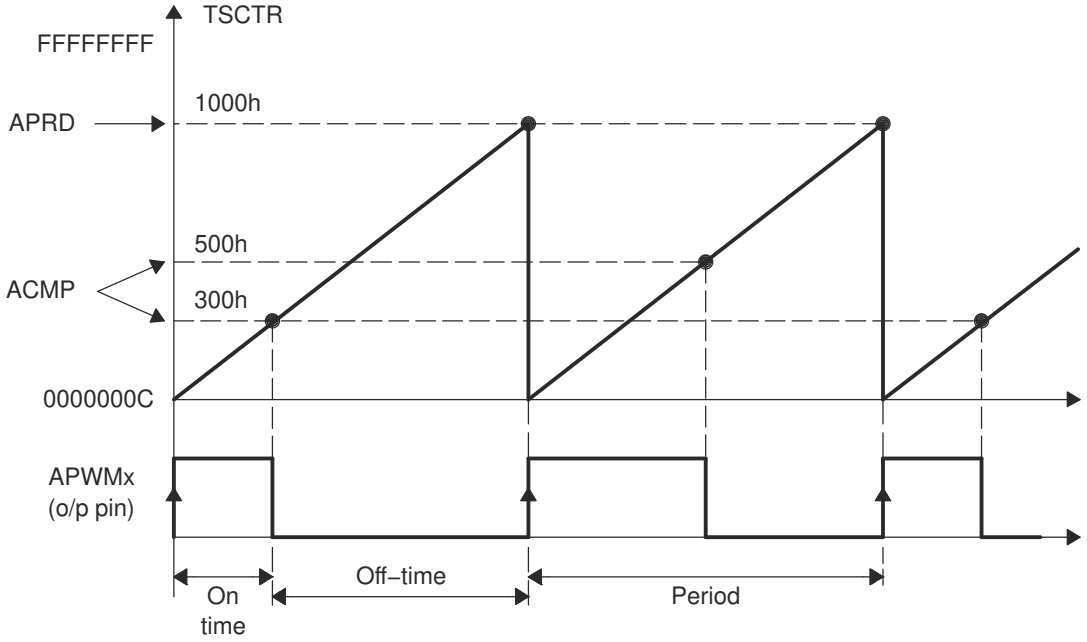

Figure 15-10. PWM Waveform Details Of APWM Mode Operation

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

```
CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period
```

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

```
CMP = 0x00000000, output high for duration of period (0% duty)

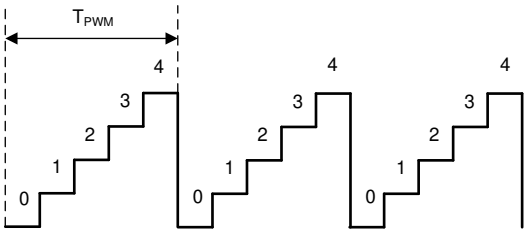
CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period
```



$$T_{PWM} = (CAP1 + 1) \times T_{TSCTR}$$

$$F_{PWM} = \frac{1}{T_{PWM}}$$

Figure 15-11. Time-Base Frequency and Period Calculation

15.6 Application of the eCAP Module

The following sections provide applications examples to show how to operate the eCAP module.

15.6.1 Example 1 - Absolute Time-Stamp Operation Rising-Edge Trigger

Figure 15-12 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFFFFFF (maximum value), the Mod4 counter wraps around to 00000000 (not shown in Figure 15-12), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram (after the fourth event); hence, event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

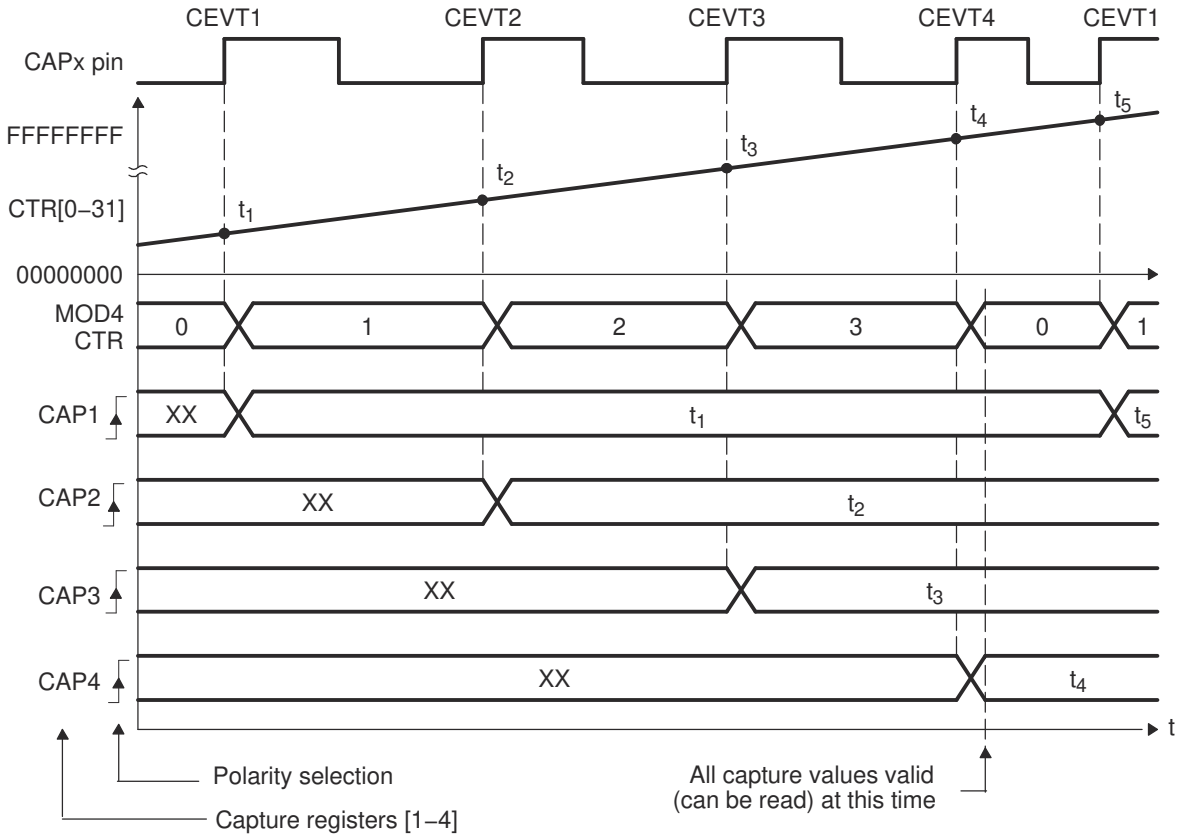


Figure 15-12. Capture Sequence for Absolute Time-stamp and Rising-Edge Detect

15.6.2 Example 2 - Absolute Time-Stamp Operation Rising- and Falling-Edge Trigger

In Figure 15-13, the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 = $t_3 - t_1$, Period2 = $t_5 - t_3$, …and so on. Duty Cycle1 (on-time %) = $(t_2 - t_1)$ / Period1 x 100%, and so on. Duty Cycle1 (off-time %) = $(t_3 - t_2)$ / Period1 x 100%, and so on.

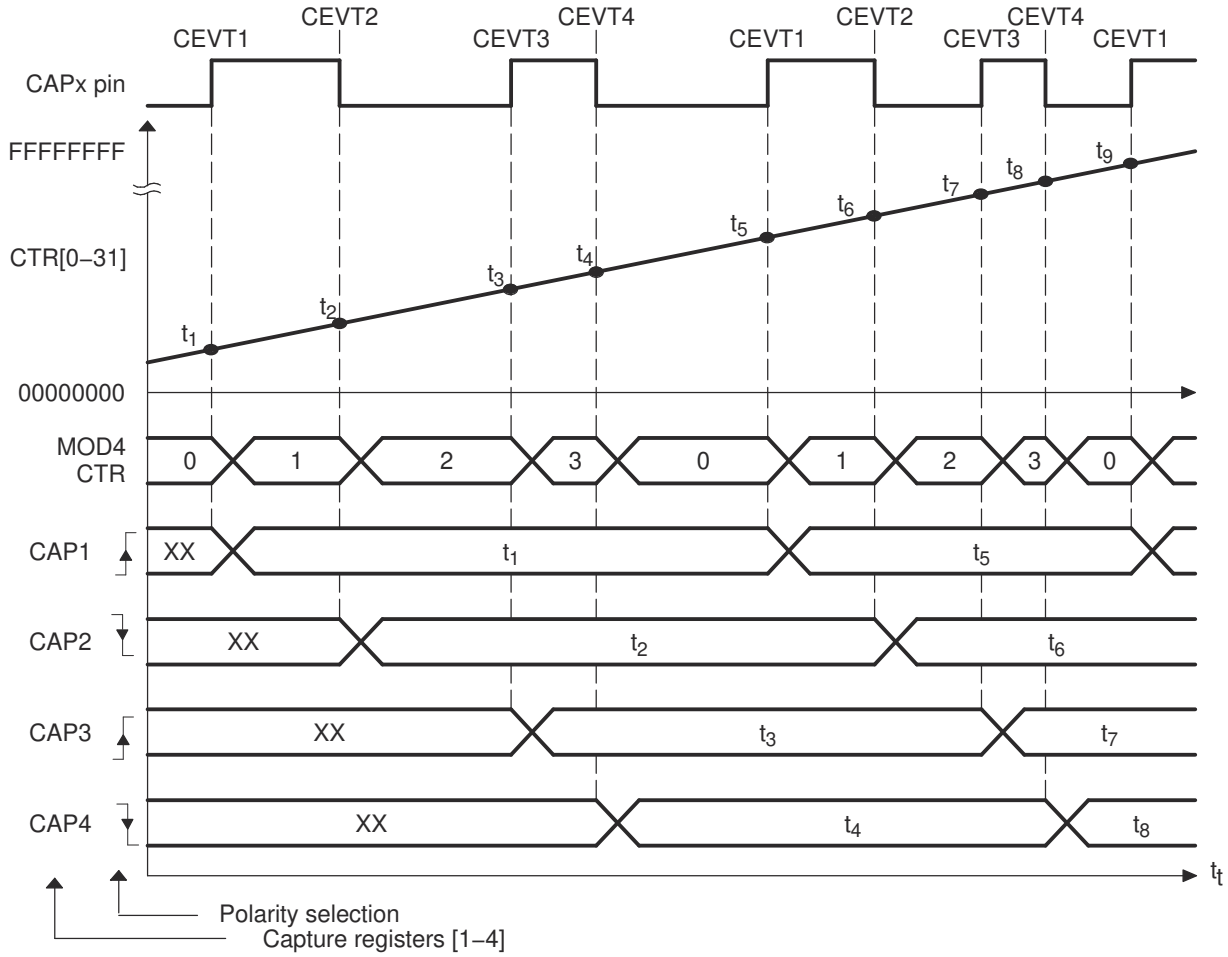

Figure 15-13. Capture Sequence for Absolute Time-stamp with Rising- and Falling-Edge Detect

15.6.3 Example 3 - Time Difference (Delta) Operation Rising-Edge Trigger

Figure 15-14 shows how the eCAP module can be used to collect delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is reset back to zero on every valid event. Here capture events are qualified as rising edge only. On an event, TSCTR contents (Time-Stamp) is captured first, and then TSCTR is reset to zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFFFFFF (maximum value), before the next event, the Mod4 counter wraps around to 00000000 and continues, a CNTOVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. The advantage of Delta-time mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is, Period1 = T_1, Period2 = T_2, and so on. As shown in Figure 15-14, the CEVT1 event is a good trigger point to read the timing data, T_1, T_2, T_3, T_4 are all valid here.

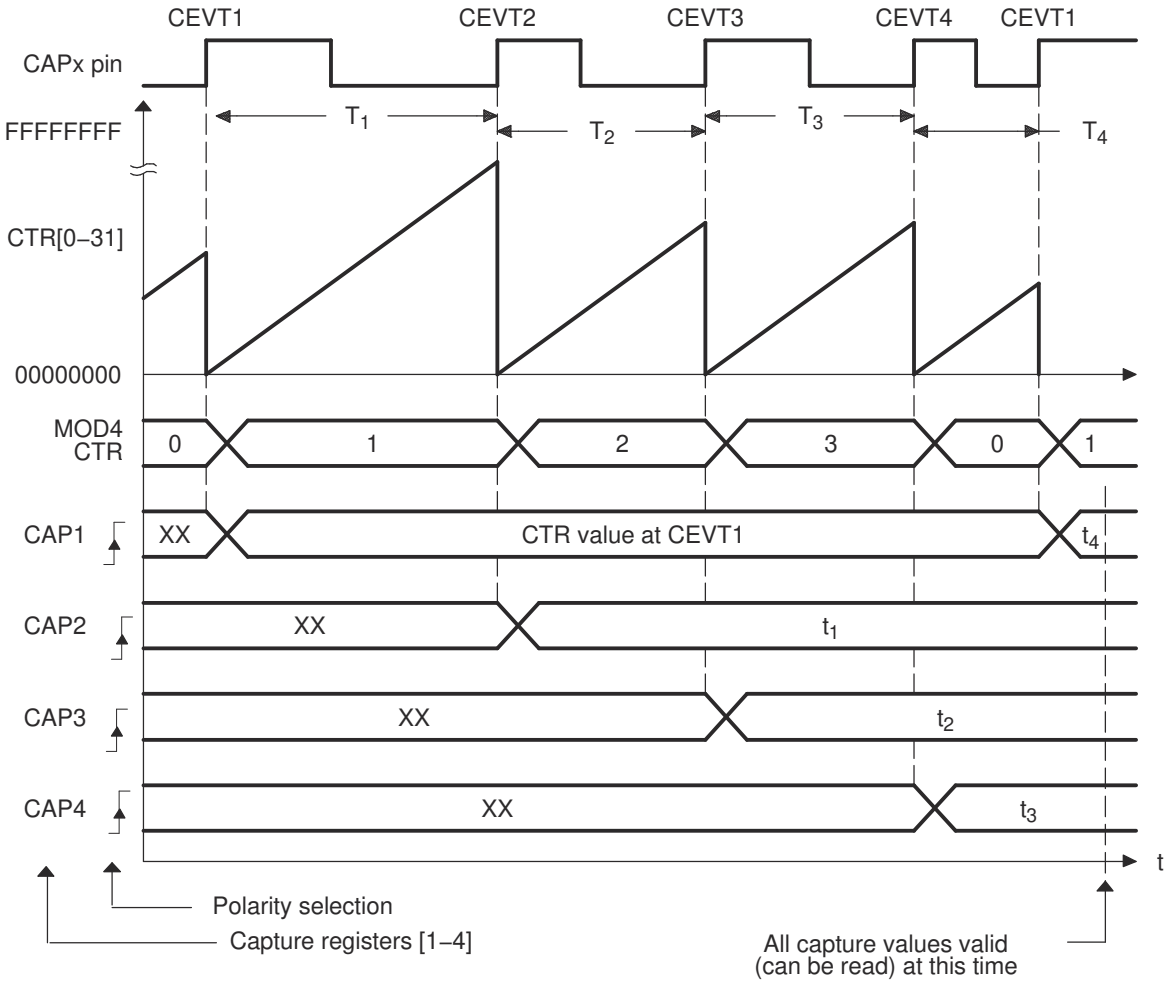

Figure 15-14. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect

15.6.4 Example 4 - Time Difference (Delta) Operation Rising- and Falling-Edge Trigger

In Figure 15-15, the eCAP operating mode is almost the same as in previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 = T_1+T_2, Period2 = T_3+T_4, and so on. Duty Cycle1 (on-time %) = T_1 / Period1 x 100%, Duty Cycle1 (off-time %) = T_2 / Period1 x 100%, and so on.

During initialization, write to the active registers for both period and compare. This action automatically copies the init values into the shadow values. For subsequent compare updates during run-time, the shadow registers must be used.

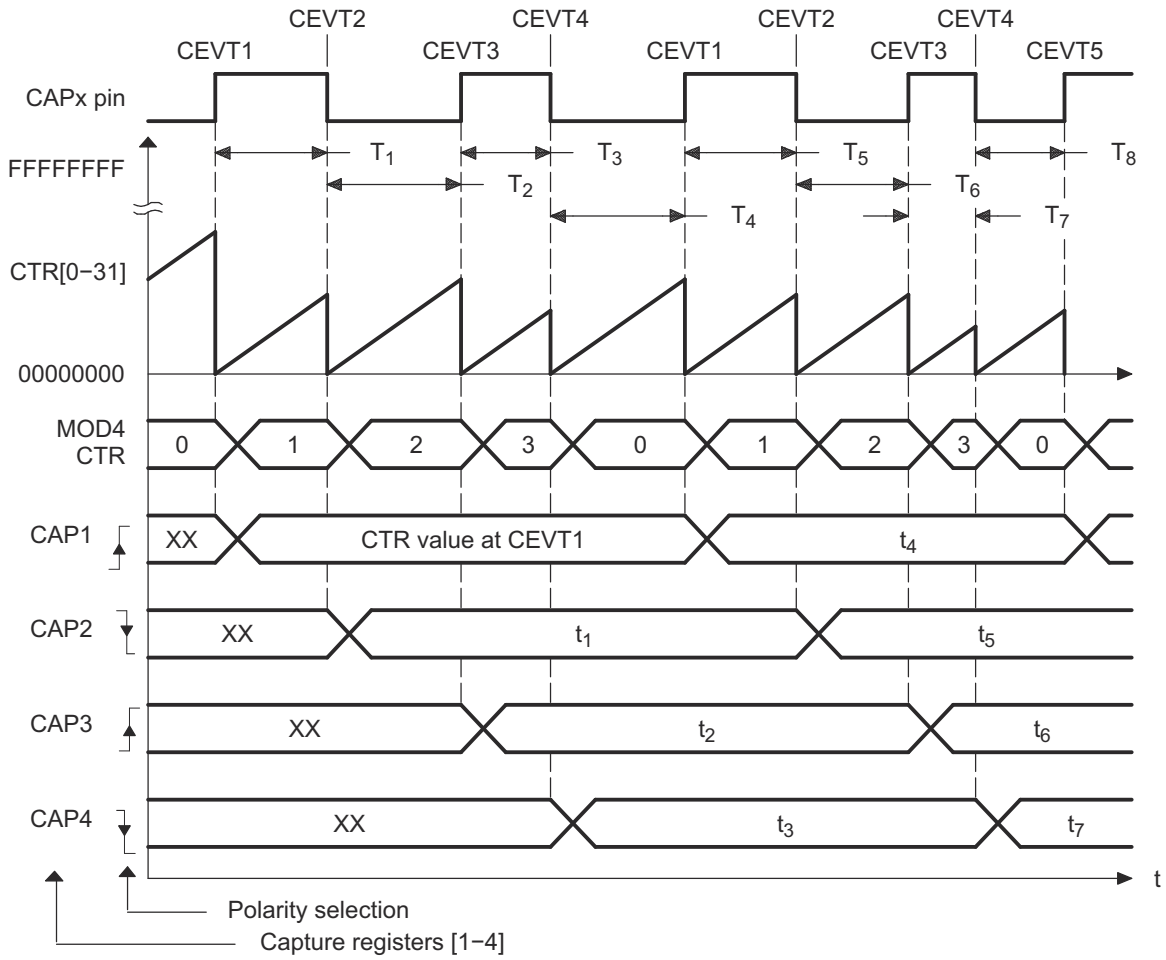

Figure 15-15. Capture Sequence for Delta Mode Time-stamp with Rising- and Falling-Edge Detect

15.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here, a very simple single-channel PWM waveform is generated from the APWMx output pin. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

15.7.1 Example 1 - Simple PWM Generation (Independent Channels)

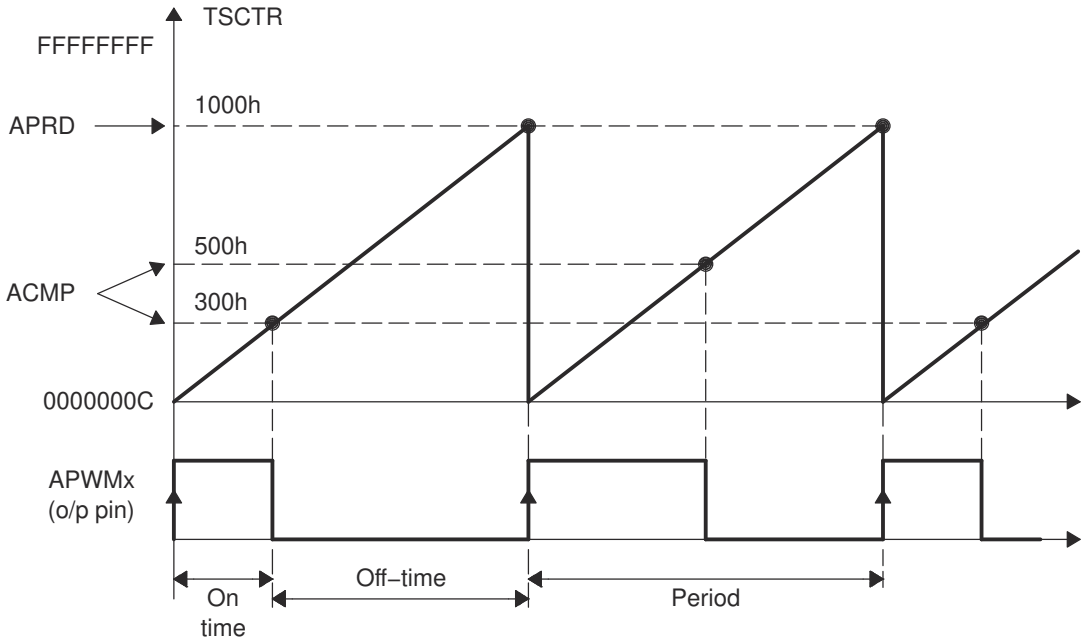

Figure 15-16. PWM Waveform Details of APWM Mode Operation

15.8 Software

15.8.1 ECAP Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/ecap

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

15.8.1.1 eCAP APWM Example

FILE: ecap_ex1_apwm.c

This program sets up the eCAP module in APWM mode. The PWM waveform will come out on GPIO5. The frequency of PWM is configured to vary between 5Hz and 10Hz using the shadow registers to load the next period/compare values.

15.8.1.2 eCAP Capture PWM Example

FILE: ecap_ex2_capture_pwm.c

This example configures ePWM3A for:
- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1 is configured to capture the time between rising and falling edge of the ePWM3A output.

External Connections
- eCAP1 is on GPIO16
- ePWM3A is on GPIO4
- Connect GPIO4 to GPIO16.

Watch Variables
- *ecap1PassCount* - Successful captures.
- *ecap1IntCount* - Interrupt counts.

15.8.1.3 eCAP APWM Phase-shift Example

FILE: ecap_ex3_apwm_phase_shift.c

This program sets up the eCAP1 and eCAP2 modules in APWM mode to generate the two phase-shifted PWM outputs of same duty and frequency value The frequency, duty and phase values can be programmed of choice by updating the defined macros. By default 10 Khz frequency, 50% duty and 30% phase shift values are used. eCAP2 output leads the eCAP1 output by 30% GPIO5 and GPIO6 are used as eCAP1/2 outputs and can be probed using analyzer/CRO to observe the waveforms.

15.8.1.4 eCAP Software Sync Example

FILE: ecap_ex4_sw_sync.c

This example configures ePWM3A for:
- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1, eCAP2 and eCAP3 are configured to capture the time between rising and falling edge of the ePWM3A output.

External Connections
- eCAP1, eCAP2, eCAP3 are on GPIO16
- ePWM3A is on GPIO4
- Connect GPIO4 to GPIO16.

Watch Variables

- *ecapPassCount* - Successful captures.
- *ecap3IntCount* - Interrupt counts.

15.9 eCAP Registers

This section describes the Enhanced Capture Registers.

15.9.1 eCAP Base Addresses

Table 15-1. eCAP Base Address Table

Device Register	Register Name	Start Address	End Address
ECap1Regs	ECAP_REGS	0x0000_5000	0x0000_501F
ECap2Regs	ECAP_REGS	0x0000_5020	0x0000_503F
ECap3Regs	ECAP_REGS	0x0000_5040	0x0000_505F
ECap4Regs	ECAP_REGS	0x0000_5060	0x0000_507F
ECap5Regs	ECAP_REGS	0x0000_5080	0x0000_509F
ECap6Regs	ECAP_REGS	0x0000_50A0	0x0000_50BF

15.9.2 ECAP_REGS Registers

Table 15-2 lists the memory-mapped registers for the ECAP_REGS registers. All register offset addresses not listed in Table 15-2 should be considered as reserved locations and the register contents should not be modified.

Table 15-2. ECAP_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	TSCTR	Time-Stamp Counter		Go
2h	CTRPHS	Counter Phase Offset Value Register		Go
4h	CAP1	Capture 1 Register		Go
6h	CAP2	Capture 2 Register		Go
8h	CAP3	Capture 3 Register		Go
Ah	CAP4	Capture 4 Register		Go
14h	ECCTL1	Capture Control Register 1		Go
15h	ECCTL2	Capture Control Register 2		Go
16h	ECEINT	Capture Interrupt Enable Register		Go
17h	ECFLG	Capture Interrupt Flag Register		Go
18h	ECCLR	Capture Interrupt Clear Register		Go
19h	ECFRC	Capture Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 15-3 shows the codes that are used for access types in this section.

Table 15-3. ECAP_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

15.9.2.1 TSCTR Register (Offset = 0h) [Reset = 00000000h]

TSCTR is shown in Figure 15-17 and described in Table 15-4.

Return to the Summary Table.

Time-Stamp Counter

Figure 15-17. TSCTR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED					APWMPOL	CAP_APWM	SWSYNC
R-0h					R/W-0h	R/W-0h	R-0/W1S-0h
7	6	5	4	3	2	1	0
SYNCO_SEL		SYNCI_EN	TSCTRSTOP	REARM	STOP_WRAP		CONT_ONESHT
R/W-0h		R/W-0h	R/W-0h	R-0/W1S-0h	R/W-3h		R/W-0h

Table 15-11. ECCTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10	APWMPOL	R/W	0h	APWM output polarity select. This is applicable only in APWM operating mode. Reset type: SYSRSn 0h (R/W) = Output is active high (Compare value defines high time) 1h (R/W) = Output is active low (Compare value defines low time)
9	CAP_APWM	R/W	0h	CAP/APWM operating mode select Reset type: SYSRSn 0h (R/W) = ECAP module operates in capture mode. This mode forces the following configuration: - Inhibits TSCTR resets via CTR = PRD event - Inhibits shadow loads on CAP1 and 2 registers - Permits user to enable CAP1-4 register load - CAPx/APWMx pin operates as a capture input 1h (R/W) = ECAP module operates in APWM mode. This mode forces the following configuration: - Resets TSCTR on CTR = PRD event (period boundary - Permits shadow loading on CAP1 and 2 registers - Disables loading of time-stamps into CAP1-4 registers - CAPx/APWMx pin operates as a APWM output
8	SWSYNC	R-0/W1S	0h	Software-forced Counter (TSCTR) Synchronizer. This provides the user a method to generate a synchronization pulse through software. In APWM mode, the synchronization pulse can also be sourced from the CTR = PRD event. Reset type: SYSRSn 0h (R/W) = Writing a zero has no effect. Reading always returns a zero 1h (R/W) = Writing a one forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to a zero.
7-6	SYNCO_SEL	R/W	0h	Sync-Out Select Reset type: SYSRSn 0h (R/W) = Select sync-in event to be the sync-out signal (pass through) 1h (R/W) = Select CTR = PRD event to be the sync-out signal. Note: Selection CTR = PRD is meaningful only in APWM mode 2h (R/W) = Disable sync out signal 3h (R/W) = Disable sync out signal

Table 15-11. ECCTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SYNCI_EN	R/W	0h	Counter (TSCTR) Sync-In select mode Reset type: SYSRSn 0h (R/W) = Disable sync-in option 1h (R/W) = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCI signal or a S/W force event.
4	TSCTRSTOP	R/W	0h	Time Stamp (TSCTR) Counter Stop (freeze) Control Reset type: SYSRSn 0h (R/W) = TSCTR stopped 1h (R/W) = TSCTR free-running
3	REARM	R-0/W1S	0h	Re-Arming Control. Note: The re-arm function is valid in one shot or continuous mode. Reset type: SYSRSn 0h (R/W) = Has no effect (reading always returns a 0) 1h (R/W) = Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to zero 2) Unfreezes the Mod4 counter 3) Enables capture register loads
2-1	STOP_WRAP	R/W	3h	Stop value for one-shot mode. This is the number (between 1-4) of captures allowed to occur before the CAP(1-4) registers are frozen, that is, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1-4) of the capture register in which the circular buffer wraps around and starts again. Notes: STOP_WRAP is compared to Mod4 counter and, when equal, 2 actions occur: - Mod4 counter is stopped (frozen) - Capture register loads are inhibited In one-shot mode, further interrupt events are blocked until re-armed. Reset type: SYSRSn 0h (R/W) = Stop after Capture Event 1 in one-shot mode Wrap after Capture Event 1 in continuous mode. 1h (R/W) = Stop after Capture Event 2 in one-shot mode Wrap after Capture Event 2 in continuous mode. 2h (R/W) = Stop after Capture Event 3 in one-shot mode Wrap after Capture Event 3 in continuous mode. 3h (R/W) = Stop after Capture Event 4 in one-shot mode Wrap after Capture Event 4 in continuous mode.
0	CONT_ONESHT	R/W	0h	Continuous or one-shot mode control (applicable only in capture mode) Reset type: SYSRSn 0h (R/W) = Operate in continuous mode 1h (R/W) = Operate in one-Shot mode

15.9.2.9 ECEINT Register (Offset = 16h) [Reset = 0000h]

ECEINT is shown in Figure 15-25 and described in Table 15-12.

Return to the Summary Table.

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers.
The proper procedure for configuring peripheral modes and interrupts is as follows:
- Disable global interrupts
- Stop eCAP counter
- Disable eCAP interrupts
- Configure peripheral registers
- Clear spurious eCAP interrupt flags
- Enable eCAP interrupts
- Start eCAP counter
- Enable global interrupts

Chapter 16

Enhanced Quadrature Encoder Pulse (eQEP)

The enhanced Quadrature Encoder Pulse (eQEP) module described here is a Type 0 eQEP. See the *C2000 Real-Time Control Peripheral Reference Guide* for a list of all devices with a module of the same type to determine the differences between types and for a list of device-specific differences within a type.

The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system.

16.1 Introduction

An incremental encoder disk is patterned with a track of slots along the periphery, as shown in Figure 16-1. These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark and light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference

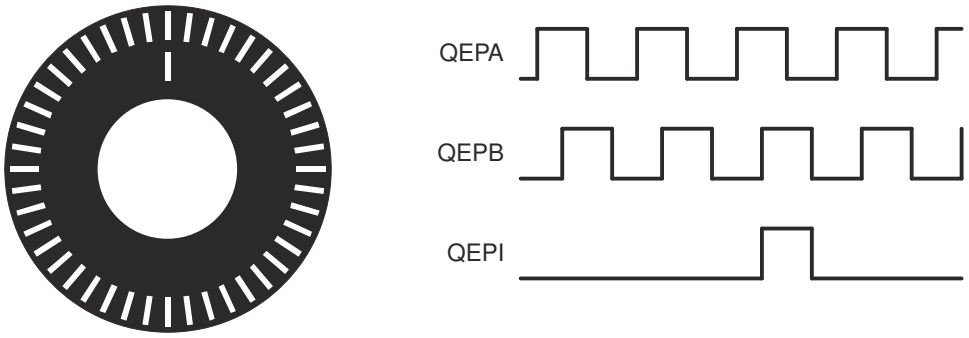

Figure 16-1. Optical Encoder Disk

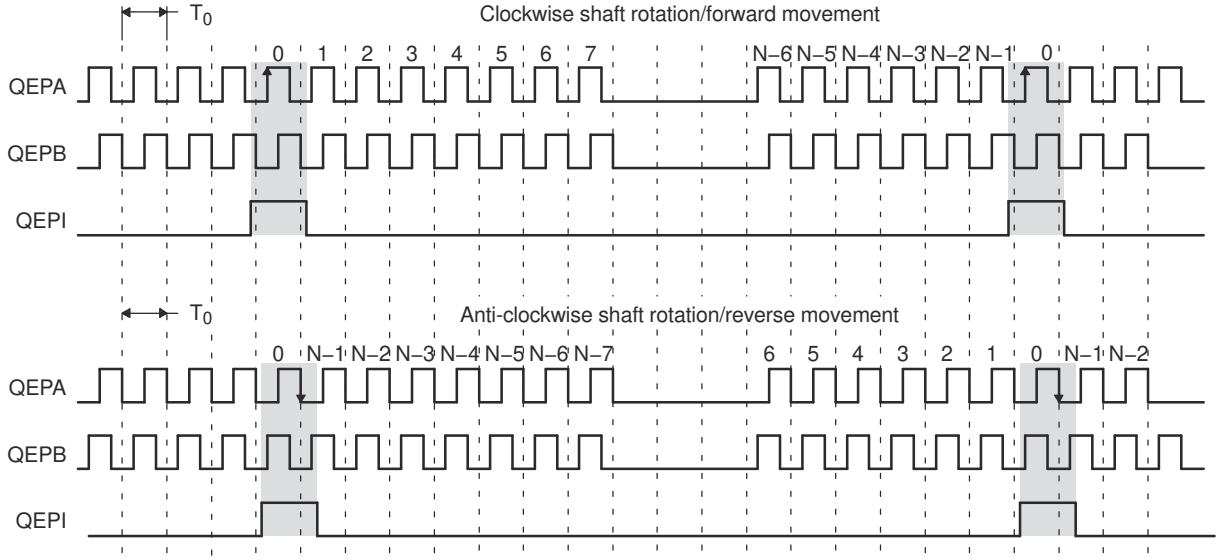
To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is detected with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90° out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and conversely, as shown in Figure 16-2.



Legend: N = lines per revolution

Figure 16-2. QEP Encoder Output Signal for Forward/Reverse Movement

The encoder wheel typically makes one revolution for every revolution of the motor, or the wheel can be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder

directly coupled to a motor running at 5000 revolutions-per-minute (rpm) results in a frequency of 166.6kHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 16-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

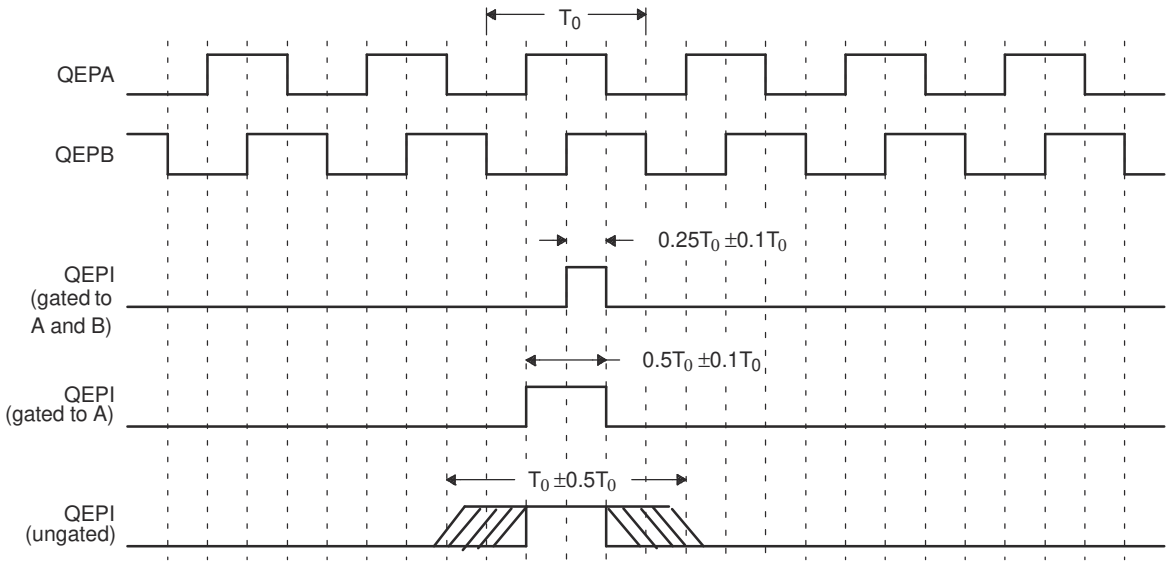


Figure 16-3. Index Pulse Example

Some typical applications of shaft encoders include robotics and computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

General Issues: Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity can be written as:

$$v(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (18)$$

$$v(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (19)$$

where:

- v(k) = Velocity at time instant k
- x(k) = Position at time instant k
- x(k-1) = Position at time instant k-1
- T = Fixed unit time or inverse of velocity calculation rate
- ΔX = Incremental position movement in unit time
- t(k) = Time instant "k"
- t(k-1) = Time instant "k-1"
- X = Fixed unit position
- ΔT = Incremental time elapsed for unit position movement

Equation 18 is the conventional approach to velocity estimation and requires a time base to provide a unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity [x(k) - x(k-1)] is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant 1/T (where T is the constant time between unit time events and is known in advance).

Estimation based on Equation 18 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T. For example, consider a 500 line-per-revolution quadrature encoder with a velocity calculation rate of 400Hz. When used for position, the quadrature encoder gives a four-fold increase in resolution; in this case, 2000 counts-per-revolution. The minimum rotation that can be detected is, therefore, 0.0005 revolutions, which gives a velocity resolution of 12rpm when sampled at 400Hz. While this resolution can be satisfactory at moderate or high speeds, for example 1% error at 1200rpm, this resolution clearly proves inadequate at low speeds. In fact, at speeds below 12rpm, the speed estimate is erroneously zero much of the time.

At low speed, Equation 19 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 19 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 18. A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 19 at low speed and have the DSP software switch over to Equation 18 when the motor speed rises above some specified threshold.

16.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper operation of the eQEP module, input GPIO pins must be configured using the GPxQSELn registers for synchronous input mode (with or without qualification). The asynchronous mode cannot be used for eQEP input pins. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

16.3 Description

This section provides the eQEP inputs, memory map, and functional description.

16.3.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input. The eQEP module requires that the QEPA, QEPB, and QEPI inputs are synchronized to SYSCLK prior to entering the module. The application code can enable the synchronous GPIO input feature on any eQEP-enabled GPIO pins (see the *General-Purpose Input/Output (GPIO)* chapter for more details).

- **QEPA/XCLK and QEPB/XDIR:** These two pins can be used in quadrature-clock mode or direction-count mode.
  - Quadrature-clock Mode: The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase. This phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and conversely. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
  - Direction-count Mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.
- **QEPI: Index or Zero Marker:** The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- **QEPS: Strobe Input:** This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

16.3.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in Figure 16-4):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)

16.4 Quadrature Decoder Unit (QDU)

Figure 16-5 shows a functional block diagram of the QDU.

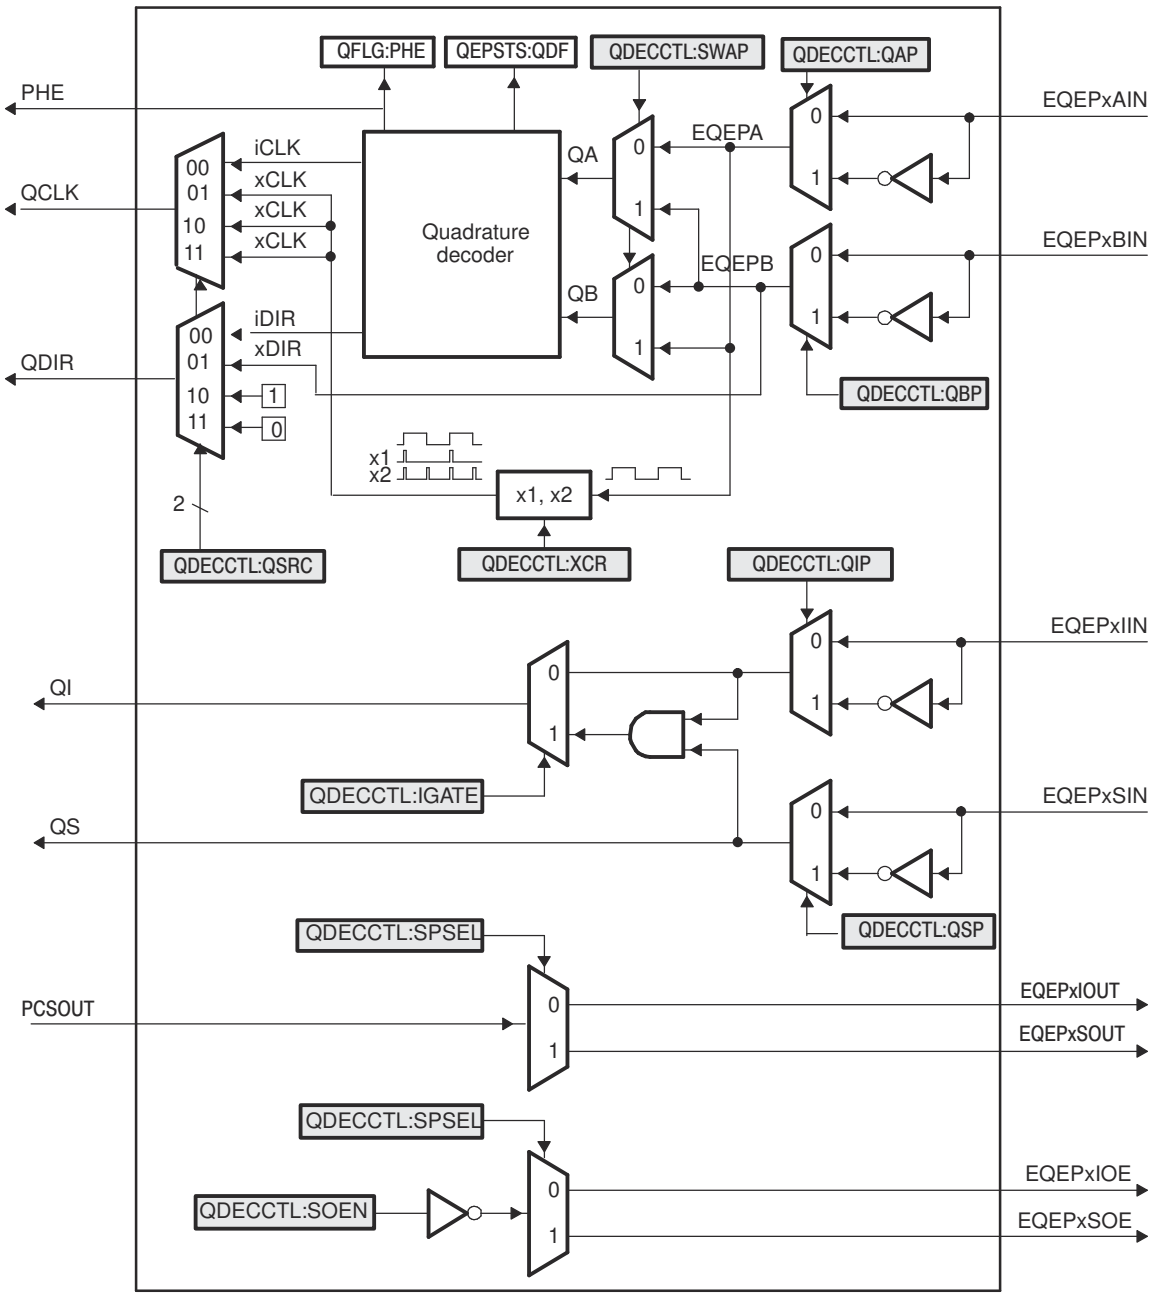

Figure 16-5. Functional Block Diagram of Decoder Unit

16.4.1 Position Counter Input Modes

Clock and direction input to the position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

16.4.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

Direction Decoding

The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QEPSTS[QDF] bit. Table 16-2 and Figure 16-6 show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 16-7 shows the direction decoding and clock generation from the eQEP input signals.

Table 16-2. Quadrature Decoder Truth Table

Previous Edge	Present Edge	QDIR	QPOSCNT
QA↑	QB↑	UP	Increment
	QB↓	DOWN	Decrement
	QA↓	TOGGLE	Increment or Decrement
QA↓	QB↓	UP	Increment
	QB↑	DOWN	Decrement
	QA↑	TOGGLE	Increment or Decrement

	QA↑	UP	Increment
	QB↑	TOGGLE	Increment or Decrement

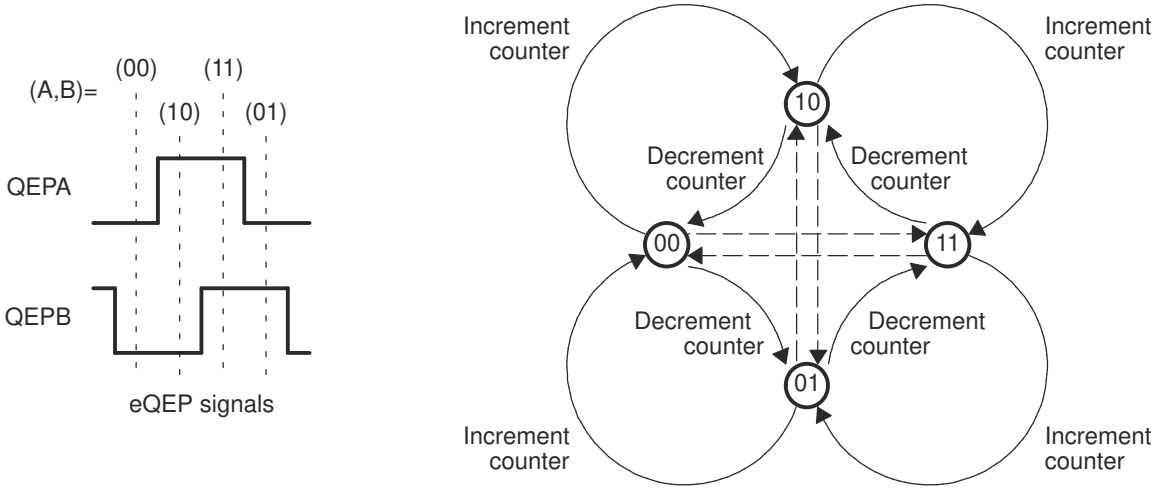

Figure 16-6. Quadrature Decoder State Machine

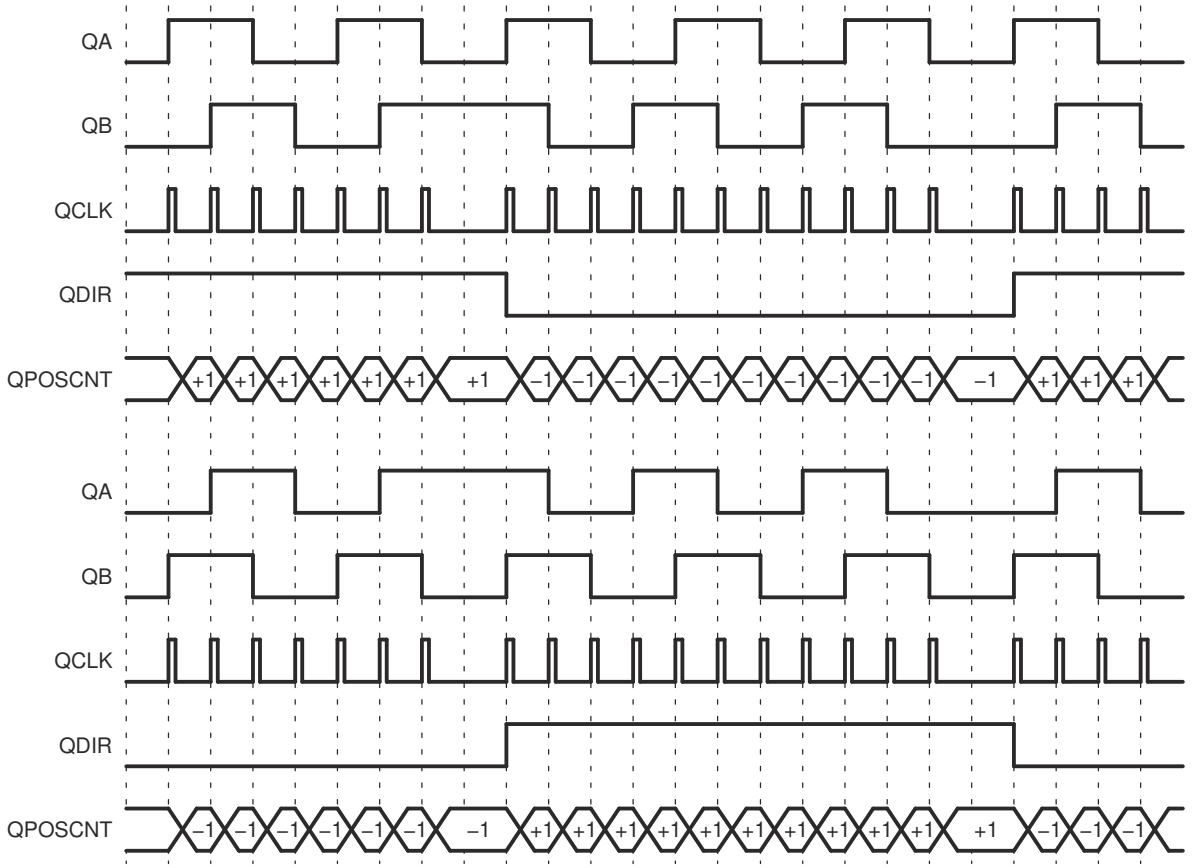

Figure 16-7. Quadrature-clock and Direction Decoding

Phase Error Flag In normal operating conditions, quadrature inputs QEPA and QEPB is 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register and the QPOSCNT value can be incorrect and offset by multiples of 1 or 3. That is, when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in Figure 16-6 are invalid transitions that generate a phase error.

Count Multiplication The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in Figure 16-7.

Reverse Count In normal quadrature count operation, QEPA input is applied to the QA input of the quadrature decoder and the QEPB input is applied to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This swaps the input to the quadrature decoder; thereby, reversing the counting direction.

16.4.1.2 Direction-Count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. The QEPA input provides the clock for the position counter and the QEPB input has the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high, and decremented when the direction input is low.

16.4.1.3 Up-Count Mode

The counter direction signal is hard-wired for up-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input; thereby, increasing the measurement resolution by a factor of 2x. In up-count mode, we recommend that the application not configure QEPB as a GPIO mux option, or make sure that a signal edge is not generated on the QEPB input.

16.4.1.4 Down-Count Mode

The counter direction signal is hardwired for a down-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by a factor of 2x. In down-count mode, the application must not configure QEPB as a GPIO mux option or make sure that a signal edge is not generated on the QEPB input.

16.4.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting the QDECCTL[QIP] bit inverts the index input.

16.4.3 Position-Compare Sync Output

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position-counter register (QPOSCNT) and the position- compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

16.5 Position Counter and Control Unit (PCCU)

The position-counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position-counter operational modes, position-counter initialization/latch modes and position-compare logic for sync signal generation.

16.5.1 Position Counter Operating Modes

Position-counter data can be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position-counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then the position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse, and the position counter provides a rotor angle with respect to the index pulse position.

The position counter can be configured to operate in following four modes

- Position-Counter Reset on Index Event
- Position-Counter Reset on Maximum Position
- Position-Counter Reset on the first Index Event
- Position-Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, the position counter is reset to 0 on overflow and to the QPOSMAX register value on underflow. Overflow occurs when the position counter counts up after the QPOSMAX value. Underflow occurs when the position counter counts down after 0. The Interrupt flag is set to indicate overflow/underflow in QFLG register.

16.5.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM]=00)

If the index event occurs during the forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock.

The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, the eQEP peripheral also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 16-8.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) is set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] must be configured to 00 or 11 when pcrm=0 and the position counter error flag/interrupt flag are generated only in index event reset mode. The position counter value is latched into the IPOSLAT register on every index marker.

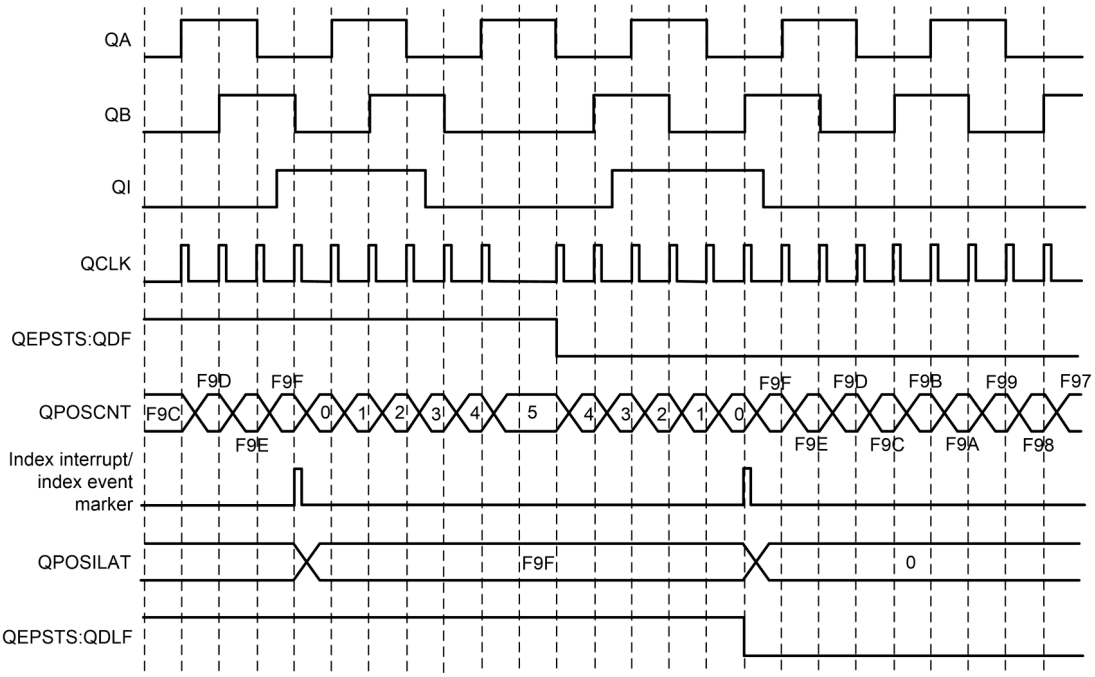

Figure 16-8. Position Counter Reset by Index Pulse for 1000-Line Encoder (QPOSMAX = 3999 or 0xF9F)

Note

In case of a boundary condition where the time period between the Index Event and the previous QCLK edge is less than SYSCLK period, then QPOSCNT gets reset to zero or QPOSMAX in the same SYSCLK cycle and does not wait for the next QCLK edge to occur.

16.5.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM]=01)

If the position counter is equal to QPOSMAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position-counter underflow flag is set. Figure 16-9 shows the position-counter reset operation in this mode.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

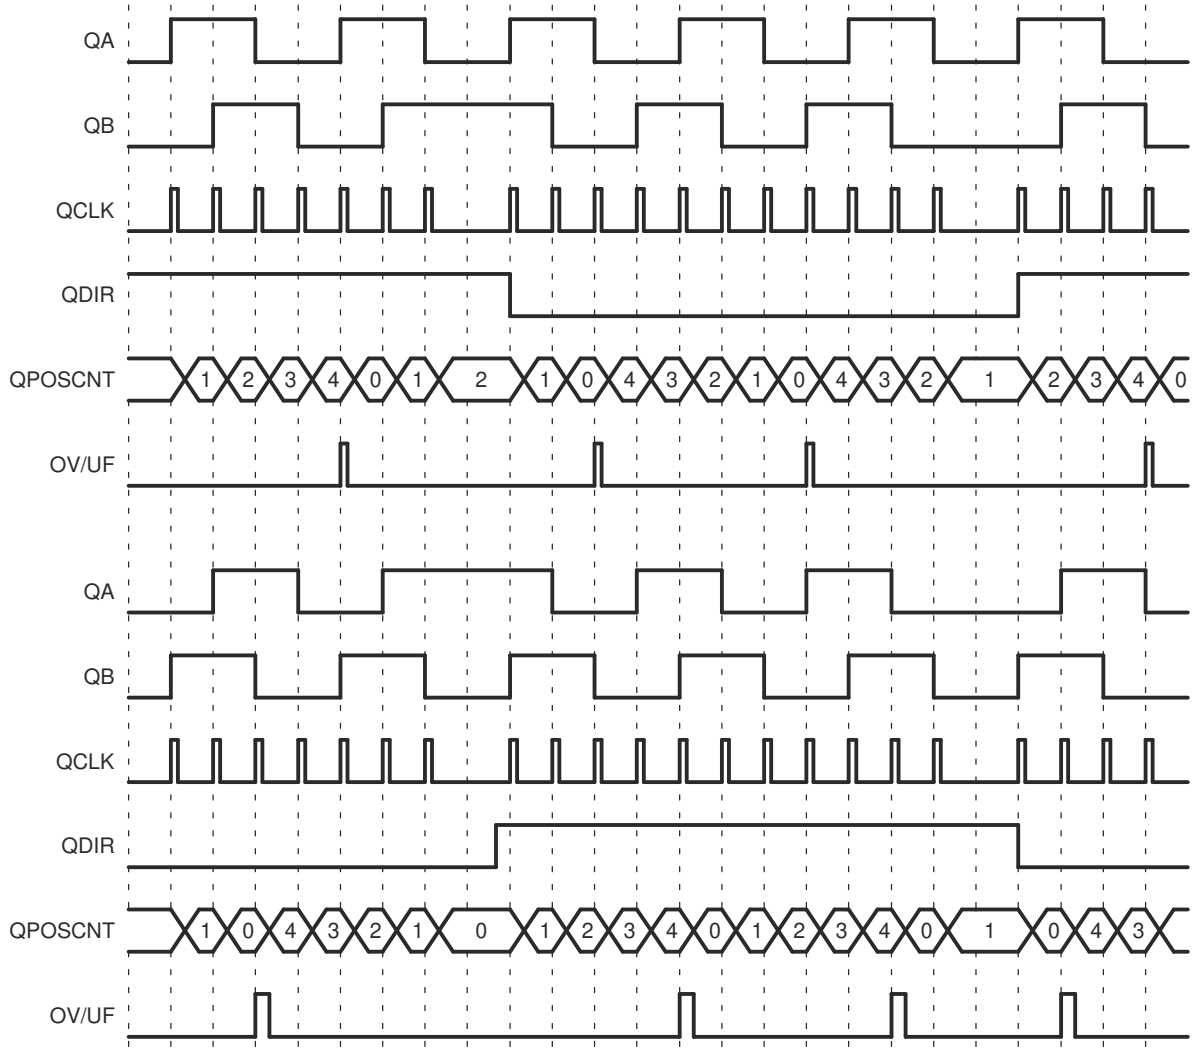

Figure 16-9. Position Counter Underflow/Overflow (QPOSMAX = 4)

16.5.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position-counter value is not reset on an index event; rather, the position-counter value is reset based on the maximum position as described in Section 16.5.1.2.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

16.5.1.4 Position Counter Reset on Unit Time-out Event (QEPCTL[PCRM] = 11)

In this mode, QPOSCNT is set to 0 or QPOMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event. This is useful for frequency measurement.

16.5.2 Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

16.5.2.1 Index Event Latch

In some applications, it is not desirable to reset the position counter on every index event and instead it can be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL]=01)
- Latch on Falling edge (QEPCTL[IEL]=10)
- Latch on Index Event Marker (QEPCTL[IEL]=11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTL[IEL]) are ignored when QEPCTL[PCRM] = 00.

Latch on Rising Edge (QEPCTL[IEL]=01)	The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.
Latch on Falling Edge (QEPCTL[IEL] = 10)	The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.
Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11	The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and the direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. The eQEP peripheral also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for latching the position counter (QEPCTL[IEL]=11).

Figure 16-10 shows the position counter latch using an index event marker.

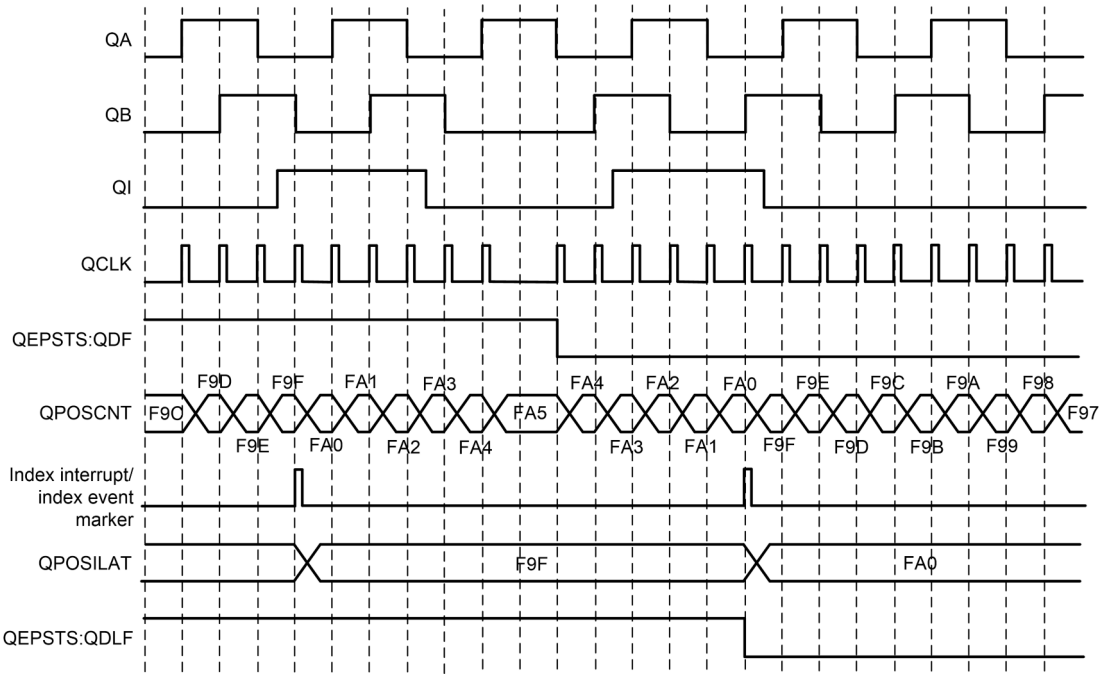

Figure 16-10. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)

16.5.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction, and on the falling edge of the strobe input for reverse direction as shown in Figure 16-11.

The strobe event latch interrupt flag (QFLG[SEL) is set when the position counter is latched to the QPOSSLAT register.

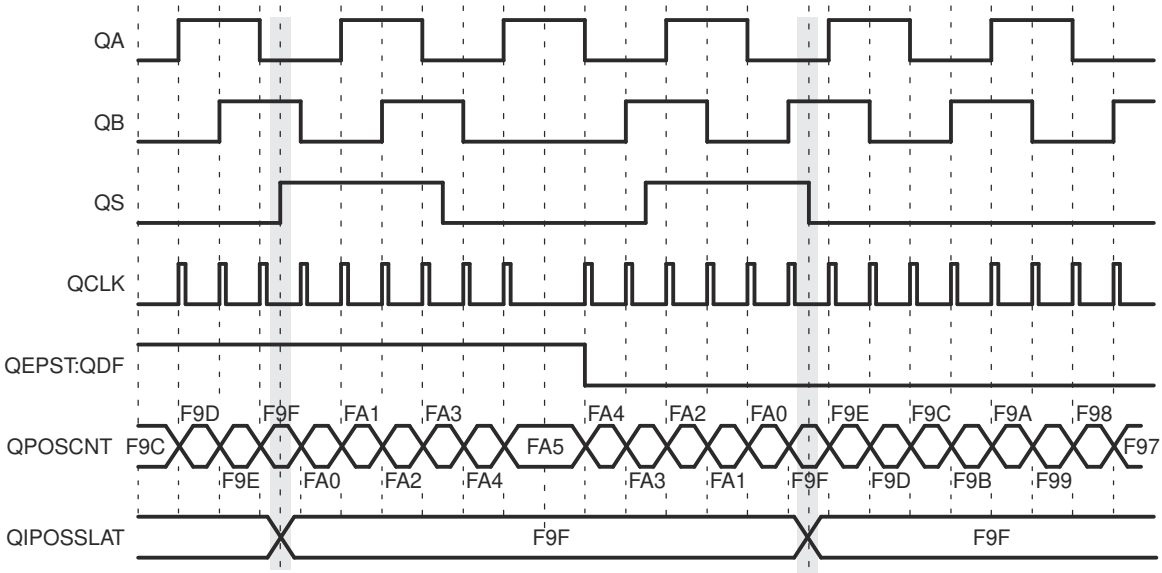

Figure 16-11. Strobe Event Latch (QEPCTL[SEL] = 1)

16.5.3 Position Counter Initialization

The position counter can be initialized using the following events:

- Index event
- Strobe event
- Software initialization

Index Event Initialization (IEI)	The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input. If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of index input. Conversely, if the QEPCTL[IEI] bits are 11, initialization is on the falling edge of the index input.
Strobe Event Initialization (SEI)	If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input. If QEPCTL[SEL] bits are 11, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.
Software Initialization (SWI)	The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit. This bit is not automatically cleared. While the bit is still set, if a 1 is written to the bit again, the position counter is re-initialized.

16.5.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and interrupt on a position-compare match. Figure 16-12 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

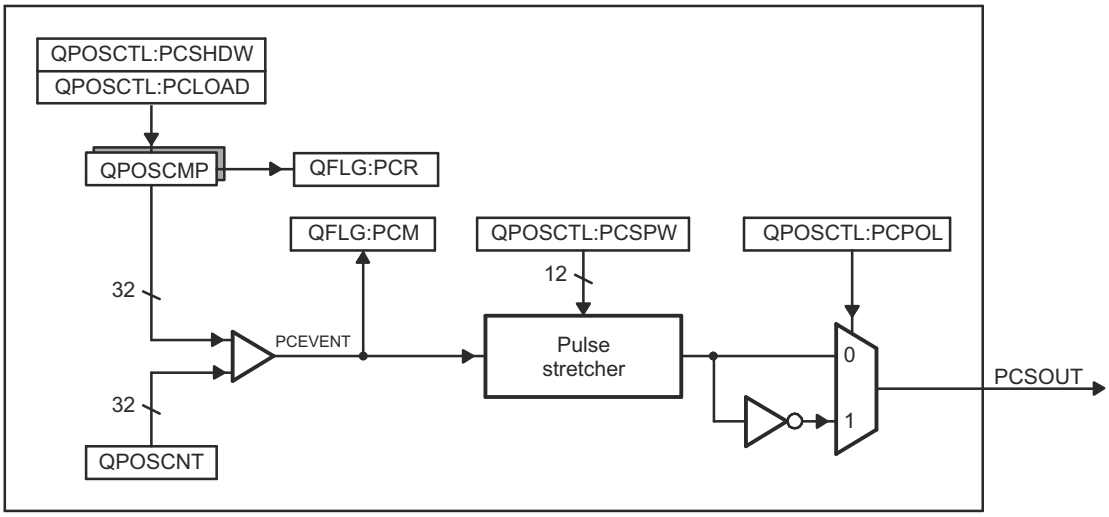

Figure 16-12. eQEP Position-compare Unit

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events, and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare-match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 16-13).

See the register section for the layout of the eQEP Position-Compare Control Register (QPOSCTL) and description of the QPOSCTL bit fields.

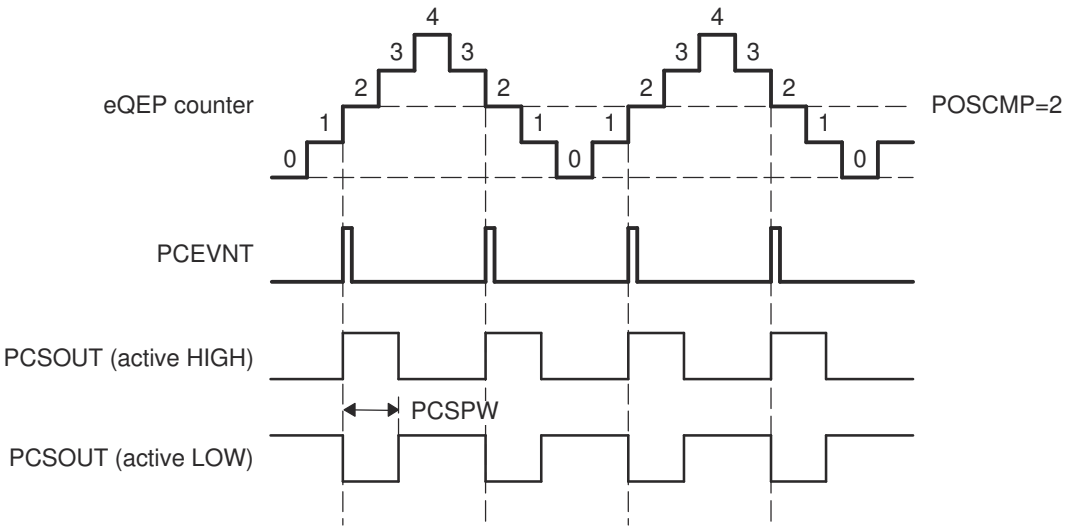

Figure 16-13. eQEP Position-compare Event Generation Points

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 16-14.

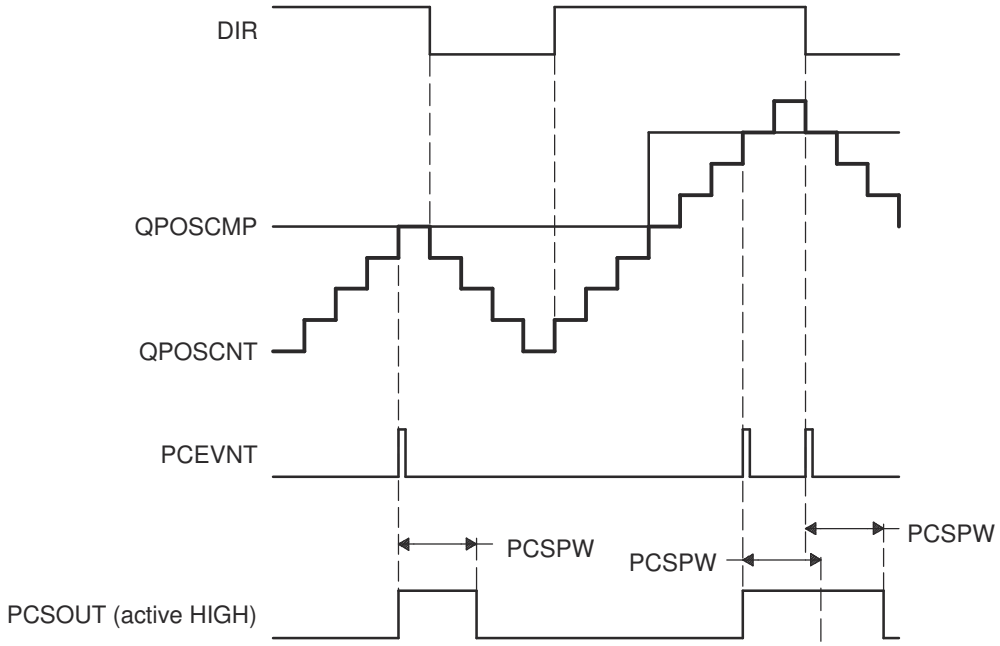

Figure 16-14. eQEP Position-compare Sync Output Pulse Stretcher

16.6 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in Figure 16-15. This feature is typically used for low-speed measurement using the following formula:

$$v(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (20)$$

where:

- X = Unit position is defined by integer multiple of quadrature edges (see Figure 16-16)
- ΔT = Elapsed time between unit position events
- v(k) = Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled SYSCLKOUT and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement, and clear the flag by writing 1.

Time measurement (ΔT) between unit position events is correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

If the QEP capture timer overflows between unit position events, then the timer sets the QEP capture overflow flag (QEPSTS[COEF]) in the status register and the QCPRDLAT register is set to 0xFFFF. If direction change occurs between the unit position events, then the error flag is set in the status register (QEPSTS[CDEF]) and the QCPRDLAT register is set to 0xFFFF.

The Capture Timer (QCTMR) and Capture Period register (QCPRD) can be configured to latch on the following events:

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

Figure 16-17 shows the capture unit operation along with the position counter.

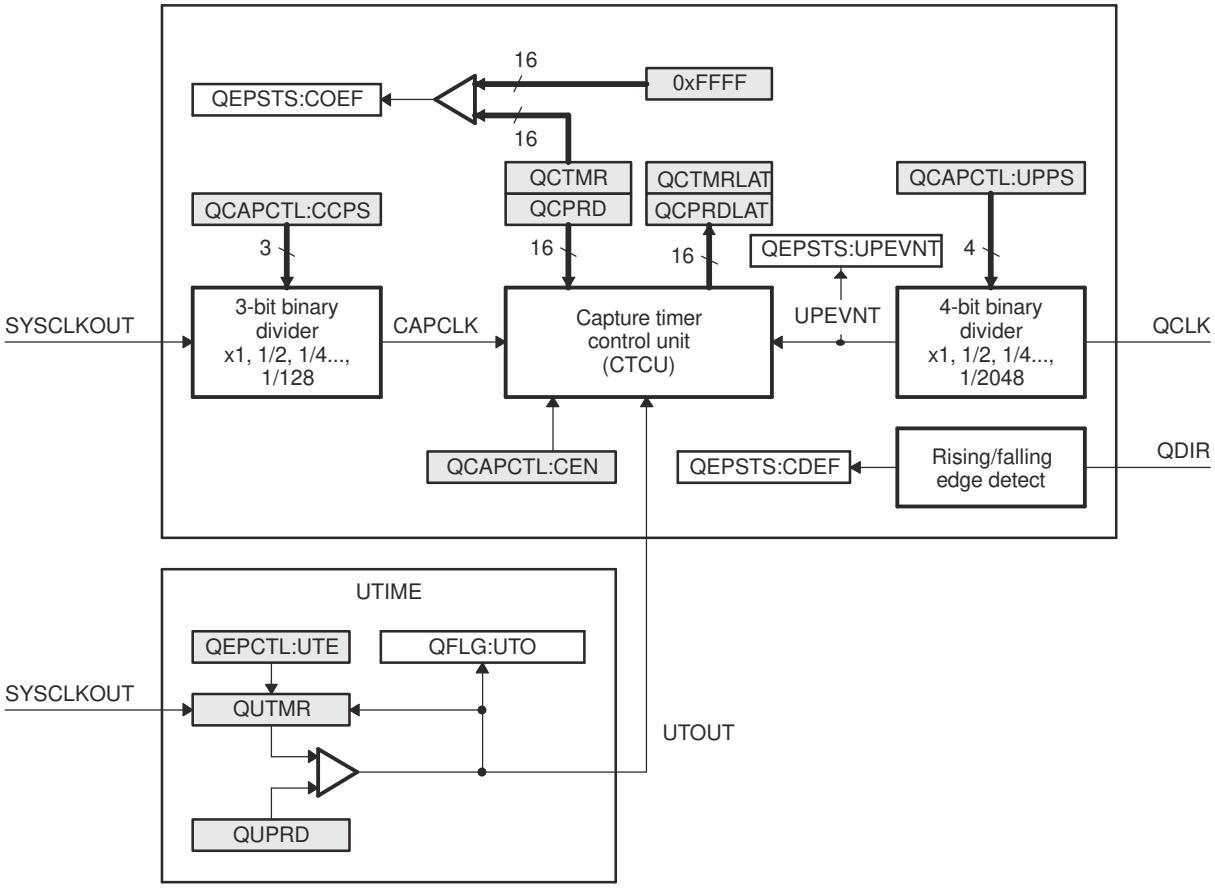

Figure 16-15. eQEP Edge Capture Unit

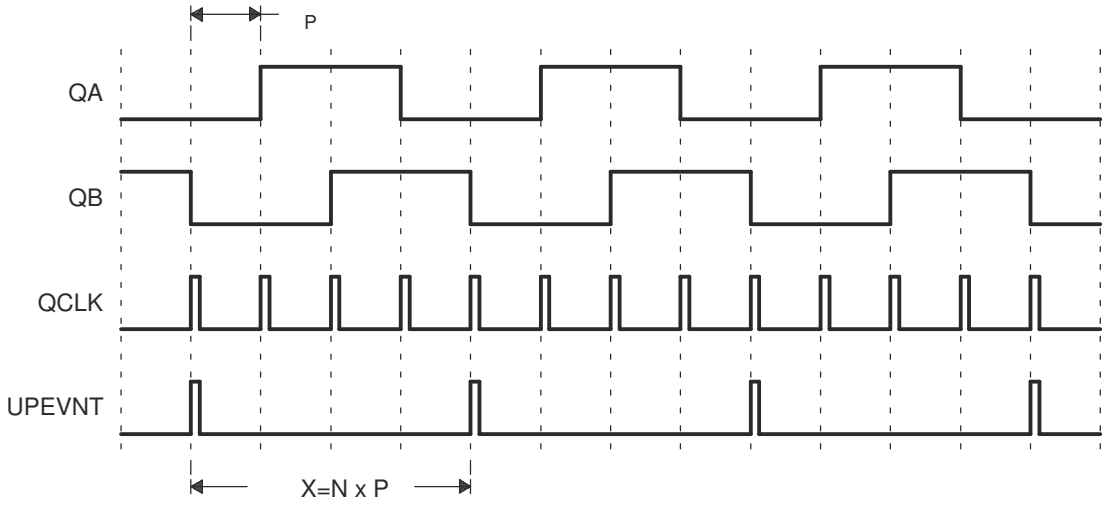
CAUTION

The QCAPCTL[UPPS] prescaler cannot be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so can result in undefined behavior. The QCAPCTL[CPPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.



N = Number of quadrature periods selected using QCAPCTL[UPPS] bits

Figure 16-16. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)

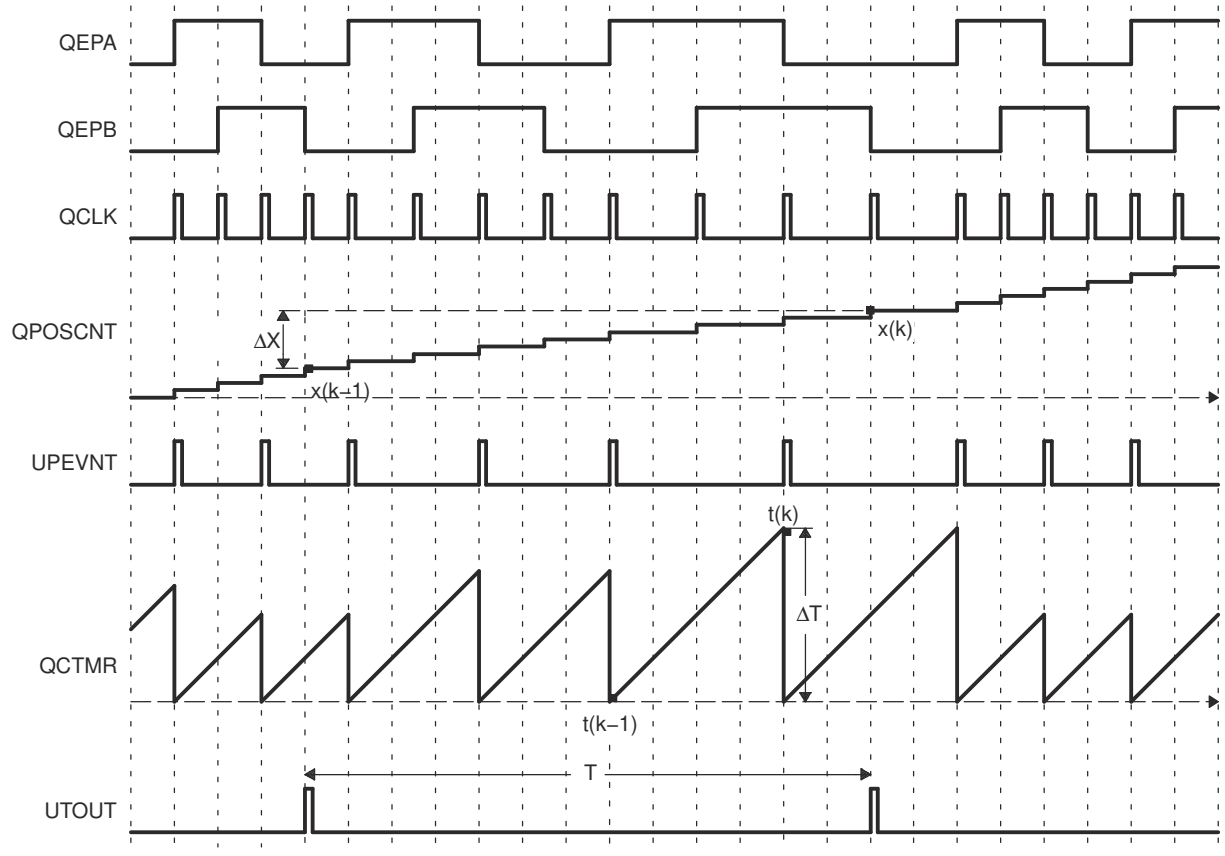


Figure 16-17. eQEP Edge Capture Unit - Timing Details

Velocity calculation equation:

$$v(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \text{ o} \quad (21)$$

where:

- v(k) = Velocity at time instant k
- x(k) = Position at time instant k
- x(k-1) = Position at time instant k-1
- T = Fixed unit time or inverse of velocity calculation rate
- ΔX = Incremental position movement in unit time
- X = Fixed unit position
- ΔT = Incremental time elapsed for unit position movement
- t(k) = Time instant "k"
- t(k-1) = Time instant "k-1"

Unit time (T) and unit period (X) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QPOSLAT and QCPRDLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (QUPRD)
ΔX	Incremental Position = QPOSLAT(k) - QPOSLAT(K-1)
X	Fixed-unit position defined by sensor resolution and QCAPCTL[UPPS] bits
ΔT	Capture Period Latch (QCPRDLAT)

16.7 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer (Figure 16-18) that monitors the quadrature clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer times out and the watchdog interrupt flag is set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

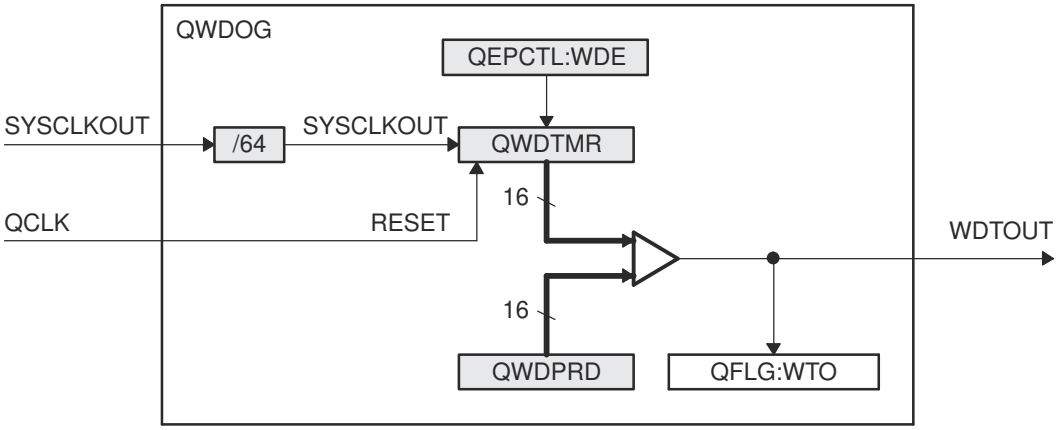

Figure 16-18. eQEP Watchdog Timer

16.8 eQEP Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations, see Figure 16-19. Whenever the unit timer (QUTMR) matches the unit period register (QUPRD), the eQEP peripheral resets the unit timer (QUTMR) and also generates the unit time out interrupt flag (QFLG[UTO]). The unit timer gets reset whenever timer value equals to configured period value.

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section 16.6.

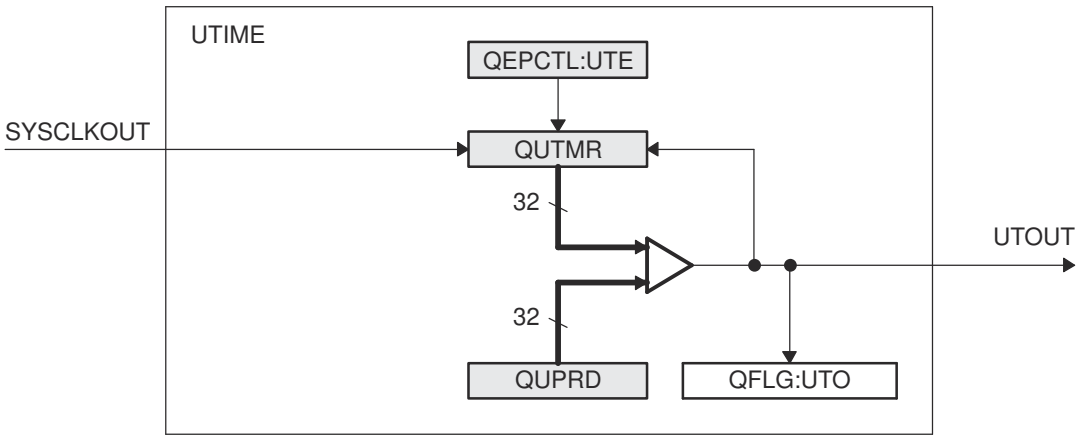

Figure 16-19. eQEP Unit Timer Base

16.9 eQEP Interrupt Structure

Figure 16-20 shows how the interrupt mechanism works in the eQEP module.

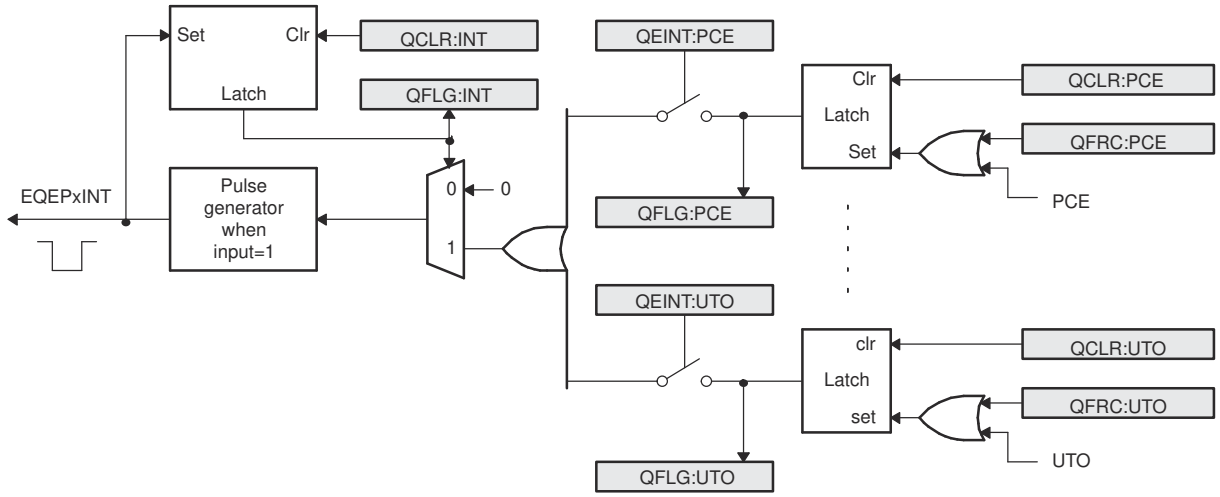

Figure 16-20. eQEP Interrupt Generation

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT).

An interrupt pulse is generated to when:

1. Interrupt is enabled for eQEP event inside QEINT register
2. Interrupt flag for eQEP event inside QFLG register is set, and
3. Global interrupt status flag bit QFLG[INT] had been cleared for previously generated interrupt event. The interrupt service routine needs to clear the global interrupt flag bit and the serviced event, by way of the interrupt clear register (QCLR), before any other interrupt pulses are generated. If either flags inside the QFLG register are not cleared, further interrupt events do not generate an interrupt to . You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

16.10 eQEP Registers

This section describes the Enhanced Quadrature Encoder Pulse Registers.

16.10.1 eQEP Base Addresses

Table 16-3. eQEP Base Address Table

Device Registers	Register Name	Start Address	End Address
EQep1Regs	EQEP_REGS	0x0000_5100	0x0000_513F
EQep2Regs	EQEP_REGS	0x0000_5140	0x0000_517F
EQep3Regs	EQEP_REGS	0x0000_5180	0x0000_51BF

16.10.2 EQEP_REGS Registers

Table 16-4 lists the memory-mapped registers for the EQEP_REGS registers. All register offset addresses not listed in Table 16-4 should be considered as reserved locations and the register contents should not be modified.

Table 16-4. EQEP_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	QPOSCNT	Position Counter		Go

Table 16-6. QPOSCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	QPOSCNT	R/W	0h	Position Counter This 32-bit position counter register counts up/down on every eQEP pulse based on direction input. This counter acts as a position integrator whose count value is proportional to position from a give reference point. This Register acts as a Read ONLY register while counter is counting up/down. Note: It is recommended to only write to the position counter register (QPOSCNT) during initialization, i.e. when the eQEP position counter is disabled (QPEN bit of QEPCTL is zero). Once the position counter is enabled (QPEN bit is one), writing to the eQEP position counter register (QPOSCNT) may cause unexpected results. Reset type: SYSRSn

16.10.2.2 QPOSINIT Register (Offset = 2h) [Reset = 00000000h]

QPOSINIT is shown in Figure 16-22 and described in Table 16-7.

Return to the Summary Table.

Position Counter Init

Figure 16-22. QPOSINIT Register

Chapter 17

Serial Peripheral Interface (SPI)

This chapter describes the serial peripheral interface (SPI) which is a high-speed synchronous serial input and output (I/O) port that allows a serial bit stream of programmed length (one to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communications between the MCU controller and external peripherals or another controller. Typical applications include external I/O or peripheral expansion using devices such as shift registers, display drivers, and analog-to-digital converters (ADCs). Multi-device communications are supported by the master or slave operation of the SPI. The port supports a 16-level, receive and transmit FIFO for reducing CPU servicing overhead.

17.1 Introduction

17.1.1 Features

The SPI module features include:

- SPISOMI: SPI slave-output/master-input pin
- SPISIMO: SPI slave-input/master-output pin
- $\overline{\text{SPISTE}}$: SPI slave transmit-enable pin
- SPICLK: SPI serial-clock pin

Note

All four pins can be used as GPIO if the SPI module is not used.

- Two operational modes: Master and Slave
- Baud rate: 125 different programmable rates. The maximum baud rate that can be employed is limited by the maximum speed of the I/O buffers used on the SPI pins. See the device data sheet for more details.
- Data word length: 1 to 16 data bits
- Four clocking schemes (controlled by clock polarity and clock phase bits) include:
  - Falling edge without phase delay: SPICLK active-high. SPI transmits data on the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
  - Falling edge with phase delay: SPICLK active-high. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge without phase delay: SPICLK inactive-low. SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge with phase delay: SPICLK inactive-low. SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
- Simultaneous receive and transmit operation (transmit function can be disabled in software)
- Transmitter and receiver operations are accomplished through either interrupt- driven or polled algorithm
- 16-level transmit/receive FIFO
- DMA support
- High-speed mode
- Delayed transmit control
- 3-wire SPI mode
- $\overline{\text{SPISTE}}$ inversion for digital audio interface receive mode on devices with two SPI modules

17.1.3 Block Diagram

Figure 17-1 shows the SPI CPU interfaces.

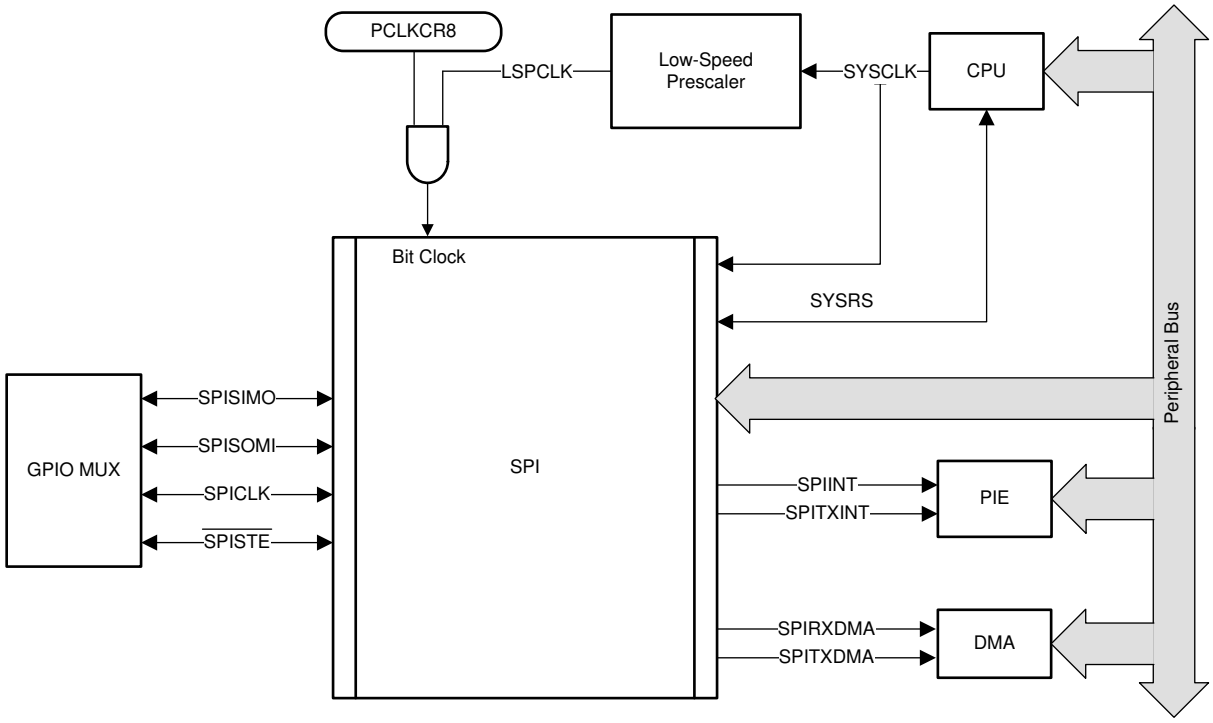

Figure 17-1. SPI CPU Interface

17.2 System-Level Integration

This section describes the various functionality that is applicable to the device integration. These features require configuration of other modules in the device that are not within the scope of this chapter.

17.2.1 SPI Module Signals

Table 17-1 classifies and provides a summary of the SPI module signals.

Table 17-1. SPI Module Signal Summary

Signal Name	Description
External Signals	
SPICLK	SPI clock
SPISIMO	SPI slave in, master out
SPISOMI	SPI slave out, master in
$\overline{\text{SPISTE}}$	SPI slave transmit enable
Control	
SPI Clock Rate	LSPCLK
Interrupt Signals	
SPIINT/SPIRXINT	Transmit interrupt/ Receive Interrupt in non FIFO mode (referred to as SPIINT)
	Receive interrupt in FIFO mode
SPITXINT	Transmit interrupt in FIFO mode
DMA Triggers	
SPITXDMA	Transmit request to DMA
SPIRXDMA	Receive request to DMA

Special Considerations

The $\overline{\text{SPISTE}}$ signal provides the ability to gate any spurious clock and data pulses when the SPI is in slave mode. A HIGH logic signal on $\overline{\text{SPISTE}}$ does not allow the slave to receive data. This prevents the SPI slave from losing synchronization with the master. TI does not recommend that the $\overline{\text{SPISTE}}$ always be tied to the active state.

If the SPI slave does ever lose synchronization with the master, toggling SPISWRESET resets the internal bit counter as well as the various status flags in the module. By resetting the bit counter, the SPI interprets the next clock transition as the first bit of a new transmission. The register bit fields that are reset by SPISWRESET are found in Section 17.6.

Configuring a GPIO to Emulate $\overline{\text{SPISTE}}$

In many systems, a SPI master can be connected to multiple SPI slaves using multiple instances of $\overline{\text{SPISTE}}$. Though this SPI module does not natively support multiple $\overline{\text{SPISTE}}$ signals, it is possible to emulate this behavior in software using GPIOs. In this configuration, the SPI must be configured as the master. Rather than using the GPIO Mux to select $\overline{\text{SPISTE}}$, the application can configure pins to be GPIO outputs, one GPIO per SPI slave. Before transmitting any data, the application can drive the desired GPIO to the active state. Immediately after the transmission has been completed, the GPIO chip select can be driven to the inactive state. This process can be repeated for many slaves that share the SPICLK, SPISIMO, and SPISOMI lines.

17.2.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

17.2.2.1 GPIOs Required for High-Speed Mode

The high-speed mode of the SPI is available on the specified GPIO mux options in the device data sheet. To enable the high-speed enhancements, set SPICCR.HS_MODE to 1. Make sure that the capacitive loading on the pin does not exceed the value stated in the device data sheet.

When not operating in high-speed mode or if the capacitive loading on the pins exceed the value stated in the device data sheet, SPICCR.HS_MODE can be set to 0.

17.2.3 SPI Interrupts

This section includes information on the available interrupts present in the SPI module. The SPI module contains two interrupt lines: SPIINT/SPIRXINT and SPITXINT. When the SPI is operating in non-FIFO mode, all available interrupts are routed together to generate the single SPIINT interrupt. When FIFO mode is used, both SPIRXINT and SPITXINT can be generated.

SPIINT/SPIRXINT

When the SPI is operating in non-FIFO mode, the interrupt generated is called SPIINT. If FIFO enhancements are enabled, the interrupt is called SPIRXINT. These interrupts share the same interrupt vector in the Peripheral Interrupt Expansion (PIE) block.

In non-FIFO mode, two conditions can trigger an interrupt: a transmission is complete (INT_FLAG), or there is overrun in the receiver (OVERRUN_FLAG). Both of these conditions share the same interrupt vector: SPIINT.

The transmission complete flag (INT_FLAG) indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced. At the same time this bit is set, the received character is placed in the receiver buffer (SPIRXBUF). The INT_FLAG generates an interrupt on the SPIINT vector if the SPIINTENA bit is set.

The receiver overrun flag (OVERRUN_FLAG) indicates that a transmit or receive operation has completed before the previous character has been read from the buffer. The OVERRUN_FLAG generates an interrupt on the SPIINT vector if the OVERRUNINTENA bit is set and OVERRUN_FLAG was previously cleared.

In FIFO mode, the SPI can interrupt the CPU upon a match condition between the current receive FIFO status (RXFFST) and the receive FIFO interrupt level (RXFFIL). If RXFFST is greater than or equal to RXFFIL, the receive FIFO interrupt flag (RXFFINT) is set. SPIRXINT is triggered in the PIE block, if RXFFINT is set and the receive FIFO interrupt is enabled (RXFFIENA = 1).

SPITXINT

The SPITXINT interrupt is not available when the SPI is operating in non-FIFO mode.

In FIFO mode, the SPITXINT behavior is similar to the SPIRXINT. SPITXINT is generated upon a match condition between the current transmit FIFO status (TXFFST) and the transmit FIFO interrupt level (TXFFIL). If TXFFST is less than or equal to TXFFIL, the transmit FIFO interrupt flag (TXFFINT) is set. SPITXINT is triggered in the PIE block, if TXFFINT is set and the transmit FIFO interrupt is enabled in the SPI module (TXFFIENA = 1).

Figure 17-2 and Table 17-2 show how these control bits influence the SPI interrupt generation.

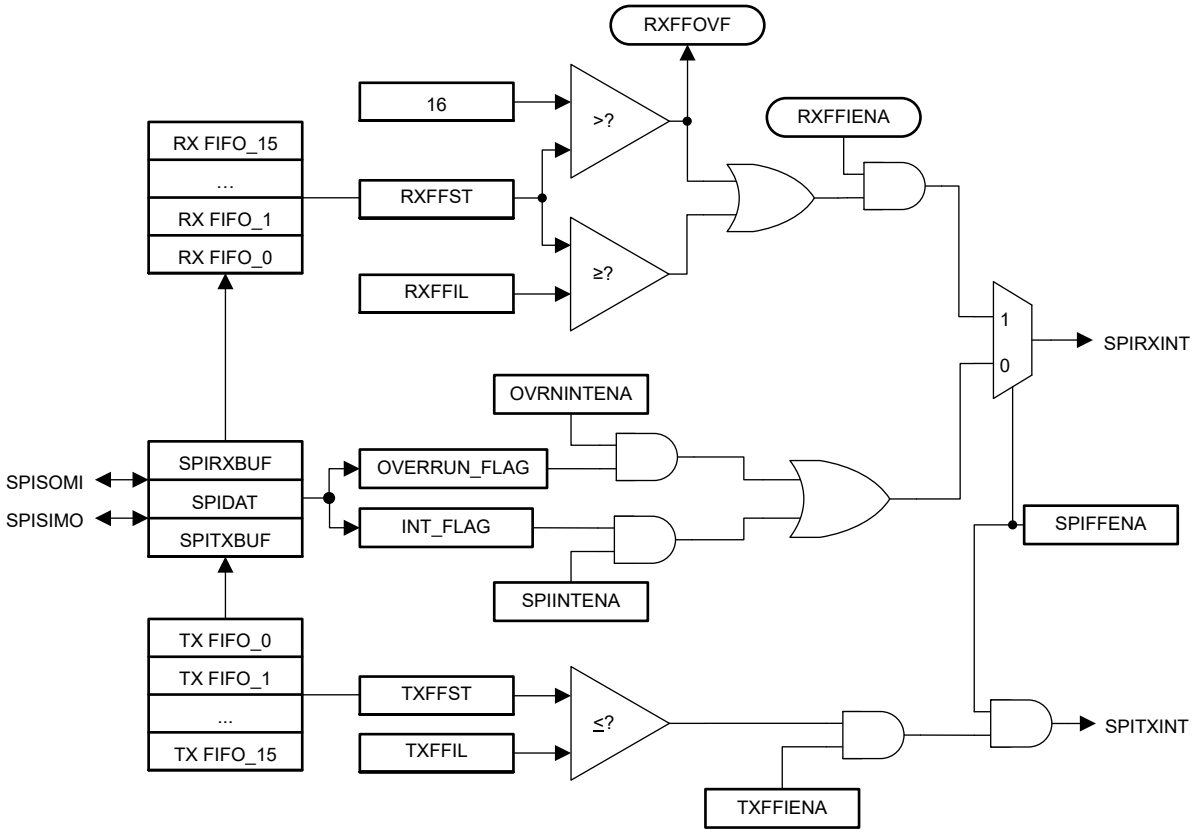

Figure 17-2. SPI Interrupt Flags and Enable Logic Generation

Table 17-2. SPI Interrupt Flag Modes

FIFO Options	SPI Interrupt Source	Interrupt Flags	Interrupt Enables	FIFO Enable (SPIFFENA)	Interrupt Line (1)
SPI without FIFO	Receive overrun	RXOVRN	OVRNINTENA	0	SPIRXINT
	Data receive	SPIINT	SPIINTENA	0	SPIRXINT
	Transmit empty	SPIINT	SPIINTENA	0	SPIRXINT
SPI FIFO mode	FIFO receive	RXFFIL	RXFFIENA	1	SPIRXINT
	Transmit empty	TXFFIL	TXFFIENA	1	SPITXINT

(1) In non-FIFO mode, SPIRXINT is the same name as the SPIINT interrupt in C28x devices.

17.2.4 DMA Support

Both the CPU and DMA have access to the SPI data registers using the internal peripheral bus. This access is limited to 16-bit register reads and writes. Each SPI module can generate two DMA events, SPITXDMA and SPIRXDMA. The DMA events are controlled by configuring the SPIFFTX.TXFFIL and SPIFFRX.RXFFIL appropriately. SPITXDMA activates when TXFFST is less than the interrupt level (TXFFIL). SPIRXDMA activates when RXFFST is greater than or equal to the interrupt level (RXFFIL).

The SPI must have FIFO enhancements enabled for the DMA triggers to be generated.

For more information on configuring the SPI for DMA transfers, refer to Section 17.3.8.

Figure 17-3 is a block diagram showing the DMA trigger generation from the SPI module.

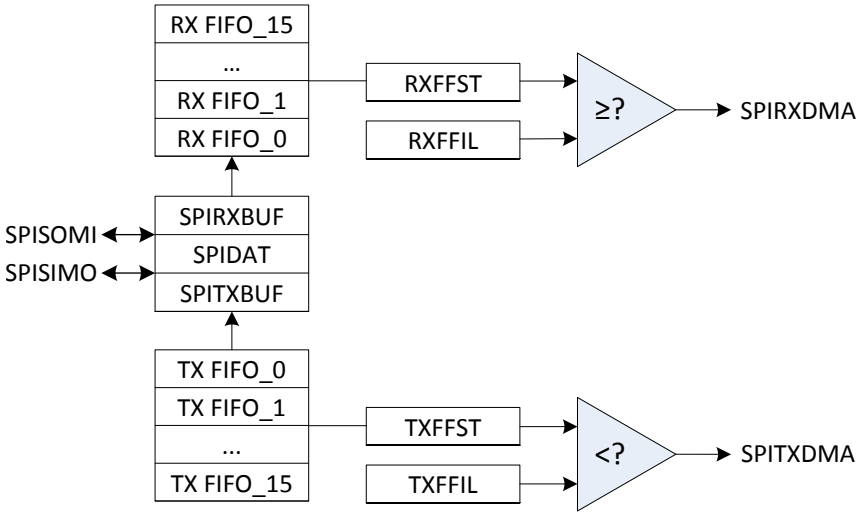

Figure 17-3. SPI DMA Trigger Diagram

17.3 SPI Operation

This section describes the various modes of operation of the SPI. Included are explanations of the operational modes, interrupts, data format, clock sources, and initialization. Typical timing diagrams for data transfers are given.

17.3.1 Introduction to Operation

Figure 17-4 shows typical connections of the SPI for communications between two controllers: a master and a slave.

The master transfers data by sending the SPICLK signal. For both the slave and the master, data is shifted out of the shift registers on one edge of the SPICLK and latched into the shift register on the opposite SPICLK clock edge. If the CLK_PHASE bit is high, data is transmitted and received a half-cycle before the SPICLK transition. As a result, both controllers send and receive data simultaneously. The application software determines whether the data is meaningful or dummy data. There are three possible methods for data transmission:

- Master sends data; slave sends dummy data.
- Master sends data; slave sends data.
- Master sends dummy data; slave sends data.

The master can initiate data transfer at any time because the master controls the SPICLK signal. The software, however, determines how the master detects when the slave is ready to broadcast data.

The SPI operates in master or slave mode. The MASTER_SLAVE bit selects the operating mode and the source of the SPICLK signal.

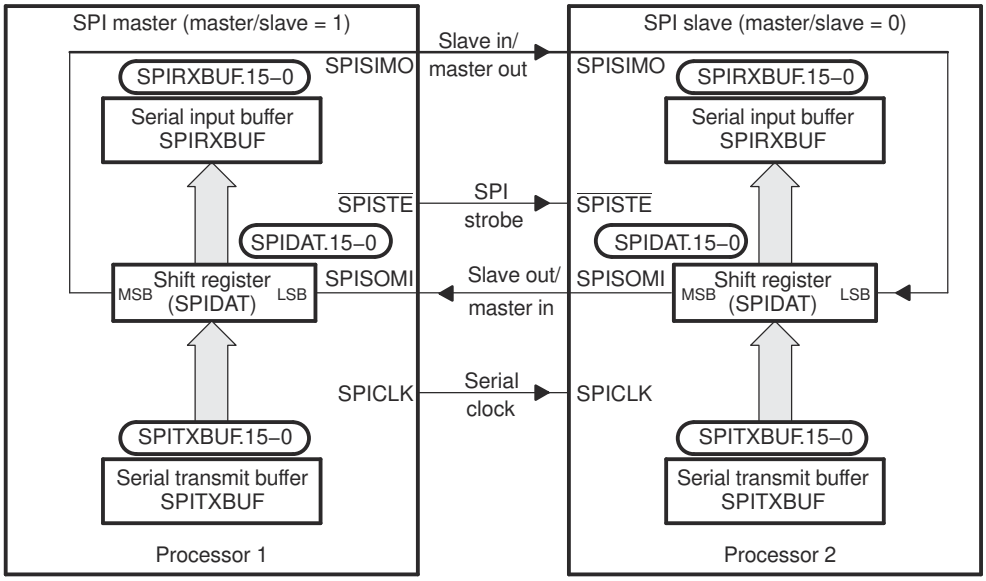

Figure 17-4. SPI Master/Slave Connection

17.3.2 Master Mode

In master mode (MASTER_SLAVE = 1), the SPI provides the serial clock on the SPICLK pin for the entire serial communications network. Data is output on the SPISIMO pin and latched from the SPISOMI pin.

The SPIBRR register determines both the transmit and receive bit transfer rate for the network. SPIBRR can select 125 different data transfer rates.

Data written to SPIDAT or SPITXBUF initiates data transmission on the SPISIMO pin, MSB (most-significant bit) first. Simultaneously, received data is shifted through the SPISOMI pin into the LSB (least- significant bit) of SPIDAT. When the selected number of bits has been transmitted, the received data is transferred to the SPIRXBUF (buffered receiver) for the CPU to read. Data is stored right-justified in SPIRXBUF.

When the specified number of data bits has been shifted through SPIDAT, the following events occur:

- SPIDAT contents are transferred to SPIRXBUF.
- INT_FLAG bit is set to 1.
- If there is valid data in the transmit buffer SPITXBUF, as indicated by the transmit buffer full flag (BUFFULL_FLAG), this data is transferred to SPIDAT and is transmitted; otherwise, SPICLK stops after all bits have been shifted out of SPIDAT.
- If the SPIINTENA bit is set to 1, an interrupt is asserted.

In a typical application, the $\overline{\text{SPISTE}}$ pin serves as a chip-enable pin for a SPI slave device. This pin is driven low by the master before transmitting data to the slave and is taken high after the transmission is complete.

Figure 17-5 is a block diagram of the SPI in master mode. The block diagram shows the basic control blocks available in SPI master mode.

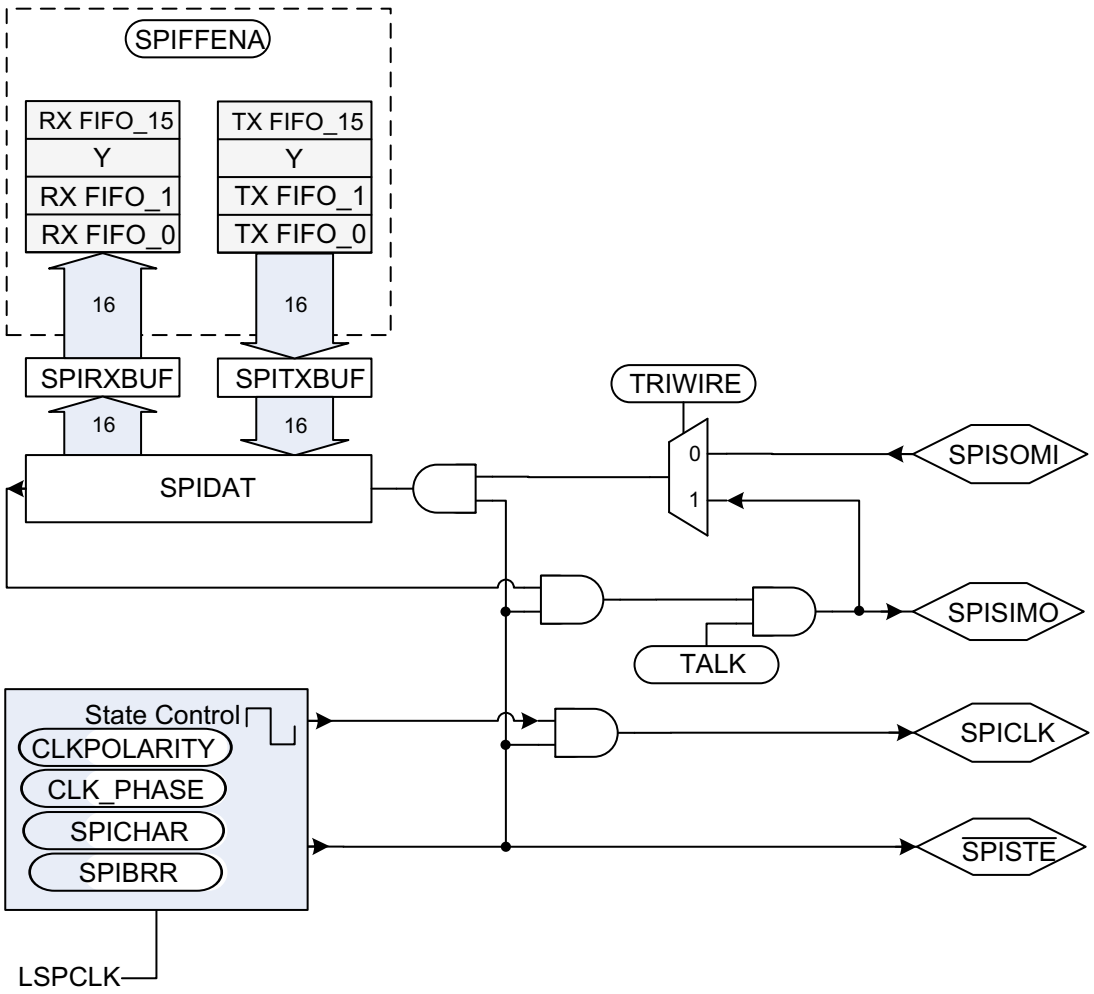

Figure 17-5. SPI Module Master Configuration

17.3.3 Slave Mode

In slave mode (MASTER_SLAVE = 0), data shifts out on the SPISOMI pin and in on the SPISIMO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network master. The transfer rate is defined by this clock. The SPICLK input frequency can be no greater than the LSPCLK frequency divided by 4.

Data written to SPIDAT or SPITXBUF is transmitted to the network when appropriate edges of the SPICLK signal are received from the network master. A character written to the SPITXBUF register is copied to the SPIDAT register when all bits of the current character in SPIDAT have been shifted out. If no character was previously copied to SPIDAT, then any character written to SPITXBUF is immediately copied to SPIDAT. If a character was previously copied to SPIDAT, any data written to SPITXBUF is not copied to SPIDAT until the current character in SPIDAT has been shifted out. To receive data, the SPI waits for the network master to send the SPICLK signal and then shifts the data on the SPISIMO pin into SPIDAT. If data is to be transmitted by the slave simultaneously, and SPIDAT has not been previously loaded, the character must be written to SPITXBUF before the beginning of the SPICLK signal.

When the TALK bit is cleared, data transmission is disabled, and the output line (SPISOMI) is put into the high-impedance state. If this occurs while a transmission is active, the current character is completely transmitted even though SPISOMI is forced into the high-impedance state. This makes sure that the SPI is still able to

receive incoming data correctly. This TALK bit allows many slave devices to be tied together on the network, but only one slave at a time is allowed to drive the SPISOMI line.

The $\overline{\text{SPISTE}}$ pin operates as the slave-select pin. An active-low signal on the $\overline{\text{SPISTE}}$ pin allows the slave SPI to transfer data to the serial data line; an inactive-high signal causes the slave SPI serial shift register to stop and the serial output pin to be put into the high-impedance state. This allows many slave devices to be tied together on the network, although only one slave device is selected at a time.

Figure 17-6 is a block diagram of the SPI in slave mode. The block diagram shows the basic control blocks available in SPI slave mode.

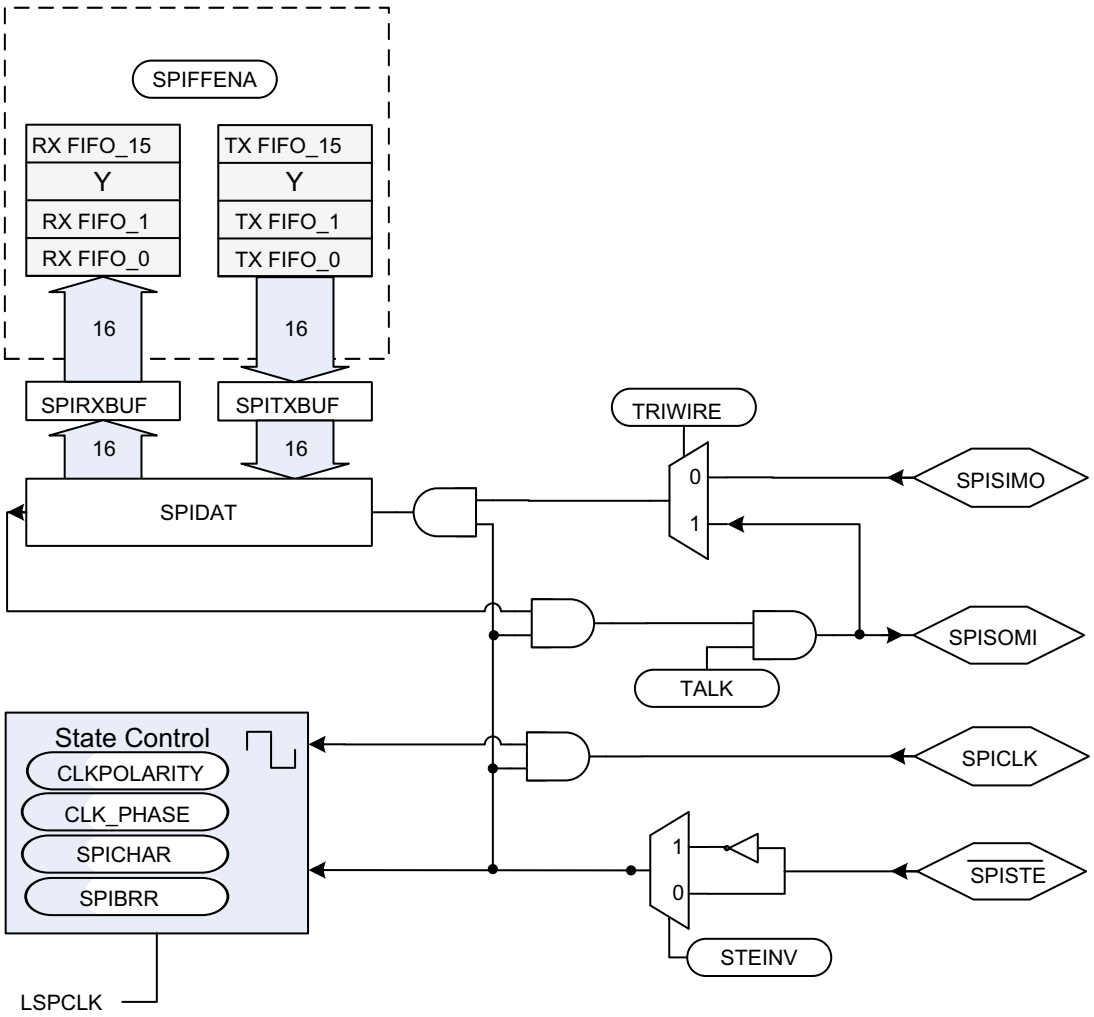

Figure 17-6. SPI Module Slave Configuration

17.3.4 Data Format

The four-bit SPICHAR register field specifies the number of bits in the data character (1 to 16). This information directs the state control logic to count the number of bits received or transmitted to determine when a complete character has been processed.

The following statements apply to characters with fewer than 16 bits:

- Data must be left-justified when written to SPIDAT and SPITXBUF.
- Data read back from SPIRXBUF is right-justified.
- SPIRXBUF contains the most recently received character, right-justified, plus any bits that remain from previous transmission(s) that have been shifted to the left (shown in Example 17-1).

Example 17-1. Transmission of Bit from SPIRXBUF

Conditions:

1. Transmission character length = 1 bit (specified in SPICHAR bits)
2. The current value of SPIDAT = 737Bh

SPIDAT (before transmission)																
	0	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1
SPIDAT (after transmission)																
(TXed) 0 ←	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x(1) ← (RXed)
SPIRXBUF (after transmission)																
	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x(1)

(1) x = 1, if SPISOMI data is high; x = 0, if SPISOMI data is low; master mode is assumed.

17.3.5 Baud Rate Selection

The SPI module supports 125 different baud rates and four different clock schemes. Depending on whether the SPI clock is in slave or master mode, the SPICLK pin can receive an external SPI clock signal or provide the SPI clock signal, respectively.

- In the slave mode, the SPI clock is received on the SPICLK pin from the external source and can be no greater than the LSPCLK frequency divided by 4.
- In the master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin and can be no greater than the LSPCLK frequency divided by 4.

Note

The baud rate must be configured to not exceed the maximum rated GPIO toggle frequency. Refer to the device data sheet for the maximum GPIO toggle frequency.

Example 17-2 shows how to determine the SPI baud rates.

Example 17-3 shows how to calculate the baud rate of the SPI module in standard SPI mode (HS_MODE = 0).

Example 17-2. Baud Rate Determination

For SPIBRR = 3 to 127:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{(\text{SPIBRR} + 1)}$$

For SPIBRR = 0, 1, or 2:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{4}$$

where:

LSPCLK = Low-speed peripheral clock frequency of the device

SPIBRR = Contents of the SPIBRR in the master SPI device

To determine what value to load into SPIBRR, you must know the device system clock (LSPCLK) frequency (that is device-specific) and the baud rate at which you are operating.

Example 17-3. Baud Rate Calculation in Non-High Speed Mode (HS_MODE = 0)

$$SPI\ Baud\ Rate = \frac{LSPCLK}{SPIBRR + 1'} \quad LSPCLK = 50\ MHz$$

$$= \frac{50 \times 10^6}{3 + 1}$$

$$= 12.5\ Mbps$$

17.3.6 SPI Clocking Schemes

The clock polarity select bit (CLKPOLARITY) and the clock phase select bit (CLK_PHASE) control four different clocking schemes on the SPICLK pin. CLKPOLARITY selects the active edge, either rising or falling, of the clock. CLK_PHASE selects a half-cycle delay of the clock. The four different clocking schemes are:

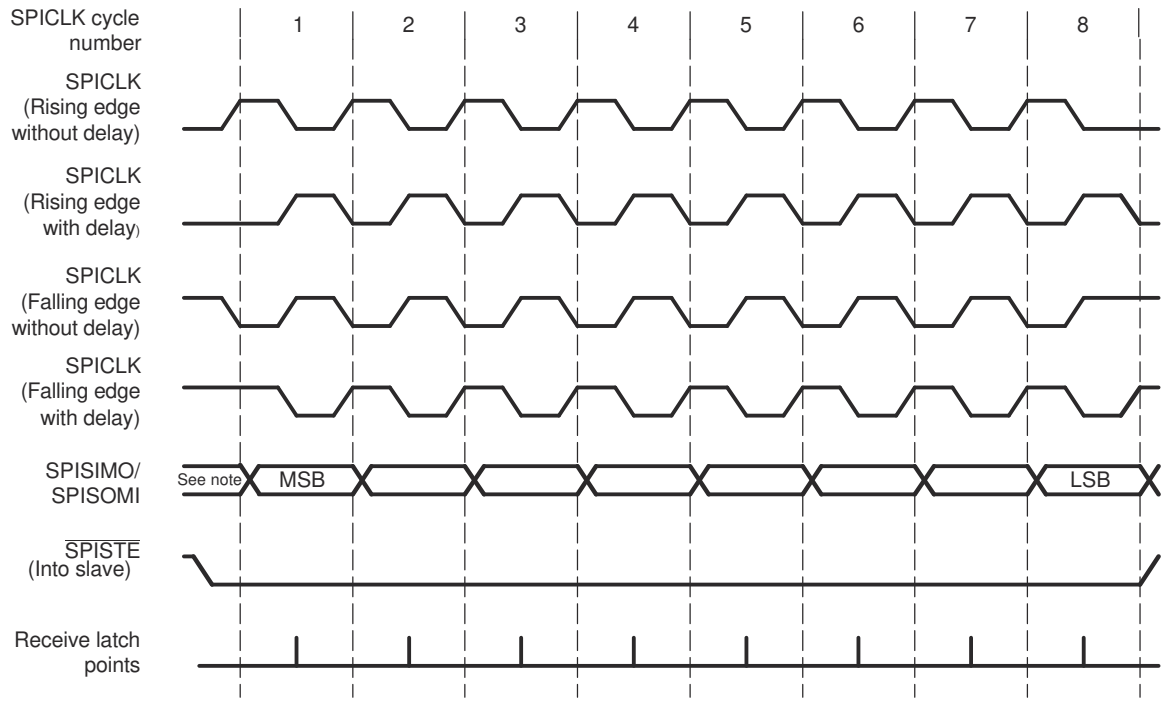
- Falling Edge Without Delay. The SPI transmits data on the falling edge of the SPICLK and receives data on the rising edge of the SPICLK.
- Falling Edge With Delay. The SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge Without Delay. The SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge With Delay. The SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.

The selection procedure for the SPI clocking scheme is shown in Table 17-3. Examples of these four clocking schemes relative to transmitted and received data are shown in Figure 17-7.

Table 17-3. SPI Clocking Scheme Selection Guide

SPICLK Scheme	CLKPOLARITY(1)	CLK_PHASE(1)
Rising edge without delay	0	0
Rising edge with delay	0	1
Falling edge without delay	1	0
Falling edge with delay	1	1

(1) The description of CLK_PHASE and CLKPOLARITY differs between manufacturers. For proper operation, select the desired waveform to determine the clock phase and clock polarity settings.



Note: Previous data bit

Figure 17-7. SPICLK Signal Options

SPICLK symmetry is retained only when the result of (SPIBRR + 1) is an even value. When (SPIBRR + 1) is an odd value and SPIBRR is greater than 3, SPICLK becomes asymmetrical. The low pulse of SPICLK is one LSPCLK cycle longer than the high pulse when CLKPOLARITY bit is clear (0). When CLKPOLARITY bit is set to 1, the high pulse of the SPICLK is one LSPCLK cycle longer than the low pulse, as shown in Figure 17-8.

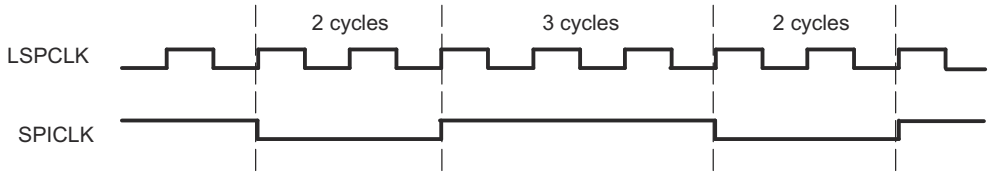


Figure 17-8. SPI: SPICLK-LSPCLK Characteristic when (BRR + 1) is Odd, BRR > 3, and CLKPOLARITY = 1

17.3.7 SPI FIFO Description

The following steps explain the FIFO features and help with programming the SPI FIFOs:

1. **Reset.** At reset the SPI powers up in standard SPI mode and the FIFO function is disabled. The FIFO registers SPIFFTX, SPIFFRX and SPIFFCT remain inactive.
2. **Standard SPI.** The standard 28x SPI mode works with SPIINT/SPIRXINT as the interrupt source.
3. **Mode change.** FIFO mode is enabled by setting the SPIFFENA bit to 1 in the SPIFFTX register. SPIRST can reset the FIFO mode at any stage of the operation.
4. **Active registers.** All the SPI registers and SPI FIFO registers SPIFFTX, SPIFFRX, and SPIFFCT are active.
5. **Interrupts.** FIFO mode has two interrupts: one for the transmit FIFO, SPITXINT; one for the receive FIFO, SPIRXINT. SPIRXINT is the common interrupt for SPI FIFO receive, receive error and receive FIFO overflow conditions. The single SPIINT for both transmit and receive sections of the standard SPI are disabled and this interrupt is serviced as SPI receive FIFO interrupt. For more information, refer to Section 17.2.3.
6. **Buffers.** Transmit and receive buffers are each supplemented with a 16-word FIFO. The one-word transmit buffer (SPITXBUF) of the standard SPI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer is loaded from transmit FIFO only after the last bit of the shift register is shifted out.
7. **Delayed transfer.** The rate at which transmit words in the FIFO are transferred to transmit shift register is programmable. The SPIFFCT register bits (7−0) FFTXDLY7−FFTXDLY0 define the delay between the word transfer. The delay is defined in number SPI serial clock cycles. The 8-bit register can define a minimum delay of 0 SPICLK cycles and a maximum of 255 SPICLK cycles. With zero delay, the SPI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 255 clock delay, the SPI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 255 SPICLK cycles between each words. The programmable delay facilitates glueless interface to various slow SPI peripherals, such as EEPROMs, ADC, DAC, and so on.
8. **FIFO status bits.** Both transmit and receive FIFOs have status bits TXFFST or RXFFST that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit (TXFIFO) and receive reset bit (RXFIFO) reset the FIFO pointers to zero when these bits are set to 1. The FIFOs resume operation from start once these bits are cleared to zero.
9. **Programmable interrupt levels.** Both transmit and receive FIFOs can generate CPU interrupts and DMA triggers. The transmit interrupt (SPITXINT) is generated whenever the transmit FIFO status bits (TXFFST) match (less than or equal to) the interrupt trigger level bits (TXFFIL). The receive interrupt (SPIRXINT) is generated whenever the receive FIFO status bits (RXFFST) match (greater than or equal to) the interrupt trigger level RXFFIL. This provides a programmable interrupt trigger for transmit and receive sections of the SPI. The default value for these trigger level bits is 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

17.3.8 SPI DMA Transfers

17.3.8.1 Transmitting Data Using SPI with DMA

When using the DMA with the TX FIFO, the DMA Burst Size (DMA_BURST_SIZE) must be no greater than 16 – TXFFIL, to prevent the DMA from writing to an already full FIFO. This leads to data loss and is not recommended.

For complete data transmission, follow these steps:

1. Calculate the total number of words to be transmitted. [NUM_WORDS]
2. Decide the transmit FIFO level. [TXFFIL]
3. Calculate the total number of DMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the DMA Burst. [DMA_BURST_SIZE]
5. Configure DMA using calculated values.
6. Configure SPI with FIFO using the calculated values.

To transfer 128 words to SPI using the DMA:

NUM_WORDS: 128

TXFFIL: 8

DMA_TRANSFER_SIZE: (NUM_WORDS /TXFFIL) – 1 = (128/8) – 1 = 15 (16 transfers)

DMA_BURST_SIZE: (16 – TXFFIL) – 1 = (16 – 8) – 1 = 7 (8 words per burst)

Note

Avoid setting TXFFIL to 0h or 10h to make sure of proper DMA configuration.

17.3.8.2 Receiving Data Using SPI with DMA

When using the DMA with the RX FIFO, the DMA Burst Size (BURST_SIZE) must be no greater than RXFFIL to prevent the DMA from reading from an empty FIFO. To make sure that the DMA correctly receives all data from the RX FIFO, the DMA Burst Size can equal RXFFIL and also be an integer divisor of the total number of SPI transmissions.

For complete data reception, follow these steps:

1. Calculate the total number of words to be received. [NUM_WORDS]
2. Calculate the necessary FIFO level [RXFFIL]
3. Calculate the total number of DMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the DMA Burst. [DMA_BURST_SIZE]
5. Configure DMA using the calculated values.
6. Configure SPI with FIFO using the calculated values.

To receive 200 words from SPI using the DMA:

NUM_WORDS = 200

RXFFIL: 4

DMA_TRANSFER_SIZE: (NUM_WORDS /RXFFIL) – 1 = (200/4) – 1 = 49 (50 transfers)

DMA_BURST_SIZE = RXFFIL-1 = 3 (4 words per burst)

Note

Avoid setting RXFFIL to 0h to make sure proper DMA configuration.

17.3.9 SPI High-Speed Mode

The SPI module is capable of reaching full-duplex communication speeds up to LSPCLK/4 (where LSPCLK equals SYSCLK). For the maximum rated speed, refer to the device data sheet.

To achieve the maximum full-duplex speeds, the following restrictions are placed on the design:

- Single master to single slave configuration is supported.
- Loading on the pins must not exceed the value stated in the device data sheet.

When configuring the GPIOs to support high-speed mode, refer to Section 17.2.2.1 for more information.

17.3.10 SPI 3-Wire Mode Description

SPI 3-wire mode allows for SPI communication over three pins instead of the normal four pins.

In master mode, if the TRIWIRE bit is set, enabling 3-wire SPI mode, SPISIMOx becomes the bi-directional SPIMOMIx (SPI master out, master in) pin, and SPISOMIx is no longer used by the SPI. In slave mode, if the TRIWIRE bit is set, SPISOMIx becomes the bi-directional SPISISOx (SPI slave in, slave out) pin, and SPISIMOx is no longer used by the SPI.

Table 17-4 indicates the pin function differences between 3-wire and 4-wire SPI mode for a master and slave SPI.

Table 17-4. 4-wire versus 3-wire SPI Pin Functions

4-wire SPI	3-wire SPI (Master)	3-wire SPI (Slave)
SPICLKx	SPICLKx	SPICLKx
SPISTEx	SPISTEx	SPISTEx
SPISIMOx	SPIMOMIx	Free
SPISOMIx	Free	SPISISOx

Because in 3-wire mode, the receive and transmit paths within the SPI are connected, any data transmitted by the SPI module is also received. The application software must take care to perform a dummy read to clear the SPI data register of the additional received data.

The TALK bit plays an important role in 3-wire SPI mode. The bit must be set to transmit data and cleared prior to reading data. In master mode, to initiate a read, the application software must write dummy data to the SPI data register (SPIDAT or SPIRXBUF) while the TALK bit is cleared (no data is transmitted out the SPIMOMI pin) before reading from the data register.

Figure 17-9 and Figure 17-10 illustrate 3-wire master and slave mode.

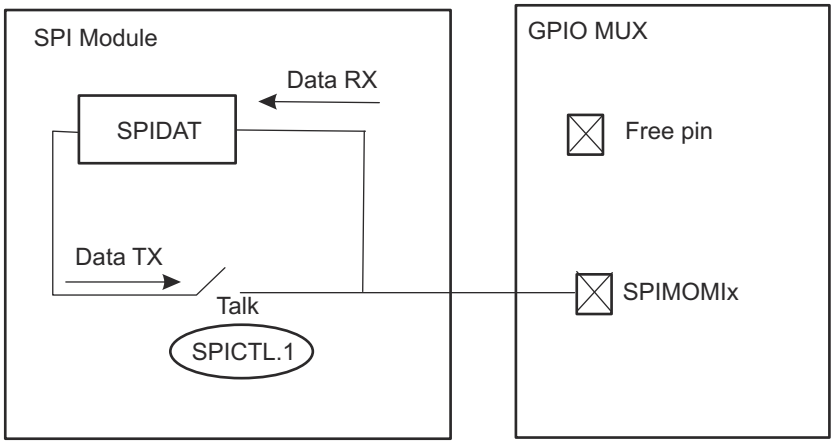

Figure 17-9. SPI 3-wire Master Mode

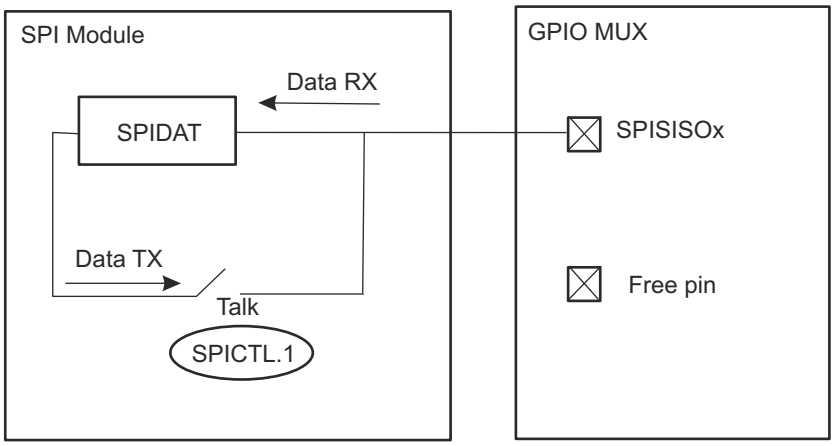

Figure 17-10. SPI 3-wire Slave Mode

Table 17-5 indicates how data is received or transmitted in the various SPI modes while the TALK bit is set or cleared.

Table 17-5. 3-Wire SPI Pin Configuration

Pin Mode	SPIPRI[TRIWIRE]	SPICTL[TALK]	SPISIMO	SPISOMI
		Master Mode		
4-wire	0	X	TX	RX
3-pin mode	1	0	RX	Disconnect from SPI
		1	TX/RX	
		Slave Mode		
4-wire	0	X	RX	TX
3-pin mode	1	0	Disconnect from SPI	RX
		1		TX/RX

17.4 Programming Procedure

This section describes the procedure for configuring the SPI for the various modes of operation.

17.4.1 Initialization Upon Reset

A system reset forces the SPI peripheral into the following default configuration:

- Unit is configured as a slave module (MASTER_SLAVE = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h

17.4.2 Configuring the SPI

This section describes the procedure in which to configure the SPI module for operation. To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPISWRESET bit before making initialization changes, and then set this bit after initialization is complete. While the SPI is held in reset (SPISWRESET = 0), configuration can be changed in any order. The following list shows the SPI configuration procedure in a logical order. However, the SPI registers can be written with single 16-bit writes, so the order is not required with the exception of SPISWRESET.

Note

Do not change the SPI configuration when communication is in progress.

To change the SPI configuration:

1. Clear the SPI Software Reset bit (SPISWRESET) to 0 to force the SPI to the reset state.
2. Configure the SPI as desired:
   - Select either master or slave mode (MASTER_SLAVE).
   - Choose SPICLK polarity and phase (CLKPOLARITY and CLK_PHASE).
   - Set the desired baud rate (SPIBRR).
   - Enable high-speed mode, if desired (HS_MODE).
   - Set the SPI character length (SPICHAR).
   - Clear the SPI Flags (OVERRUN_FLAG, INT_FLAG).
   - Enable $\overline{\text{SPISTE}}$ inversion (STEINV), if needed.
   - Enable 3-wire mode (TRIWIRE), if needed.
   - If using FIFO enhancements:
     - Enable the FIFO enhancements (SPIFFENA).
     - Clear the FIFO Flags (TXFFINTCLR, RXFFOVFCLR, and RXFFINTCLR).
     - Release transmit and receive FIFO resets (TXFIFO and RXFIFORESET).
     - Release SPI FIFO channels from reset (SPIRST).
3. If interrupts are used:
   - In non-FIFO mode, enable the receiver overrun and/or SPI interrupts (OVERRUNINTENA and SPIINTENA).
   - In FIFO mode, set the transmit and receive interrupt levels (TXFFIL and RXFFIL) then enable the interrupts (TXFFIENA and RXFFIENA).
4. Set SPISWRESET to 1 to release the SPI from the reset state.

17.4.3 Configuring the SPI for High-Speed Mode

To achieve the maximum rated speeds, the following settings must be made. This example assumes that the device is operating at 100MHz.

Set LSPCLK equal to SYSCLK:

```
ClkCfgRegs.LOSPCP.bit.LSPCLKDIV = 0;
```

Select the appropriate Pin Mux options in GPIO_CTRL_REGS.

During the SPI configuration procedure:

Set HS_MODE to 1.

```
SpiaRegs.SPICCR.bit.HS_MODE = 0x1;
```

Set SPIBRR to 3. SPICLK = LSPCLK/(SPIBRR+1) = 25MHz

```
SpiaRegs.SPIBRR = 0x3;
```

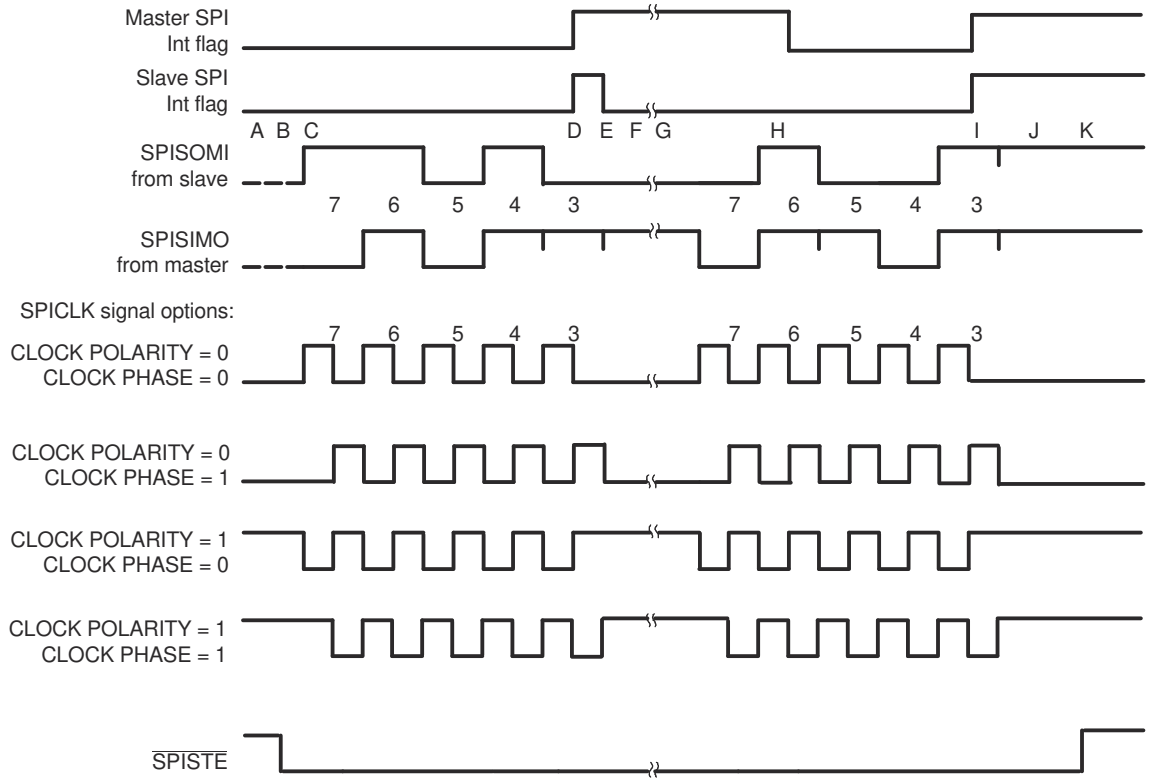
There are no other differences in the configuration from normal SPI operation. Sending and receiving data, DMA operation, and interrupts operates without change.

17.4.4 Data Transfer Example

The timing diagram shown in Figure 17-11 shows an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK asymmetrical (Figure 17-8) shares similar characterizations with Figure 17-11 except that the data transfer is one LSPCLK cycle longer per bit during the low pulse (CLKPOLARITY = 0) or during the high pulse (CLKPOLARITY = 1) of the SPICLK.

Figure 17-11 is applicable for 8-bit SPI only and is not for C28x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.



A. Slave writes 0D0h to SPIDAT and waits for the master to shift out the data.
B. Master sets the slave $\overline{\text{SPISTE}}$ signal low (active).
C. Master writes 058h to SPIDAT, which starts the transmission procedure.
D. First byte is finished and sets the interrupt flags.
E. Slave reads 0Bh from the SPIRXBUF (right-justified).
F. Slave writes 04Ch to SPIDAT and waits for the master to shift out the data.
G. Master writes 06Ch to SPIDAT, which starts the transmission procedure.
H. Master reads 01Ah from the SPIRXBUF (right-justified).
I. Second byte is finished and sets the interrupt flags.
J. Master reads 89h and the slave reads 8Dh from the respective SPIRXBUF. After the user software masks off the unused bits, the master receives 09h and the slave receives 0Dh.
K. Master clears the slave $\overline{\text{SPISTE}}$ signal high (inactive).

Figure 17-11. Five Bits per Character

17.4.5 SPI 3-Wire Mode Code Examples

In addition to the normal SPI initialization, to configure the SPI module for 3-wire mode, the TRIWIRE bit (SPIPRI.0) must be set to 1. After initialization, there are several considerations to take into account when transmitting and receiving data in 3-wire master and slave mode. The following examples demonstrate these considerations.

In 3-wire master mode, SPICLKx, $\overline{\text{SPISTE}}$x, and SPISIMOx pins must be configured as SPI pins (SPISOMIx pin can be configured as non-SPI pin). When the master transmits, the master receives the data the master transmits (because SPISIMOx and SPISOMIx are connected internally in 3-wire mode). Therefore, the junk data received must be cleared from the receive buffer every time data is transmitted.

Example 17-4. 3-Wire Master Mode Transmit

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data; // Master transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data because
                                                // rx'd same data as tx'd
```

To receive data in 3-wire master mode, the master must clear the TALK (SPICTL.1) bit to 0 to close the transmit path and then transmit dummy data to initiate the transfer from the slave. Because the TALK bit is 0, unlike in transmit mode, the master dummy data does not appear on the SPISIMOx pin, and the master does not receive the dummy data. Instead, the data from the slave is received by the master.

Example 17-5. 3-Wire Master Mode Receive

```
Uint16 rdata;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
     SpiaRegs.SPITXBUF = dummy;                 // Send dummy to start tx
     // NOTE: because TALK = 0, data does not tx onto SPISIMOA pin
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data received
     rdata = SpiaRegs.SPIRXBUF;                 // Master reads data
```

In 3-wire slave mode, SPICLKx, SPISTEx, and SPISOMIx pins must be configured as SPI pins (SPISIMOx pin can be configured as non-SPI pin). Like in master mode, when transmitting, the slave receives the data transmitted and must clear this junk data from the receive buffer.

Example 17-6. 3-Wire Slave Mode Transmit

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data;                  // Slave transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data
```

As in 3-wire master mode, the TALK bit must be cleared to 0. Otherwise, the slave receives data normally.

Example 17-7. 3-Wire Slave Mode Receive

```
Uint16 rdata;
    SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
    rdata = SpiaRegs.SPIRXBUF;                 // Slave reads data
```

17.4.6 SPI STEINV Bit in Digital Audio Transfers

On those devices with two SPI modules, enabling the STEINV bit on one of the SPI modules allows the pair of SPIs to receive both left and right-channel digital audio data in slave mode. The SPI module that receives a normal active-low $\overline{\text{SPISTE}}$ signal stores right-channel data, and the SPI module that receives an inverted active-high $\overline{\text{SPISTE}}$ signal stores left-channel data from the master. To receive digital audio data from a digital audio interface receiver, the SPI modules can be connected as shown in Figure 17-12.

Note

This configuration is only applicable to slave mode (MASTER_SLAVE = 0). When the SPI is configured as master (MASTER_SLAVE = 1), the STEINV bit has no effect on the $\overline{\text{SPISTE}}$ pin.

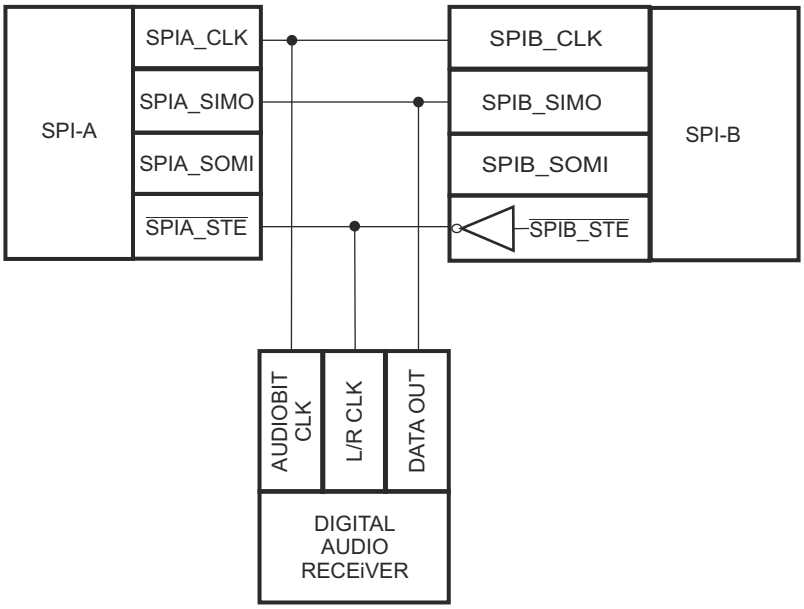


Figure 17-12. SPI Digital Audio Receiver Configuration Using Two SPIs

Standard C28x SPI timing requirements limit the number of digital audio interface formats supported using the 2-SPI configuration with the STEINV bit. See the device data sheet electrical specifications for SPI timing requirements. With the SPI clock phase configured such that the CLKPOLARITY bit is 0 and the CLK_PHASE bit is 1 (data latched on rising edge of clock), standard right-justified digital audio interface data format is supported as shown in Figure 17-13.

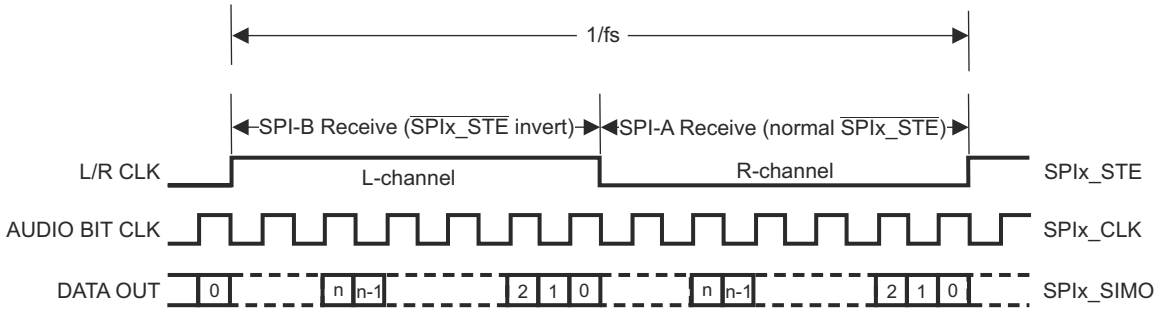

Figure 17-13. Standard Right-Justified Digital Audio Data Format

17.5 Software

17.5.1 SPI Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/spi

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

17.5.1.1 SPI Digital Loopback

FILE: spi_ex1_loopback.c

This program uses the internal loopback test mode of the SPI module. This is a very basic loopback that does not use the FIFOs or interrupts. A stream of data is sent and then compared to the received stream. The pinmux and SPI modules are configure through the sysconfig file.

The sent data looks like this:
0000 0001 0002 0003 0004 0005 0006 0007 .... FFFE FFFF 0000

This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data

17.5.1.2 SPI Digital Loopback with FIFO Interrupts

FILE: spi_ex2_loopback_fifo_interrupts.c

This program uses the internal loopback test mode of the SPI module. Both the SPI FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

17.5.1.3 SPI Digital External Loopback without FIFO Interrupts

FILE: spi_ex3_external_loopback.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and interrupts are not used in this example. SPIA is configured as a peripheral and SPI B is configured as controller. This example demonstrates full duplex communication where both controller and peripheral transmits and receives data simultaneously.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*
Refer to SysConfig for external connections (GPIO pin numbers) specific to each device

Watch Variables
- *TxData_SPIA* - Data send from SPIA (peripheral)
- *TxData_SPIB* - Data send from SPIB (controller)
- *RxData_SPIA* - Data received by SPIA (peripheral)
- *RxData_SPIB* - Data received by SPIB (controller)

17.5.1.4 SPI Digital External Loopback with FIFO Interrupts

FILE: spi_ex4_external_loopback_fifo_interrupts.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and their interrupts are used. SPIA is configured as a peripheral and receives data from SPI B which is configured as a controller.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*
Refer to SysConfig for external connections (GPIO pin numbers) specific to each device

Watch Variables
- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

17.5.1.5 SPI Digital Loopback with DMA

FILE: spi_ex5_loopback_dma.c

This program uses the internal loopback test mode of the SPI module. Both DMA interrupts and the SPI FIFOs are used. When the SPI transmit FIFO has enough space (as indicated by its FIFO level interrupt signal), the DMA will transfer data from global variable sData into the FIFO. This will be transmitted to the receive FIFO via the internal loopback.

When enough data has been placed in the receive FIFO (as indicated by its FIFO level interrupt signal), the DMA will transfer the data from the FIFO into global variable rData.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data

17.5.1.6 SPI EEPROM

FILE: spi_ex6_eeprom.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256. Note: SPI character length is configured to 8 bits in SysConfig, and not changed throughout the execution of the program. Runtime updation of character length when CS pin is not controlled by the SPI module can lead to unpredictable behaviour

External Connections
ExternalConnections

- Connect external SPI EEPROM
- Connect GPIO16 (PICO) to external EEPROM SI pin
- Connect GPIO17 (POCI) to external EEPROM SO pin
- Connect GPIO18 (CLK) to external EEPROM SCK pin
- Connect GPIO11 (CS) to external EEPROM CS pin
- Connect the external EEPROM VCC and GND pins

Watch Variables

- writeBuffer - Data that is written to external EEPROM
- readBuffer - Data that is read back from EEPROM
- error - Error count

17.5.1.7 SPI DMA EEPROM

FILE: spi_ex7_eeprom_dma.c

This program will write 8 bytes to EEPROM and read them back. The device communicates with the EEPROM via SPI using DMA and specific opcodes. This example is written to work with the SPI Serial EEPROM AT25128/256. Note: Runtime updation of character length when CS pin is not controlled by the SPI module can lead to unpredictable behaviour

External Connections
ExternalConnections

- Connect external SPI EEPROM
- Connect GPIO16 (PICO) to external EEPROM SI pin
- Connect GPIO17 (POCI) to external EEPROM SO pin
- Connect GPIO18 (CLK) to external EEPROM SCK pin
- Connect GPIO11 (CS) to external EEPROM CS pin
- Connect the external EEPROM VCC and GND pins

Watch Variables

- writeBuffer - Data that is written to external EEPROM
- SPI_DMA_Handle.RXdata - Data that is read back from EEPROM when number of received bytes is less than 4
- SPI_DMA_Handle.pSPIRXDMA->pbuffer - Start address of received data from EEPROM
- error - Error count

17.6 SPI Registers

This section describes the Serial Peripheral Interface registers. It is important to note that the SPI registers only allow 16-bit accesses.

17.6.1 SPI Base Addresses

Table 17-6. SPI Base Address Table

Device Registers	Register Name	Start Address	End Address
SpiaRegs	SPI_REGS	0x0000_6100	0x0000_610F
SpibRegs	SPI_REGS	0x0000_6110	0x0000_611F
SpicRegs	SPI_REGS	0x0000_6120	0x0000_612F

17.6.2 SPI_REGS Registers

Table 17-7 lists the memory-mapped registers for the SPI_REGS registers. All register offset addresses not listed in Table 17-7 should be considered as reserved locations and the register contents should not be modified.

Table 17-7. SPI_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SPICCR	SPI Configuration Control Register		Go
1h	SPICTL	SPI Operation Control Register		Go
2h	SPISTS	SPI Status Register		Go
4h	SPIBRR	SPI Baud Rate Register		Go
6h	SPIRXEMU	SPI Emulation Buffer Register		Go
7h	SPIRXBUF	SPI Serial Input Buffer Register		Go
8h	SPITXBUF	SPI Serial Output Buffer Register		Go
9h	SPIDAT	SPI Serial Data Register		Go
Ah	SPIFFTX	SPI FIFO Transmit Register		Go
Bh	SPIFFRX	SPI FIFO Receive Register		Go
Ch	SPIFFCT	SPI FIFO Control Register		Go
Fh	SPIPRI	SPI Priority Control Register		Go

Complex bit access types are encoded to fit into small table cells. Table 17-8 shows the codes that are used for access types in this section.

Table 17-8. SPI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value

17.6.2.1 SPICCR Register (Offset = 0h) [Reset = 0000h]

SPICCR is shown in Figure 17-14 and described in Table 17-9.

Return to the Summary Table.

SPICCR controls the setup of the SPI for operation.

Figure 17-14. SPICCR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
SPISWRESET	CLKPOLARITY	HS_MODE	SPILBK	SPICHAR			
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h			

Table 17-9. SPICCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	SPISWRESET	R/W	0h	SPI Software Reset When changing configuration, you should clear this bit before the changes and set this bit before resuming operation. Reset type: SYSRSn 0h (R/W) = Initializes the SPI operating flags to the reset condition. Specifically, the RECEIVER OVERRUN Flag bit (SPISTS.7), the SPI INT FLAG bit (SPISTS.6), and the TXBUF FULL Flag bit (SPISTS.5) are cleared. SPISTE will become inactive. SPICLK will be immediately driven to 0 regardless of the clock polarity. The SPI configuration remains unchanged. 1h (R/W) = SPI is ready to transmit or receive the next character. When the SPI SW RESET bit is a 0, a character written to the transmitter will not be shifted out when this bit is set. A new character must be written to the serial data register. SPICLK will be returned to its inactive state one SPICLK cycle after this bit is set.
6	CLKPOLARITY	R/W	0h	Shift Clock Polarity This bit controls the polarity of the SPICLK signal. CLOCK POLARITY and POLARITY CLOCK PHASE (SPICTL.3) control four clocking schemes on the SPICLK pin. Reset type: SYSRSn 0h (R/W) = Data is output on rising edge and input on falling edge. When no SPI data is sent, SPICLK is at low level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the rising edge of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first rising edge of the SPICLK signal and on subsequent falling edges of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. 1h (R/W) = Data is output on falling edge and input on rising edge. When no SPI data is sent, SPICLK is at high level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the falling edge of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first falling edge of the SPICLK signal and on subsequent rising edges of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal.

Table 17-9. SPICCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	HS_MODE	R/W	0h	High Speed Mode Enable Bits This bit determines if the High Speed mode is enabled. The correct GPIOs should be selected in the GPxGMUX/GPxMUX registers. Reset type: SYSRSn 0h (R/W) = SPI High Speed mode disabled. This is the default value after reset. 1h (R/W) = SPI High Speed mode enabled,
4	SPILBK	R/W	0h	SPI Loopback Mode Select Loopback mode allows module validation during device testing. This mode is valid only in master mode of the SPI. Reset type: SYSRSn 0h (R/W) = SPI loopback mode disabled. This is the default value after reset. 1h (R/W) = SPI loopback mode enabled, SIMO/SOMI lines are connected internally. Used for module self-tests.
3-0	SPICHAR	R/W	0h	Character Length Control Bits These four bits determine the number of bits to be shifted in or SPI CHAR0 out as a single character during one shift sequence. SPICHAR = Word length - 1 Reset type: SYSRSn 0h (R/W) = 1-bit word 1h (R/W) = 2-bit word 7h (R/W) = 8-bit word Fh (R/W) = 16-bit word

17.6.2.2 SPICTL Register (Offset = 1h) [Reset = 0000h]

SPICTL is shown in Figure 17-15 and described in Table 17-10.

Return to the Summary Table.

SPICTL controls data transmission, the SPI's ability to generate interrupts, the SPICLK phase, and the operational mode (slave or master).

Figure 17-15. SPICTL Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0

R-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 17-10. SPICTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-5	RESERVED	R	0h	Reserved
4	OVERRUNINTENA	R/W	0h	Overrun Interrupt Enable Overrun Interrupt Enable. Setting this bit causes an interrupt to be generated when the RECEIVER OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by the RECEIVER OVERRUN Flag bit and the SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. Reset type: SYSRSn 0h (R/W) = Disable RECEIVER OVERRUN interrupts. 1h (R/W) = Enable RECEIVER_OVERRUN interrupts.
3	CLK_PHASE	R/W	0h	SPI Clock Phase Select This bit controls the phase of the SPICLK signal. CLOCK PHASE and CLOCK POLARITY (SPICCR.6) make four different clocking schemes possible (see clocking figures in SPI chapter). When operating with CLOCK PHASE high, the SPI (master or slave) makes the first bit of data available after SPIDAT is written and before the first edge of the SPICLK signal, regardless of which SPI mode is being used. Reset type: SYSRSn 0h (R/W) = Normal SPI clocking scheme, depending on the CLOCK POLARITY bit (SPICCR.6). 1h (R/W) = SPICLK signal delayed by one half-cycle. Polarity determined by the CLOCK POLARITY bit.
2	MASTER_SLAVE	R/W	0h	SPI Network Mode Control This bit determines whether the SPI is a network master or slave. SLAVE During reset initialization, the SPI is automatically configured as a network slave. Reset type: SYSRSn 0h (R/W) = SPI is configured as a slave. 1h (R/W) = SPI is configured as a master.

Table 17-10. SPICTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	TALK	R/W	0h	Transmit Enable The TALK bit can disable data transmission (master or slave) by placing the serial data output in the high-impedance state. If this bit is disabled during a transmission, the transmit shift register continues to operate until the previous character is shifted out. When the TALK bit is disabled, the SPI is still able to receive characters and update the status flags. TALK is cleared (disabled) by a system reset. Reset type: SYSRSn 0h (R/W) = Disables transmission: - Slave mode operation: If not previously configured as a general-purpose I/O pin, the SPISOMI pin will be put in the high-impedance state. - Master mode operation: If not previously configured as a general-purpose I/O pin, the SPISIMO pin will be put in the high-impedance state. 1h (R/W) = Enables transmission For the 4-pin option, ensure to enable the receiver's SPISTEn input pin.
0	SPIINTENA	R/W	0h	SPI Interrupt Enable This bit controls the SPI's ability to generate a transmit/receive interrupt. The SPI INT FLAG bit (SPISTS.6) is unaffected by this bit. Reset type: SYSRSn 0h (R/W) = Disables the interrupt. 1h (R/W) = Enables the interrupt.

17.6.2.3 SPISTS Register (Offset = 2h) [Reset = 0000h]

SPISTS is shown in Figure 17-16 and described in Table 17-11.

Return to the Summary Table.

SPISTS contains interrupt and status bits.

Figure 17-16. SPISTS Register

15	14	13	12	11	10	9	8

Table 17-11. SPISTS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	OVERRUN_FLAG	W1C	0h	SPI Receiver Overrun Flag This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit is cleared in one of three ways: - Writing a 1 to this bit - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited. Reset type: SYSRSn 0h (R/W) = A receive overrun condition has not occurred. 1h (R/W) = The last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application). Writing a '1' will clear this bit. The RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received.

Table 17-11. SPISTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	INT_FLAG	RC	0h	SPI Interrupt Flag SPI INT FLAG is a read-only flag. Hardware sets this bit to indicate that the SPI has completed sending or receiving the last bit and is ready to be serviced. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. The received character is placed in the receiver buffer at the same time this bit is set. This bit is cleared in one of three ways: - Reading SPIRXBUF - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system Note: This bit should not be used if FIFO mode is enabled. The internal process of copying the received word from SPIRXBUF to the Receive FIFO will clear this bit. Use the FIFO status, or FIFO interrupt bits for similar functionality. Reset type: SYSRSn 0h (R/W) = No full words have been received or transmitted. 1h (R/W) = Indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced.
5	BUFFULL_FLAG	R	0h	SPI Transmit Buffer Full Flag This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete. Reset type: SYSRSn 0h (R/W) = Transmit buffer is not full. 1h (R/W) = Transmit buffer is full.
4-0	RESERVED	R	0h	Reserved

17.6.2.4 SPIBRR Register (Offset = 4h) [Reset = 0000h]

SPIBRR is shown in Figure 17-17 and described in Table 17-12.

Return to the Summary Table.

SPIBRR contains the bits used for baud-rate selection.

Figure 17-17. SPIBRR Register

RESERVED	SPI_BIT_RATE						
R-0h	R/W-0h						

Table 17-12. SPIBRR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6-0	SPI_BIT_RATE	R/W	0h	SPI Baud Rate Control These bits determine the bit transfer rate if the SPI is the network SPI BIT RATE 0 master. There are 125 data-transfer rates (each a function of the CPU clock, LSPCLK) that can be selected. One data bit is shifted per SPICLK cycle. (SPICLK is the baud rate clock output on the SPICLK pin.) If the SPI is a network slave, the module receives a clock on the SPICLK pin from the network master. Therefore, these bits have no effect on the SPICLK signal. The frequency of the input clock from the master should not exceed the slave SPI's LSPCLK signal divided by 4. In master mode, the SPI clock is generated by the SPI and is output on the SPICLK pin. The SPI baud rates are determined by the following formula: For SPIBRR = 3 to 127: SPI Baud Rate = LSPCLK / (SPIBRR + 1) For SPIBRR = 0, 1, or 2: SPI Baud Rate = LSPCLK / 4 Reset type: SYSRSn 3h (R/W) = SPI Baud Rate = LSPCLK/4 4h (R/W) = SPI Baud Rate = LSPCLK/5 7Eh (R/W) = SPI Baud Rate = LSPCLK/127 7Fh (R/W) = SPI Baud Rate = LSPCLK/128

17.6.2.5 SPIRXEMU Register (Offset = 6h) [Reset = 0000h]

SPIRXEMU is shown in Figure 17-18 and described in Table 17-13.

Return to the Summary Table.

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit of SPISTS. This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

Figure 17-18. SPIRXEMU Register

15	14	13	12	11	10	9	8
ERXBn							
R-0h							
7	6	5	4	3	2	1	0
ERXBn							
R-0h							

Table 17-13. SPIRXEMU Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	ERXBn	R	0h	Emulation Buffer Received Data SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set. This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately. It is recommended that you view SPIRXEMU in the normal emulator run mode. Reset type: SYSRSn

17.6.2.6 SPIRXBUF Register (Offset = 7h) [Reset = 0000h]

SPIRXBUF is shown in Figure 17-19 and described in Table 17-14.

Return to the Summary Table.

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit in SPISTS. If FIFO mode is enabled, reading this register will also decrement the RXFFST counter in SPIFFRX.

Figure 17-19. SPIRXBUF Register

15	14	13	12	11	10	9	8

R-0h							

Table 17-14. SPIRXBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	RXBn	R	0h	Received Data Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register. Reset type: SYSRSn

17.6.2.7 SPITXBUF Register (Offset = 8h) [Reset = 0000h]

SPITXBUF is shown in Figure 17-20 and described in Table 17-15.

Return to the Summary Table.

SPITXBUF stores the next character to be transmitted. Writing to this register sets the TX BUF FULL Flag bit in SPISTS. When the transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no transmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set.
In master mode, if no transmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

Table 17-15. SPITXBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TXBn	R/W	0h	Transmit Data Buffer This is where the next character to be transmitted is stored. When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared. Writes to SPITXBUF must be left-justified. Reset type: SYSRSn

17.6.2.8 SPIDAT Register (Offset = 9h) [Reset = 0000h]

SPIDAT is shown in Figure 17-21 and described in Table 17-16.

Return to the Summary Table.

SPIDAT is the transmit and receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

Table 17-16. SPIDAT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	SDATn	R/W	0h	Serial Data Shift Register - It provides data to be output on the serial output pin if the TALK bit (SPICTL.1) is set. - When the SPI is operating as a master, a data transfer is initiated. When initiating a transfer, check the CLOCK POLARITY bit (SPICCR.6) described in Section 10.2.1.1 and the CLOCK PHASE bit (SPICTL.3) described in Section 10.2.1.2, for the requirements. In master mode, writing dummy data to SPIDAT initiates a receiver sequence. Since the data is not hardware-justified for characters shorter than sixteen bits, transmit data must be written in left-justified form, and received data read in right-justified form. Reset type: SYSRSn

17.6.2.9 SPIFFTX Register (Offset = Ah) [Reset = A000h]

SPIFFTX is shown in Figure 17-22 and described in Table 17-17.

Return to the Summary Table.

SPIFFTX contains both control and status bits related to the output FIFO buffer. This includes FIFO reset control, FIFO interrupt level control, FIFO level status, as well as FIFO interrupt enable and clear bits.

Bit	Field	Type	Reset	Description
4-0	TXFFIL	R/W	0h	Transmit FIFO Interrupt Level Bits Transmit FIFO will generate interrupt when the FIFO status bits (TXFFST4-0) and FIFO level bits (TXFFIL4-0) match (less than or equal to). Reset type: SYSRSn 0h (R/W) = A TX FIFO interrupt request is generated when there are no words remaining in the TX buffer. 1h (R/W) = A TX FIFO interrupt request is generated when there is 1 word or no words remaining in the TX buffer. 2h (R/W) = A TX FIFO interrupt request is generated when there is 2 words or fewer remaining in the TX buffer. 10h (R/W) = A TX FIFO interrupt request is generated when there are 16 words or fewer remaining in the TX buffer. 1Fh (R/W) = Reserved.

17.6.2.10 SPIFFRX Register (Offset = Bh) [Reset = 201Fh]

SPIFFRX is shown in Figure 17-23 and described in Table 17-18.

Return to the Summary Table.

SPIFFRX contains both control and status bits related to the input FIFO buffer. This includes FIFO reset control, FIFO interrupt level control, FIFO level status, as well as FIFO interrupt enable and clear bits.

Figure 17-23. SPIFFRX Register

Table 17-18. SPIFFRX Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RXFFOVF	R	0h	Receive FIFO Overflow Flag Reset type: SYSRSn 0h (R/W) = Receive FIFO has not overflowed. This is a read-only bit. 1h (R/W) = Receive FIFO has overflowed, read-only bit. More than 16 words have been received in to the FIFO, and the first received word is lost.
14	RXFFOVFCLR	W	0h	Receive FIFO Overflow Clear Reset type: SYSRSn 0h (R/W) = Write 0 does not affect RXFFOVF flag bit, Bit reads back a zero. 1h (R/W) = Write 1 to clear SPIFFRX[RXFFOVF].
13	RXFIFORESET	R/W	1h	Receive FIFO Reset Reset type: SYSRSn 0h (R/W) = Write 0 to reset the FIFO pointer to zero, and hold in reset. 1h (R/W) = Re-enable receive FIFO operation.
12-8	RXFFST	R	0h	Receive FIFO Status Reset type: SYSRSn 0h (R/W) = Receive FIFO is empty. 1h (R/W) = Receive FIFO has 1 word. 2h (R/W) = Receive FIFO has 2 words. 10h (R/W) = Receive FIFO has 16 words, which is the maximum. 1Fh (R/W) = Reserved.
7	RXFFINT	R	0h	Receive FIFO Interrupt Flag Reset type: SYSRSn 0h (R/W) = RXFIFO interrupt has not occurred. This is a read-only bit. 1h (R/W) = RXFIFO interrupt has occurred. This is a read-only bit.
6	RXFFINTCLR	W	0h	Receive FIFO Interrupt Clear Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on RXFIFINT flag bit, Bit reads back a zero. 1h (R/W) = Write 1 to clear SPIFFRX[RXFFINT] flag
5	RXFFIENA	R/W	0h	RX FIFO Interrupt Enable Reset type: SYSRSn 0h (R/W) = RX FIFO interrupt based on RXFFIL match (greater than or equal to) will be disabled. 1h (R/W) = RX FIFO interrupt based on RXFFIL match (greater than or equal to) will be enabled.

Table 17-18. SPIFFRX Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-0	RXFFIL	R/W	1Fh	Receive FIFO Interrupt Level Bits Receive FIFO generates an interrupt when the FIFO status bits (RXFFST4-0) are greater than or equal to the FIFO level bits (RXFFIL4-0). The default value of these bits after reset is 11111. This avoids frequent interrupts after reset, as the receive FIFO will be empty most of the time. Reset type: SYSRSn 0h (R/W) = A RX FIFO interrupt request is generated when there is 0 or more words in the RX buffer. 1h (R/W) = A RX FIFO interrupt request is generated when there are 1 or more words in the RX buffer. 2h (R/W) = A RX FIFO interrupt request is generated when there are 2 or more words in the RX buffer. 10h (R/W) = A RX FIFO interrupt request is generated when there are 16 words in the RX buffer. 1Fh (R/W) = Reserved.

17.6.2.11 SPIFFCT Register (Offset = Ch) [Reset = 0000h]

SPIFFCT is shown in Figure 17-24 and described in Table 17-19.

Return to the Summary Table.

SPIFFCT controls the FIFO transmit delay bits.

Figure 17-24. SPIFFCT Register

Table 17-19. SPIFFCT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7-0	TXDLY	R/W	0h	FIFO Transmit Delay Bits These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 serial clock cycles and a maximum of 255 serial clock cycles. In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In the FIFO mode TXBUF should not be treated as one additional level of buffer. Reset type: SYSRSn 0h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF immediately upon completion of transmission of the previous word. 1h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF1 serial clock cycle after completion of transmission of the previous word. 2h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 2 serial clock cycles after completion of transmission of the previous word. FFh (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 255 serial clock cycles after completion of transmission of the previous word.

17.6.2.12 SPIPRI Register (Offset = Fh) [Reset = 0000h]

SPIPRI is shown in Figure 17-25 and described in Table 17-20.

Return to the Summary Table.

SPIPRI controls auxiliary functions for the SPI including emulation control, SPISTE inversion, and 3-wire control.

Figure 17-25. SPIPRI Register

15	14	13	12	11	10	9	8

Table 17-20. SPIPRI Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RESERVED	R/W	0h	Reserved
5	SOFT	R/W	0h	Emulation Soft Run This bit only has an effect when the FREE bit is 0. Reset type: SYSRSn 0h (R/W) = Transmission stops midway in the bit stream while TSUSPEND is asserted. Once TSUSPEND is deasserted without a system reset, the remainder of the bits pending in the DATBUF are shifted. Example: If SPIDAT has shifted 3 out of 8 bits, the communication freezes right there. However, if TSUSPEND is later deasserted without resetting the SPI, SPI starts transmitting from where it had stopped (fourth bit in this case) and will transmit 8 bits from that point. 1h (R/W) = If the emulation suspend occurs before the start of a transmission, (that is, before the first SPICLK pulse) then the transmission will not occur. If the emulation suspend occurs after the start of a transmission, then the data will be shifted out to completion. When the start of transmission occurs is dependent on the baud rate used. Standard SPI mode: Stop after transmitting the words in the shift register and buffer. That is, after TXBUF and SPIDAT are empty. In FIFO mode: Stop after transmitting the words in the shift register and buffer. That is, after TX FIFO and SPIDAT are empty.
4	FREE	R/W	0h	Emulation Free Run These bits determine what occurs when an emulation suspend occurs (for example, when the debugger hits a breakpoint). The peripheral can continue whatever it is doing (free-run mode) or, if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete. Reset type: SYSRSn 0h (R/W) = Emulation mode is selected by the SOFT bit 1h (R/W) = Free run, continue SPI operation regardless of suspend or when the suspend occurred.
3-2	RESERVED	R	0h	Reserved
1	STEINV	R/W	0h	SPISTEn Inversion Bit On devices with 2 SPI modules, inverting the SPISTE signal on one of the modules allows the device to receive left and right- channel digital audio data. This bit is only applicable to slave mode. Writing to this bit while configured as master (MASTER_SLAVE = 1) has no effect Reset type: SYSRSn 0h (R/W) = SPISTEn is active low (normal) 1h (R/W) = SPISTE is active high (inverted)

Table 17-20. SPIPRI Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	TRIWIRE	R/W	0h	SPI 3-wire Mode Enable Reset type: SYSRSn 0h (R/W) = Normal 4-wire SPI mode. 1h (R/W) = 3-wire SPI mode enabled. The unused pin becomes a GPIO pin. In master mode, the SPISIMO pin becomes the SPIMOMI (master receive and transmit) pin and SPISOMI is free for non-SPI use. In slave mode, the SPISOMI pin becomes the SPISISO (slave receive and transmit) pin and SPISIMO is free for non-SPI use.

Chapter 18

Serial Communications Interface (SCI)

This chapter describes the features and operation of the serial communication interface (SCI) module. SCI is a two-wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format. The SCI receiver and transmitter each have a 16-level deep FIFO for reducing servicing overhead, and each has a separate enable and interrupt bits. Both can be operated independently for half-duplex communication, or simultaneously for full-duplex communication.

To specify data integrity, the SCI checks received data for break detection, parity, overrun, and framing errors. The bit rate is programmable to different speeds through a 16-bit baud-select register.

18.1 Introduction

The SCI interfaces are shown in Figure 18-1.

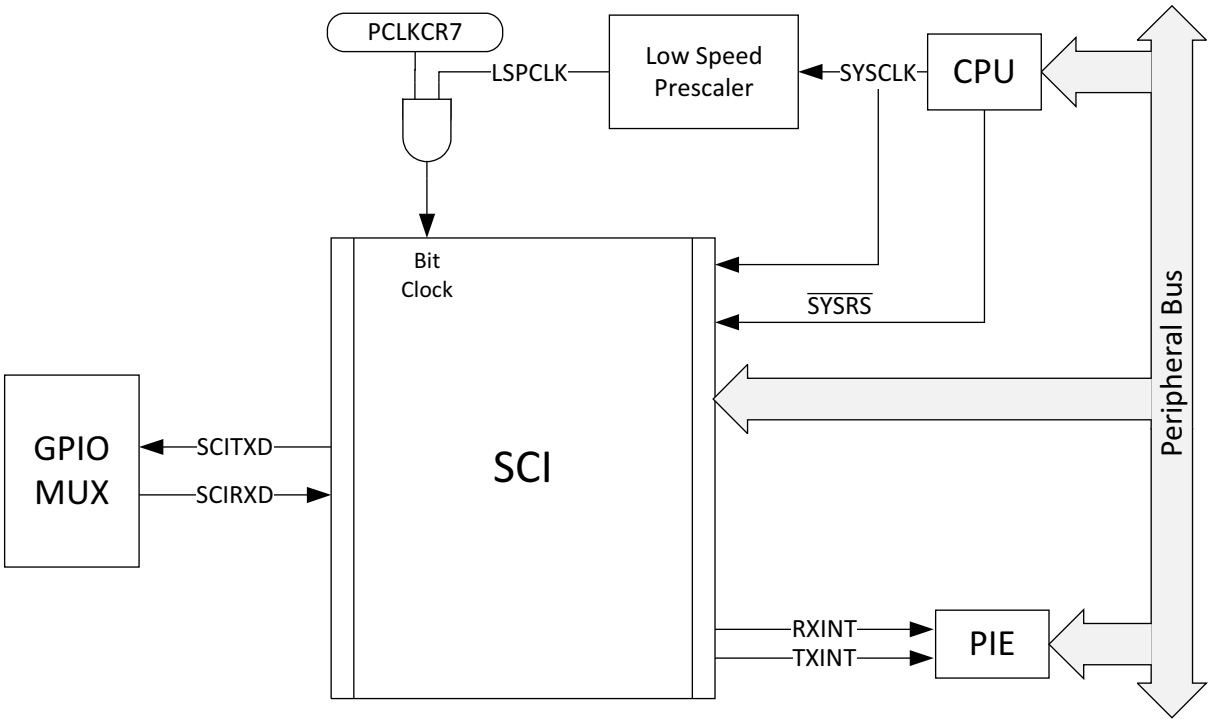

Figure 18-1. SCI CPU Interface

18.1.1 Features

Features of the SCI module include:

- Two external pins (both pins can be used as GPIO, if not used for SCI):
  - SCITXD: SCI transmit-output pin
  - SCIRXD: SCI receive-input pin
- Baud rate programmable to 64K different rates
- Data-word format
  - One start bit
  - Data-word length programmable from one to eight bits
  - Optional even/odd/no parity bit
  - One or two stop bits
  - An extra bit to distinguish addresses from data (address bit mode only)
- Four error-detection flags: parity, overrun, framing, and break detection
- Two wake-up multiprocessor modes: idle-line and address bit
- Half- or full-duplex operation
- Double-buffered receive and transmit functions
- Transmitter and receiver operations can be accomplished through interrupt-driven or polled algorithms with status flags
- Separate enable bits for transmitter and receiver interrupts (except BRKDT)
- NRZ (non-return-to-zero) format

Enhanced features include:

- Auto-baud-detect hardware logic
- 16-level transmit/receive FIFO

18.1.3 Block Diagram

Figure 18-2 shows the SCI module block diagram. The SCI port operation is configured and controlled by the registers listed in Section 18.15.

18.2 Architecture

The major elements used in full-duplex operation are shown in Figure 18-2 and include:

- A transmitter (TX) and the major registers (upper half of Figure 18-2):
  - SCITXBUF — transmitter data buffer register. Contains data (loaded by the CPU) to be transmitted
  - TXSHF register — transmitter shift register. Accepts data from register SCITXBUF and shifts data onto the SCITXD pin, one bit at a time
- A receiver (RX) and the major registers (lower half of Figure 18-2):
  - RXSHF register — receiver shift register. Shifts data in from SCIRXD pin, one bit at a time
  - SCIRXBUF — receiver data buffer register. Contains data to be read by the CPU. Data from a remote processor is loaded into register RXSHF and then into registers SCIRXBUF and SCIRXEMU
- A programmable baud generator
- Control and status registers

The SCI receiver and transmitter can operate either independently or simultaneously.

18.3 SCI Module Signal Summary

A summarized description of each SCI signal name is shown in Table 18-1.

Table 18-1. SCI Module Signal Summary

Signal Name	Description
External signals	
SCIRXD	SCI Asynchronous Serial Port receive data
SCITXD	SCI Asynchronous Serial Port transmit data
Control	
Baud clock	LSPCLK Prescaled clock
Interrupt signals	
TXINT	Transmit interrupt
RXINT	Receive interrupt

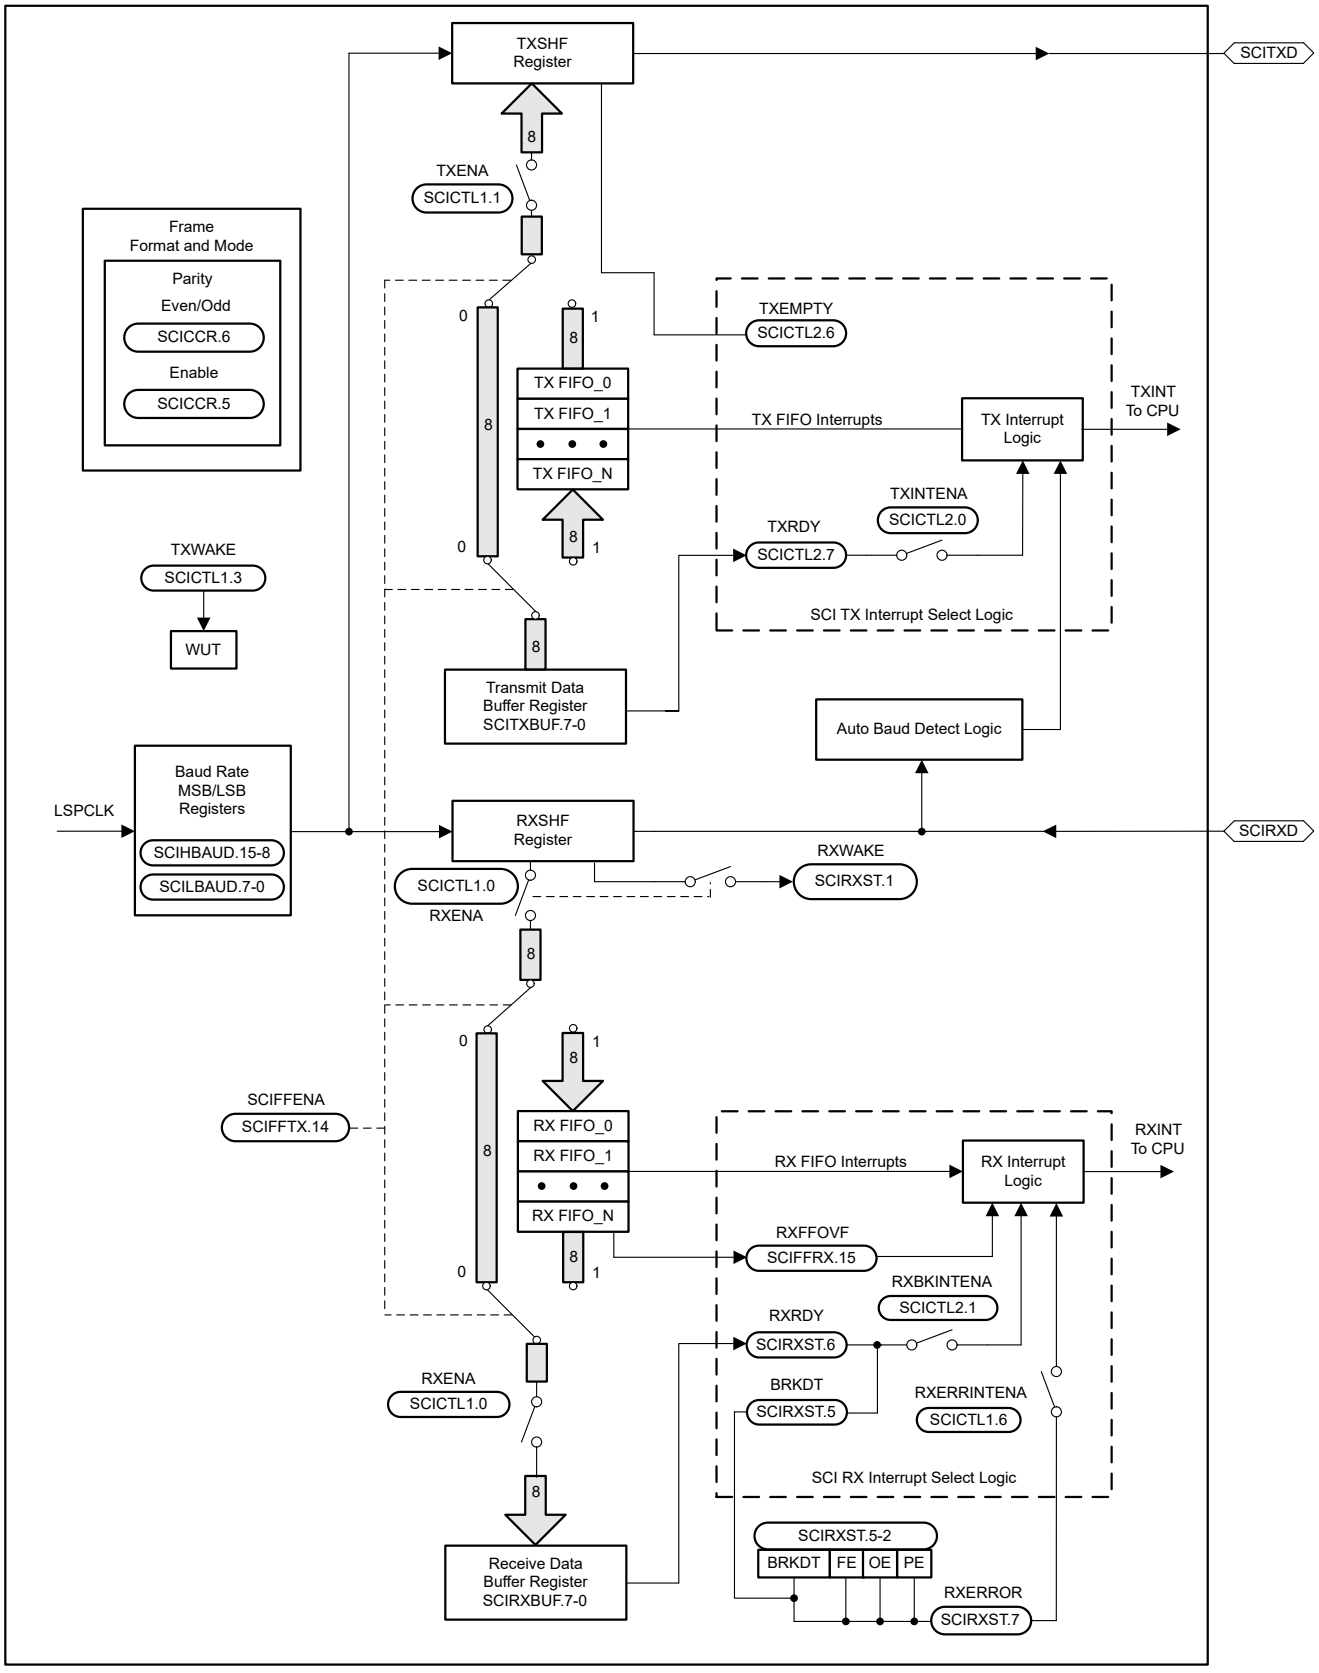

Figure 18-2. Serial Communications Interface (SCI) Module Block Diagram

18.4 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

18.5 Multiprocessor and Asynchronous Communication Modes

The SCI has two multiprocessor protocols, the idle-line multiprocessor mode (see Section 18.8) and the address-bit multiprocessor mode (see Section 18.9). These protocols allow efficient data transfer between multiple processors.

The SCI offers the universal asynchronous receiver/transmitter (UART) communications mode for interfacing with many popular peripherals. The asynchronous mode (see Section 18.10) requires two lines to interface with many standard devices such as terminals and printers that use RS-232-C formats. Data transmission characteristics include:

- One start bit
- One to eight data bits
- An even/odd parity bit or no parity bit
- One or two stop bits

18.6 SCI Programmable Data Format

SCI data, both receive and transmit, is in NRZ (non-return-to-zero) format. The NRZ data format, shown in Figure 18-3, consists of:

- One start bit
- One to eight data bits
- An even/odd parity bit (optional)
- One or two stop bits
- An extra bit to distinguish addresses from data (address-bit mode only)

The basic unit of data is called a character and is one to eight bits in length. Each character of data is formatted with a start bit, one or two stop bits, and optional parity and address bits. A character of data with formatting information is called a frame and is shown in Figure 18-3.

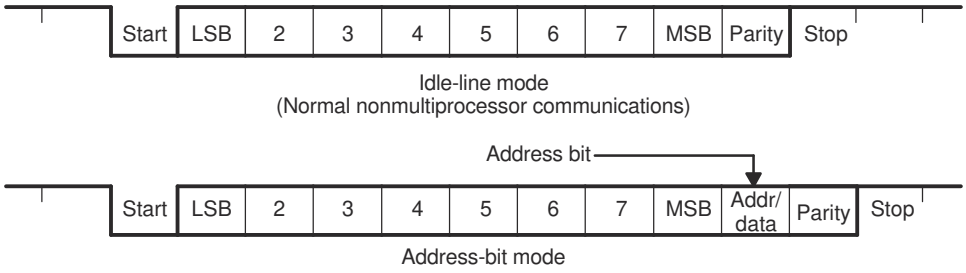

Figure 18-3. Typical SCI Data Frame Formats

To program the data format, use the SCICCR register. The bits used to program the data format are shown in Table 18-2.

Table 18-2. Programming the Data Format Using SCICCR

Bits	Bit Name	Designation	Functions
2-0	SCICHAR	SCICCR.2:0	Select the character (data) length (one to eight bits).
5	PARITYENA (ENABLE)	SCICCR.5	Enables the parity function if set to 1, or disables the parity function if cleared to 0.
6	PARITY (EVEN/ODD)	SCICCR.6	If parity is enabled, selects odd parity if cleared to 0; even parity if set to 1.
7	STOPBITS	SCICCR.7	Determines the number of stop bits transmitted—one stop bit if cleared to 0 or two stop bits if set to 1.

18.7 SCI Multiprocessor Communication

The multiprocessor communication format allows one processor to efficiently send blocks of data to other processors on the same serial link. On one serial line, there can be only one transfer at a time. In other words, there can be only one talker on a serial line at a time.

Address Byte

The first byte of a block of information that the talker sends contains an address byte that is read by all listeners. Only listeners with the correct address can be interrupted by the data bytes that follow the address byte. The listeners with an incorrect address remain uninterrupted until the next address byte.

Sleep Bit

All processors on the serial link set the SCI SLEEP bit (bit 2 of SCICTL1) to 1 so that the processor is interrupted only when the address byte is detected. When the processor reads a block address that corresponds to the CPU device address as set by your application software, your program must clear the SLEEP bit to enable the SCI to generate an interrupt on receipt of each data byte.

Although the receiver still operates when the SLEEP bit is 1, the receiver does not set RXRDY, RXINT, or any of the receiver error status bits to 1 unless the address byte is detected and the address bit in the received frame is a 1 (applicable to address-bit mode). The SCI does not alter the SLEEP bit; your software must alter the SLEEP bit.

18.7.1 Recognizing the Address Byte

A processor recognizes an address byte differently, depending on the multiprocessor mode used. For example:

- The idle-line mode (Section 18.8) leaves a quiet space before the address byte. This mode does not have an extra address/data bit and is more efficient than the address-bit mode for handling blocks that contain more than 10 bytes of data. The idle-line mode must be used for typical non-multiprocessor SCI communication.
- The address-bit mode (Section 18.9) adds an extra bit (that is, an address bit) into every byte to distinguish addresses from data. This mode is more efficient in handling many small blocks of data because, unlike the idle mode, this mode does not wait between blocks of data. However, at a high transmit speed, the program is not fast enough to avoid a 10-bit idle in the transmission stream.

18.7.2 Controlling the SCI TX and RX Features

The multiprocessor mode is software selectable using the ADDR/IDLE MODE bit (SCICCR, bit 3). Both modes use the TXWAKE flag bit (SCICTL1, bit 3), RXWAKE flag bit (SCIRXST, bit1), and the SLEEP flag bit (SCICTL1, bit 2) to control the SCI transmitter and receiver features of these modes.

18.7.3 Receipt Sequence

In both multiprocessor modes, the receive sequence is as follows:

1. At the receipt of an address block, the SCI port wakes up and requests an interrupt (bit number 1 RX/BK INT ENA-of SCICTL2 must be enabled to request an interrupt in non-FIFO mode of operation. In FIFO mode, RXFFINT serves this purpose and to enable this, RXFFINTEN in SCIFFRX register must be enabled with RXFFIL in the same register set to 1). The SCI reads the first frame of the block, which contains the destination address.
2. A software routine is entered through the interrupt and checks the incoming address. This address byte is checked against the device address byte stored in memory.
3. If the check shows that the block is addressed to the device CPU, the CPU clears the SLEEP bit and reads the rest of the block. If not, the software routine exits with the SLEEP bit still set, and does not receive interrupts until the next block start.

18.8 Idle-Line Multiprocessor Mode

In the idle-line multiprocessor protocol (ADDR/IDLE MODE bit=0), blocks are separated by having a longer idle time between the blocks than between frames in the blocks. An idle time of ten or more high-level bits after a frame indicates the start of a new block. The time of a single bit is calculated directly from the baud value (bits per second). The idle-line multiprocessor communication format is shown in Figure 18-4 (ADDR/IDLE MODE bit is bit 3 of SCICCR).

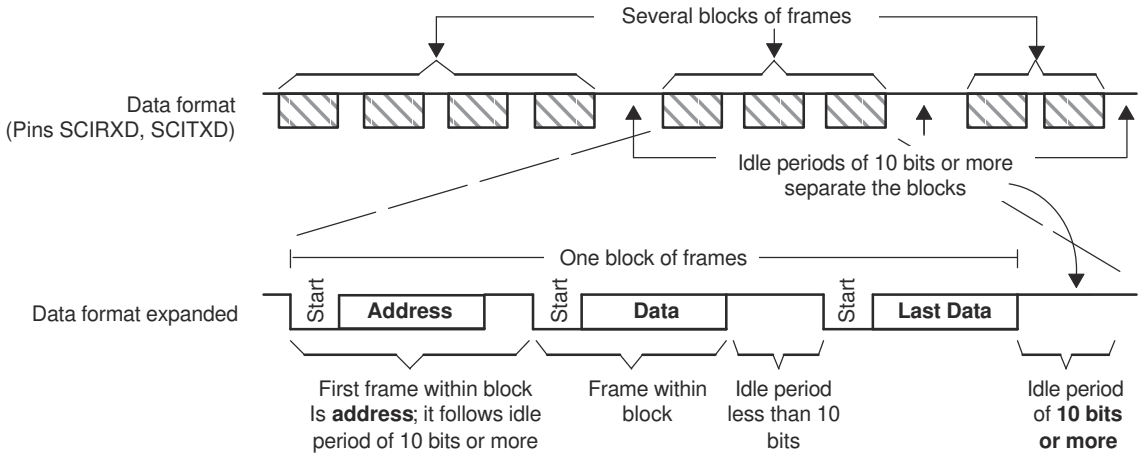

Figure 18-4. Idle-Line Multiprocessor Communication Format

18.8.1 Idle-Line Mode Steps

The steps followed by the idle-line mode:

1. SCI wakes up after receipt of the block-start signal.
2. The processor recognizes the next SCI interrupt.
3. The interrupt service routine compares the received address (sent by a remote transmitter) to the ISR address.
4. If the CPU is being addressed, the service routine clears the SLEEP bit and receives the rest of the data block.
5. If the CPU is not being addressed, the SLEEP bit remains set. This lets the CPU continue to execute the main program without being interrupted by the SCI port until the next detection of a block start.

Note

In IDLE mode, if the SCI is taking greater than 10 bit periods to read all the RXDATA from the FIFO, the SCI can miss the immediate block start to be detected.

The RXWAKE logic asserts only one time when the SCI identifies 10 bit periods of IDLE. The SCI does not assert again if RXBUF is read (which clears the WAKE condition) even if the line continues to be idle after RXBUF read.

So, if the ISR is taking more than 10 bit periods of time to read all the RXDATA from the FIFO using RXBUF, the SCI can miss to detect the next block start. This is applicable for both FIFO and Non-FIFO mode when the CPU takes greater than 10 bit clocks of SCI to read the data from RXBUF/ FIFO.

To avoid this, either of the following is recommended:

- Set SCICTL1.SWRESET after reading all RX data at the end of the ISR.
- Read and check RXWAKE status bit before reading the RXBUF register. If RXWAKE is set, don't set SLEEP bit for RX at the end of the ISR.

18.8.2 Block Start Signal

There are two ways to send a block-start signal:

- **Method 1:** Deliberately leave an idle time of ten bits or more by delaying the time between the transmission of the last frame of data in the previous block and the transmission of the address frame of the new block.
- **Method 2:** The SCI port first sets the TXWAKE bit (SCICTL1, bit 3) to 1 before writing to the SCITXBUF register. This sends an idle time of exactly 11 bits. In this method, the serial communications line is not idle any longer than necessary. (A don't care byte has to be written to SCITXBUF after setting TXWAKE, and before sending the address, so as to transmit the idle time.)

18.8.3 Wake-Up Temporary (WUT) Flag

Associated with the TXWAKE bit is the wake-up temporary (WUT) flag. WUT is an internal flag, double-buffered with TXWAKE. When TXSHF is loaded from SCITXBUF, WUT is loaded from TXWAKE, and the TXWAKE bit is cleared to 0. This arrangement is shown in Figure 18-5.

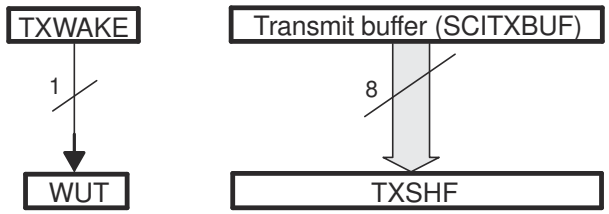

Figure 18-5. Double-Buffered WUT and TXSHF

18.8.3.1 Sending a Block Start Signal

To send out a block-start signal of exactly one frame time during a sequence of block transmissions:

1. Write a 1 to the TXWAKE bit.
2. Write a data word (content not important: a don’t care) to the SCITXBUF register (transmit data buffer) to send a block-start signal. (The first data word written is suppressed while the block-start signal is sent out and ignored after that.) When the TXSHF (transmit shift register) is free again, SCITXBUF contents are shifted to TXSHF, the TXWAKE value is shifted to WUT, and then TXWAKE is cleared.

   Because TXWAKE was set to a 1, the start, data, and parity bits are replaced by an idle period of 11 bits transmitted following the last stop bit of the previous frame.
3. Write a new address value to SCITXBUF.

   A don’t-care data word must first be written to register SCITXBUF so that the TXWAKE bit value can be shifted to WUT. After the don’t-care data word is shifted to the TXSHF register, the SCITXBUF (and TXWAKE, if necessary) can be written to again because TXSHF and WUT are both double-buffered.

18.8.4 Receiver Operation

The receiver operates regardless of the SLEEP bit. However, the receiver neither sets RXRDY nor the error status bits, nor does it request a receive interrupt until an address frame is detected.

18.9 Address-Bit Multiprocessor Mode

In the address-bit protocol (ADDR/IDLE MODE bit=1), frames have an extra bit called an address bit that immediately follows the last data bit. The address bit is set to 1 in the first frame of the block and to 0 in all other frames. The idle period timing is irrelevant (see Figure 18-6).

18.9.1 Sending an Address

The TXWAKE bit value is placed in the address bit. During transmission, when the SCITXBUF register and TXWAKE are loaded into the TXSHF register and WUT respectively, TXWAKE is reset to 0 and WUT becomes the value of the address bit of the current frame. Thus, to send an address:

1. Set the TXWAKE bit to 1 and write the appropriate address value to the SCITXBUF register.

   When this address value is transferred to the TXSHF register and shifted out, the address bit is sent as a 1. This flags the other processors on the serial link to read the address.
2. Write to SCITXBUF and TXWAKE after TXSHF and WUT are loaded. (Can be written to immediately since both TXSHF and WUT are both double-buffered.
3. Leave the TXWAKE bit set to 0 to transmit non-address frames in the block.

Note

As a general rule, the address-bit format is typically used for data frames of 11 bytes or less. This format adds one bit value (1 for an address frame, 0 for a data frame) to all data bytes transmitted. The idle-line format is typically used for data frames of 12 bytes or more.

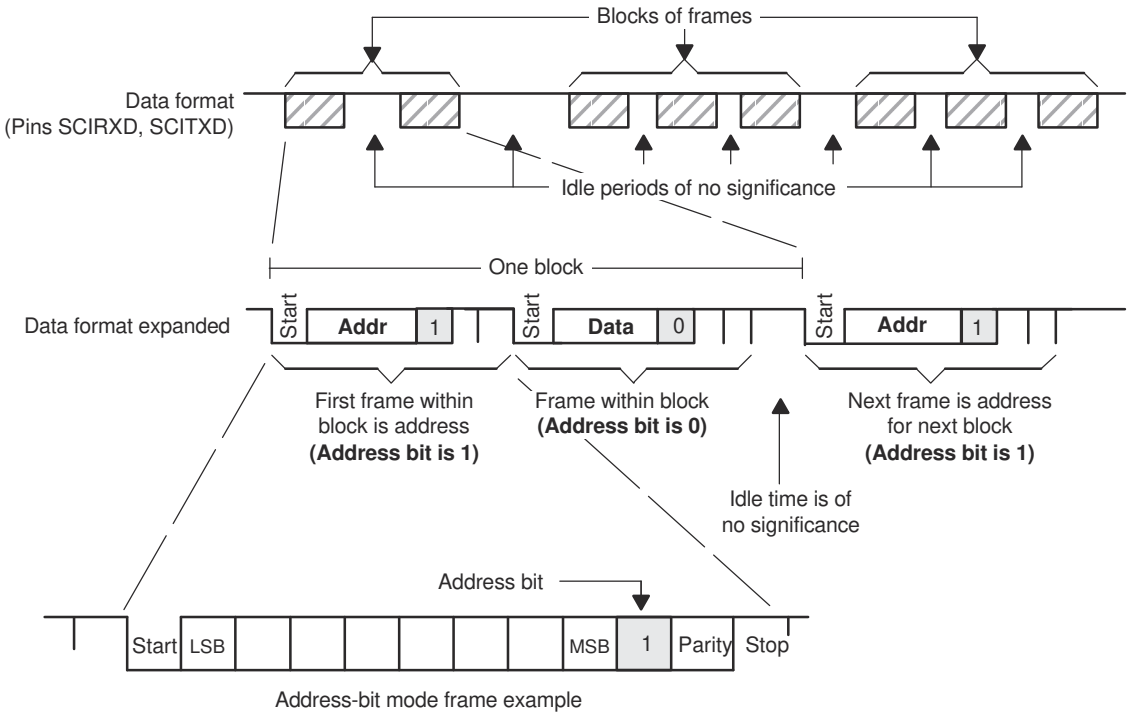

Figure 18-6. Address-Bit Multiprocessor Communication Format

18.10 SCI Communication Format

The SCI asynchronous communication format uses either single line (one way) or two line (two way) communications. In this mode, the frame consists of a start bit, one to eight data bits, an optional even/odd parity bit, and one or two stop bits (shown in Figure 18-7). There are eight SCICLK periods per data bit.

The receiver begins operation on receipt of a valid start bit. A valid start bit is identified by four consecutive internal SCICLK periods of zero bits as shown in Figure 18-7. If any bit is not zero, then the processor starts over and begins looking for another start bit.

For the bits following the start bit, the processor determines the bit value by making three samples in the middle of the bits. These samples occur on the fourth, fifth, and sixth SCICLK periods, and bit-value determination is on a majority (two out of three) basis. Figure 18-7 illustrates the asynchronous communication format for this with a start bit showing where a majority vote is taken.

Since the receiver synchronizes to frames, the external transmitting and receiving devices do not use a synchronized serial clock. The clock can be generated locally.

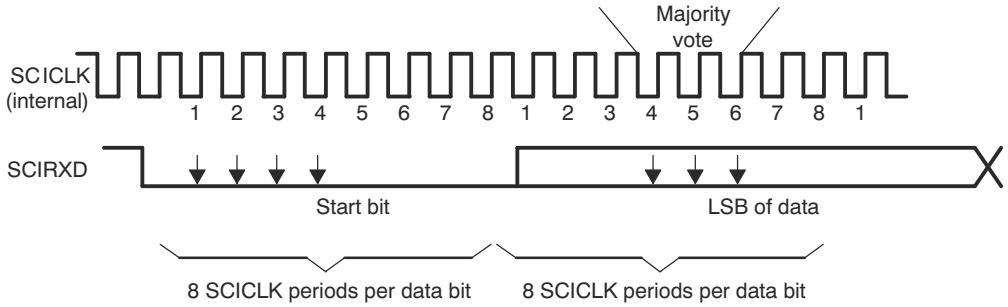

Figure 18-7. SCI Asynchronous Communications Format

18.10.1 Receiver Signals in Communication Modes

Figure 18-8 illustrates an example of receiver signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Six bits per character

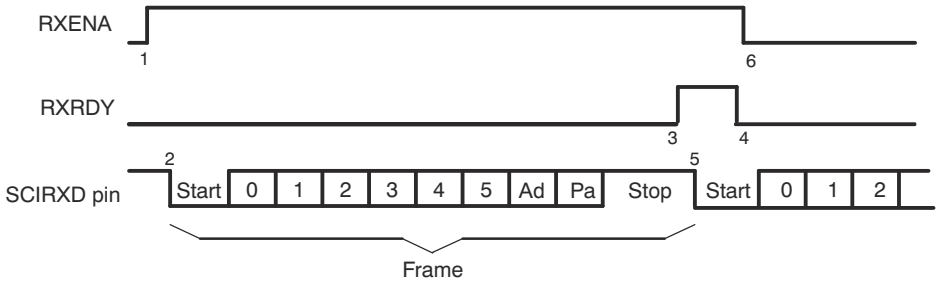

Figure 18-8. SCI RX Signals in Communication Modes

Notes:

1. Flag bit RXENA (SCICTL1, bit 0) goes high to enable the receiver.
2. Data arrives on the SCIRXD pin, start bit detected.
3. Data is shifted from RXSHF to the receiver buffer register (SCIRXBUF); an interrupt is requested. Flag bit RXRDY (SCIRXST, bit 6) goes high to signal that a new character has been received.
4. The program reads SCIRXBUF; flag RXRDY is automatically cleared.
5. The next byte of data arrives on the SCIRXD pin; the start bit is detected, then cleared.
6. Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.

18.10.2 Transmitter Signals in Communication Modes

Figure 18-9 illustrates an example of transmitter signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Three bits per character

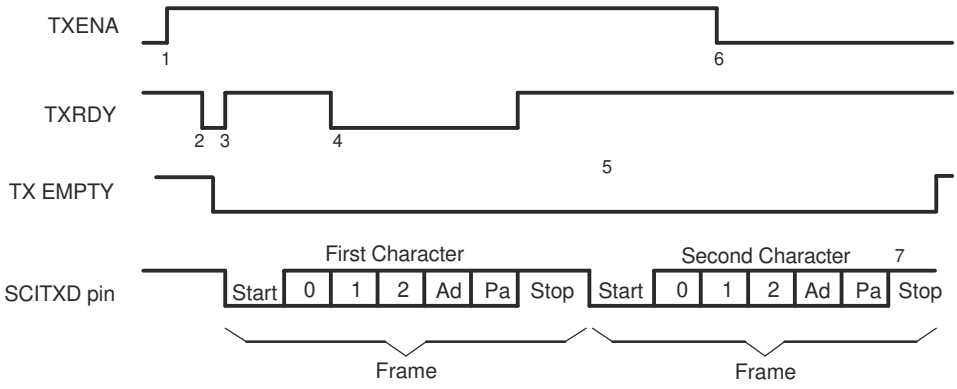

Figure 18-9. SCI TX Signals in Communications Mode

Notes:

1. Bit TXENA (SCICTL1, bit 1) goes high, enabling the transmitter to send data.
2. SCITXBUF is written to; thus, (1) the transmitter is no longer empty, and (2) TXRDY goes low.
3. The SCI transfers data to the shift register (TXSHF). The transmitter is ready for a second character (TXRDY goes high), and it requests an interrupt (to enable an interrupt, bit TX INT ENA — SCICTL2, bit 0 — must be set).
4. The program writes a second character to SCITXBUF after TXRDY goes high (item 3). (TXRDY goes low again after the second character is written to SCITXBUF.)
5. Transmission of the first character is complete. Transfer of the second character to shift register TXSHF begins.
6. Bit TXENA goes low to disable the transmitter; the SCI finishes transmitting the current character.
7. Transmission of the second character is complete; transmitter is empty and ready for new character.

18.11 SCI Port Interrupts

The SCI receiver and transmitter can be interrupt controlled. The SCICTL2 register has one flag bit (TXRDY) that indicates active interrupt conditions, and the SCIRXST register has two interrupt flag bits (RXRDY and BRKDT), plus the RX ERROR interrupt flag that is a logical-OR of the FE, OE, BRKDT, and PE conditions. The transmitter and receiver have separate interrupt-enable bits. When not enabled, the interrupts are not asserted; however, the condition flags remain active, reflecting transmission and receipt status.

The SCI has independent peripheral interrupt vectors for the receiver and transmitter. Peripheral interrupt requests can be either high priority or low priority. This is indicated by the priority bits that are output from the peripheral to the PIE controller. When both RX and TX interrupt requests are made at the same priority level, the receiver always has higher priority than the transmitter, reducing the possibility of receiver overrun.

The operation of peripheral interrupts is described in the Peripheral Interrupts section of the *System Control and Interrupts* chapter.

- If the RX/BK INT ENA bit (SCICTL2, bit 1) is set, the receiver peripheral interrupt request is asserted when one of the following events occurs:
  - The SCI receives a complete frame and transfers the data in the RXSHF register to the SCIRXBUF register. This action sets the RXRDY flag (SCIRXST, bit 6) and initiates an interrupt.
  - A break detect condition occurs (the SCIRXD is low for 9.625 bit periods following a missing stop bit). This action sets the BRKDT flag bit (SCIRXST, bit 5) and initiates an interrupt.
- If the TX INT ENA bit (SCICTL2.0) is set, the transmitter peripheral interrupt request is asserted whenever the data in the SCITXBUF register is transferred to the TXSHF register, indicating that the CPU can write to SCITXBUF; this action sets the TXRDY flag bit (SCICTL2, bit 7) and initiates an interrupt.

Note

Interrupt generation due to the RXRDY and BRKDT bits is controlled by the RX/BK INT ENA bit (SCICTL2, bit 1). Interrupt generation due to the RX ERROR bit is controlled by the RX ERR INT ENA bit (SCICTL1, bit 6).

18.11.1 Break Detect

A "break" signal (also called a "break detect" or "break sequence") can be sent to the module to signal to the bus a specific condition. This break signal is defined as a low pulse of a certain amount of time, typically at least 1 packet wide (including a missed stop bit). The SCI has two main methods for detecting a "break" signal sent on the line, with certain limitations for each.

The first for break detect method involves reading the SCIRXST.BRKDT bit. A break condition that triggers the BRKDT bit occurs when the SCI receiver data line (SCIRXD) remains continuously low for at least 9.625 bits, beginning after a missing first stop bit. If the SCIRX line goes high at any point during the 9.625 bits then the SCI does not flag a break detect. To trigger the first stop bit missed, the typical method is to hold the RX line low for:

- 1 start bit
- 8 data bits
- (optional) 1 address bit
- (optional) 1 parity bit
- 1 stop bit
- 9.625 bits of additional time held low

This is a total of 19.625 (systems using no parity or address bit), 20.625 (systems using either parity or address bit but not both), or 21.625 (systems using both parity and address bit) bit times held low.

The second method for break detect is to instead use the SCIRXST.FE, SCIRXST.PE and SCIRXBUF.SAR bits to detect a break signal of 10 or 11 bits of low. ISR code can use the following combination of flags and received data to determine if a break detect occurred:

- Break signal = 11 bits low (requires parity enabled)
  - FE==1
  - PE==1 for odd parity, PE==0 for even parity
  - SCIRXBUF.SAR (received character)==0x00
- Break signal = 10 bits low (requires parity disabled)
  - FE==1
  - SCIRXBUF.SAR (received character)==0x00

18.12 SCI Baud Rate Calculations

The internally generated serial clock is determined by the low-speed peripheral clock LSPCLK) and the baud-select registers. The SCI uses the 16-bit value of the baud-select registers to select one of the 64K different serial clock rates possible for a given LSPCLK.

See the bit descriptions in the baud-select registers, for the formula to use when calculating the SCI asynchronous baud. Table 18-3 shows the baud-select values for common SCI bit rates. LSPCLK/16 is the maximum baud rate. For example, if LSPCLK is 100MHz, then the maximum baud rate is 6.25Mbps.

Table 18-3. Asynchronous Baud Register Values for Common SCI Bit Rates

	LSPCLK Clock Frequency, 100MHz		
Baud Rate	BRR	Actual Baud Rate	% Error
2400	5207 (1457h)	2400	0
4800	2603 (A2Bh)	4800	0
9600	1301 (515h)	9601	0.01
19200	650 (28Ah)	19201	0.01
38400	324 (144h)	38462	0.16

18.13 SCI Enhanced Features

The C28x SCI features autobaud detection and transmit/receive FIFO. The following section explains the FIFO operation.

18.13.1 SCI FIFO Description

The following steps explain the FIFO features and help with programming the SCI with FIFOs.

1. **Reset.** At reset the SCI powers up in standard SCI mode and the FIFO function is disabled. The FIFO registers SCIFFTX, SCIFFRX, and SCIFFCT remain inactive.
2. **Standard SCI.** The standard SCI modes work normally with TXINT/RXINT interrupts as the interrupt source for the module.
3. **FIFO enable.** FIFO mode is enabled by setting the SCIFFEN bit in the SCIFFTX register. SCIRST can reset the FIFO mode at any stage of the operation.
4. **Active registers.** All the SCI registers and SCI FIFO registers (SCIFFTX, SCIFFRX, and SCIFFCT) are active.
5. **Interrupts.** FIFO mode has two interrupts; transmit FIFO (TXINT) and receive FIFO (RXINT). The RXINT is the common interrupt for SCI FIFO receive, receive error, and receive FIFO overflow conditions. The TXINT of the standard SCI is disabled and this interrupt serves as SCI transmit FIFO interrupt.
6. **Buffers.** Transmit and receive buffers are supplemented with two 16-level FIFOs. The transmit FIFO registers are 8-bits wide and receive FIFO registers are 10-bits wide. The one-word transmit buffer (SCITXBUF) of the standard SCI functions as a transition buffer before the transmit FIFO and shift register. SCITXBUF is loaded into either the FIFO (when FIFO is enabled) or the TXSHF (when FIFO is disabled). When FIFO is enabled, SCITXBUF loads into the FIFO only after the last bit of the shift register is shifted out, so SCITXBUF cannot be treated as an additional level of buffer. With the FIFO enabled, TXSHF is directly loaded from the FIFO (not TXBUF) after an optional delay value (SCIFFCT). When FIFO mode is enabled for SCI, characters written to SCITXBUF are queued in to SCI-TXFIFO and the characters received in SCI-RXFIFO can be read using SCIRXBUF.
7. **Delayed transfer.** The rate that words in the FIFO are transferred to the transmit shift register is programmable. The SCIFFCT register bits (7−0) FFTXDLY7−FFTXDLY0 define the delay between the word transfer. The delay is defined in the number SCI baud clock cycles. The 8 bit register can define a minimum delay of 0 baud clock cycles and a maximum of 256-baud clock cycles. With zero delay, the SCI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 256 clock delay the SCI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 256 baud clocks between each words. The programmable delay facilitates communication with slow SCI/UARTs with little CPU intervention.
8. **FIFO status bits.** Both the transmit and receive FIFOs have status bits TXFFST or RXFFST (bits 12−8) that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit TXFIFO and receive reset bit RXFIFO reset the FIFO pointers to zero when these bits are cleared to 0. The FIFOs resumes operation from start once these bits are set to 1.
9. **Programmable interrupt levels.** Both transmit and receive FIFO can generate CPU interrupts. The interrupt trigger is generated whenever the transmit FIFO status bits TXFFST (bits 12−8) match (less than or equal to) the interrupt trigger level bits TXFFIL (bits 4−0). This provides a programmable interrupt trigger for transmit and receive sections of the SCI. Default value for these trigger level bits is 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

Figure 18-10 and Table 18-4 explain the operation/configuration of SCI interrupts in nonFIFO/FFO mode.

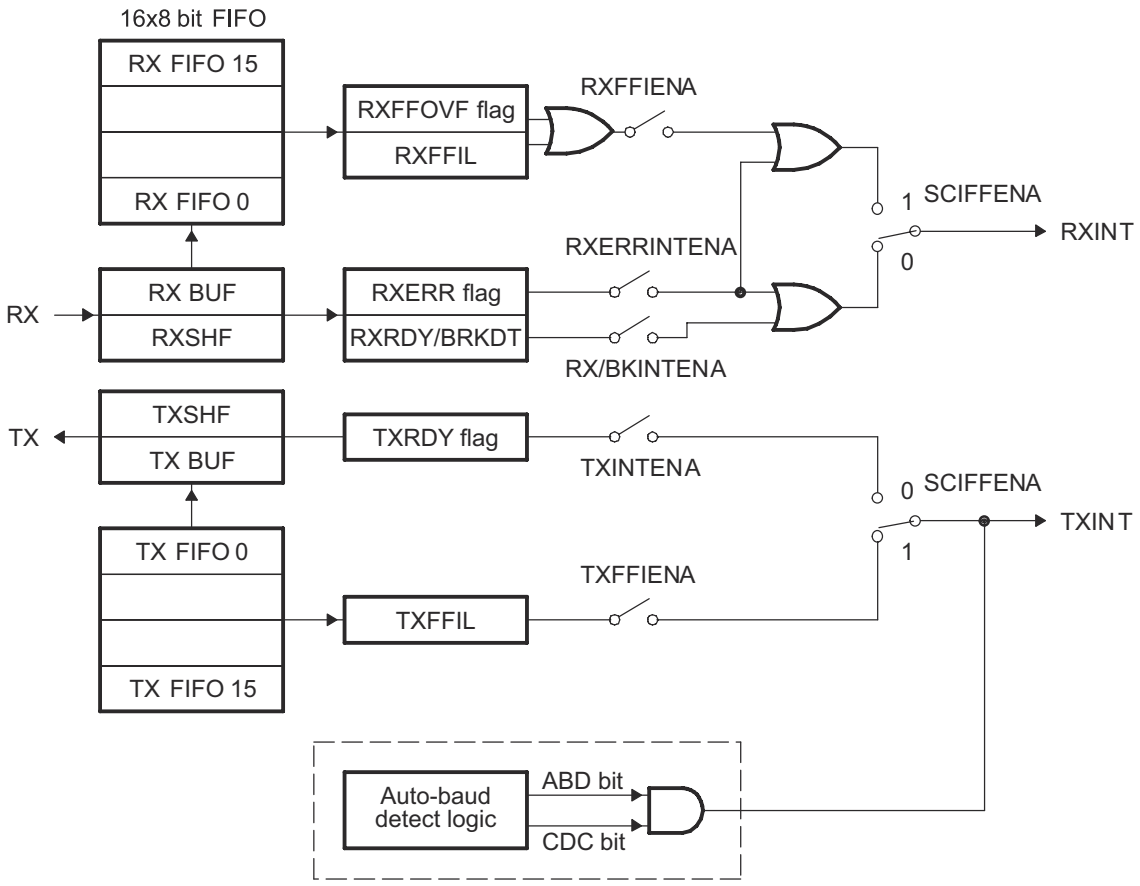

Figure 18-10. SCI FIFO Interrupt Flags and Enable Logic

Table 18-4. SCI Interrupt Flags

FIFO Options[1]	SCI Interrupt Source	Interrupt Flags	Interrupt Enables	FIFO Enable SCIFFENA	Interrupt Line
SCI without FIFO	Receive error	RXERR[2]	RXERRINTENA	0	RXINT
	Receive break	BRKDT	RX/BKINTENA	0	RXINT
	Data receive	RXRDY	RX/BKINTENA	0	RXINT
	Transmit empty	TXRDY	TXINTENA	0	TXINT
SCI with FIFO	Receive error and receive break	RXERR	RXERRINTENA	1	RXINT
	FIFO receive	RXFFIL	RXFFIENA	1	RXINT
	Transmit empty	TXFFIL	TXFFIENA	1	TXINT
Auto-baud	Auto-baud detected	ABD	Don't care	x	TXINT

(1) FIFO mode TXSHF is directly loaded after delay value, TXBUF is not used.
(2) RXERR can be set by BRKDT, FE, OE, PE flags. In FIFO mode, BRKDT interrupt is only through RXERR flag.

18.13.2 SCI Auto-Baud

Most SCI modules do not have an auto-baud detect logic built-in hardware. These SCI modules are integrated with embedded controllers whose clock rates are dependent on PLL reset values. Often embedded controller clocks change after final design. In the enhanced feature set this module supports an autobaud-detect logic in hardware. The following section explains the enabling sequence for autobaud-detect feature.

18.13.3 Autobaud-Detect Sequence

Bits ABD and CDC in SCIFFCT control the autobaud logic. The SCIRST bit can be enabled to make autobaud logic work.

If ABD is set while CDC is 1, which indicates auto-baud alignment, SCI transmit FIFO interrupt occurs (TXINT). After the interrupt service, the CDC bit must be cleared by software. If CDC remains set even after interrupt service, there can be no repeat interrupts.

1. Enable autobaud-detect mode for the SCI by setting the CDC bit (bit 13) in SCIFFCT and clearing the ABD bit (bit 15) by writing a 1 to ABDCLR bit (bit 14).
2. Initialize the baud register to be 1 or less than a baud rate limit of 500Kbps.
3. Allow SCI to receive either character "A" or "a" from a host at the desired baud rate. If the first character is either "A" or "a", the autobaud-detect hardware detects the incoming baud rate and sets the ABD bit.
4. The auto-detect hardware updates the baud rate register with the equivalent baud value hex. The logic also generates an interrupt to the CPU.
5. Respond to the interrupt clear ADB bit by writing a 1 to ABD CLR (bit 14) of SCIFFCT register and disable further autobaud locking by clearing CDC bit by writing a 0.
6. Read the receive buffer for character "A" or "a" to empty the buffer and buffer status.
7. If ABD is set while CDC is 1, which indicates autobaud alignment, the SCI transmit FIFO interrupt occurs (TXINT). After the interrupt service, the CDC bit must be cleared by software.

Note

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications can work well, this slew rate can limit reliable autobaud detection at higher baud rates (typically beyond 100k baud) and cause the auto-baudlock feature to fail.

To avoid this, the following is recommended:

- Achieve a baud-lock between the host and C28x SCI boot loader using a lower baud rate.
- The host can then handshake with the loaded C28x application to set the SCI baud rate register to the desired higher baud rate.

18.14 Software

18.14.1 SCI Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/sci

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

18.15 SCI Registers

The section describes the Serial Communication Interface module registers.

18.15.1 SCI Base Addresses

Table 18-5. SCI Base Address Table

Device Registers	Register Name	Start Address	End Address
SciaRegs	SCI_REGS	0x0000_7200	0x0000_720F
ScibRegs	SCI_REGS	0x0000_7210	0x0000_721F
ScicRegs	SCI_REGS	0x0000_7220	0x0000_722F
ScidRegs	SCI_REGS	0x0000_7230	0x0000_723F

18.15.2 SCI_REGS Registers

Table 18-6 lists the memory-mapped registers for the SCI_REGS registers. All register offset addresses not listed in Table 18-6 should be considered as reserved locations and the register contents should not be modified.

Table 18-6. SCI_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SCICCR	Communications control register		Go
1h	SCICTL1	Control register 1		Go
2h	SCIHBAUD	Baud rate (high) register		Go
3h	SCILBAUD	Baud rate (low) register		Go
4h	SCICTL2	Control register 2		Go
5h	SCIRXST	Receive status register		Go
6h	SCIRXEMU	Receive emulation buffer register		Go
7h	SCIRXBUF	Receive data buffer		Go
9h	SCITXBUF	Transmit data buffer		Go
Ah	SCIFFTX	FIFO transmit register		Go
Bh	SCIFFRX	FIFO receive register		Go
Ch	SCIFFCT	FIFO control register		Go
Fh	SCIPRI	SCI priority control		Go

Complex bit access types are encoded to fit into small table cells. Table 18-7 shows the codes that are used for access types in this section.

Table 18-7. SCI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

18.15.2.1 SCICCR Register (Offset = 0h) [Reset = 0000h]

SCICCR is shown in Figure 18-11 and described in Table 18-8.

Return to the Summary Table.

SCICCR defines the character format, protocol, and communications mode used by the SCI.

Figure 18-11. SCICCR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
STOPBITS	PARITY	PARITYENA	LOOPBKENA	ADDRIDLE_MODE	SCICHAR		
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h		

Table 18-8. SCICCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	STOPBITS	R/W	0h	SCI number of stop bits. This bit specifies the number of stop bits transmitted. The receiver checks for only one stop bit. Reset type: SYSRSn 0h (R/W) = One stop bit 1h (R/W) = Two stop bits
6	PARITY	R/W	0h	SCI parity odd/even selection. If the PARITY ENABLE bit (SCICCR, bit 5) is set, PARITY (bit 6) designates odd or even parity (odd or even number of bits with the value of 1 in both transmitted and received characters). Reset type: SYSRSn 0h (R/W) = Odd parity 1h (R/W) = Even parity
5	PARITYENA	R/W	0h	SCI parity enable. This bit enables or disables the parity function. If the SCI is in the addressbit multiprocessor mode (set using bit 3 of this register), the address bit is included in the parity calculation (if parity is enabled). For characters of less than eight bits, the remaining unused bits should be masked out of the parity calculation. Reset type: SYSRSn 0h (R/W) = Parity disabled no parity bit is generated during transmission or is expected during reception 1h (R/W) = Parity is enabled
4	LOOPBKENA	R/W	0h	Loop Back test mode enable. This bit enables the Loop Back test mode where the Tx pin is internally connected to the Rx pin. Reset type: SYSRSn 0h (R/W) = Loop Back test mode disabled 1h (R/W) = Loop Back test mode enabled

Table 18-8. SCICCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	ADDRIDLE_MODE	R/W	0h	SCI multiprocessor mode control bit. This bit selects one of the multiprocessor protocols.Multiprocessor communication is different from the other communication modes because it uses SLEEP and TXWAKE functions (bits SCICTL1, bit 2 and SCICTL1, bit 3, respectively). The idle-line mode is usually used for normal communications because the address-bit mode adds an extra bit to the frame. The idle-line mode does not add this extra bit and is compatible with RS-232 type communications. Reset type: SYSRSn 0h (R/W) = Idle-line mode protocol selected 1h (R/W) = Address-bit mode protocol selected
2-0	SCICHAR	R/W	0h	Character-length control bits 2-0. These bits select the SCI character length from one to eight bits. Characters of less than eight bits are right-justified in SCIRXBUF and SCIRXEMU and are padded with leading zeros in SCIRXBUF. SCITXBUF doesn't need to be padded with leading zeros. Reset type: SYSRSn 0h (R/W) = SCICHAR_LENGTH_1 1h (R/W) = SCICHAR_LENGTH_2 2h (R/W) = SCICHAR_LENGTH_3 3h (R/W) = SCICHAR_LENGTH_4 4h (R/W) = SCICHAR_LENGTH_5 5h (R/W) = SCICHAR_LENGTH_6 6h (R/W) = SCICHAR_LENGTH_7 7h (R/W) = SCICHAR_LENGTH_8

18.15.2.2 SCICTL1 Register (Offset = 1h) [Reset = 0000h]

SCICTL1 is shown in Figure 18-12 and described in Table 18-9.

Return to the Summary Table.

SCICTL1 controls the receiver/transmitter enable, TXWAKE and SLEEP functions, and the SCI software reset.

Figure 18-12. SCICTL1 Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED	RXERRINTENA	SWRESET	RESERVED	TXWAKE	SLEEP	TXENA	RXENA
R-0h	R/W-0h	R/W-0h	R-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 18-9. SCICTL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RXERRINTENA	R/W	0h	SCI receive error interrupt enable. Setting this bit enables an interrupt if the RX ERROR bit (SCIRXST, bit 7) becomes set because of errors occurring. Reset type: SYSRSn 0h (R/W) = Receive error interrupt disabled 1h (R/W) = Receive error interrupt enabled
5	SWRESET	R/W	0h	SCI software reset (active low). Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition. This reset will not reset the FIFO pointers or flush out the data in TX/RX FIFO. If you need to clear the FIFO then perform SWRESET + TXFFINT + RXFFINT or refer to a channel reset SCIFFTX[SCIRST]. The SW RESET bit does not affect any of the configuration bits. All affected logic is held in the specified reset state until a 1 is written to SW RESET (the bit values following a reset are shown beneath each register diagram in this section). Thus, after a system reset, re-enable the SCI by writing a 1 to this bit. Clear this bit after a receiver break detect (BRKDT flag, bit SCIRXST, bit 5). SW RESET affects the operating flags of the SCI, but it neither affects the configuration bits nor restores the reset values. Once SW RESET is asserted, the flags are frozen until the bit is deasserted. The affected flags are as follows: Value After SW SCI Flag Register Bit RESET 1 TXRDY SCICTL2, bit 7 1 TX EMPTY SCICTL2, bit 6 0 RXWAKE SCIRXST, bit 1 0 PE SCIRXST, bit 2 0 OE SCIRXST, bit 3 0 FE SCIRXST, bit 4 0 BRKDT SCIRXST, bit 5 0 RXRDY SCIRXST, bit 6 0 RX ERROR SCIRXST, bit 7 Reset type: SYSRSn 0h (R/W) = Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition. 1h (R/W) = After a system reset, re-enable the SCI by writing a 1 to this bit. There is no time requirement to meet before writing a one to this bit after writing a zero.
4	RESERVED	R	0h	Reserved

Table 18-9. SCICTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	TXWAKE	R/W	0h	SCI transmitter wake-up method select. The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3) Reset type: SYSRSn 0h (R/W) = Transmit feature is not selected. In idle-line mode: write a 1 to TXWAKE, then write data to register SCITXBUF to generate an idle period of 11 data bits In address-bit mode: write a 1 to TXWAKE, then write data to SCITXBUF to set the address bit for that frame to 1 1h (R/W) = Transmit feature selected is dependent on the mode, idle-line or address-bit: TXWAKE is not cleared by the SW RESET bit (SCICTL1, bit 5) it is cleared by a system reset or the transfer of TXWAKE to the WUT flag.
2	SLEEP	R/W	0h	SCI sleep. The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3). In a multiprocessor configuration, this bit controls the receiver sleep function. Clearing this bit brings the SCI out of the sleep mode. The receiver still operates when the SLEEP bit is set however, operation does not update the receiver buffer ready bit (SCIRXST, bit 6, RXRDY) or the error status bits (SCIRXST, bit 5-2: BRKDT, FE, OE, and PE) unless the address byte is detected. SLEEP is not cleared when the address byte is detected. Reset type: SYSRSn 0h (R/W) = Sleep mode disabled 1h (R/W) = Sleep mode enabled
1	TXENA	R/W	0h	SCI transmitter enable. Data is transmitted through the SCITXD pin only when TXENA is set. If reset, transmission is halted but only after all data previously written to SCITXBUF has been sent. Data written into SCITXBUF when TXENA is disabled will not be transmitted even if the TXENA is enabled later. Reset type: SYSRSn 0h (R/W) = Transmitter disabled 1h (R/W) = Transmitter enabled
0	RXENA	R/W	0h	SCI receiver enable. Data is received on the SCIRXD pin and is sent to the receiver shift register and then the receiver buffers. This bit enables or disables the receiver (transfer to the buffers). Clearing RXENA stops received characters from being transferred to the two receiver buffers and also stops the generation of receiver interrupts. However, this will not stop RX errors from triggering interrupts. To disable interrupts from RX errors use the RXERRINTENA bit. To stop propagation of the BRKDT interrupt use the RXBKINTENA bit. The receiver shift register can continue to assemble characters even while RXENA is cleared. Thus, if RXENA is set during the reception of a character, the complete character will be transferred into the receiver buffer registers, SCIRXEMU and SCIRXBUF. Reset type: SYSRSn 0h (R/W) = Prevent received characters from transfer into the SCIRXEMU and SCIRXBUF receiver buffers 1h (R/W) = Send received characters to SCIRXEMU and SCIRXBUF

18.15.2.3 SCIHBAUD Register (Offset = 2h) [Reset = 0000h]

SCIHBAUD is shown in Figure 18-13 and described in Table 18-10.

Return to the Summary Table.

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

15-8	RESERVED	R	0h	Reserved
7-0	BAUD	R/W	0h	SCI 16-bit baud selection Registers SCIHBAUD (MSbyte). The internally-generated serial clock is determined by the low speed peripheral clock (LSPCLK) signal and the two baud-select registers. The SCI uses the 16-bit value of these registers to select one of 64K serial clock rates for the communication modes. BRR = (SCIHBAUD << 8) + (SCILBAUD) The SCI baud rate is calculated using the following equation: SCI Asynchronous Baud = LSPCLK / ((BRR + 1) *8) Alternatively, BRR = LSPCLK / (SCI Asynchronous Baud * 8) - 1 Note that the above formulas are applicable only when 0 < BRR < 65536. If BRR = 0, then SCI Asynchronous Baud = LSPCLK / 16 Where: BRR = the 16-bit value (in decimal) in the baud-select registers Reset type: SYSRSn

18.15.2.4 SCILBAUD Register (Offset = 3h) [Reset = 0000h]

SCILBAUD is shown in Figure 18-14 and described in Table 18-11.

Return to the Summary Table.

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

Table 18-12. SCICTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	TXRDY	R	1h	Transmitter buffer register ready flag. When set, this bit indicates that the transmit data buffer register, SCITXBUF, is ready to receive another character. Writing data to the SCITXBUF automatically clears this bit. When set, this flag asserts a transmitter interrupt request if the interrupt-enable bit, TX INT ENA (SCICTL2.0), is also set. TXRDY is set to 1 by enabling the SW RESET bit (SCICTL1.5) or by a system reset. Reset type: SYSRSn 0h (R/W) = SCITXBUF is full 1h (R/W) = SCITXBUF is ready to receive the next character
6	TXEMPTY	R	1h	Transmitter empty flag. This flag's value indicates the contents of the transmitter's buffer register (SCITXBUF) and shift register (TXSHF). An active SW RESET (SCICTL1.5), or a system reset, sets this bit. This bit does not cause an interrupt request. Reset type: SYSRSn 0h (R/W) = Transmitter buffer or shift register or both are loaded with data 1h (R/W) = Transmitter buffer and shift registers are both empty
5-2	RESERVED	R	0h	Reserved
1	RXBKINTENA	R/W	0h	Receiver-buffer/break interrupt enable. This bit controls the interrupt request caused by either the RXRDY flag or the BRKDT flag (bits SCIRXST.6 and .5) being set. However, RX/BK INT ENA does not prevent the setting of these flags. Reset type: SYSRSn 0h (R/W) = Disable RXRDY/BRKDT interrupt 1h (R/W) = Enable RXRDY/BRKDT interrupt

Table 18-12. SCICTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	TXINTENA	R/W	0h	SCITXBUF-register interrupt enable. This bit controls the interrupt request caused by the setting of TXRDY flag bit (SCICTL2.7). However, it does not prevent the TXRDY flag from being set (which indicates SCITXBUF is ready to receive another character). 0 Disable TXRDY interrupt 1 Enable TXRDY interrupt. In non-FIFO mode, a dummy (or a valid) data has to be written to SCITXBUF for the first transmit interrupt to occur. This is the case when you enable the transmit interrupt for the first time and also when you re-enable (disable and then enable) the transmit interrupt. If TXINTENA is enabled after writing the data to SCITXBUF, it will not generate an interrupt. Reset type: SYSRSn 0h (R/W) = Disable TXRDY interrupt 1h (R/W) = Enable TXRDY interrupt

18.15.2.6 SCIRXST Register (Offset = 5h) [Reset = 0000h]

SCIRXST is shown in Figure 18-16 and described in Table 18-13.

Return to the Summary Table.

SCIRXST contains seven bits that are receiver status flags (two of which can generate interrupt requests). Each time a complete character is transferred to the receiver buffers (SCIRXEMU and SCIRXBUF), the status flags are updated.

Figure 18-16. SCIRXST Register

Table 18-13. SCIRXST Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	RXERROR	R	0h	SCI receiver error flag. The RX ERROR flag indicates that one of the error flags in the receiver status register is set. RX ERROR is a logical OR of the break detect, framing error, overrun, and parity error enable flags (bits 5-2: BRKDT, FE, OE, and PE). A 1 on this bit will cause an interrupt if the RX ERR INT ENA bit (SCICTL1.6) is set. This bit can be used for fast error-condition checking during the interrupt service routine. This error flag cannot be cleared directly it is cleared by an active SW RESET, channel reset (SCIRST), or by a system reset. Reset type: SYSRSn 0h (R/W) = No error flags set 1h (R/W) = Error flag(s) set
6	RXRDY	R	0h	SCI receiver-ready flag. When a new character is ready to be read from the SCIRXBUF register, the receiver sets this bit, and a receiver interrupt is generated if the RX/BK INT ENA bit (SCICTL2.1) is a 1. RXRDY is cleared by a reading of the SCIRXBUF register, by an active SW RESET, channel reset (SCIRST), or by a system reset. Reset type: SYSRSn 0h (R/W) = No new character in SCIRXBUF 1h (R/W) = Character ready to be read from SCIRXBUF

Table 18-13. SCIRXST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	BRKDT	R	0h	SCI break-detect flag. The SCI sets this bit when a break condition occurs. A break condition occurs when the SCI receiver data line (SCIRXD) remains continuously low for at least 9.625 bits, beginning after a missing first stop bit. If the SCIRX line goes high at any point during the 9.625 bits then the SCI will not flag a break detect. In order to trigger the first stop bit missed, the typical method is to hold the RX line low for 1 start bit, 8 data bits, 1 optional address bit, 1 optional parity bit, 1 stop bit, and 9.625 bits of additional time held low. This is a total of 19.625 (no parity/address bit), 20.625 (either parity or address bit), or 21.625 (both parity and address bit) bit times. To instead detect a 'break seq' or 'break sequence' of 11 bits of low voltage level (0), ISR code can use the following combination of flags and received data: FE==1 && PE==1 && SCIRXBUF.SAR (received character)==0x00. This assumes parity enabled and odd parity set. With even parity, PE==0 instead. The detection of 11 bits of low/0 can be reduced to 10 bits of low if no parity bit is used (then PE flag does not matter to detect the sequence). The occurrence of a break causes a receiver interrupt to be generated if the RX/BK INT ENA bit is a 1, but it does not cause the receiver buffer to be loaded. A BRKDT interrupt can occur even if the receiver SLEEP bit is set to 1. BRKDT is cleared by an active SW RESET, SCIRST bit, or by a system reset. It is not cleared by receipt of a character after the break is detected. If Break Detect (BRKDT) is set, then RXRDY won't be set and there will be no further interrupts after the first interrupt where there is an error detected if a SW reset, channel reset, or system reset is not performed. In order to receive more characters, the SCI must be reset by toggling the SW RESET bit, channel reset (SCIRST), or by a system reset. NOTE: If your system is susceptible to break detects, ensure that you have a pull-up resistor on the SCI-RX pin to provide proper return-to-high signal behavior and noise immunity. NOTE: To monitor a break detect, place an oscilloscope on the C2000 SCI-RX line and monitor for a low-signal greater than 9.625 bits wide. If this is found and a break is not expected, please correct the software in the other device that is transmitting to this C2000 device. There should never be a low-signal greater than 9.625 bits wide on the SCI-RX line of the C2000 device unless a break detect is being transmitted purposely. Reset type: SYSRSn 0h (R/W) = No break condition 1h (R/W) = Break condition occurred
4	FE	R	0h	SCI framing-error flag. The SCI sets this bit when an expected stop bit is not found. Only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. The FE bit is reset by a clearing of the SW RESET bit, channel reset (SCIRST), or by a system reset. NOTE: FE will be flagged prior to BRKDT, except when RX is in sleep mode. In sleep mode, when there is no RX WAKEUP and RXD line is low for greater than 10 bits, BRKDT will be flagged while FE will not be flagged. Reset type: SYSRSn 0h (R/W) = No framing error detected 1h (R/W) = Framing error detected

Table 18-13. SCIRXST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	OE	R	0h	SCI overrun-error flag. The SCI sets this bit when a character is transferred into registers SCIRXEMU and SCIRXBUF before the previous character is fully read by the CPU or DMAC. The previous character is overwritten and lost. The OE flag bit is reset by an active SW RESET, channel reset (SCIRST), or a system reset. Reset type: SYSRSn 0h (R/W) = No overrun error detected 1h (R/W) = Overrun error detected
2	PE	R	0h	SCI parity-error flag. This flag bit is set when a character is received with a mismatch between the number of 1s and its parity bit. The address bit is included in the calculation. If parity generation and detection is not enabled, the PE flag is disabled and read as 0. The PE bit is reset by an active SW RESET, channel reset (SCIRST), or a system reset. Reset type: SYSRSn 0h (R/W) = No parity error or parity is disabled 1h (R/W) = Parity error is detected
1	RXWAKE	R	0h	Receiver wake-up-detect flag Reset type: SYSRSn 0h (R/W) = No detection of a receiver wake-up condition 1h (R/W) = A value of 1 in this bit indicates detection of a receiver wake-up condition. In the address-bit multiprocessor mode (SCICCR.3 = 1), RXWAKE reflects the value of the address bit for the character contained in SCIRXBUF. In the idle-line multiprocessor mode, RXWAKE is set if the SCIRXD data line is detected as idle. RXWAKE is a read-only flag, cleared by one of the following: - The transfer of the first byte after the address byte to SCIRXBUF (only in non-FIFO mode) - The reading of SCIRXBUF - An active SW RESET - Channel reset (SCIRST) - A system reset
0	RESERVED	R	0h	Reserved

18.15.2.7 SCIRXEMU Register (Offset = 6h) [Reset = 0000h]

SCIRXEMU is shown in Figure 18-17 and described in Table 18-14.

Return to the Summary Table.

Normal SCI data-receive operations read the data received from the SCIRXBUF register. The SCIRXEMU register is used principally by the emulator (EMU) because it can continuously read the data received for screen updates without clearing the RXRDY flag. SCIRXEMU is cleared by a system reset. This is the register that should be used in an emulator watch window to view the contents of the SCIRXBUF register. SCIRXEMU is not physically implemented
it is just a different address location to access the SCIRXBUF register without clearing the RXRDY flag.

18.15.2.8 SCIRXBUF Register (Offset = 7h) [Reset = 0000h]

SCIRXBUF is shown in Figure 18-18 and described in Table 18-15.

Return to the Summary Table.

When the current data received is shifted from RXSHF to the receiver buffer, flag bit RXRDY is set and the data is ready to be read. If the RXBKINTENA bit (SCICTL2.1) is set, this shift also causes an interrupt. When SCIRXBUF is read, the RXRDY flag is reset. SCIRXBUF is cleared by a system reset.

Table 18-15. SCIRXBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
15	SCIFFFE	R	0h	SCIFFFE. SCI FIFO Framing error flag bit (applicable only if the FIFO is enabled) Note: 'SCIFFFE' is meant to serve as a flag for the specific set of data being received/read in the SCIRXBUF register. Each set of data received into the FIFO will have this information. The 'FE' bit within the SCIRXST register can be thought off as high level error flag where the flag will get set if any data that has been received has a framing error. Reset type: SYSRSn 0h (R/W) = No frame error occurred while receiving the character, in bits 7-0. This bit is associated with the character on the top of the FIFO. 1h (R/W) = A frame error occurred while receiving the character in bits 7-0. This bit is associated with the character on the top of the FIFO.
14	SCIFFPE	R	0h	SCIFFPE. SCI FIFO parity error flag bit (applicable only if the FIFO is enabled) Note: 'SCIFFPE' is meant to serve as a flag for the specific set of data being received/read in the SCIRXBUF register. Each set of data received into the FIFO will have this information. The 'PE' bit within the SCIRXST register can be thought off as high level error flag where the flag will get set if any data that has been received has a parity error. Note: If the parity is changed in the middle of data reception, the SCI module will not reinterpret the data with the new parity or other settings that may have changed. Therefore, changing the parameter, the FIFO should be cleared or the user should acknowledge that there will most likely be errors in the data caused by the change. Note: If RX parity errors are occurring intermittently this could be due to the length of the SCI ISR. To help prevent this, ensure that interrupt nesting is limited, increase the SCI interrupt priority, and move as much of the processing as possible out of the ISR (to reduce ISR time to the absolute minimum). Reset type: SYSRSn 0h (R/W) = No parity error occurred while receiving the character, in bits 7-0. This bit is associated with the character on the top of the FIFO. 1h (R/W) = A parity error occurred while receiving the character in bits 7-0. This bit is associated with the character on the top of the FIFO.

18.15.2.9 SCITXBUF Register (Offset = 9h) [Reset = 0000h]

SCITXBUF is shown in Figure 18-19 and described in Table 18-16.

Return to the Summary Table.

Data bits to be transmitted are written to SCITXBUF. These bits must be rightjustified because the leftmost bits are ignored for characters less than eight bits long. The transfer of data from this register to the TXSHF transmitter shift register sets the TXRDY flag (SCICTL2.7), indicating that SCITXBUF is ready to receive another set of data. If bit TXINTENA (SCICTL2.0) is set, this data transfer also causes an interrupt.

Bit	Field	Type	Reset	Description
15	RXFFOVF	R	0h	Receive FIFO overflow. This will function as flag, but cannot generate interrupt by itself. This condition will occur while receive interrupt is active. Receive interrupts should service this flag condition. This bit is cleared by RXFFOVRCLR, a channel reset (SCIRST), or a system reset. Reset type: SYSRSn 0h (R/W) = Receive FIFO has not overflowed, read-only bit 1h (R/W) = Receive FIFO has overflowed, read-only bit. More than 16 words have been received in to the FIFO, and the first received word is lost
14	RXFFOVRCLR	R-0/W1S	0h	RXFFOVF clear Note: Both RXFFIL and RXFFOVF flags are ORed together, so they need to be cleared at the same time (RXFFINTCLR & RXFFOVRCLR) during overflow scenarios else it will prevent further interrupts from occurring. Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on RXFFOVF flag bit, Bit reads back a zero 1h (R/W) = Write 1 to clear RXFFOVF flag in bit 15
13	RXFIFORESET	R/W	1h	Receive FIFO reset Reset type: SYSRSn 0h (R/W) = Write 0 to reset the FIFO pointer to zero, and hold in reset. 1h (R/W) = Re-enable receive FIFO operation

Table 18-18. SCIFFRX Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12-8	RXFFST	R	0h	FIFO status Reset type: SYSRSn 0h (R/W) = Receive FIFO is empty 1h (R/W) = Receive FIFO has 1 words 2h (R/W) = Receive FIFO has 2 words 3h (R/W) = Receive FIFO has 3 words 4h (R/W) = Receive FIFO has 4 words 5h (R/W) = Receive FIFO has 5 words 6h (R/W) = Receive FIFO has 6 words 7h (R/W) = Receive FIFO has 7 words 8h (R/W) = Receive FIFO has 8 words 9h (R/W) = Receive FIFO has 9 words Ah (R/W) = Receive FIFO has 10 words Bh (R/W) = Receive FIFO has 11 words Ch (R/W) = Receive FIFO has 12 words Dh (R/W) = Receive FIFO has 13 words Eh (R/W) = Receive FIFO has 14 words Fh (R/W) = Receive FIFO has 15 words 10h (R/W) = Receive FIFO has 16 words
7	RXFFINT	R	0h	Receive FIFO interrupt Reset type: SYSRSn 0h (R/W) = RXFIFO interrupt has not occurred, read-only bit 1h (R/W) = RXFIFO interrupt has occurred, read-only bit
6	RXFFINTCLR	W	0h	Receive FIFO interrupt clear Note: Both RXFFIL and RXFFOVF flags are ORed together, so they need to be cleared at the same time (RXFFINTCLR & RXFFOVRCLR) during overflow scenarios else it will prevent further interrupts from occurring. Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on RXFIFINT flag bit. Bit reads back a zero. 1h (R/W) = Write 1 to clear RXFFINT flag in bit 7
5	RXFFIENA	R/W	0h	Receive FIFO interrupt enable Reset type: SYSRSn 0h (R/W) = RX FIFO interrupt is disabled 1h (R/W) = RX FIFO interrupt is enabled. This interrupt is triggered whenever the receive FIFO status (RXFFST) bits match (equal to or greater than) the interrupt trigger level bits RXFFIL (bits 4-0).
4-0	RXFFIL	R/W	1Fh	Receive FIFO interrupt level bits The receive FIFO generates an interrupt whenever the FIFO status bits (RXFFST4-0) are greater than or equal to the FIFO level bits (RXFFIL4-0). The maximum value that can be assigned to these bits to generate an interrupt cannot be more than the depth of the RX FIFO. The default value of these bits after reset is 11111b. Users should set RXFFIL to best fit their application needs by weighing between the CPU overhead to service the ISR and the best possible usage of received SCI data. Reset type: SYSRSn

18.15.2.12 SCIFFCT Register (Offset = Ch) [Reset = 0000h]

SCIFFCT is shown in Figure 18-22 and described in Table 18-19.

Return to the Summary Table.

SCIFFCT contains the status of auto-baud detect, clears the auto-baud flag, and calibrate for A-detect bit.

Figure 18-22. SCIFFCT Register

15	14	13	12	11	10	9	8
ABD	ABDCLR	CDC	RESERVED				
R-0h	W-0h	R/W-0h	R-0h				
7	6	5	4	3	2	1	0
FFTXDLY							
R/W-0h							

Table 18-19. SCIFFCT Register Field Descriptions

Bit	Field	Type	Reset	Description
15	ABD	R	0h	Auto-baud detect (ABD) bit Reset type: SYSRSn 0h (R/W) = Auto-baud detection is not complete. 'A','a' character has not been received successfully. 1h (R/W) = Auto-baud hardware has detected 'A' or 'a' character on the SCI receive register. Auto-detect is complete.
14	ABDCLR	W	0h	ABD-clear bit Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on ABD flag bit. Bit reads back a zero. 1h (R/W) = Write 1 to clear ABD flag in bit 15.
13	CDC	R/W	0h	CDC calibrate A-detect bit Reset type: SYSRSn 0h (R/W) = Disables auto-baud alignment 1h (R/W) = Enables auto-baud alignment
12-8	RESERVED	R	0h	Reserved
7-0	FFTXDLY	R/W	0h	FIFO transfer delay. These bits define the delay between every transfer from FIFO transmit bufferto transmit shift register. The delay is defined in the number of SCI serial baud clock cycles. The 8 bit register could define a minimum delay of 0 baud clock cycles and a maximum of 256 baud clock cycles In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In FIFO mode, TXBUF should not be treated as one additional level of buffer. The delayed transmit feature will help to create an auto-flow scheme without RTS/CTS controls as in standard UARTS. When SCI is configured for one stop-bit, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to. When SCI is configured for two stop-bits, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to minus 1. Reset type: SYSRSn

18.15.2.13 SCIPRI Register (Offset = Fh) [Reset = 0000h]

SCIPRI is shown in Figure 18-23 and described in Table 18-20.

Return to the Summary Table.

SCIPRI determines what happens when an emulation suspend event occurs.

Figure 18-23. SCIPRI Register

Chapter 19

Inter-Integrated Circuit Module (I2C)

This chapter describes the features and operation of the inter-integrated circuit (I2C) module. The I2C module provides an interface between one of these devices and devices compliant with the NXP Semiconductors Inter-IC bus (I2C bus) specification version 2.1, and connected by way of an I2C bus. External components attached to this 2-wire serial bus can transmit/receive 1- to 8-bit data to/from the device through the I2C module. This chapter assumes the reader is familiar with the I2C bus specification.

Note

A unit of data transmitted or received by the I2C module can have fewer than 8 bits; however, for convenience, a unit of data is called a data byte throughout this chapter. The number of bits in a data byte is selectable by way of the BC bits of the mode register, I2CMDR.

19.1 Introduction

The I2C module supports any slave or master I2C-compatible device. Figure 19-1 shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

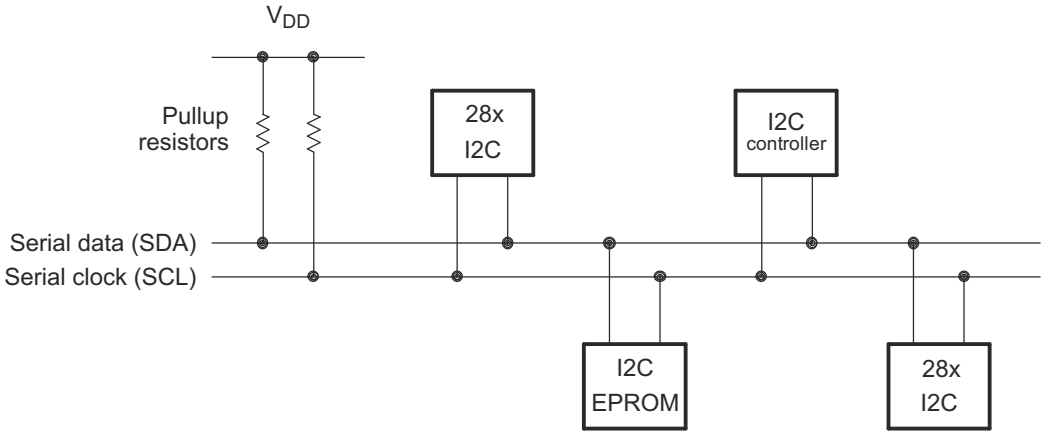

Figure 19-1. Multiple I2C Modules Connected

19.1.2 Features

The I2C module has the following features:

- Compliance with the NXP Semiconductors I2C bus specification (version 2.1):
  - Support for 8-bit format transfers
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple master-transmitters and slave-receivers
  - Support for multiple slave-transmitters and master-receivers
  - Combined master transmit/receive and receive/transmit mode
  - Data transfer rate from 10kbps up to 400kbps (Fast-mode)
- Receive FIFO and Transmitter FIFO (16-deep x 8-bit FIFO)
- Supports two ePIE interrupts:
  - I2Cx Interrupt – Any of the following events can be configured to generate an I2Cx interrupt:
    - Transmit-data ready
    - Receive-data ready
    - Register-access ready
    - No-acknowledgment received
    - Arbitration lost
    - Stop condition detected
    - Addressed as slave
  - I2Cx_FIFO interrupts:
    - Transmit FIFO interrupt
    - Receive FIFO interrupt
- Module enable and disable capability
- Free data format mode

19.1.3 Features Not Supported

The I2C module does not support:

- High-speed mode (Hs-mode)
- CBUS-compatibility mode

19.1.4 Functional Overview

Each device connected to an I2C bus is recognized by a unique address. Each device can operate as either a transmitter or a receiver, depending on the function of the device. A device connected to the I2C bus can also be considered as the master or the slave when performing data transfers. A master device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave. The I2C module supports the multi-master mode, in which one or more devices capable of controlling an I2C bus can be connected to the same I2C bus.

For data communication, the I2C module has a serial data pin (SDA) and a serial clock pin (SCL), as shown in Figure 19-2. These two pins carry information between the C28x device and other devices connected to the I2C bus. The SDA and SCL pins are both bidirectional and each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

There are two major transfer techniques:

- Standard Mode: Send exactly n data values, where n is a value you program in an I2C module register. See the I2CCNT register in the *I2C Registers* section for more information.
- Repeat Mode: Keep sending data values until you use software to initiate a STOP condition or a new START condition. See the I2CMDR register in the *I2C Registers* section for RM bit information.

The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers and FIFOs to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU
- Control and status registers
- A peripheral bus interface to enable the CPU to access the I2C module registers and FIFOs.
- A clock synchronizer to synchronize the I2C input clock (from the device clock generator) and the clock on the SCL pin, and to synchronize data transfers with masters of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module
- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when the I2C module is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- FIFO interrupt generation logic, so that FIFO access can be synchronized to data reception and data transmission in the I2C module

Figure 19-2 shows the four registers used for transmission and reception in non-FIFO mode. The CPU writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out on the SDA pin one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

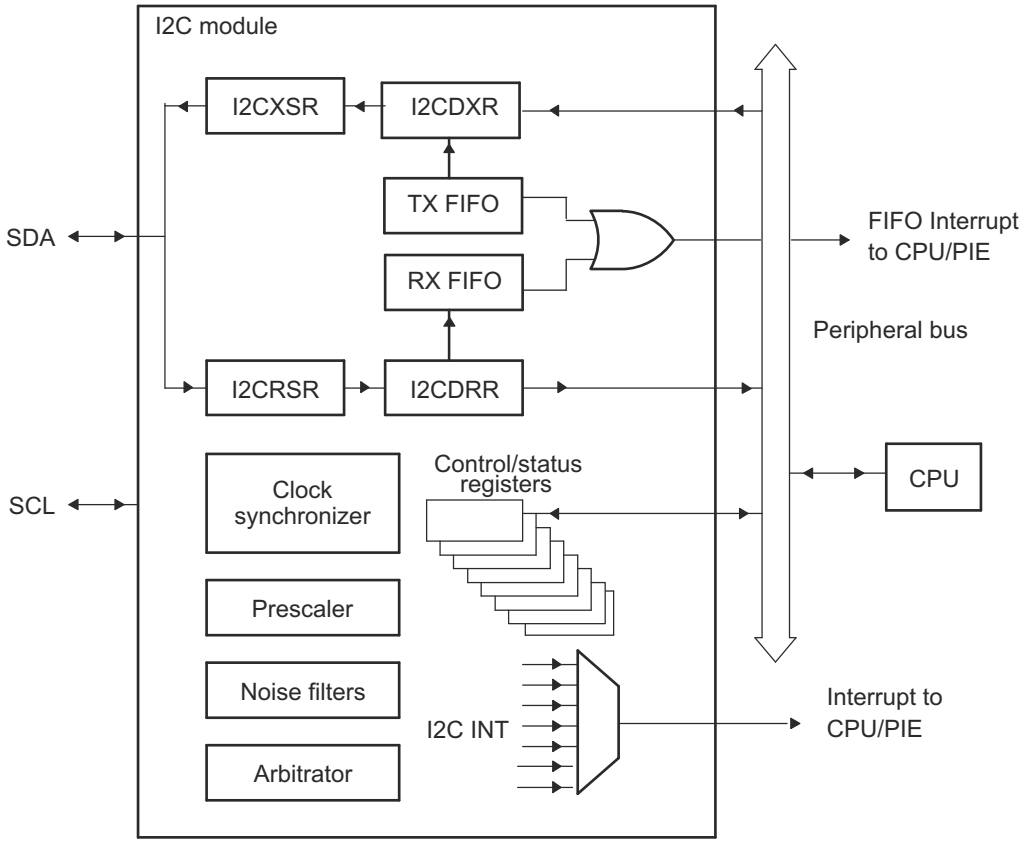

Figure 19-2. I2C Module Conceptual Block Diagram

19.1.5 Clock Generation

The I2C module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the SYSCLK to produce the I2C module clock and this I2C module clock is divided further to produce the I2C master clock on the SCL pin. Figure 19-3 shows the clock generation diagram for I2C module.

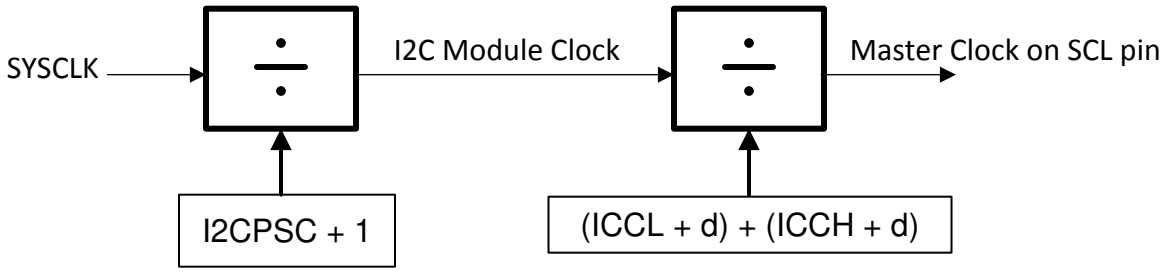

Figure 19-3. Clocking Diagram for the I2C Module

Note

To meet all of the I2C protocol timing specifications, the I2C module clock must be between 7 to 12MHz.

To specify the divide-down value, initialize the IPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$\text{I2C Module Clock (Fmod)} = \frac{\text{SYSCLK}}{(\text{I2CPSC} + 1)} \quad (22)$$

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

The master clock appears on the SCL pin when the I2C module is configured to be a master on the I2C bus. This clock controls the timing of communication between the I2C module and a slave. As shown in Figure 19-3, a second clock divider in the I2C module divides down the module clock to produce the master clock. The clock divider uses the ICCL value of I2CCLKL to divide down the low portion of the module clock signal and uses the ICCH value of I2CCLKH to divide down the high portion of the module clock signal. See Section 19.1.6 for the master clock frequency equation.

19.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)

As explained in Section 19.1.5, when the I2C module is a master, the I2C module clock is divided down further to use as the master clock on the SCL pin. As shown in Figure 19-4, the shape of the master clock depends on two divide-down values:

- ICCL in I2CCLKL. For each master clock cycle, ICCL determines the amount of time the signal is low.
- ICCH in I2CCKLH. For each master clock cycle, ICCH determines the amount of time the signal is high.

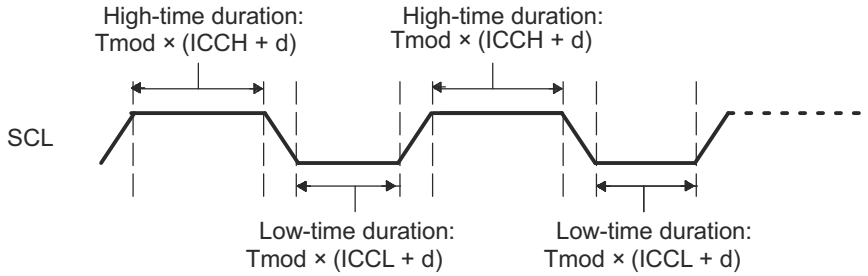

Figure 19-4. Roles of the Clock Divide-Down Values (ICCL and ICCH)

19.1.6.1 Formula for the Master Clock Period

The master clock period (Tmst) is a multiple of the period of the I2C Module Clock (Tmod):

$$\text{Master Clock period (Tmst)} = \frac{[\,(\text{ICCH} + d) + (\text{ICCL} + d)\,]}{\text{I2C Module Clock (Fmod)}} \quad (23)$$

where d depends on the divide-down value IPSC, as shown in Table 19-1. IPSC is described in the I2CPSC register.

Table 19-1. Dependency of Delay d on the Divide-Down Value IPSC

IPSC	d
0	7
1	6
Greater than 1	5

19.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

19.3 I2C Module Operational Details

This section provides an overview of the I2C bus protocol and how it is implemented.

19.3.1 Input and Output Voltage Levels

One clock pulse is generated by the master device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I2C bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of V_{DD}. For details, see the device data sheet.

19.3.2 Selecting Pullup Resistors

The chosen pullup resistor must meet the I2C standard timings. In most circumstances, 2.2kΩ of total bus resistance to VDDIO is sufficient. The value of the pullup resistance used on both the SCL and SDA pins be matched is also recommended. For evaluating pullup resistor values for a particular design, see the *I2C Bus Pullup Resistor Calculation Application Report*.

19.3.3 Data Validity

The data on SDA must be stable during the high period of the clock (see Figure 19-5). The high or low state of the data line, SDA, must change only when the clock signal on SCL is low.

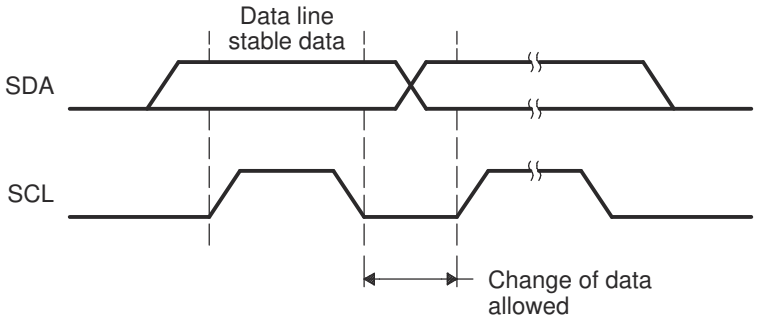

Figure 19-5. Bit Transfer on the I2C bus

19.3.4 Operating Modes

The I2C module has four basic operating modes to support data transfers as a master and as a slave. See Table 19-2 for the names and descriptions of the modes.

If the I2C module is a master, the I2C module begins as a master-transmitter and typically transmits an address for a particular slave. When giving data to the slave, the I2C module must remain a master-transmitter. To receive data from a slave, the I2C module must be changed to the master-receiver mode.

If the I2C module is a slave, the I2C module begins as a slave-receiver and typically sends acknowledgment when the I2C module recognizes the slave address from a master. If the master is sending data to the I2C module, the module must remain a slave-receiver. If the master has requested data from the I2C module, the module must be changed to the slave-transmitter mode.

Table 19-2. Operating Modes of the I2C Module

Operating Mode	Description
Slave-receiver mode	The I2C module is a slave and receives data from a master. All slaves begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the master. As a slave, the I2C module does not generate the clock signal, but can hold SCL low while the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received. See Section 19.3.8 for more details.
Slave-transmitter mode	The I2C module is a slave and transmits data to a master. This mode can be entered only from the slave-receiver mode; the I2C module must first receive a command from the master. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the slave-transmitter mode if the slave address byte is the same as the address (in I2COAR) and the master has transmitted R/ $\overline{W}$ = 1. As a slave-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the master. While a slave, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted. See Section 19.3.8 for more details.
Master-receiver mode	The I2C module is a master and receives data from a slave. This mode can be entered only from the master-transmitter mode; the I2C module must first transmit a command to the slave. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the master-receiver mode after transmitting the slave address byte and R/ $\overline{W}$ = 1. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received.
Master-transmitter mode	The I2C module is a master and transmits control information and data to a slave. All masters begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted.

To summarize, SCL is held low in the following conditions:

- When an overrun condition is detected (RSFULL = 1), in Slave-receiver mode.
- When an underflow condition is detected (XSMT = 0), in Slave-transmitter mode.

I2C slave nodes accept and provide data when the I2C master node requests data.

- To release SCL in slave-receiver mode, read data from I2CDRR.
- To release SCL in slave-transmitter mode, write data to I2CDXR.
- To force a release without handling the data, reset the module using the I2CMDR.IRS bit.

Table 19-3. Master-Transmitter/Receiver Bus Activity Defined by the RM, STT, and STP Bits of I2CMDR

RM	STT	STP	Bus Activity(1)	Description
0	0	0	None	No activity
0	0	1	P	STOP condition
0	1	0	S-A-D..(n)..D.	START condition, slave address, n data bytes (n = value in I2CCNT)
0	1	1	S-A-D..(n)..D-P	START condition, slave address, n data bytes, STOP condition (n = value in I2CCNT)
1	0	0	None	No activity
1	0	1	P	STOP condition
1	1	0	S-A-D-D-D.	Repeat mode transfer: START condition, slave address, continuous data transfers until STOP condition or next START condition
1	1	1	None	Reserved bit combination (No activity)

(1) S = START condition; A = Address; D = Data byte; P = STOP condition;

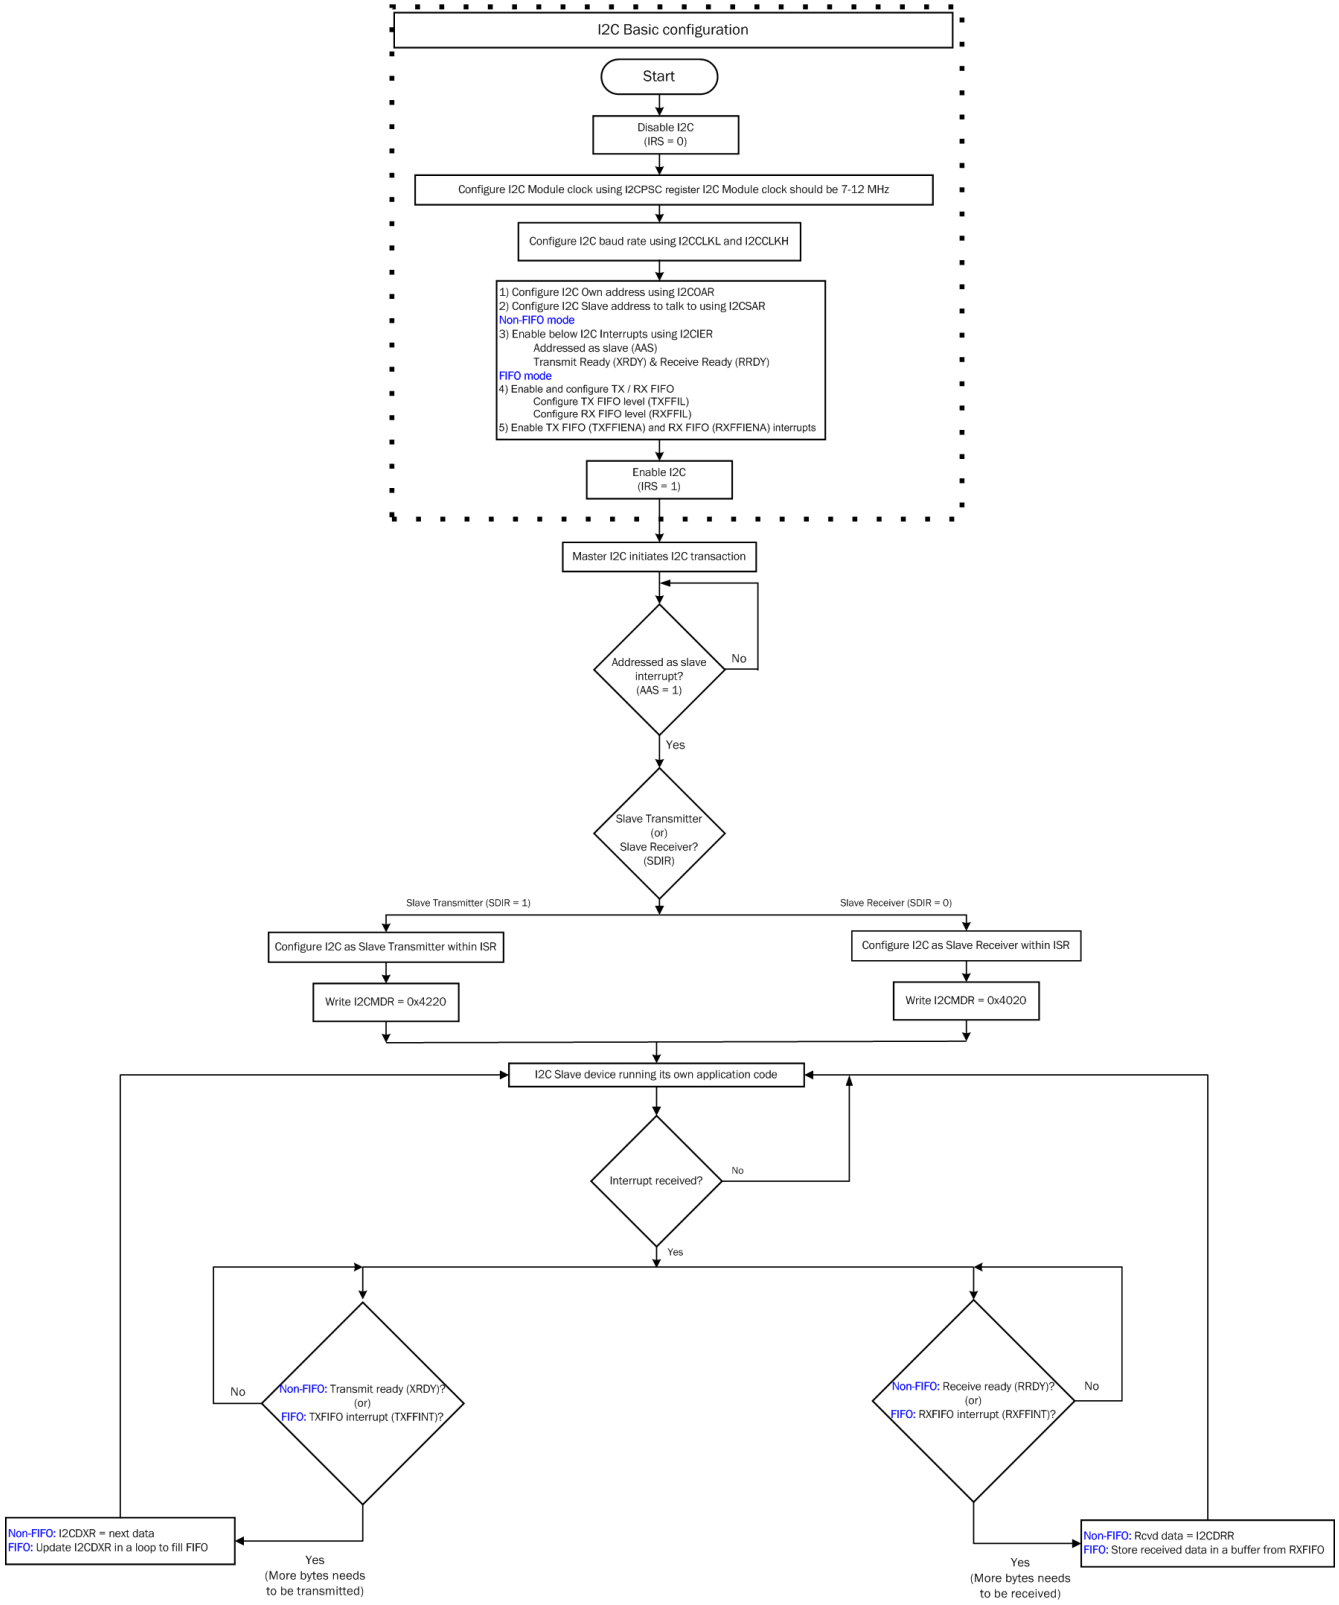

Figure 19-6. I2C Slave TX / RX Flowchart

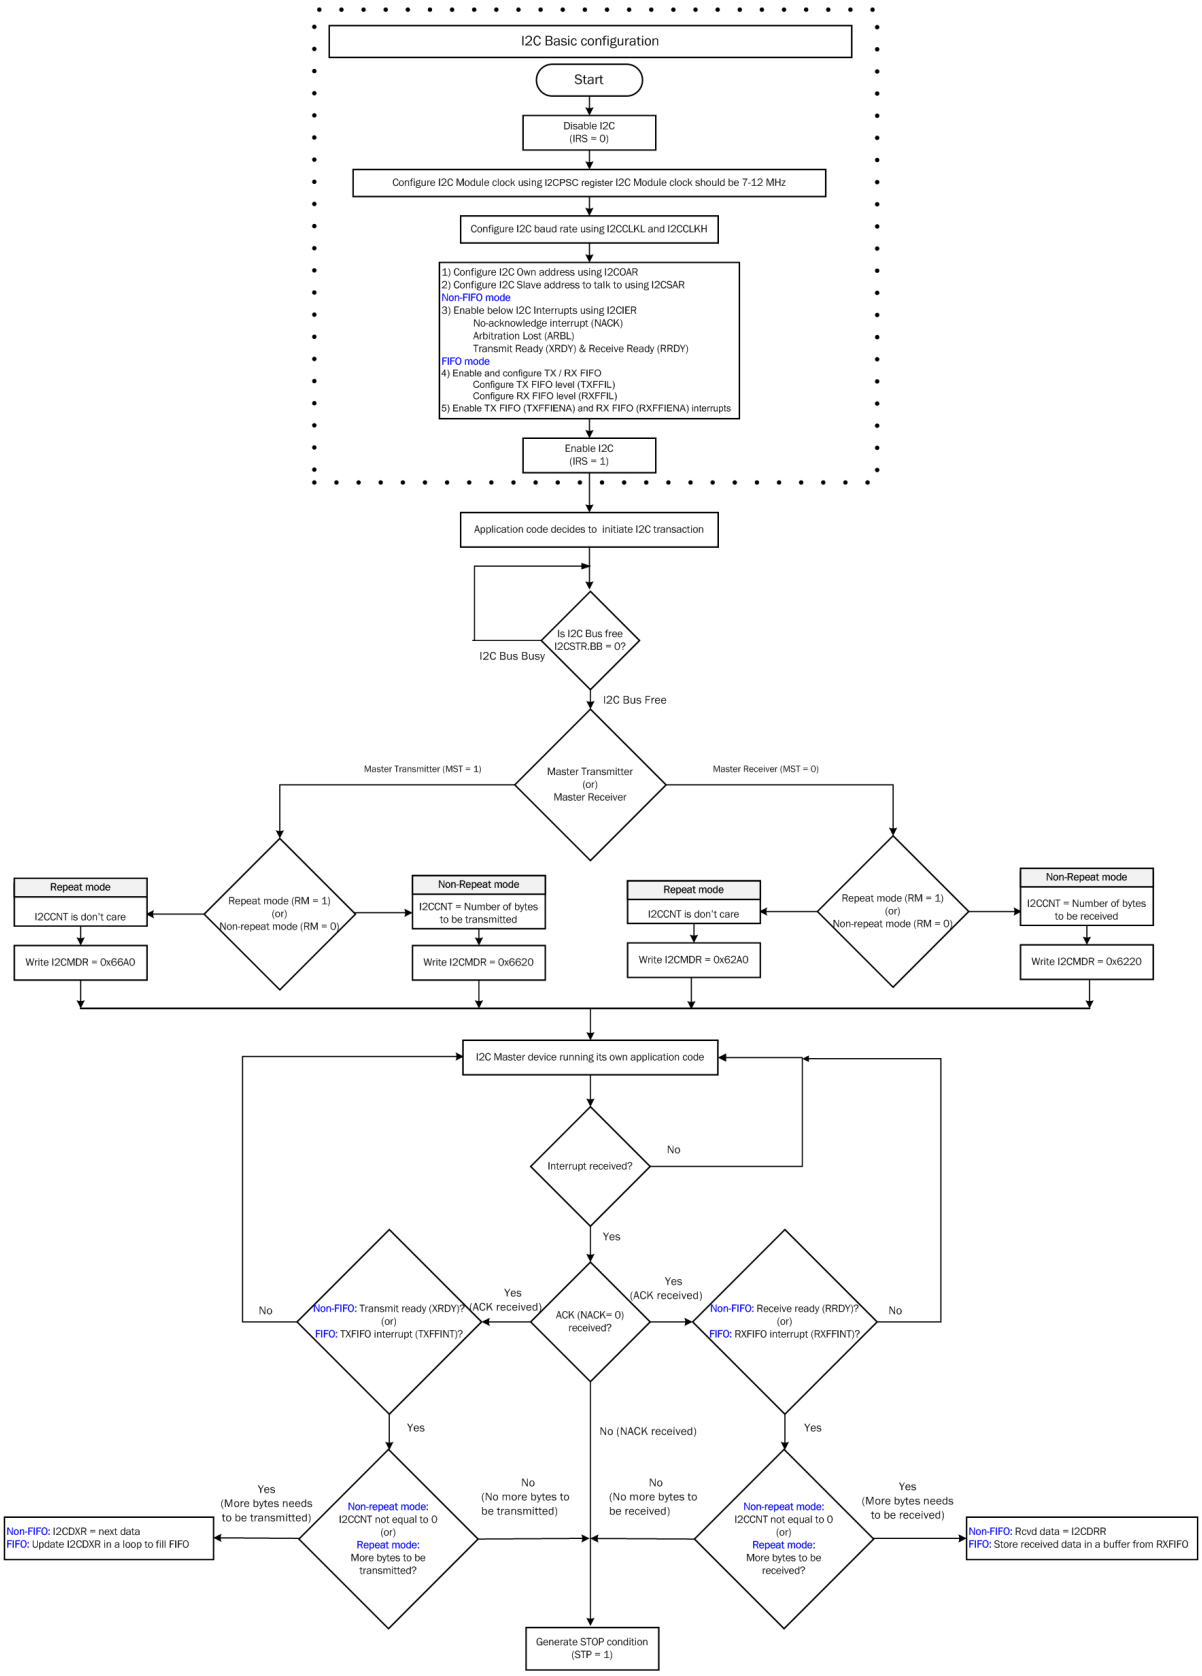

Figure 19-7. I2C Master TX / RX Flowchart

19.3.5 I2C Module START and STOP Conditions

START and STOP conditions can be generated by the I2C module when the module is configured to be a master on the I2C bus. As shown in Figure 19-8:

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A master drives this condition to indicate the start of a data transfer.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A master drives this condition to indicate the end of a data transfer.

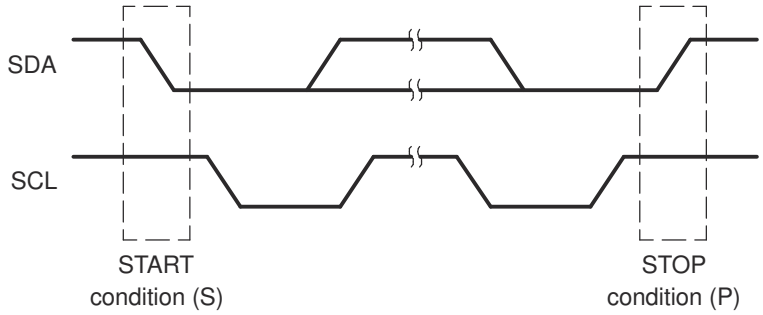

Figure 19-8. I2C Module START and STOP Conditions

After a START condition and before a subsequent STOP condition, the I2C bus is considered busy, and the bus busy (BB) bit of I2CSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the master mode bit (MST) and the START condition bit (STT) in I2CMDR must both be 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated. For a description of I2CMDR and the bits (including MST, STT, and STP), see Section 19.7.

The I2C peripheral cannot detect a START or STOP condition while in reset (IRS = 0). The BB bit remains in the cleared state (BB = 0) while the I2C peripheral is in reset (IRS = 0). When the I2C peripheral is taken out of reset (IRS set to 1), the BB bit does not correctly reflect the I2C bus status until a START or STOP condition is detected.

Follow these steps before initiating the first data transfer with I2C:

1. After taking the I2C peripheral out of reset by setting the IRS bit to 1, wait a period larger than the total time taken for the longest data transfer in the application. By waiting for a period of time after I2C comes out of reset, make sure that at least one START or STOP condition has occurred on the I2C bus and has been captured by the BB bit. After this period, the BB bit correctly reflects the state of the I2C bus.
2. Check the BB bit and verify that BB = 0 (bus not busy) before proceeding.
3. Begin data transfers.

Not resetting the I2C peripheral in between transfers makes sure that the BB bit reflects the actual bus status. If users must reset the I2C peripheral in between transfers, repeat steps 1 through 3 every time the I2C peripheral is taken out of reset.

19.3.6 Non-repeat Mode versus Repeat Mode

Non-repeat mode:

- When I2CMDR.RM = 0, I2C module is configured in non-repeat mode.
- I2CCNT register determines the number of bytes to be transmitted or received.
- If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0.
- If STP = 1, ARDY bit does not get set and I2C module generates a STOP condition when the internal data counter counts down to 0.

Note

In non-repeat mode (RM = 0), if I2CCNT is set to 0, I2C state machine expects to transmit or receive 65536 bytes and not 0 bytes.

Repeat mode:

- When I2CMDR.RM = 1, I2C module is configured in repeat mode.
- I2CCNT register contents do not determine the number of bytes to be transmitted or received.
- Number of bytes to be transmitted or received can be controlled by software.
- ARDY bit gets set at end of transmission and reception of each byte.

Note

Once you start I2C transaction in non-repeat mode or repeat mode, you cannot switch into another mode until the I2C transaction is completed with a STOP condition.

19.3.7 Serial Data Formats

Figure 19-9 shows an example of a data transfer on the I2C bus. The I2C module supports 1 to 8-bit data values. In Figure 19-9, 8-bit data is transferred. Each bit put on the SDA line equates to 1 pulse on the SCL line, and the values are always transferred with the most significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted. The serial data format used in Figure 19-9 is the 7-bit addressing format. The I2C module supports the formats shown in Figure 19-10 through Figure 19-12 and described in the paragraphs that follow the figures.

Note

In Figure 19-9 through Figure 19-12, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

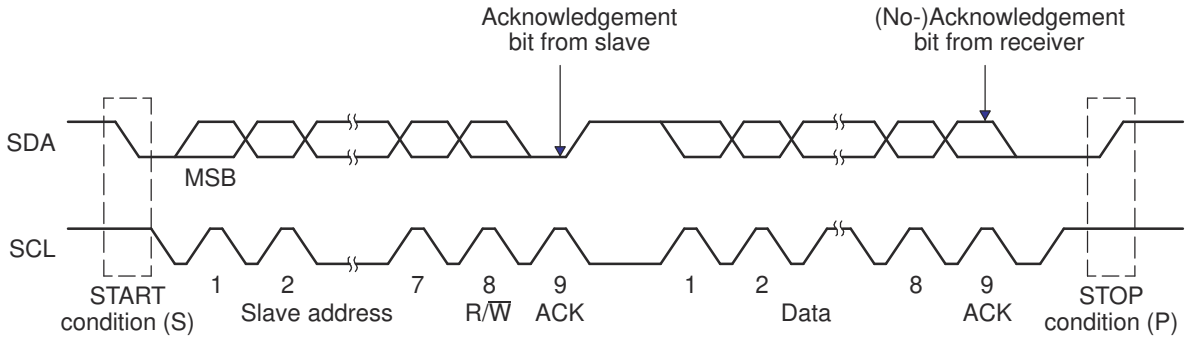

Figure 19-9. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown)

19.3.7.1 7-Bit Addressing Format

The 7-bit addressing format is the default format after reset. Disabling expanded address (I2CMDR.XA = 0) and free data format (I2CMDR.FDF = 0) enables 7-bit addressing format.

In this format (see Figure 19-10), the first byte after a START condition (S) consists of a 7-bit slave address followed by a R/$\overline{W}$ bit. R/$\overline{W}$ determines the direction of the data:

- R/$\overline{W}$ = 0: The I2C master writes (transmits) data to the addressed slave. This can be achieved by setting I2CMDR.TRX = 1 (Transmitter mode)
- R/$\overline{W}$ = 1: The I2C master reads (receives) data from the slave. This can be achieved by setting I2CMDR.TRX = 0 (Receiver mode)

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after each byte. If the ACK bit is inserted by the slave after the first byte from the master, it is followed by n bits of data from the transmitter (master or slave, depending on the R/$\overline{W}$ bit). n is a number from 1 to 8 determined by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

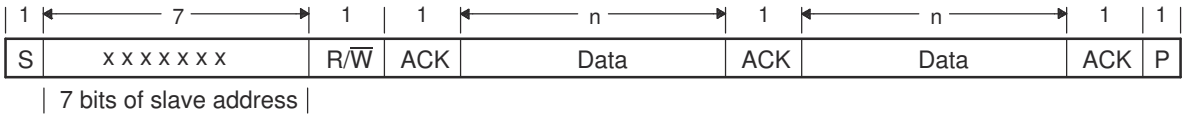

Figure 19-10. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR)

19.3.7.2 10-Bit Addressing Format

The 10-bit addressing format can be enabled by setting expanded address (I2CMDR.XA = 1) and disabling free data format (I2CMDR.FDF = 0).

The 10-bit addressing format (see Figure 19-11) is similar to the 7-bit addressing format, but the master sends the slave address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit slave address, and R/$\overline{W}$. The second byte is the remaining 8 bits of the 10-bit slave address. The slave must send acknowledgment after each of the two byte transfers. Once the master has written the second byte to the slave, the master can either write data or use a repeated START condition to change the data direction. For more details about using 10-bit addressing, see the NXP Semiconductors I2C bus specification.

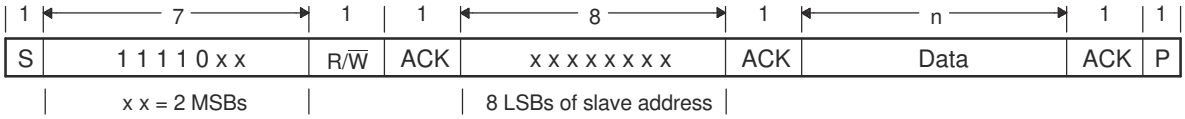

Figure 19-11. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR)

19.3.7.3 Free Data Format

The free data format can be enabled by setting I2CMDR. FDF = 1.

In this format (see Figure 19-12), the first byte after a START condition (S) is a data byte. An ACK bit is inserted after each data byte, which can be from 1 to 8 bits, depending on the BC field of I2CMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

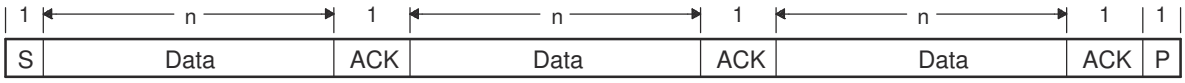

Figure 19-12. I2C Module Free Data Format (FDF = 1 in I2CMDR)

Note

The free data format is not supported in the digital loopback mode (I2CMDR.DLB = 1).

Table 19-4. How the MST and FDF Bits of I2CMDR Affect the Role of the TRX Bit of I2CMDR

MST	FDF	I2C Module State	Function of TRX
0	0	In slave mode but not free data format mode	TRX is a don't care. Depending on the command from the master, the I2C module responds as a receiver or a transmitter.
0	1	In slave mode and free data format mode	The free data format mode requires that the I2C module remains the transmitter or the receiver throughout the transfer. TRX identifies the role of the I2C module: TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	0	In master mode but not free data format mode	TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	1	In master mode and free data format mode	TRX = 0: The I2C module is a receiver. TRX = 1: The I2C module is a transmitter.

19.3.7.4 Using a Repeated START Condition

I2C master can communicate with multiple slave addresses without having to give up control of the I2C bus by driving a STOP condition. This can be achieved by driving another START condition at the end of each data type. The repeated START condition can be used with the 7-bit addressing and 10-bit addressing. Figure 19-13 shows a repeated START condition in the 7-bit addressing format.

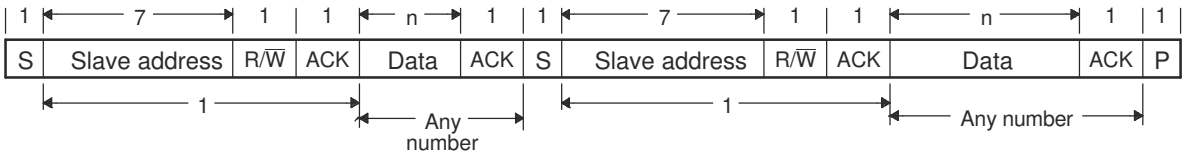

Figure 19-13. Repeated START Condition (in This Case, 7-Bit Addressing Format)

Note

In Figure 19-13, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

19.3.8 Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more masters and the clock must be synchronized so that the data output can be compared. Figure 19-14 illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start a low period. The SCL is held low by the device with the longest low period. The other devices that finish the low periods must wait for SCL to be released, before starting the high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a slave slows down a fast master and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

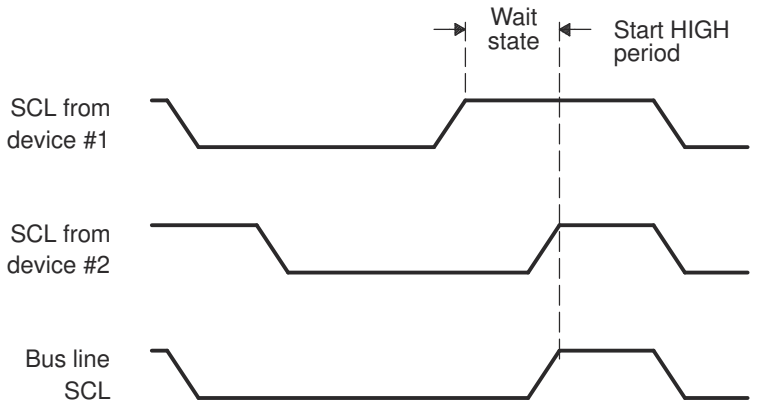

Figure 19-14. Synchronization of Two I2C Clock Generators During Arbitration

19.3.9 Arbitration

If two or more master-transmitters attempt to start a transmission on the same bus at approximately the same time, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. Figure 19-15 illustrates the arbitration procedure between two devices. The first master-transmitter that releases the SDA line high is overruled by another master-transmitter that drives the SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing master, the I2c module switches to the slave-receiver mode, sets the arbitration lost (ARBL) flag, and generates the arbitration-lost interrupt request.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the master-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

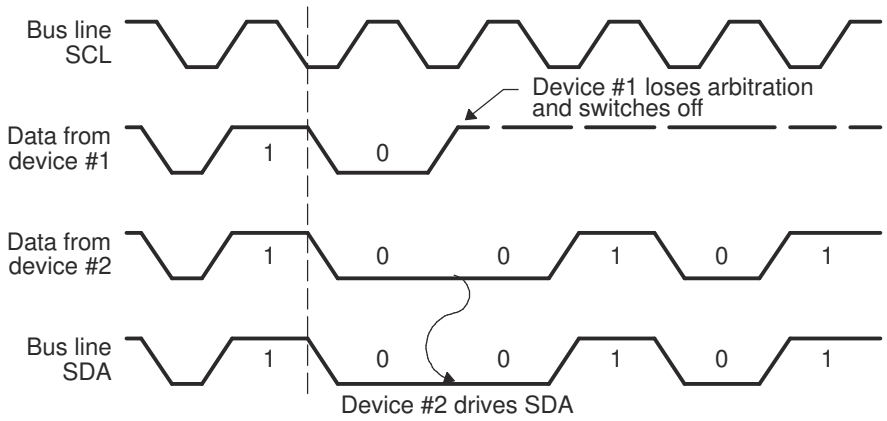

Figure 19-15. Arbitration Procedure Between Two Master-Transmitters

19.3.10 Digital Loopback Mode

The I2C module support a self-test mode called digital loopback, which is enabled by setting the DLB bit in the I2CMDR register. In this mode, data transmitted out of the I2CDXR register is received in the I2CDRR register. The data follows an internal path, and takes n cycles to reach I2CDRR, where:

n = 8 * (SYSCLK) / (I2C module clock (Fmod))

The transmit clock and the receive clock are the same. The address seen on the external SDA pin is the address in the I2COAR register. Figure 19-16 shows the signal routing in digital loopback mode.

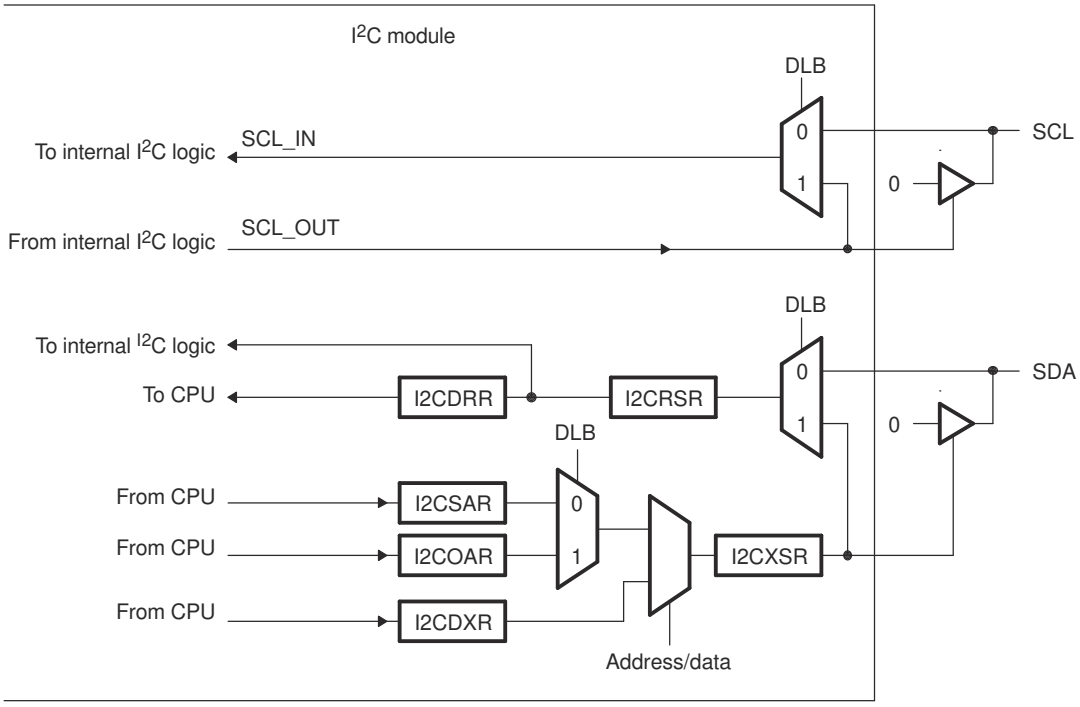

Figure 19-16. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit

Note

The free data format (I2CMDR.FDF = 1) is not supported in digital loopback mode.

19.3.11 NACK Bit Generation

When the I2C module is a receiver (master or slave), the I2C module can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 19-5 summarizes the various ways you can allow the I2C module to send a NACK bit.

Note

When a NACK is sent, the following occurs:

1. The STP in I2CMDR is cleared
2. SCL is held low
3. The NACK in I2CSTR is set

Table 19-5. Ways to Generate a NACK Bit

I2C Module Condition	NACK Bit Generation Options
Slave-receiver modes	Allow an overrun condition (RSFULL = 1 in I2CSTR) Reset the module (IRS = 0 in I2CMDR) Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Master-receiver mode AND Repeat mode (RM = 1 in I2CMDR)	Generate a STOP condition (STP = 1 in I2CMDR) Reset the module (IRS = 0 in I2CMDR) Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Master-receiver mode AND Nonrepeat mode (RM = 0 in I2CMDR)	If STP = 1 in I2CMDR, allow the internal data counter to count down to 0 and thus force a STOP condition If STP = 0, make STP = 1 to generate a STOP condition Reset the module (IRS = 0 in I2CMDR) Set STP = 1 to generate a STOP condition Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive

19.4 Interrupt Requests Generated by the I2C Module

Each I2C module can generate two CPU interrupts.

1. Basic I2C interrupt: Possible basic I2C interrupt sources that can trigger this interrupt are described in Section 19.4.1.
2. I2C FIFO interrupt: Possible I2C FIFO interrupt sources that can trigger this interrupt are described in Section 19.4.2

19.4.1 Basic I2C Interrupt Requests

The I2C module generates the interrupt requests described in Table 19-6. As shown in Figure 19-17, all requests are multiplexed through an arbiter to a single I2C interrupt request to the CPU. Each interrupt request has a flag bit in the status register (I2CSTR) and an enable bit in the interrupt enable register (I2CIER). When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the request is forwarded to the CPU as an I2C interrupt.

The I2C interrupt is one of the maskable interrupts of the CPU. As with any maskable interrupt request, if the request is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (I2CINT1A_ISR). The I2CINT1A_ISR for the I2C interrupt can determine the interrupt source by reading the interrupt source register, I2CISRC. Then the I2CINT1A_ISR can branch to the appropriate subroutine.

After the CPU reads I2CISRC, the following events occur:

1. The flag for the source interrupt is cleared in I2CSTR. Exception: The ARDY, RRDY, and XRDY bits in I2CSTR are not cleared when I2CISRC is read. To clear one of these bits, write a 1 to the bit.
2. The arbiter determines which of the remaining interrupt requests has the highest priority, writes the code for that interrupt to I2CISRC, and forwards the interrupt request to the CPU.

Table 19-6. Descriptions of the Basic I2C Interrupt Requests

I2C Interrupt Request	Interrupt Source
XRDYINT	Transmit ready condition: The data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). As an alternative to using XRDYINT, the CPU can poll the XRDY bit of the status register, I2CSTR. XRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead.
RRDYINT	Receive ready condition: The data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. As an alternative to using RRDYINT, the CPU can poll the RRDY bit of I2CSTR. RRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead.
ARDYINT	Register-access ready condition: The I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The specific events that generate ARDYINT are the same events that set the ARDY bit of I2CSTR. As an alternative to using ARDYINT, the CPU can poll the ARDY bit.
NACKINT	No-acknowledgment condition: The I2C module is configured as a master-transmitter and did not received acknowledgment from the slave-receiver. As an alternative to using NACKINT, the CPU can poll the NACK bit of I2CSTR.
ARBLINT	Arbitration-lost condition: The I2C module has lost an arbitration contest with another master-transmitter. As an alternative to using ARBLINT, the CPU can poll the ARBL bit of I2CSTR.
SCDINT	Stop condition detected: A STOP condition was detected on the I2C bus. As an alternative to using SCDINT, the CPU can poll the SCD bit of the status register, I2CSTR.
AASINT	Addressed as slave condition: The I2C has been addressed as a slave device by another master on the I2C bus. As an alternative to using AASINT, the CPU can poll the AAS bit of the status register, I2CSTR.

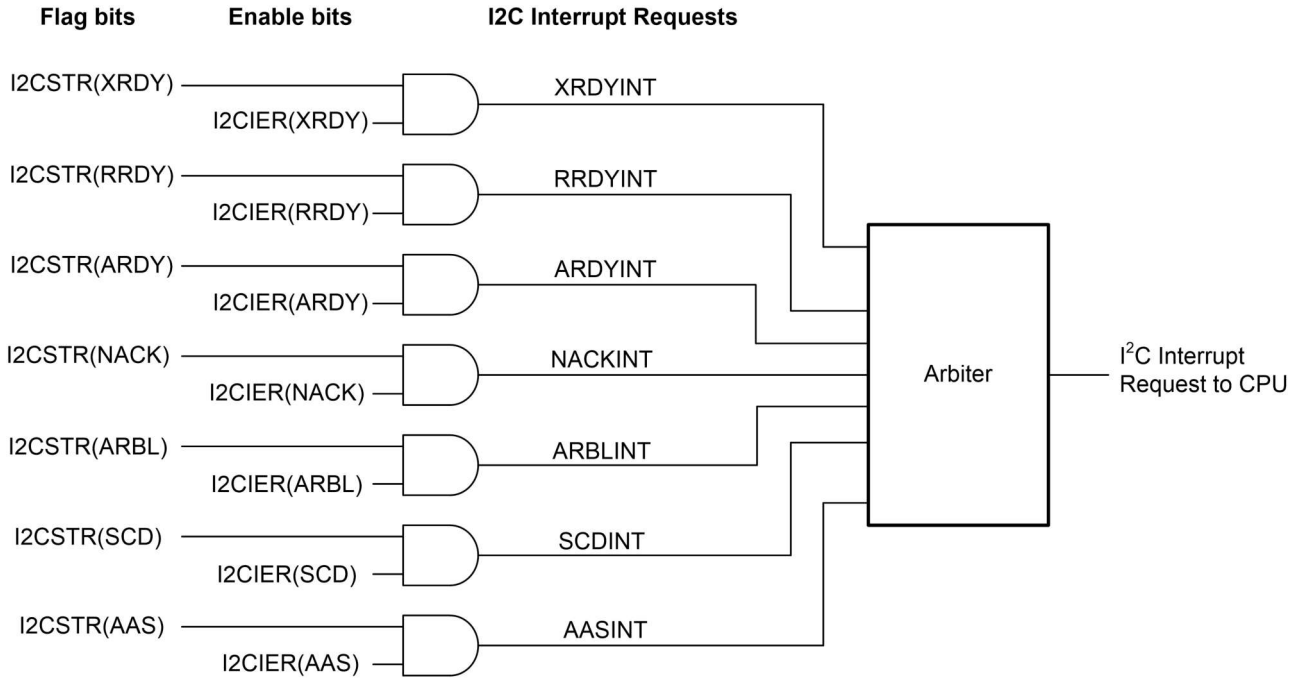

Figure 19-17. Enable Paths of the I2C Interrupt Requests

The priorities of the basic I2C interrupt requests are listed in order of highest priority to lowest priority:

1. ARBLINT
2. NACKINT
3. ARDYINT
4. RRDYINT
5. XRDYINT
6. SCDINT
7. AASINT

The I2C module has a backwards compatibility bit (BC) in the I2CEMDR register. The timing diagram in Figure 19-18 demonstrates the effect the backwards compatibility bit has on I2C module registers and interrupts when configured as a slave-transmitter.

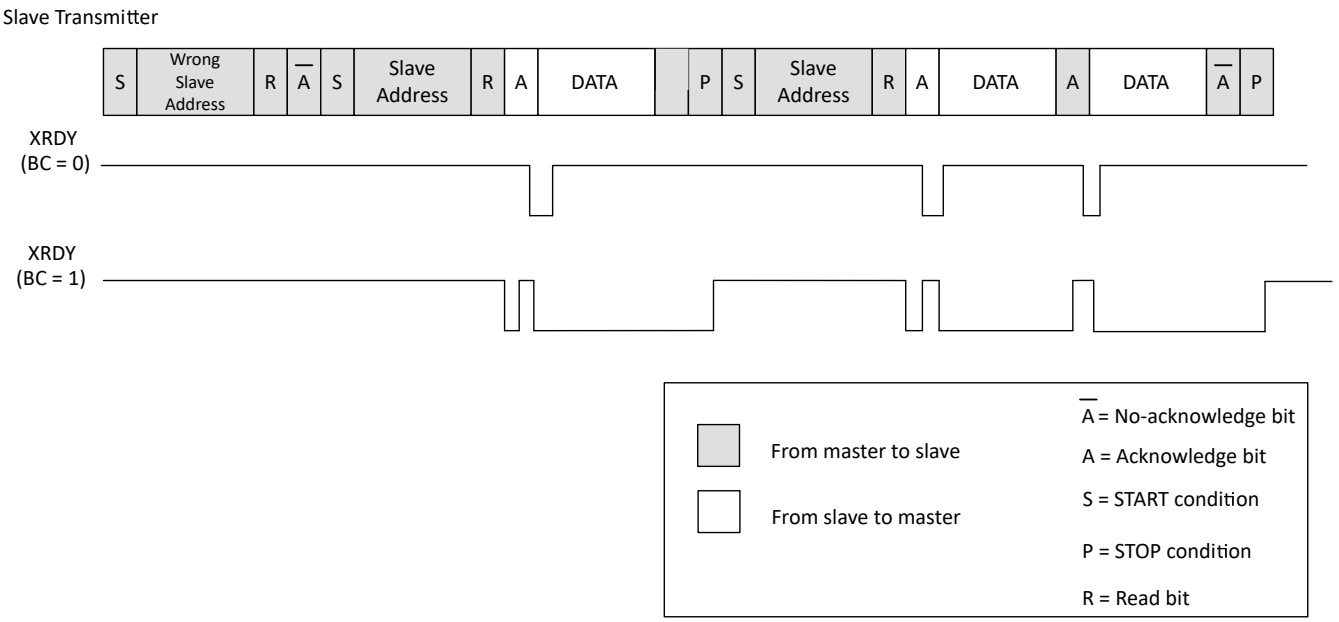

Figure 19-18. Backwards Compatibility Mode and Forward Compatibility Bit, Slave Transmitter

19.4.2 I2C FIFO Interrupts

In addition to the seven basic I2C interrupts, the transmit and receive FIFOs each contain the ability to generate an interrupt (I2CINT2A). The transmit FIFO can be configured to generate an interrupt after transmitting a defined number of bytes, up to 16. The receive FIFO can be configured to generate an interrupt after receiving a defined number of bytes, up to 16. These two interrupt sources are ORed together into a single maskable CPU interrupt. Figure 19-19 shows the structure of I2C FIFO interrupt. The interrupt service routine can then read the FIFO interrupt status flags to determine from which source the interrupt came. See the I2C transmit FIFO register (I2CFFTX) and the I2C receive FIFO register (I2CFFRX) descriptions.

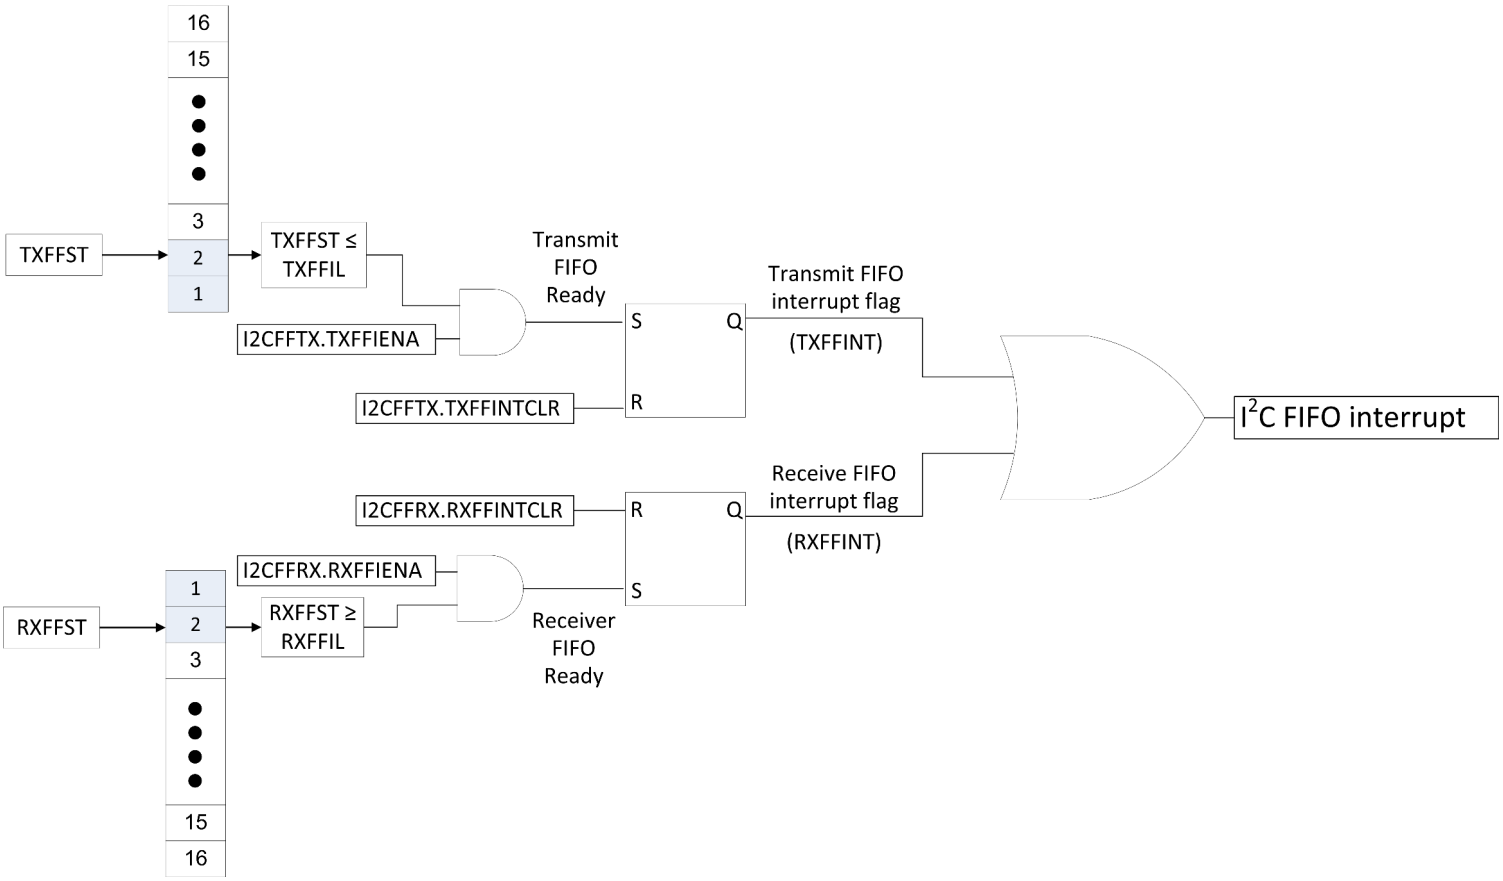

Figure 19-19. I2C FIFO Interrupt

19.5 Resetting or Disabling the I2C Module

You can reset or disable the I2C module in two ways:

- Write 0 to the I2C reset bit (IRS) in the I2C mode register (I2CMDR). All status bits (in I2CSTR) are forced to the default values, and the I2C module remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high-impedance state.
- Initiate a device reset by driving the $\overline{\text{XRS}}$ pin low. The entire device is reset and is held in the reset state until you drive the pin high. When the $\overline{\text{XRS}}$ pin is released, all I2C module registers are reset to the default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until you write 1 to IRS.

The IRS must be 0 while you configure or reconfigure the I2C module. Forcing IRS to 0 can be used to save power and to clear error conditions.

19.6 Software

19.6.1 I2C Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/i2c

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

19.6.1.1 C28x-I2C Library source file for FIFO interrupts

FILE: i2cLib_FIFO_controller_interrupt.c

19.6.1.2 C28x-I2C Library source file for FIFO using polling

FILE: i2cLib_FIFO_polling.c

19.6.1.3 C28x-I2C Library source file for FIFO interrupts

FILE: i2cLib_FIFO_controller_target_interrupt.c

19.6.1.4 I2C Digital Loopback with FIFO Interrupts

FILE: i2c_ex1_loopback.c

This program uses the internal loopback test mode of the I2C module. Both the TX and RX I2C FIFOs and their interrupts are used. The pinmux and I2C initialization is done through the sysconfig file.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
This pattern is repeated forever.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections*

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

19.6.1.5 I2C EEPROM

FILE: i2c_ex2_eeprom.c

This program will write 1-14 words to EEPROM and read them back. The data written and the EEPROM address written to are contained in the message structure, i2cMsgOut. The data read back will be contained in the message structure i2cMsgIn.

External Connections

- Connect external I2C EEPROM at address 0x50
- Connect DEVICE_GPIO_PIN_SDAA on to external EEPROM SDA (serial data) pin
- Connect DEVICE_GPIO_PIN_SCLA on to external EEPROM SCL (serial clock) pin

Watch Variables

- *i2cMsgOut* - Message containing data to write to EEPROM

- *i2cMsgIn* - Message containing data read from EEPROM

19.6.1.6 I2C Digital External Loopback with FIFO Interrupts

FILE: i2c_ex3_external_loopback.c

This program uses the I2CA and I2CB modules for achieving external loopback. The I2CA TX FIFO and the I2CB RX FIFO are used along with their interrupts.

A stream of data is sent on I2CA and then compared to the received stream on I2CB. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
This pattern is repeated forever.

External Connections
- Connect SCLA(DEVICE_GPIO_PIN_SCLA) to SCLB (DEVICE_GPIO_PIN_SCLB)
- and SDAA(DEVICE_GPIO_PIN_SDAA) to SDAB (DEVICE_GPIO_PIN_SDAB)
- Connect DEVICE_GPIO_PIN_LED1 to an LED used to depict data transfers.

Watch Variables
- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

19.6.1.7 I2C EEPROM

FILE: i2c_ex4_eeprom_polling.c

This program will shows how to perform different EEPROM write and read commands using I2C polling method EEPROM used for this example is AT24C256

External Connections

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM

SCL | DEVICE_GPIO_PIN_SCLA | SCL SDA | DEVICE_GPIO_PIN_SDAA | SDA

Make sure to connect GND pins if EEPROM and C2000 device are in different board.

19.6.1.8 I2C controller target communication using FIFO interrupts

FILE: i2c_ex5_controller_target_interrupt.c

This program shows how to use I2CA and I2CB modules in both controller and target configuration This example uses I2C FIFO interrupts and doesn't using polling

Example1: I2CA as controller Transmitter and I2CB working target Receiver Example2: I2CA as controller Receiver and I2CB working target Transmitter Example3: I2CB as controller Transmitter and I2CA working target Receiver Example4: I2CB as controller Receiver and I2CA working target Transmitter

\b External \b Connections on launchpad should be made as shown below \n Signal | I2CA | I2CB

SCL | DEVICE_GPIO_PIN_SCLA | DEVICE_GPIO_PIN_SCLB

SDA | DEVICE_GPIO_PIN_SDAA | DEVICE_GPIO_PIN_SDAB

Watch Variables in memory window
- *I2CA_TXdata*

- *I2CA_RXdata*
- *I2CB_TXdata*
- *I2CB_RXdata* stream for error checking

19.6.1.9 I2C EEPROM

FILE: i2c_ex6_eeprom_interrupt.c

This program will shows how to perform different EEPROM write and read commands using I2C interrupts EEPROM used for this example is AT24C256

External Connections

- Connect external I2C EEPROM at address 0x50 Signal | I2CA | EEPROM

SCL | DEVICE_GPIO_PIN_SCLA | SCL SDA | DEVICE_GPIO_PIN_SDAA | SDA

Make sure to connect GND pins if EEPROM and C2000 device are in different board.

//Example 1: EEPROM Byte Write //Example 2: EEPROM Byte Read //Example 3: EEPROM word (16-bit) write //Example 4: EEPROM word (16-bit) read //Example 5: EEPROM Page write //Example 6: EEPROM word Paged read

Watch Variables

- *TX_MsgBuffer* - Message buffer which stores the data to be transmitted
- *RX_MsgBuffer* - Message buffer which stores the data to be received

19.7 I2C Registers

This section describes the I2C Module Registers.

19.7.1 I2C Base Addresses

Table 19-7. I2C Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
Instance	Structure							
I2caRegs	I2C_REGS	I2CA_BASE	0x0000_7300	YES	YES	-	-	YES
I2cbRegs	I2C_REGS	I2CB_BASE	0x0000_7340	YES	YES	-	-	YES

19.7.2 I2C_REGS Registers

Table 19-8 lists the memory-mapped registers for the I2C_REGS registers. All register offset addresses not listed in Table 19-8 should be considered as reserved locations and the register contents should not be modified.

Table 19-8. I2C_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	I2COAR	I2C Own address		Go
1h	I2CIER	I2C Interrupt Enable		Go
2h	I2CSTR	I2C Status		Go
3h	I2CCLKL	I2C Clock low-time divider		Go
4h	I2CCLKH	I2C Clock high-time divider		Go
5h	I2CCNT	I2C Data count		Go
6h	I2CDRR	I2C Data receive		Go
7h	I2CSAR	I2C Slave address		Go
8h	I2CDXR	I2C Data Transmit		Go
9h	I2CMDR	I2C Mode		Go
Ah	I2CISRC	I2C Interrupt Source		Go
Bh	I2CEMDR	I2C Extended Mode		Go
Ch	I2CPSC	I2C Prescaler		Go
20h	I2CFFTX	I2C FIFO Transmit		Go
21h	I2CFFRX	I2C FIFO Receive		Go

Complex bit access types are encoded to fit into small table cells. Table 19-9 shows the codes that are used for access types in this section.

Table 19-9. I2C_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

19.7.2.1 I2COAR Register (Offset = 0h) [Reset = 0000h]

I2COAR is shown in Figure 19-20 and described in Table 19-10.

Return to the Summary Table.

The I2C own address register (I2COAR) is a 16-bit register. The I2C module uses this register to specify its own slave address, which distinguishes it from other slaves connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 are used
write 0s to bits 9-7.

Figure 19-20. I2COAR Register

15	14	13	12	11	10	9	8
RESERVED						OAR	
R-0h						R/W-0h	
7	6	5	4	3	2	1	0
OAR							
R/W-0h							

Table 19-10. I2COAR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-0	OAR	R/W	0h	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit slave address of the I2C module. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit slave address of the I2C module. Reset type: SYSRSn

19.7.2.2 I2CIER Register (Offset = 1h) [Reset = 0000h]

I2CIER is shown in Figure 19-21 and described in Table 19-11.

Return to the Summary Table.

I2CIER is used by the CPU to individually enable or disable I2C interrupt requests.

Figure 19-21. I2CIER Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED	AAS	SCD	XRDY	RRDY	ARDY	NACK	ARBL

Table 19-11. I2CIER Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	AAS	R/W	0h	Addressed as slave interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
5	SCD	R/W	0h	Stop condition detected interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
4	XRDY	R/W	0h	Transmit-data-ready interrupt enable bit. This bit should not be set when using FIFO mode. Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
3	RRDY	R/W	0h	Receive-data-ready interrupt enable bit. This bit should not be set when using FIFO mode. Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
2	ARDY	R/W	0h	Register-access-ready interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
1	NACK	R/W	0h	No-acknowledgment interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
0	ARBL	R/W	0h	Arbitration-lost interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled

19.7.2.3 I2CSTR Register (Offset = 2h) [Reset = 0410h]

I2CSTR is shown in Figure 19-22 and described in Table 19-12.

Return to the Summary Table.

The I2C status register (I2CSTR) is a 16-bit register used to determine which interrupt has occurred and to read status information.

Figure 19-22. I2CSTR Register

Table 19-12. I2CSTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	SDIR	R/W1C	0h	Slave direction bit Reset type: SYSRSn 0h (R/W) = I2C is not addressed as a slave transmitter. SDIR is cleared by one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - Digital loopback mode is enabled. - A START or STOP condition occurs on the I2C bus. 1h (R/W) = I2C is addressed as a slave transmitter.
13	NACKSNT	R/W1C	0h	NACK sent bit. This bit is used when the I2C module is in the receiver mode. One instance in which NACKSNT is affected is when the NACK mode is used (see the description for NACKMOD in Reset type: SYSRSn 0h (R/W) = NACK not sent. NACKSNT bit is cleared by any one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset (either when 0 is written to the IRS bit of I2CMDR or when the whole device is reset). 1h (R/W) = NACK sent: A no-acknowledge bit was sent during the acknowledge cycle on the I2C-bus.
12	BB	R	0h	Bus busy bit. BB indicates whether the I2C-bus is busy or is free for another data transfer. See the paragraph following the table for more information Reset type: SYSRSn 0h (R/W) = Bus free. BB is cleared by any one of the following events: - The I2C module receives or transmits a STOP bit (bus free). - The I2C module is reset. 1h (R/W) = Bus busy: The I2C module has received or transmitted a START bit on the bus.

Table 19-12. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	RSFULL	R	0h	Receive shift register full bit. RSFULL indicates an overrun condition during reception. Overrun occurs when new data is received into the shift register (I2CRSR) and the old data has not been read from the receive register (I2CDRR). As new bits arrive from the SDA pin, they overwrite the bits in I2CRSR. The new data will not be copied to ICDRR until the previous data is read. Reset type: SYSRSn 0h (R/W) = No overrun detected. RSFULL is cleared by any one of the following events: - I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit. - The I2C module is reset. 1h (R/W) = Overrun detected
10	XSMT	R	1h	Transmit shift register empty bit. XSMT = 0 indicates that the transmitter has experienced underflow. Underflow occurs when the transmit shift register (I2CXSR) is empty but the data transmit register (I2CDXR) has not been loaded since the last I2CDXR-to-I2CXSR transfer. The next I2CDXR-to-I2CXSR transfer will not occur until new data is in I2CDXR. If new data is not transferred in time, the previous data may be re-transmitted on the SDA pin. Reset type: SYSRSn 0h (R/W) = Underflow detected (empty) 1h (R/W) = No underflow detected (not empty). XSMT is set by one of the following events: - Data is written to I2CDXR. - The I2C module is reset
9	AAS	R	0h	Addressed-as-slave bit Reset type: SYSRSn 0h (R/W) = In the 7-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or a repeated START condition. In the 10-bit addressing mode, the AAS bit is cleared when receiving a NACK, a STOP condition, or by a slave address different from the I2C peripheral's own slave address. 1h (R/W) = The I2C module has recognized its own slave address or an address of all zeros (general call).
8	AD0	R	0h	Address 0 bits Reset type: SYSRSn 0h (R/W) = AD0 has been cleared by a START or STOP condition. 1h (R/W) = An address of all zeros (general call) is detected.
7-6	RESERVED	R	0h	Reserved
5	SCD	R/W1C	0h	Stop condition detected bit. SCD is set when the I2C sends or receives a STOP condition. The I2C module delays clearing of the I2CMDR[STP] bit until the SCD bit is set. Reset type: SYSRSn 0h (R/W) = STOP condition not detected since SCD was last cleared. SCD is cleared by any one of the following events: - I2CISRC is read by the CPU when it contains the value 110b (stop condition detected). Emulator reads of the I2CISRC do not affect this bit. - SCD is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = A STOP condition has been detected on the I2C bus.

Table 19-12. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	XRDY	R	1h	Transmit-data-ready interrupt flag bit. When not in FIFO mode, XRDY indicates that the data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). The CPU can poll XRDY or use the XRDY interrupt request When in FIFO mode, use TXFFINT instead. Reset type: SYSRSn 0h (R/W) = I2CDXR not ready. XRDY is cleared when data is written to I2CDXR. 1h (R/W) = I2CDXR ready: Data has been copied from I2CDXR to I2CXSR. XRDY is also forced to 1 when the I2C module is reset.
3	RRDY	R/W1C	0h	Receive-data-ready interrupt flag bit. When not in FIFO mode, RRDY indicates that the data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. The CPU can poll RRDY or use the RRDY interrupt request When in FIFO mode, use RXFFINT instead. Reset type: SYSRSn 0h (R/W) = I2CDRR not ready. RRDY is cleared by any one of the following events: - I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit. - RRDY is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = I2CDRR ready: Data has been copied from I2CRSR to I2CDRR.
2	ARDY	R/W1C	0h	Register-access-ready interrupt flag bit (only applicable when the I2C module is in the master mode). ARDY indicates that the I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The CPU can poll ARDY or use the ARDY interrupt request. Reset type: SYSRSn 0h (R/W) = The registers are not ready to be accessed. ARDY is cleared by any one of the following events: - The I2C module starts using the current register contents. - ARDY is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = The registers are ready to be accessed. In the nonrepeat mode (RM = 0 in I2CMDR): If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0. If STP = 1, ARDY is not affected (instead, the I2C module generates a STOP condition when the counter reaches 0). In the repeat mode (RM = 1): ARDY is set at the end of each byte transmitted from I2CDXR.

Table 19-12. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	NACK	R/W1C	0h	No-acknowledgment interrupt flag bit. NACK applies when the I2C module is a master transmitter. NACK indicates whether the I2C module has detected an acknowledge bit (ACK) or a noacknowledge bit (NACK) from the slave receiver. The CPU can poll NACK or use the NACK interrupt request. Reset type: SYSRSn 0h (R/W) = ACK received/NACK not received. This bit is cleared by any one of the following events: - An acknowledge bit (ACK) has been sent by the slave receiver. - NACK is manually cleared. To clear this bit, write a 1 to it. - The CPU reads the interrupt source register (I2CISRC) and the register contains the code for a NACK interrupt. Emulator reads of the I2CISRC do not affect this bit. - The I2C module is reset. 1h (R/W) = NACK bit received. The hardware detects that a no-acknowledge (NACK) bit has been received. Note: While the I2C module performs a general call transfer, NACK is 1, even if one or more slaves send acknowledgment.
0	ARBL	R/W1C	0h	Arbitration-lost interrupt flag bit (only applicable when the I2C module is a master-transmitter). ARBL primarily indicates when the I2C module has lost an arbitration contest with another master/transmitter. The CPU can poll ARBL or use the ARBL interrupt request. Reset type: SYSRSn 0h (R/W) = Arbitration not lost. AL is cleared by any one of the following events: - AL is manually cleared. To clear this bit, write a 1 to it. - The CPU reads the interrupt source register (I2CISRC) and the register contains the code for an AL interrupt. Emulator reads of the I2CISRC do not affect this bit. - The I2C module is reset. 1h (R/W) = Arbitration lost. AL is set by any one of the following events: - The I2C module senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously. - The I2C module attempts to start a transfer while the BB (bus busy) bit is set to 1. When AL becomes 1, the MST and STP bits of I2CMDR are cleared, and the I2C module becomes a slave-receiver.

19.7.2.4 I2CCLKL Register (Offset = 3h) [Reset = 0000h]

I2CCLKL is shown in Figure 19-23 and described in Table 19-13.

To produce the high time duration of the master clock, the period of the module clock is multiplied by (ICCL + d). d is an adjustment factor based on the prescaler. See the Clock Divider Registers section of the Introduction for details. Note: These bits must be set to a non-zero value for proper I2C clock generation. Reset type: SYSRSn

19.7.2.6 I2CCNT Register (Offset = 5h) [Reset = 0000h]

I2CCNT is shown in Figure 19-25 and described in Table 19-15.

Return to the Summary Table.

I2CCNT is a 16-bit register used to indicate how many data bytes to transfer when the I2C module is configured as a transmitter, or to receive when configured as a master receiver. In the repeat mode (RM = 1), I2CCNT is not used.
The value written to I2CCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each byte transferred (I2CCNT remains unchanged). If a STOP condition is requested in the master mode (STP = 1 in I2CMDR), the I2C module terminates the transfer with a STOP condition when the countdown is complete (that is, when the last byte has been transferred).

R/W-0h							

Table 19-15. I2CCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	I2CCNT	R/W	0h	Data count value. I2CCNT indicates the number of data bytes to transfer or receive. If a STOP condition is specified (STP=1) then I2CCNT will decrease after each byte is sent until it reaches zero, which in turn will generate a STOP condition. The value in I2CCNT is a don't care when the RM bit in I2CMDR is set to 1. Reset type: SYSRSn 0h (R/W) = data count value is 65536 1h (R/W) = data count value is 1 2h (R/W) = data count value is 2 FFFFh (R/W) = data count value is 65535

19.7.2.7 I2CDRR Register (Offset = 6h) [Reset = 0000h]

I2CDRR is shown in Figure 19-26 and described in Table 19-16.

Return to the Summary Table.

I2CDRR is a 16-bit register used by the CPU to read received data. The I2C module can receive a data byte with 1 to 8 bits. The number of bits is selected with the bit count (BC) bits in I2CMDR. One bit at a time is shifted in from the SDA pin to the receive shift register (I2CRSR). When a complete data byte has been received, the I2C module copies the data byte from I2CRSR to I2CDRR. The CPU cannot access I2CRSR directly.
If a data byte with fewer than 8 bits is in I2CDRR, the data value is right-justified, and the other bits of I2CDRR(7-0) are undefined. For example, if BC = 011 (3-bit data size), the receive data is in I2CDRR(2-0), and the content of I2CDRR(7-3) is undefined.
When in the receive FIFO mode, the I2CDRR register acts as the receive FIFO buffer.

19.7.2.8 I2CSAR Register (Offset = 7h) [Reset = 03FFh]

I2CSAR is shown in Figure 19-27 and described in Table 19-17.

Return to the Summary Table.

The I2C slave address register (I2CSAR) is a 16-bit register for storing the next slave address that will be transmitted by the I2C module when it is a master. The SAR field of I2CSAR contains a 7-bit or 10-bit slave address. When the I2C module is not using the free data format (FDF = 0 in I2CMDR), it uses this address to initiate data transfers with a slave, or slaves. When the address is nonzero, the address is for a particular slave. When the address is 0, the address is a general call to all slaves. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 of I2CSAR are used
write 0s to bits 9-7.

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-0	SAR	R/W	3FFh	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit slave address that the I2C module transmits when it is in the master-transmitter mode. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit slave address that the I2C module transmits when it is in the master transmitter mode. Reset type: SYSRSn

19.7.2.9 I2CDXR Register (Offset = 8h) [Reset = 0000h]

I2CDXR is shown in Figure 19-28 and described in Table 19-18.

Return to the Summary Table.

The CPU writes transmit data to I2CDXR. This 16-bit register accepts a data byte with 1 to 8 bits. Before writing to I2CDXR, specify how many bits are in a data byte by loading the appropriate value into the bit count (BC) bits of I2CMDR. When writing a data byte with fewer than 8 bits, make sure the value is right-aligned in I2CDXR. After a data byte is written to I2CDXR, the I2C module copies the data byte to the transmit shift register (I2CXSR). The CPU cannot access I2CXSR directly. From I2CXSR, the I2C module shifts the data byte out on the SDA pin, one bit at a time.
When in the transmit FIFO mode, the I2CDXR register acts as the transmit FIFO buffer.

Table 19-19. I2CMDR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	NACKMOD	R/W	0h	NACK mode bit. This bit is only applicable when the I2C module is acting as a receiver. Reset type: SYSRSn 0h (R/W) = In the slave-receiver mode: The I2C module sends an acknowledge (ACK) bit to the transmitter during each acknowledge cycle on the bus. The I2C module only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit. In the master-receiver mode: The I2C module sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. At that point, the I2C module sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit 1h (R/W) = In either slave-receiver or master-receiver mode: The I2C module sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared. Important: To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit.
14	FREE	R/W	0h	This bit controls the action taken by the I2C module when a debugger breakpoint is encountered. Reset type: SYSRSn 0h (R/W) = When I2C module is master: If SCL is low when the breakpoint occurs, the I2C module stops immediately and keeps driving SCL low, whether the I2C module is the transmitter or the receiver. If SCL is high, the I2C module waits until SCL becomes low and then stops. When I2C module is slave: A breakpoint forces the I2C module to stop when the current transmission/reception is complete. 1h (R/W) = The I2C module runs free that is, it continues to operate when a breakpoint occurs.
13	STT	R/W	0h	START condition bit (only applicable when the I2C module is a master). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions (see Table 9-6). Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS = 0. Reset type: SYSRSn 0h (R/W) = In the master mode, STT is automatically cleared after the START condition has been generated. 1h (R/W) = In the master mode, setting STT to 1 causes the I2C module to generate a START condition on the I2C-bus
12	RESERVED	R	0h	Reserved

Table 19-19. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	STP	R/W	0h	STOP condition bit (only applicable when the I2C module is a master). In the master mode, the RM,STT, and STP bits determine when the I2C module starts and stops data transmissions. Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS=0. When in non-repeat mode, at least one byte must be transferred before a stop condition can be generated. The I2C module delays clearing of this bit until after the I2CSTR[SCD] bit is set. To avoid disrupting the I2C state machine, the user must wait until this bit is clear before initiating a new message. Reset type: SYSRSn 0h (R/W) = STP is automatically cleared after the STOP condition has been generated 1h (R/W) = STP has been set by the device to generate a STOP condition when the internal data counter of the I2C module counts down to 0.
10	MST	R/W	0h	Master mode bit. MST determines whether the I2C module is in the slave mode or the master mode. MST is automatically changed from 1 to 0 when the I2C master generates a STOP condition Reset type: SYSRSn 0h (R/W) = Slave mode. The I2C module is a slave and receives the serial clock from the master. 1h (R/W) = Master mode. The I2C module is a master and generates the serial clock on the SCL pin.
9	TRX	R/W	0h	Transmitter mode bit. When relevant, TRX selects whether the I2C module is in the transmitter mode or the receiver mode. Reset type: SYSRSn 0h (R/W) = Receiver mode. The I2C module is a receiver and receives data on the SDA pin. 1h (R/W) = Transmitter mode. The I2C module is a transmitter and transmits data on the SDA pin.
8	XA	R/W	0h	Expanded address enable bit. Reset type: SYSRSn 0h (R/W) = 7-bit addressing mode (normal address mode). The I2C module transmits 7-bit slave addresses (from bits 6-0 of I2CSAR), and its own slave address has 7 bits (bits 6-0 of I2COAR). 1h (R/W) = 10-bit addressing mode (expanded address mode). The I2C module transmits 10-bit slave addresses (from bits 9-0 of I2CSAR), and its own slave address has 10 bits (bits 9-0 of I2COAR).
7	RM	R/W	0h	Repeat mode bit (only applicable when the I2C module is a master-transmitter or master-receiver). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions Reset type: SYSRSn 0h (R/W) = Nonrepeat mode. The value in the data count register (I2CCNT) determines how many bytes are received/transmitted by the I2C module. 1h (R/W) = Repeat mode. A data byte is transmitted each time the I2CDXR register is written to (or until the transmit FIFO is empty when in FIFO mode) until the STP bit is manually set. The value of I2CCNT is ignored. The ARDY bit/interrupt can be used to determine when the I2CDXR (or FIFO) is ready for more data, or when the data has all been sent and the CPU is allowed to write to the STP bit.

Table 19-19. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	DLB	R/W	0h	Digital loopback mode bit. Reset type: SYSRSn 0h (R/W) = Digital loopback mode is disabled. 1h (R/W) = Digital loopback mode is enabled. For proper operation in this mode, the MST bit must be 1. In the digital loopback mode, data transmitted out of I2CDXR is received in I2CDRR after n device cycles by an internal path, where: n = ((I2C input clock frequency/module clock frequency) x 8) The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2COAR. Note: The free data format (FDF = 1) is not supported in the digital loopback mode.
5	IRS	R/W	0h	I2C module reset bit. Reset type: SYSRSn 0h (R/W) = The I2C module is in reset/disabled. When this bit is cleared to 0, all status bits (in I2CSTR) are set to their default values. 1h (R/W) = The I2C module is enabled. This has the effect of releasing the I2C bus if the I2C peripheral is holding it.
4	STB	R/W	0h	START byte mode bit. This bit is only applicable when the I2C module is a master. As described in version 2.1 of the Philips Semiconductors I2C-bus specification, the START byte can be used to help a slave that needs extra time to detect a START condition. When the I2C module is a slave, it ignores a START byte from a master, regardless of the value of the STB bit. Reset type: SYSRSn 0h (R/W) = The I2C module is not in the START byte mode. 1h (R/W) = The I2C module is in the START byte mode. When you set the START condition bit (STT), the I2C module begins the transfer with more than just a START condition. Specifically, it generates: 1. A START condition 2. A START byte (0000 0001b) 3. A dummy acknowledge clock pulse 4. A repeated START condition Then, as normal, the I2C module sends the slave address that is in I2CSAR.
3	FDF	R/W	0h	Free data format mode bit. Reset type: SYSRSn 0h (R/W) = Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit. 1h (R/W) = Free data format mode is enabled. Transfers have the free data (no address) format described in Section 9.2.5. The free data format is not supported in the digital loopback mode (DLB=1).

Table 19-19. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	BC	R/W	0h	Bit count bits. BC defines the number of bits (1 to 8) in the next data byte that is to be received or transmitted by the I2C module. The number of bits selected with BC must match the data size of the other device. Notice that when BC = 000b, a data byte has 8 bits. BC does not affect address bytes, which always have 8 bits. Note: If the bit count is less than 8, receive data is right-justified in I2CDRR(7-0), and the other bits of I2CDRR(7-0) are undefined. Also, transmit data written to I2CDXR must be right-justified Reset type: SYSRSn 0h (R/W) = 8 bits per data byte 1h (R/W) = 1 bit per data byte 2h (R/W) = 2 bits per data byte 3h (R/W) = 3 bits per data byte 4h (R/W) = 4 bits per data byte 5h (R/W) = 5 bits per data byte 6h (R/W) = 6 bits per data byte 7h (R/W) = 7 bits per data byte

19.7.2.11 I2CISRC Register (Offset = Ah) [Reset = 0000h]

I2CISRC is shown in Figure 19-30 and described in Table 19-20.

Return to the Summary Table.

The I2C interrupt source register (I2CISRC) is a 16-bit register used by the CPU to determine which event generated the I2C interrupt.

Figure 19-30. I2CISRC Register

15	14	13	12	11	10	9	8
RESERVED				WRITE_ZEROS			
R-0h				R/W-0h			
7	6	5	4	3	2	1	0
RESERVED						INTCODE	
R-0h						R-0h	

Table 19-20. I2CISRC Register Field Descriptions

Bit	Field	Type	Reset	Description
15-12	RESERVED	R	0h	Reserved
11-8	WRITE_ZEROS	R/W	0h	TI internal testing bits These reserved bit locations should always be written as zeros. Reset type: SYSRSn
7-3	RESERVED	R	0h	Reserved
2-0	INTCODE	R	0h	Interrupt code bits. The binary code in INTCODE indicates the event that generated an I2C interrupt. A CPU read will clear this field. If another lower priority interrupt is pending and enabled, the value corresponding to that interrupt will then be loaded. Otherwise, the value will stay cleared. The interrupt events below are listed in descending order of priority. That is INTCODE 1 (Arbitration lost) has the highest priority and INTCODE 7 (Addressed as slave) has the lowest priority. In the case of an arbitration lost, a no-acknowledgment condition detected, or a stop condition detected, a CPU read will also clear the associated interrupt flag bit in the I2CSTR register. Emulator reads will not affect the state of this field or of the status bits in the I2CSTR register. Reset type: SYSRSn 0h (R/W) = None 1h (R/W) = Arbitration lost 2h (R/W) = No-acknowledgment condition detected 3h (R/W) = Registers ready to be accessed 4h (R/W) = Receive data ready 5h (R/W) = Transmit data ready 6h (R/W) = Stop condition detected 7h (R/W) = Addressed as slave

19.7.2.12 I2CEMDR Register (Offset = Bh) [Reset = 0001h]

I2CEMDR is shown in Figure 19-31 and described in Table 19-21.

Return to the Summary Table.

Reset type: SYSRSn 0h (R/W) = See the 'Backwards Compatibility Mode Bit, Slave Transmitter' Figure for details. 1h (R/W) = See the 'Backwards Compatibility Mode Bit, Slave Transmitter' Figure for details.

19.7.2.13 I2CPSC Register (Offset = Ch) [Reset = 0000h]

I2CPSC is shown in Figure 19-32 and described in Table 19-22.

Return to the Summary Table.

The I2C prescaler register (I2CPSC) is a 16-bit register (see Figure 14-21) used for dividing down the I2C input clock to obtain the desired module clock for the operation of the I2C module. See the device-specific data manual for the supported range of values for the module clock frequency.
IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

7-0	IPSC	R/W	0h	I2C prescaler divide-down value. IPSC determines how much the CPU clock is divided to create the module clock of the I2C module: module clock frequency = I2C input clock frequency/(IPSC + 1) Note: IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). Reset type: SYSRSn

19.7.2.14 I2CFFTX Register (Offset = 20h) [Reset = 0000h]

I2CFFTX is shown in Figure 19-33 and described in Table 19-23.

Return to the Summary Table.

The I2C transmit FIFO register (I2CFFTX) is a 16-bit register that contains the I2C FIFO mode enable bit as well as the control and status bits for the transmit FIFO mode of operation on the I2C peripheral.

Figure 19-33. I2CFFTX Register

15	14	13	12	11	10	9	8
RESERVED	I2CFFEN	TXFFRST	TXFFST

R-0h	R-0/W1S-0h	R/W-0h	R/W-0h				

Table 19-23. I2CFFTX Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	I2CFFEN	R/W	0h	I2C FIFO mode enable bit. This bit must be enabled for either the transmit or the receive FIFO to operate correctly. Reset type: SYSRSn 0h (R/W) = Disable the I2C FIFO mode. 1h (R/W) = Enable the I2C FIFO mode.
13	TXFFRST	R/W	0h	Transmit FIFO Reset Reset type: SYSRSn 0h (R/W) = Reset the transmit FIFO pointer to 0000 and hold the transmit FIFO in the reset state. 1h (R/W) = Enable the transmit FIFO operation.
12-8	TXFFST	R	0h	Contains the status of the transmit FIFO: xxxxx Transmit FIFO contains xxxxx bytes. 00000 Transmit FIFO is empty. Note: Since these bits are reset to zero, the transmit FIFO interrupt flag will be set when the transmit FIFO operation is enabled and the I2C is taken out of reset. This will generate a transmit FIFO interrupt if enabled. To avoid any detrimental effects from this, write a one to the TXFFINTCLR once the transmit FIFO operation is enabled and the I2C is taken out of reset. Reset type: SYSRSn
7	TXFFINT	R	0h	Transmit FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the TXFFINTCLR bit. If the TXFFIENA bit is set, this bit will generate an interrupt when it is set. Reset type: SYSRSn 0h (R/W) = Transmit FIFO interrupt condition has not occurred. 1h (R/W) = Transmit FIFO interrupt condition has occurred.
6	TXFFINTCLR	R-0/W1S	0h	Transmit FIFO Interrupt Flag Clear Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a 0. 1h (R/W) = Writing a 1 to this bit clears the TXFFINT flag.
5	TXFFIENA	R/W	0h	Transmit FIFO Interrupt Enable Reset type: SYSRSn 0h (R/W) = Disabled. TXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. TXFFINT flag does generate an interrupt when set.

Table 19-23. I2CFFTX Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-0	TXFFIL	R/W	0h	Transmit FIFO interrupt level. These bits set the status level that will set the transmit interrupt flag. When the TXFFST4-0 bits reach a value equal to or less than these bits, the TXFFINT flag will be set. This will generate an interrupt if the TXFFIENA bit is set. Because the I2C on this device has a 16-level transmit FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

19.7.2.15 I2CFFRX Register (Offset = 21h) [Reset = 0000h]

I2CFFRX is shown in Figure 19-34 and described in Table 19-24.

Return to the Summary Table.

The I2C receive FIFO register (I2CFFRX) is a 16-bit register that contains the control and status bits for the receive FIFO mode of operation on the I2C peripheral.

Figure 19-34. I2CFFRX Register

15	14	13	12	11	10	9	8

R-0h	R-0/W1S-0h	R/W-0h	R/W-0h				

Table 19-24. I2CFFRX Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13	RXFFRST	R/W	0h	I2C receive FIFO reset bit Reset type: SYSRSn 0h (R/W) = Reset the receive FIFO pointer to 0000 and hold the receive FIFO in the reset state. 1h (R/W) = Enable the receive FIFO operation.
12-8	RXFFST	R	0h	Contains the status of the receive FIFO: xxxxx Receive FIFO contains xxxxx bytes 00000 Receive FIFO is empty. Reset type: SYSRSn
7	RXFFINT	R	0h	Receive FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the RXFFINTCLR bit. If the RXFFIENA bit is set, this bit will generate an interrupt when it is set Reset type: SYSRSn 0h (R/W) = Receive FIFO interrupt condition has not occurred. 1h (R/W) = Receive FIFO interrupt condition has occurred.
6	RXFFINTCLR	R-0/W1S	0h	Receive FIFO interrupt flag clear bit. Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a zero. 1h (R/W) = Writing a 1 to this bit clears the RXFFINT flag.
5	RXFFIENA	R/W	0h	Receive FIFO interrupt enable bit. Reset type: SYSRSn 0h (R/W) = Disabled. RXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. RXFFINT flag does generate an interrupt when set.
4-0	RXFFIL	R/W	0h	Receive FIFO interrupt level. These bits set the status level that will set the receive interrupt flag. When the RXFFST4-0 bits reach a value equal to or greater than these bits, the RXFFINT flag is set. This will generate an interrupt if the RXFFIENA bit is set. Note: Since these bits are reset to zero, the receive FIFO interrupt flag will be set if the receive FIFO operation is enabled and the I2C is taken out of reset. This will generate a receive FIFO interrupt if enabled. To avoid this, modify these bits on the same instruction as or prior to setting the RXFFRST bit. Because the I2C on this device has a 16-level receive FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

Chapter 20

Multichannel Buffered Serial Port (McBSP)

This chapter describes the multichannel buffered serial port (McBSP).

20.1 Introduction

This device provides up to two high-speed multichannel buffered serial ports (McBSPs) that allow direct interface to codecs and other devices in a system. The McBSP consists of a data-flow path and a control path connected to external devices by six pins as shown in Figure 20-1.

Data is communicated to devices interfaced with the McBSP via the data transmit (DX) pin for transmission and via the data receive (DR) pin for reception. Control information in the form of clocking and frame synchronization is communicated via the following pins: CLKX (transmit clock), CLKR (receive clock), FSX (transmit frame synchronization), and FSR (receive frame synchronization).

The CPU and the DMA controller communicate with the McBSP through 16-bit wide registers accessible via the internal peripheral bus. The CPU or the DMA controller writes the data to be transmitted to the data transmit registers (DXR1, DXR2). Data written to the DXRs is shifted out to the DX pin via the transmit shift registers (XSR1, XSR2). Similarly, receive data on the DR pin is shifted into the receive shift registers (RSR1, RSR2) and copied into the receive buffer registers (RBR1, RBR2). The contents of the receive buffer registers (RBRs) is then copied to the data receive registers (DRRs), which can be read by the CPU or the DMA controller. This allows simultaneous movement of internal and external data communications.

If the serial word length is 8 bits, 12 bits, or 16 bits, the DRR2, RBR2, RSR2, DXR2, and XSR2 registers are not used (written, read, or shifted) For larger word lengths, these registers are needed to hold the most significant bits.

The frame and clock loop-back is implemented at chip level to enable CLKX and FSX to drive CLKR and FSR. If the loop-back is enabled, the CLKR and FSR get their signals from the CLKX and FSX pads; instead of the CLKR and FSR pins.

20.1.1 MCBSP Related Collateral

Foundational Materials

- C2000 Academy - McBSP
- *KeyStone Architecture Multichannel Buffered Serial Port (McBSP)*

20.1.2 Features of the McBSPs

The McBSPs feature:

- Full-duplex communication
- Double-buffered transmission and triple-buffered reception, allowing a continuous data stream
- Independent clocking and framing for reception and transmission
- The capability to send interrupts to the CPU and to send DMA events to the DMA controller
- 128 channels for transmission and reception
- Multichannel selection modes that enable or disable block transfers in each of the channels
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices
- Support for external generation of clock signals and frame-synchronization signals
- A programmable sample rate generator for internal generation and control of clock signals and frame-synchronization signals
- Programmable polarity for frame-synchronization pulses and clock signals
- Direct interface to:
  - T1/E1 framers
  - IOM-2 compliant devices
  - AC97-compliant devices (the necessary multiphase frame capability is provided)
  - I2S compliant devices
  - SPI devices

- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits

Note

A value of the chosen data size is referred to as a *serial word* or *word* throughout the McBSP chapter. Elsewhere, *word* is used to describe a 16-bit value.

- μ-law and A-law companding
- The option of transmitting/receiving 8-bit data with the LSB first
- Status bits for flagging exception/error conditions
- ABIS mode is not supported

20.1.3 McBSP Pins/Signals

Table 20-1 describes the McBSP interface pins and some internal signals.

Table 20-1. McBSP Interface Pins/Signals

McBSP-A Pin	McBSP-B Pin	Type	Description
MCLKRA	MCLKRB	I/O	Supplies or reflects the receive clock; supplies the input clock of the sample rate generator
MCLKXA	MCLKXB	I/O	Supplies or reflects the transmit clock; supplies the input clock of the sample rate generator
MDRA	MDRB	I	Serial data receive pin
MDXA	MDXB	O	Serial data transmit pin
MFSRA	MFSRB	I/O	Supplies or reflects the receive frame-sync signal; controls sample rate generator synchronization when GSYNC = 1 (see Section 20.4.3)
MFSXA	MFSXB	I/O	Supplies or reflects the transmit frame-sync signal
CPU Interrupt Signals			
MRINT			Receive interrupt to CPU
MXINT			Transmit interrupt to CPU
DMA Events			
REVT			Receive synchronization event to DMA
XEVT			Transmit synchronization event to DMA

20.1.3.1 McBSP Generic Block Diagram

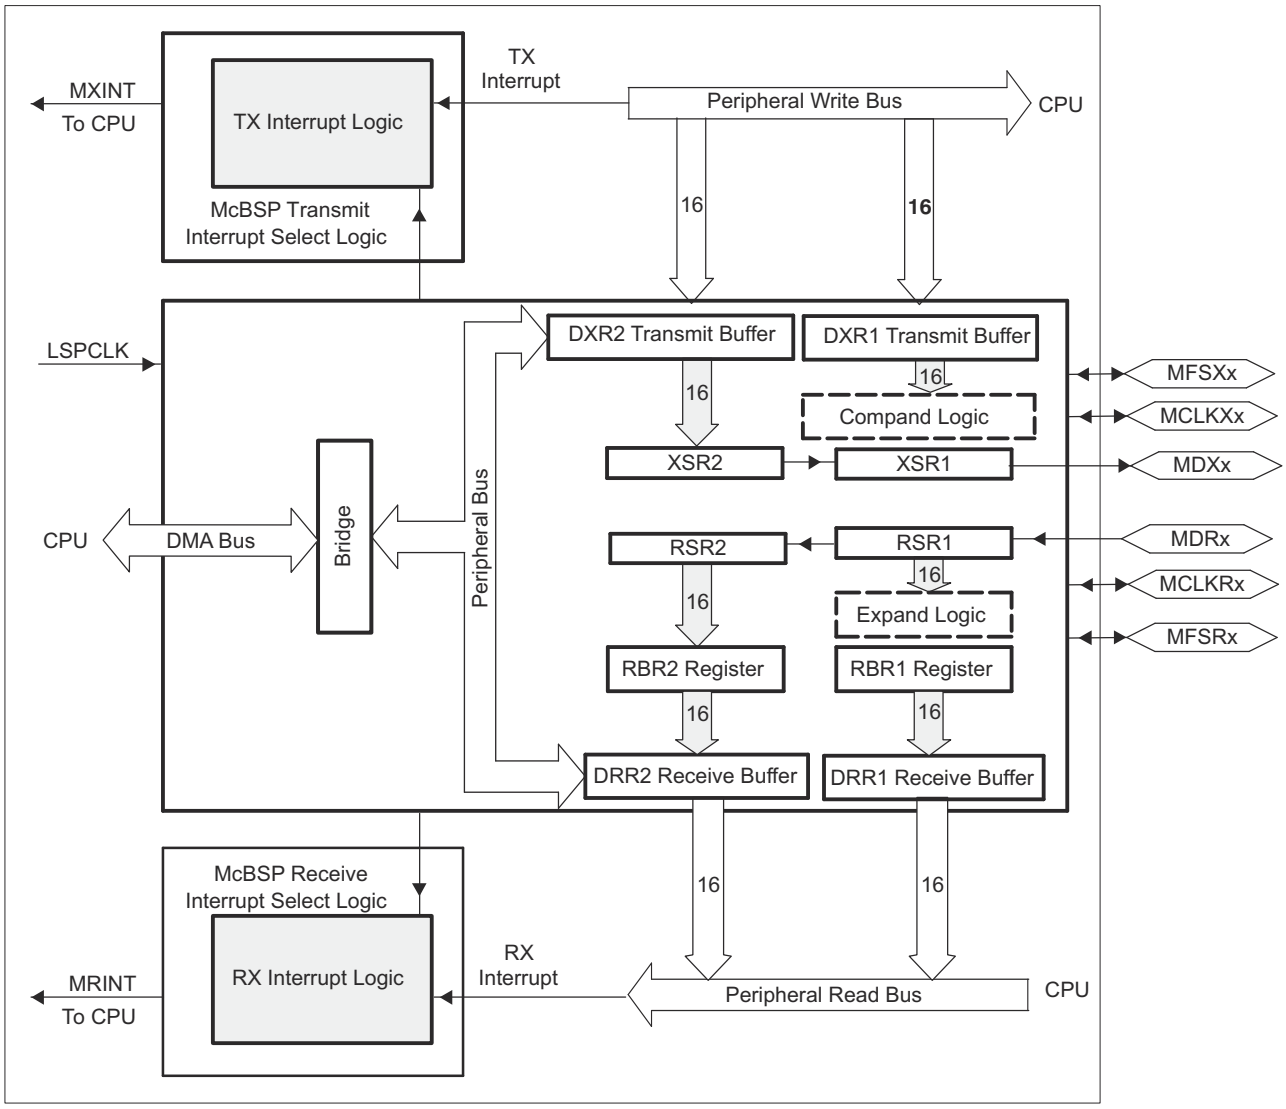
The McBSP consists of a data-flow path and a control path connected to external devices by six pins as shown in Figure 20-1. The figure and the text in this section use generic pin names.

20.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.



A. Not available in all devices. See the device-specific data sheet.

Figure 20-1. Conceptual Block Diagram of the McBSP

20.3 McBSP Operation

This section addresses the following topics:

- Data transfer process
- Companding (compressing and expanding) data
- Clocking and framing data
- Frame phases
- McBSP reception
- McBSP transmission
- Interrupts and DMA events generated by McBSPs

20.3.1 Data Transfer Process of McBSPs

Figure 20-2 shows a diagram of the McBSP data transfer paths. The McBSP receive operation is triple-buffered, and transmit operation is double-buffered. The use of registers varies, depending on whether the defined length of each serial word is 16 bits.

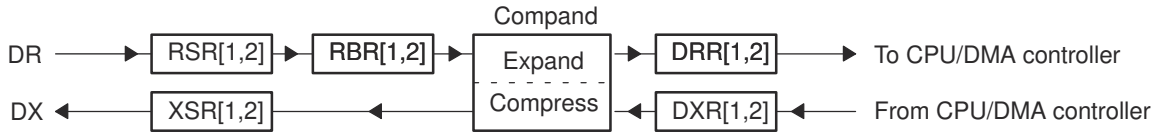


Figure 20-2. McBSP Data Transfer Paths

20.3.1.1 Data Transfer Process for Word Length of 8, 12, or 16 Bits

If the word length is 16 bits or smaller, only one 16-bit register is needed at each stage of the data transfer paths. The registers DRR2, RBR2, RSR2, DXR2, and XSR2 are not used (written, read, or shifted).

Receive data arrives on the DR pin and is shifted into receive shift register 1 (RSR1). Once a full word is received, the content of RSR1 is copied to the receive buffer register 1 (RBR1), that is, if RBR1 is not full with previous data. RBR1 is then copied to the data receive register 1 (DRR1), unless the previous content of DRR1 has not been read by the CPU or the DMA controller. If the companding feature of the McBSP is implemented, the required word length is 8 bits and receive data is expanded into the appropriate format before being passed from RBR1 to DRR1. For more details about reception, see Section 20.3.5.

Transmit data is written by the CPU or the DMA controller to the data transmit register 1 (DXR1). If there is no previous data in the transmit shift register (XSR1), the value in DXR1 is copied to XSR1; otherwise, DXR1 is copied to XSR1 when the last bit of the previous data is shifted out on the DX pin. If selected, the companding module compresses 16-bit data into the appropriate 8-bit format before passing it to XSR1. After transmit frame synchronization, the transmitter begins shifting bits from XSR1 to the DX pin. For more details about transmission, see Section 20.3.6.

20.3.1.2 Data Transfer Process for Word Length of 20, 24, or 32 Bits

If the word length is larger than 16 bits, two 16-bit registers are needed at each stage of the data transfer paths. The registers DRR2, RBR2, RSR2, DXR2, and XSR2 are needed to hold the most significant bits.

Receive data arrives on the DR pin and is shifted first into RSR2 and then into RSR1. Once the full word is received, the contents of RSR2 and RSR1 are copied to RBR2 and RBR1, respectively, if RBR1 is not full. Then the contents of RBR2 and RBR1 are copied to DRR2 and DRR1, respectively, unless the previous content of DRR1 has not been read by the CPU or the DMA controller. The CPU or the DMA controller must read data from DRR2 first and then from DRR1. When DRR1 is read, the next RBR-to-DRR copy occurs. For more details about reception, see Section 20.3.5.

For transmission, the CPU or the DMA controller must write data to DXR2 first and then to DXR1. When new data arrives in DXR1, if there is no previous data in XSR1, the contents of DXR2 and DXR1 are copied to XSR2 and XSR1, respectively; otherwise, the contents of the DXRs are copied to the XSRs when the last bit of the previous data is shifted out on the DX pin. After transmit frame synchronization, the transmitter begins shifting bits from the XSRs to the DX pin. For more details about transmission, see Section 20.3.6.

20.3.2 Companding (Compressing and Expanding) Data

Companding (COMpressing and exPANDing) hardware allows compression and expansion of data in either μ-law or A-law format. The companding standard employed in the United States and Japan is μ-law. The European companding standard is referred to as A-law. The specifications for μ-law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and μ-law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

The μ-law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 20-3 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or μ-law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to twos complement format.

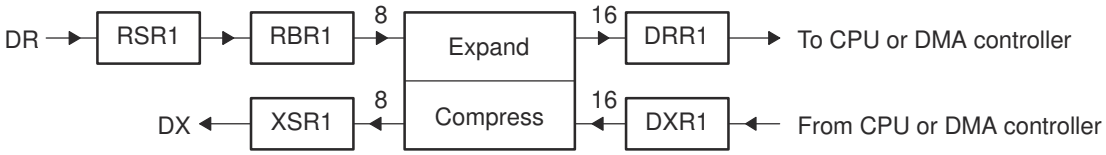

Figure 20-3. Companding Processes

20.3.2.1 Companding Formats

For reception, the 8-bit compressed data in RBR1 is expanded to left-justified 16-bit data in DRR1. The receive sign-extension and justification mode specified in RJUST is ignored when companding is used.

For transmission using μ-law compression, the 14 data bits must be left-justified in DXR1 with the remaining two low-order bits filled with 0s as shown in Figure 20-4.

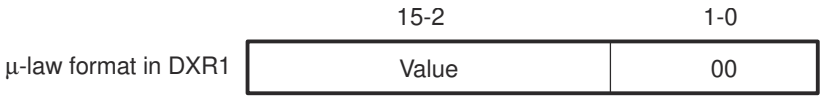

Figure 20-4. μ-Law Transmit Data Companding Format

For transmission using A-law compression, the 13 data bits must be left-justified in DXR1, with the remaining three low-order bits filled with 0s as shown in Figure 20-5.

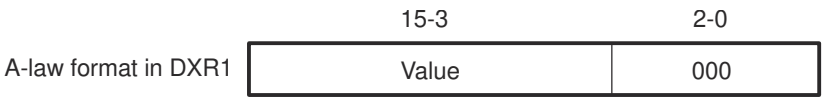

Figure 20-5. A-Law Transmit Data Companding Format

20.3.2.2 Capability to Compand Internal Data

If the McBSP is unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. This can be used to:

- Convert linear to the appropriate μ-law or A-law format
- Convert μ-law or A-law to the linear format
- Observe the quantization effects in companding by transmitting linear data and compressing and re-expanding this data. This is useful only if both XCOMPAND and RCOMPAND enable the same companding format.

Figure 20-6 shows two methods by which the McBSP can compand internal data. Data paths for these two methods are used to indicate:

- When both the transmit and receive sections of the serial port are reset, DRR1 and DXR1 are connected internally through the companding logic. Values from DXR1 are compressed, as selected by XCOMPAND, and then expanded, as selected by RCOMPAND. RRDY and XRDY bits are not set. However, data is available in DRR1 within four CPU clocks after being written to DXR1.

The advantage of this method is the speed. The disadvantage is that there is no synchronization available to the CPU and DMA to control the flow. DRR1 and DXR1 are internally connected if the (X/R)COMPAND bits are set to 10b or 11b (compand using μ-law or A-law).

- The McBSP is enabled in digital loopback mode with companding appropriately enabled by RCOMPAND and XCOMPAND. Receive and transmit interrupts (RINT when RINTM = 0 and XINT when XINTM = 0) or synchronization events (REVT and XEVT) allow synchronization of the CPU or DMA to these conversions, respectively. Here, the time for this companding depends on the serial bit rate selected.

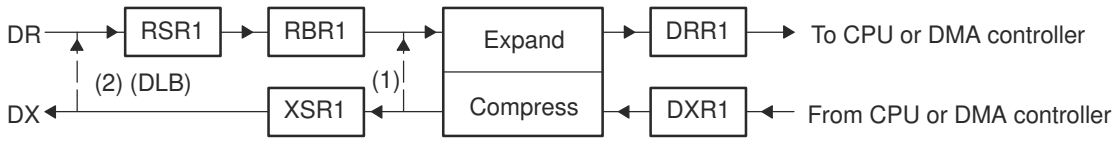

Figure 20-6. Two Methods by Which the McBSP Can Compand Internal Data

20.3.2.3 Reversing Bit Order: Option to Transfer LSB First

Generally, the McBSP transmits or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set XCOMPAND = 01b in XCR2, the bit ordering of 8-bit words is reversed (LSB first) before being sent from the serial port. If you set RCOMPAND = 01b in RCR2, the bit ordering of 8-bit words is reversed during reception. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits, and LSB-first ordering is done.

20.3.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

20.3.3.1 Clocking

Note

The McBSP cannot operate at a frequency faster than ½ the LSPCLK frequency. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX and/or CLKR, choose an appropriate input clock frequency and divide down value (CLKDV) (that is, be certain that CLKX or CLKR ≤ LSPCLK/2).

Data is shifted one bit at a time from the DR pin to the RSRs or from the XSRs to the DX pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR) controls bit transfers from the DR pin to the RSRs. The transmit clock signal (CLKX) controls bit transfers from the XSRs to the DX pin. CLKR or CLKX can be derived from a pin at the boundary of the McBSP or derived from inside the McBSP. The polarities of CLKR and CLKX are programmable.

Figure 20-7 shows how the clock signal controls the timing of each bit transfer on the pin.

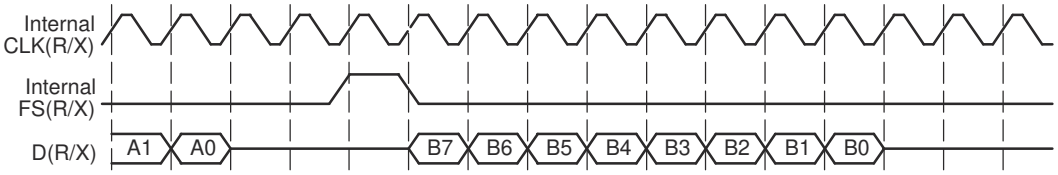

Figure 20-7. Example - Clock Signal Control of Bit Transfer Timing

20.3.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (DR or DX) are transferred in a group called a serial word. You can define how many bits are in a word.

Bits coming in on the DR pin are held in RSR until RSR holds a full serial word. Only then is the word passed to RBR (and ultimately to the DRR).

During transmission, XSR does not accept new data from DXR until a full serial word has been passed from XSR to the DX pin.

In the exmaple in Figure 20-7, an 8-bit word size was defined (see bits 7 through 0 of word B being transferred).

20.3.3.3 Frames and Frame Synchronization

One or more words are transferred in a group called a frame. You can define how many words are in a frame.

All of the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR) signal initiate frame transfers on the DR data pin. Pulses on the transmit frame-sync (FSX) signal initiate frame transfers on DX. FSR or FSX can be derived from a pin at the boundary of the McBSP or derived from inside the McBSP.

In Figure 20-7, a one-word frame is transferred when a frame-synchronization pulse occurs.

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

20.3.3.4 Generating Transmit and Receive Interrupts

The McBSP can send receive and transmit interrupts to the CPU to indicate specific events in the McBSP. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses. Set the appropriate interrupt mode bits to 10b (for reception, RINTM = 10b; for transmission, XINTM = 10b).

20.3.3.4.1 Detecting Frame-Synchronization Pulses, Even in Reset State

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating RINT when the receiver is in reset). In this case, FSRM/FSXM and FSRP/FSXP still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the CPU clock and then sent to the CPU in the form of RINT and XINT at the point at which they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and after this occurs the CPU can take the serial port out of reset safely.

20.3.3.5 Ignoring Frame-Synchronization Pulses

The McBSP can be configured to ignore transmit and/or receive frame-synchronization pulses. To have the receiver or transmitter recognize frame-synchronization pulses, clear the appropriate frame-synchronization ignore bit (RFIG = 0 for the receiver, XFIG = 0 for the transmitter). To have the receiver or transmitter ignore frame-synchronization pulses until the desired frame length or number of words is reached, set the appropriate frame-synchronization ignore bit (RFIG = 1 for the receiver, XFIG = 1 for the transmitter). For more details on unexpected frame-synchronization pulses, see one of the following topics:

- *Unexpected Receive Frame-Synchronization Pulse* (see Section 20.5.3)
- *Unexpected Transmit Frame-Synchronization Pulse* (see Section 20.5.6)

You can also use the frame-synchronization ignore function for data packing (for more details, see Section 20.11.2).

20.3.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined by the equation:

$$\text{Frame Frequency} = \frac{\text{Clock Frequency}}{\text{Number of Clock Cycles Between Frame- Sync Pulses}}$$

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

20.3.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined by the equation:

$$\text{Maximum Frame Frequency} = \frac{\text{Clock Frequency}}{\text{Number of Bits Per Frame}}$$

Figure 20-8 shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

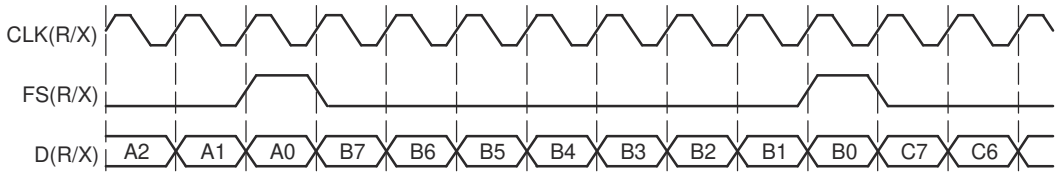

Figure 20-8. McBSP Operating at Maximum Packet Frequency

If there is a 1-bit data delay as shown in Figure 20-8, the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, making frame-synchronization pulses redundant. Theoretically, only an initial frame-synchronization pulse is required to initiate a multipacket transfer.

The McBSP supports operation of the serial port in this fashion by ignoring the successive frame-synchronization pulses. Data is clocked into the receiver or clocked out of the transmitter during every clock cycle.

Note

For XDATDLY = 0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX). For more details, see Section 20.9.13.

20.3.4 Frame Phases

The McBSP allows you to configure each frame to contain one or two phases. The number of words and the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, you might define a frame as consisting of one phase containing two words of 16 bits each, followed by a second phase consisting of 10 words of 8 bits each. This configuration permits you to compose frames for custom applications or, in general, to maximize the efficiency of data transfers.

20.3.4.1 Number of Phases, Words, and Bits Per Frame

Table 20-2 shows which bit-fields in the receive control registers (RCR1 and RCR2) and in the transmit control registers (XCR1 and XCR2) determine the number of phases per frame, the number of words per frame, and number of bits per word for each phase, for the receiver and transmitter. The maximum number of words per frame is 128 for a single-phase frame and 256 for a dual-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

Table 20-2. Register Bits That Determine the Number of Phases, Words, and Bits

Operation	Number of Phases	Words per Frame Set With	Bits per Word Set With
Reception	1 (RPHASE = 0)	RFRLEN1	RWDLEN1
Reception	2 (RPHASE = 1)	RFRLEN1 and RFRLEN2	RWDLEN1 for phase 1
			RWDLEN2 for phase 2
Transmission	1 (XPHASE = 0)	XFRLEN1	XWDLEN1
Transmission	2 (XPHASE = 1)	XFRLEN1 and XFRLEN2	XWDLEN1 for phase 1
			XWDLEN2 for phase 2

20.3.4.2 Single-Phase Frame Example

Figure 20-9 shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the DX and DR pins are available one clock cycle after FS(R/X) goes active. The figure makes the following assumptions:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0b: 1 word per frame
- (R/X)WDLEN1 = 000b: 8-bit word length
- (R/X)FRLEN2 and (R/X)WDLEN2 are ignored
- CLK(X/R)P = 0: Receive data clocked on falling edge; transmit data clocked on rising edge
- FS(R/X)P = 0: Active-high frame-synchronization signals
- (R/X)DATDLY = 01b: 1-bit data delay

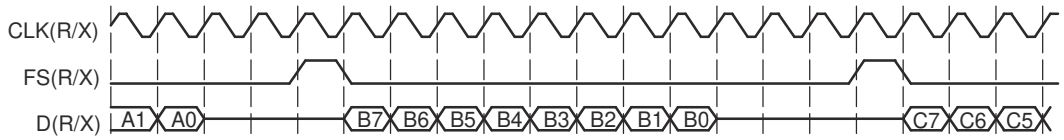

Figure 20-9. Single-Phase Frame for a McBSP Data Transfer

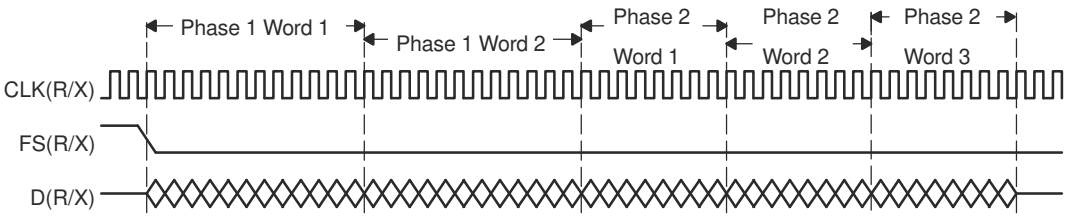
20.3.4.3 Dual-Phase Frame Example

Figure 20-10 shows an example of a frame where the first phase consists of two words of 12 bits each, followed by a second phase of three words of 8 bits each. The entire bit stream in the frame is contiguous. There are no gaps either between words or between phases.



A. XRDY gets asserted once per phase. So, if there are 2 phases, XRDY gets asserted twice (once per phase).

Figure 20-10. Dual-Phase Frame for a McBSP Data Transfer

20.3.4.4 Implementing the AC97 Standard With a Dual-Phase Frame

Figure 20-11 shows an example of the Audio Codec '97 (AC97) standard, which uses the dual-phase frame feature. Notice that words, not individual bits, are shown on the D(R/X) signal. The first phase (P1) consists of a single 16-bit word. The second phase (P2) consists of twelve 20-bit words. The phase configurations are listed after the figure.

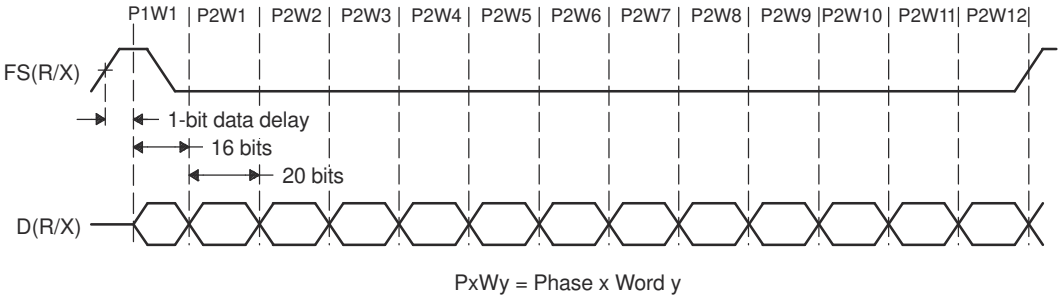


Figure 20-11. Implementing the AC97 Standard With a Dual-Phase Frame

- (R/X)PHASE = 1: Dual-phase frame
- (R/X)FRLEN1 = 0000000b: 1 word in phase 1
- (R/X)WDLEN1 = 010b: 16 bits per word in phase 1
- (R/X)FRLEN2 = 0001011b: 12 words in phase 2
- (R/X)WDLEN2 = 011b: 20 bits per word in phase 2
- CLKRP/CLKXP= 0: Receive data sampled on falling edge of internal CLKR / transmit data clocked on rising edge of internal CLKX
- FSRP/FSXP = 0: Active-high frame-sync signal
- (R/X)DATDLY = 01b: Data delay of 1 clock cycle (1-bit data delay)

Figure 20-12 shows the timing of an AC97-standard data transfer near frame synchronization. In this figure, individual bits are shown on D(R/X). Specifically, it shows the last two bits of phase 2 of one frame and the first four bits of phase 1 of the next frame. Regardless of the data delay, data transfers can occur without gaps. The first bit of the second frame (P1W1B15) immediately follows the last bit of the first frame (P2W12B0). Because a 1-bit data delay has been chosen, the transition on the frame-sync signal can occur when P2W12B0 is transferred.

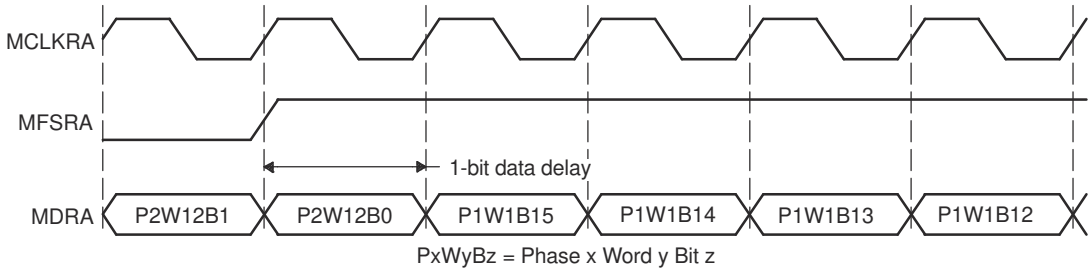

Figure 20-12. Timing of an AC97-Standard Data Transfer Near Frame Synchronization

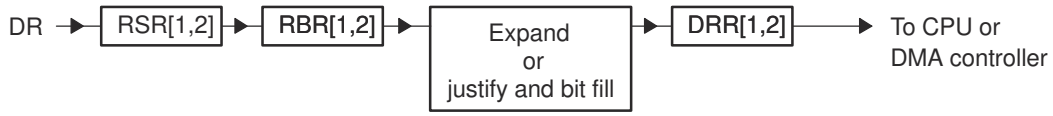
20.3.5 McBSP Reception

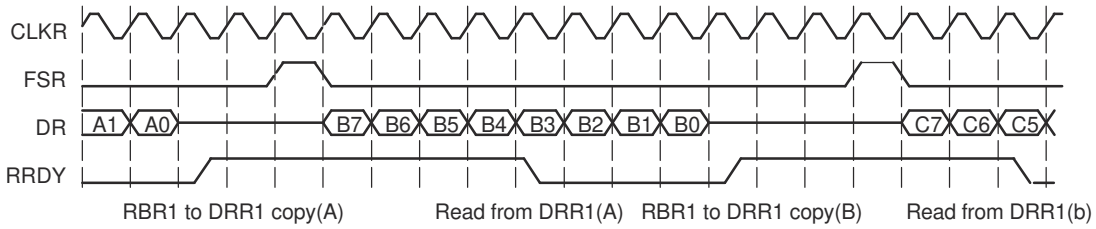
This section explains the fundamental process of reception in the McBSP. For details about how to program the McBSP receiver, see Section 20.8.

Figure 20-13 and Figure 20-14 show how reception occurs in the McBSP. Figure 20-13 shows the physical path for the data. Figure 20-14 is a timing diagram showing signal activity for one possible reception scenario. A description of the process follows the figures.



A. RSR[1,2]: Receive shift registers 1 and 2
B. RBR[1,2]: Receive buffer registers 1 and 2
C. DRR[1,2]: Data receive registers 1 and 2

Figure 20-13. McBSP Reception Physical Data Path



A. CLKR: Internal receive clock
B. FSR: Internal receive frame-synchronization signal
C. DR: Data on DR pin
D. RRDY: Status of receiver ready bit (high is 1)

Figure 20-14. McBSP Reception Signal Activity

The following process describes how data travels from the DR pin to the CPU or to the DMA controller:

1. The McBSP waits for a receive frame-synchronization pulse on internal FSR.
2. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the RDATDLY bits of RCR2.
   In the preceding timing diagram, a 1-bit data delay is selected.
3. The McBSP accepts data bits on the DR pin and shifts them into the receive shift registers.
   If the word length is 16 bits or smaller, only RSR1 is used. If the word length is larger than 16 bits, RSR2 and RSR1 are used and RSR2 contains the most-significant bits. For details on choosing a word length, see Section 20.8.8.
4. When a full word is received, the McBSP copies the contents of the receive shift registers to the receive buffer registers, provided that RBR1 is not full with previous data.
   If the word length is 16 bits or smaller, only RBR1 is used. If the word length is larger than 16 bits, RBR2 and RBR1 are used and RBR2 contains the most-significant bits.
5. The McBSP copies the contents of the receive buffer registers into the data receive registers, provided that DRR1 is not full with previous data. When DRR1 receives new data, the receiver ready bit (RRDY) is set in SPCR1. This indicates that received data is ready to be read by the CPU or the DMA controller.
   If the word length is 16 bits or smaller, only DRR1 is used. If the word length is larger than 16 bits, DRR2 and DRR1 are used and DRR2 contains the most-significant bits.
   If companding is used during the copy (RCOMPAND = 10b or 11b in RCR2), the 8-bit compressed data in RBR1 is expanded to a left-justified 16-bit value in DRR1. If companding is disabled, the data copied from RBR[1,2] to DRR[1,2] is justified and bit filled according to the RJUST bits.

6. The CPU or the DMA controller reads the data from the data receive registers. When DRR1 is read, RRDY is cleared and the next RBR-to-DRR copy is initiated.

Note

If both DRRs are required (word length larger than 16 bits), the CPU or the DMA controller must read from DRR2 first and then from DRR1. As soon as DRR1 is read, the next RBR-to-DRR copy is initiated. If DRR2 is not read first, the data in DRR2 is lost.

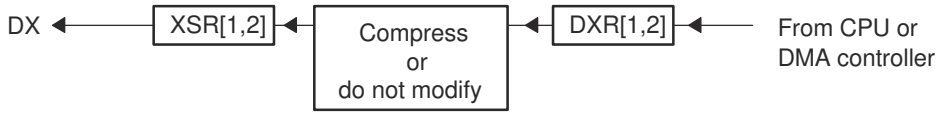
When activity is not properly timed, errors can occur. See the following topics for more details:

- Section 20.5.2
- Section 20.5.3

20.3.6 McBSP Transmission

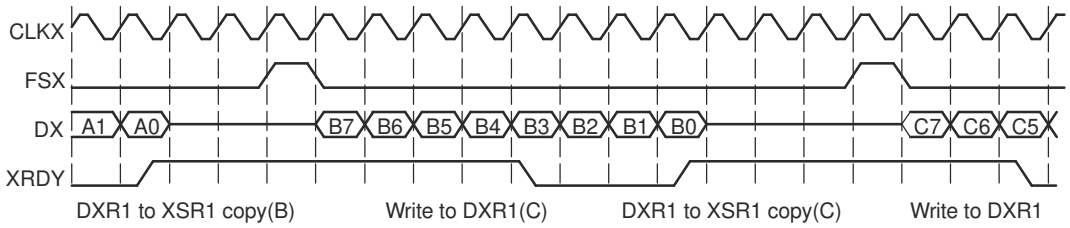
This section explains the fundamental process of transmission in the McBSP. For details about how to program the McBSP transmitter, see Section 20.9.

Figure 20-15 and Figure 20-16 show how transmission occurs in the McBSP. Figure 20-15 shows the physical path for the data. Figure 20-16 is a timing diagram showing signal activity for one possible transmission scenario. A description of the process follows the figures.



A. XSR[1,2]: Transmit shift registers 1 and 2
B. DXR[1,2]: Data transmit registers 1 and 2

Figure 20-15. McBSP Transmission Physical Data Path



A. CLKX: Internal transmit clock
B. FSX: Internal transmit frame-synchronization signal
C. DX: Data on DX pin
D. XRDY: Status of transmitter ready bit (high is 1)

Figure 20-16. McBSP Transmission Signal Activity

1. The CPU or the DMA controller writes data to the data transmit registers. When DXR1 is loaded, the transmitter ready bit (XRDY) is cleared in SPCR2 to indicate that the transmitter is not ready for new data. If the word length is 16 bits or smaller, only DXR1 is used. If the word length is larger than 16 bits, DXR2 and DXR1 are used and DXR2 contains the most-significant bits. For details on choosing a word length, see Section 20.9.9.

Note

If both DXRs are needed (word length larger than 16 bits), the CPU or the DMA controller must load DXR2 first and then load DXR1. As soon as DXR1 is loaded, the contents of both DXRs are copied to the transmit shift registers (XSRs), as described in the next step. If DXR2 is not loaded first, the previous content of DXR2 is passed to the XSR2.

2. When new data arrives in DXR1, the McBSP copies the content of the data transmit registers to the transmit shift registers. In addition, the transmit ready bit (XRDY) is set. This indicates that the transmitter is ready to accept new data from the CPU or the DMA controller.
   If the word length is 16 bits or smaller, only XSR1 is used. If the word length is larger than 16 bits, XSR2 and XSR1 are used and XSR2 contains the most-significant bits.
   If companding is used during the transfer (XCOMPAND = 10b or 11b in XCR2), the McBSP compresses the 16-bit data in DXR1 to 8-bit data in the μ-law or A-law format in XSR1. If companding is disabled, the McBSP passes data from the DXRs to the XSRs without modification.
3. The McBSP waits for a transmit frame-synchronization pulse on internal FSX.
4. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the XDATDLY bits of XCR2.
   In the preceding timing diagram (Figure 20-16), a 1-bit data delay is selected.
5. The McBSP shifts data bits from the transmit shift registers to the DX pin.

When activity is not properly timed, errors can occur. See the following topics for more details:

- Section 20.5.4
- Section 20.5.5
- Section 20.5.6

20.3.7 Interrupts and DMA Events Generated by a McBSP

The McBSP sends notification of important events to the CPU and DMA via the internal signals shown in Table 20-3.

Table 20-3. Interrupts and DMA Events Generated by a McBSP

Internal Signal	Description
RINT	Receive interrupt The McBSP sends a receive interrupt request to the CPU based upon a selected condition in the receiver of the McBSP (a condition selected by the RINTM bits of SPCR1).
XINT	Transmit interrupt The McBSP sends a transmit interrupt request to the CPU based upon a selected condition in the transmitter of the McBSP (a condition selected by the XINTM bits of SPCR2).
REVT	Receive synchronization event An REVT signal is sent to the DMA when data has been received in the data receive registers (DRRs).
XEVT	Transmit synchronization event An XEVT signal is sent to the DMA when the data transmit registers (DXRs) are ready to accept the next serial word for transmission.

20.4 McBSP Sample Rate Generator

Each McBSP contains a sample rate generator (SRG) that can be programmed to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive (DR) pin and/or the data transmit (DX) pin. FSG can be used to initiate frame transfers on DR and/or DX. Figure 20-17 is a conceptual block diagram of the sample rate generator.

20.4.1 Block Diagram

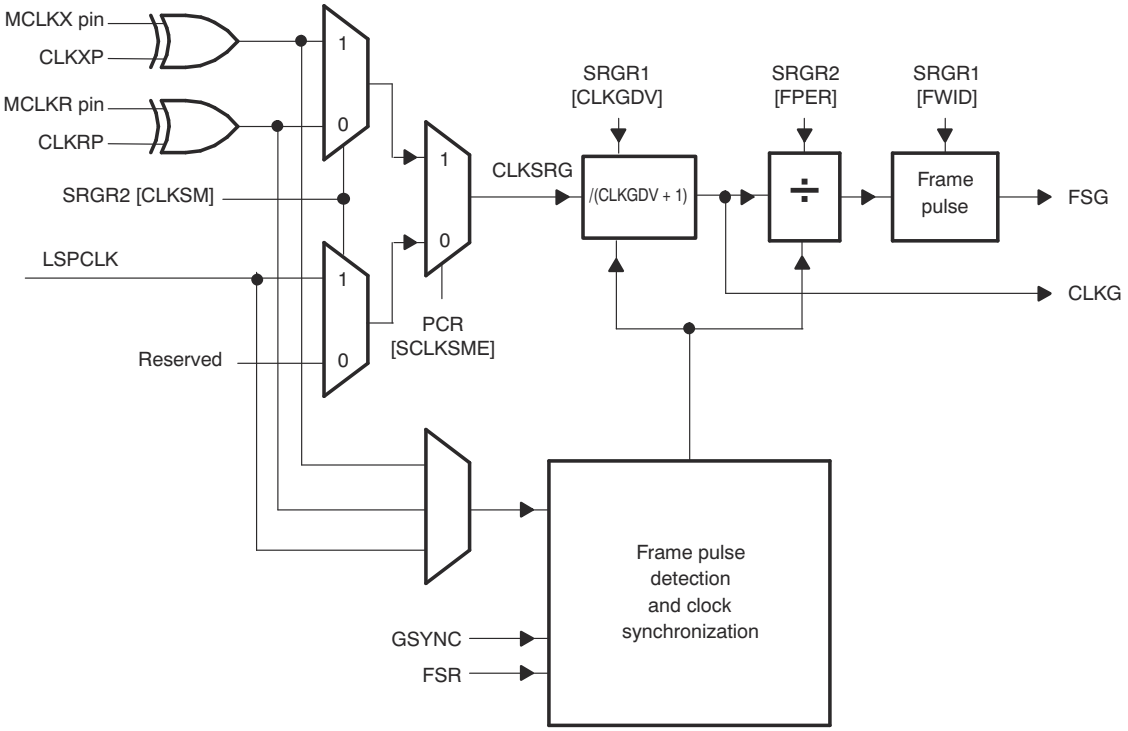


Figure 20-17. Conceptual Block Diagram of the Sample Rate Generator

The source clock for the sample rate generator (labeled CLKSRG in the diagram) can be supplied by the LSPCLK, or by an external pin (MCLKX or MCLKR). The source is selected with the SCLKME bit of PCR and the CLKSM bit of SRGR2. If a pin is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (CLKXP of PCR or CLKRP of PCR).

The sample rate generator has a three-stage clock divider that gives CLKG and FSG programmability. The three stages provide:

- Clock divide-down. The source clock is divided according to the CLKGDV bits of SRGR1 to produce CLKG.
- Frame period divide-down. CLKG is divided according to the FPER bits of SRGR2 to control the period from the start of a frame-pulse to the start of the next pulse.
- Frame-synchronization pulse-width countdown. CLKG cycles are counted according to the FWID bits of SRGR1 to control the width of each frame-synchronization pulse.

Note

The McBSP cannot operate at a frequency faster than ½ the source clock frequency. You must choose an input clock frequency and a CLKGDV value such that CLKG is less than or equal to ½ the source clock frequency.

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the FSR pin. This feature is enabled or disabled with the GSYNC bit of SRGR2.

For details on getting the sample rate generator ready for operation, see Section 20.4.4.

20.4.1.1 Clock Generation in the Sample Rate Generator

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the sample rate generator to drive clocking is controlled by the clock mode bits (CLKRM and CLKXM) in the pin control register (PCR). When a clock mode bit is set to 1 (CLKRM = 1 for reception, CLKXM = 1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal sample rate generator output clock (CLKG).

The effects of CLKRM = 1 and CLKXM = 1 on the McBSP are partially affected by the use of the digital loopback mode and the clock stop (SPI) mode, respectively, as described in Table 20-4. The digital loopback mode (described in Section 20.8.4) is selected with the DLB bit of SPCR1. The clock stop mode (described in Section 20.7.2) is selected with the CLKSTP bits of SPCR1.

When using the sample rate generator as a clock source, make sure the sample rate generator is enabled (GRST = 1).

Table 20-4. Effects of DLB and CLKSTP on Clock Modes

Mode Bit Settings		Effect
CLKRM = 1	DLB = 0 (Digital loopback mode disabled)	CLKR is an output pin driven by the sample rate generator output clock (CLKG).
	DLB = 1 (Digital loopback mode enabled)	CLKR is an output pin driven by internal CLKX. The source for CLKX depends on the CLKXM bit.
CLKXM = 1	CLKSTP = 00b or 01b (Clock stop (SPI) mode disabled)	CLKX is an output pin driven by the sample rate generator output clock (CLKG).
	CLKSTP = 10b or 11b (Clock stop (SPI) mode enabled)	The McBSP is a master in an SPI system. Internal CLKX drives internal CLKR and the shift clocks of any SPI-compliant slave devices in the system. CLKX is driven by the internal sample rate generator.

20.4.1.2 Choosing an Input Clock

The sample rate generator must be driven by an input clock signal from one of the three sources selectable with the SCLKME bit of PCR and the CLKSM bit of SRGR2 (see Table 20-5). When CLKSM = 1, the minimum divide down value in CLKGDV bits is 1. CLKGDV is described in Section 20.4.1.4.

Table 20-5. Choosing an Input Clock for the Sample Rate Generator with the SCLKME and CLKSM Bits

SCLKME	CLKSM	Input Clock for Sample Rate Generator
0	0	Reserved
0	1	LSPCLK
1	0	Signal on MCLKR pin
1	1	Signal on MCLKX pin

20.4.1.3 Choosing a Polarity for the Input Clock

As shown in Figure 20-18, when the input clock is received from a pin, you can choose the polarity of the input clock. The rising edge of CLKSRG generates CLKG and FSG, but you can determine which edge of the input clock causes a rising edge on CLKSRG. The polarity options and their effects are described in Table 20-6.

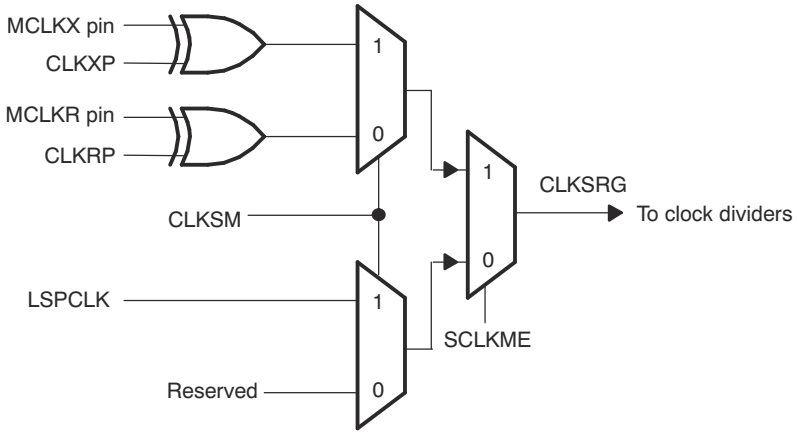

Figure 20-18. Possible Inputs to the Sample Rate Generator and the Polarity Bits

Table 20-6. Polarity Options for the Input to the Sample Rate Generator

Input Clock	Polarity Option	Effect
LSPCLK	Always positive polarity	Rising edge of CPU clock generates transitions on CLKG and FSG.
Signal on MCLKR pin	CLKRP = 0 in PCR	Falling edge on MCLKR pin generates transitions on CLKG and FSG.
	CLKRP = 1 in PCR	Rising edge on MCLKR pin generates transitions on CLKG and FSG.
Signal on MCLKX pin	CLKXP = 0 in PCR	Rising edge on MCLKX pin generates transitions on CLKG and FSG.
	CLKXP = 1 in PCR	Falling edge on MCLKX pin generates transitions on CLKG and FSG.

20.4.1.4 Choosing a Frequency for the Output Clock (CLKG)

The input clock (LSPCLK or external clock) can be divided down by a programmable value to drive CLKG. Regardless of the source to the sample rate generator, the rising edge of CLKSRG (see Section 20.4.1.2) generates CLKG and FSG.

The first divider stage of the sample rate generator creates the output clock from the input clock. This divider stage uses a counter that is preloaded with the divide down value in the CLKGDV bits of SRGR1. The output of this stage is the data clock (CLKG). CLKG has the frequency represented by the following equation:

$$\text{CLKG frequency} = \frac{\text{Input clock frequency}}{(\text{CLKGDV} + 1)}$$

20.4.1.4.1 CLKG Frequency

Thus, the input clock frequency is divided by a value between 1 and 256. When CLKGDV is odd or equal to 0, the CLKG duty cycle is 50%. When CLKGDV is an even value, 2p, representing an odd divide down, the high-state duration is p+1 cycles and the low-state duration is p cycles.

20.4.1.5 Keeping CLKG Synchronized to External MCLKR

When the MCLKR pin is used to drive the sample rate generator (see Section 20.4.1.2), the GSYNC bit in SRGR2 and the FSR pin can be used to configure the timing of the output clock (CLKG) relative to the input clock. Note that this feature is available only when the MCLKR pin is used to feed the external clock.

GSYNC = 1 ensures that the McBSP and an external device are dividing down the input clock with the same phase relationship. If GSYNC = 1, an inactive-to-active transition on the FSR pin triggers a resynchronization of CLKG and generation of FSG.

For more details about synchronization, see Section 20.4.3.

20.4.2 Frame Synchronization Generation in the Sample Rate Generator

The sample rate generator can produce a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure FSRM = 1. (When FSRM = 0, receive frame synchronization is supplied via the FSR pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- FSXM = 1 in PCR: This indicates that transmit frame synchronization is supplied by the McBSP itself rather than from the FSX pin.
- FSGM = 1 in SRGR2: This indicates that when FSXM = 1, transmit frame synchronization is supplied by the sample rate generator. (When FSGM = 0 and FSXM = 1, the transmitter uses frame-synchronization pulses generated every time data is transferred from DXR[1,2] to XSR[1,2].)

In either case, the sample rate generator must be enabled (GRST = 1) and the frame-synchronization logic in the sample rate generator must be enabled (FRST = 1).

20.4.2.1 Choosing the Width of the Frame-Synchronization Pulse on FSG

Each pulse on FSG has a programmable width. You program the FWID bits of SRGR1, and the resulting pulse width is (FWID + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

20.4.2.2 Controlling the Period Between the Starting Edges of Frame-Synchronization Pulses on FSG

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the sample rate generator:

- If the sample rate generator is using an external input clock and GSYNC = 1 in SRGR2, FSG pulses in response to an inactive-to-active transition on the FSR pin. Thus, the frame-synchronization period is controlled by an external device.
- Otherwise, you program the FPER bits of SRGR2, and the resulting frame-synchronization period is (FPER + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

20.4.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the sample rate generator (see Section 20.4.1.2) , the GSYNC bit of SRGR2 and the FSR pin can be used to configure the timing of FSG pulses.

GSYNC = 1 ensures that the McBSP and an external device are dividing down the input clock with the same phase relationship. If GSYNC = 1, an inactive-to-active transition on the FSR pin triggers a resynchronization of CLKG and generation of FSG.

See Section 20.4.3 for more details about synchronization.

20.4.3 Synchronizing Sample Rate Generator Outputs to an External Clock

The sample rate generator can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) based on an input clock signal that is either the CPU clock signal or a signal at the MCLKR or MCLKX pin. When an external clock is selected to drive the sample rate generator, the GSYNC bit of SRGR2 and the FSR pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock.

Make GSYNC = 1 when you want the McBSP and an external device to divide down the input clock with the same phase relationship. If GSYNC = 1:

- An inactive-to-active transition on the FSR pin triggers a resynchronization of CLKG and a pulsing of FSG.
- CLKG always begins with a high state after synchronization.
- FSR is always detected at the same edge of the input clock signal that generates CLKG, no matter how long the FSR pulse is.
- The FPER bits of SRGR2 are ignored because the frame-synchronization period on FSG is determined by the arrival of the next frame-synchronization pulse on the FSR pin.

If GSYNC = 0, CLKG runs freely and is not resynchronized, and the frame-synchronization period on FSG is determined by FPER.

20.4.3.1 Operating the Transmitter Synchronously with the Receiver

When GSYNC = 1, the transmitter can operate synchronously with the receiver, provided that:

- FSX is programmed to be driven by FSG (FSGM = 1 in SRGR2 and FSXM = 1 in PCR). If the input FSR has appropriate timing so that it can be sampled by the falling edge of CLKG, it can be used, instead, by setting FSXM = 0 and connecting FSR to FSX externally.
- The sample rate generator clock drives the transmit and receive clocking (CLKRM = CLKXM = 1 in PCR).

20.4.3.2 Synchronization Examples

Figure 20-19 and Figure 20-20 show the clock and frame-synchronization operation with various polarities of CLKR and FSR. These figures assume FWID = 0 in SRGR1, for an FSG pulse that is one CLKG cycle wide. The FPER bits of SRGR2 are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the FSR pin. Each of the figures shows what happens to CLKG when it is initially synchronized and GSYNC = 1, and when it is not initially synchronized and GSYNC = 1. Figure 20-20 has a slower CLKG frequency (it has a larger divide-down value in the CLKGDV bits of SRGR1).

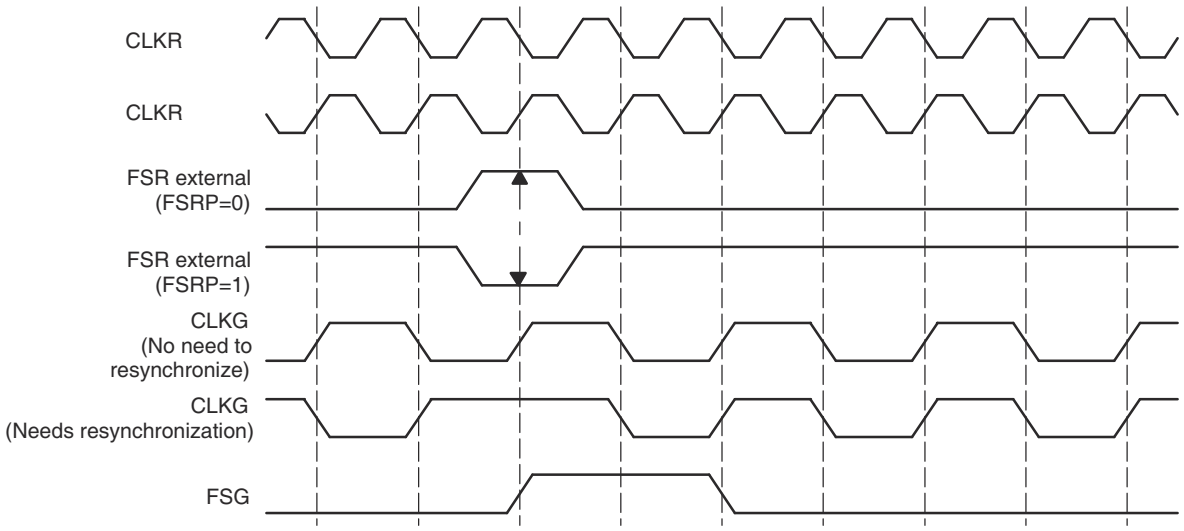

Figure 20-19. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 1

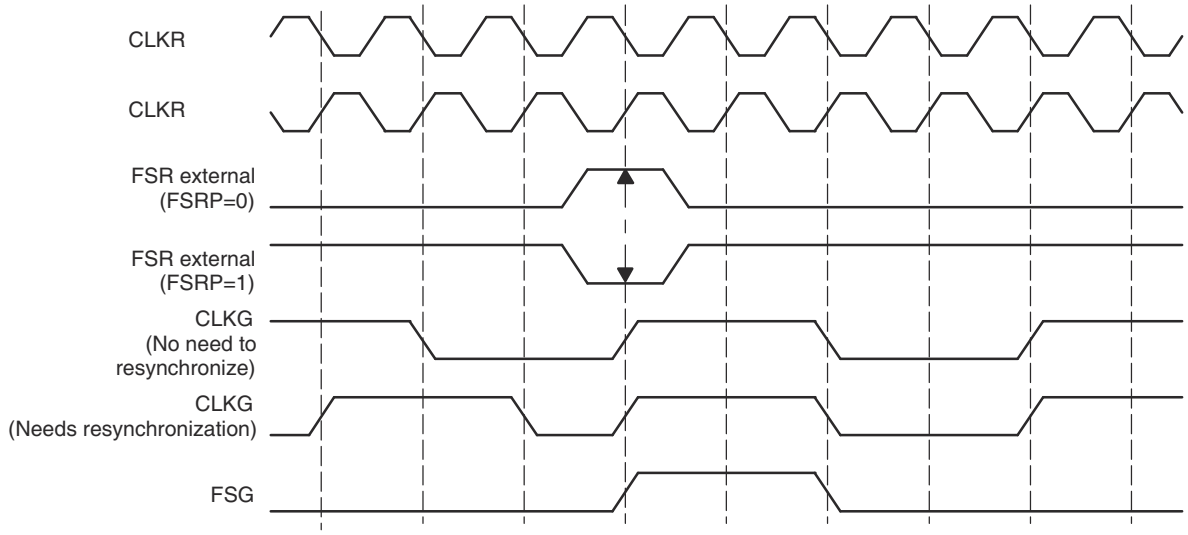

Figure 20-20. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 3

20.4.4 Reset and Initialization Procedure for the Sample Rate Generator

To reset and initialize the sample rate generator:

1. Place the McBSP/sample rate generator in reset.

   During a DSP reset, the sample rate generator, the receiver, and the transmitter reset bits (GRST, RRST, and XRST) are automatically forced to 0. Otherwise, during normal operation, the sample rate generator can be reset by setting GRST = 0 in SPCR2, provided that CLKG and/or FSG is not used by any portion of the McBSP. Depending on your system, you can reset the receiver (RRST = 0 in SPCR1) and reset the transmitter (XRST = 0 in SPCR2).

   If GRST = 0 due to a device reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven inactive-low. If GRST = 0 due to program code, CLKG and FSG are driven low (inactive).
2. Program the registers that affect the sample rate generator.

   Program the sample rate generator registers (SRGR1 and SRGR2) as required for your application. If necessary, other control registers can be loaded with desired values, provided the respective portion of the McBSP (the receiver or transmitter) is in reset.

   After the sample rate generator registers are programmed, wait 2 CLKSRG cycles. This makes sure of proper synchronization internally.
3. Enable the sample rate generator (take the sample rate generator out of reset).

   In SPCR2, make GRST = 1 to enable the sample rate generator.

   After the sample rate generator is enabled, wait two CLKG cycles for the sample rate generator logic to stabilize.

   On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to the following CLKG frequency equation:

$$\text{CLKG frequency} = \frac{\text{Input clock frequency}}{(\text{CLKGDV} + 1)}$$

   where the input clock is selected with the SCLKME bit of PCR and the CLKSM bit of SRGR2 in one of the configurations shown in Table 20-7.

Table 20-7. Input Clock Selection for Sample Rate Generator

SCLKME	CLKSM	Input Clock for Sample Rate Generator
0	0	Reserved
0	1	LSPCLK
1	0	Signal on MCLKR pin
1	1	Signal on MCLKX pin

4. If necessary, enable the receiver and/or the transmitter.

   If necessary, remove the receiver and/or transmitter from reset by setting RRST and/or XRST = 1.
5. If necessary, enable the frame-synchronization logic of the sample rate generator.

After the required data acquisition setup is done (DXR[1,2] is loaded with data), set GRST = 1 in SPCR2 if an internally generated frame-synchronization pulse is required. FSG is generated with an active-high edge after the programmed number of CLKG clocks (FPER + 1) have elapsed.

20.5 McBSP Exception/Error Conditions

This section describes exception/error conditions and how to handle them.

20.5.1 Types of Errors

There are five serial port events that can constitute a system error:

- Receiver overrun (RFULL = 1)

  This error occurs when DRR1 has not been read since the last RBR-to-DRR copy. Consequently, the receiver does not copy a new word from the RBRs to the DRRs and the RSRs are now full with another new word shifted in from DR. Therefore, RFULL = 1 indicates an error condition wherein any new data that can arrive at this time on DR replaces the contents of the RSRs, and the previous word is lost. The RSRs continue to be overwritten as long as new data arrives on DR and DRR1 is not read. For more details about overrun in the receiver, see Section 20.5.2.
- Unexpected receive frame-synchronization pulse (RSYNCERR = 1)

  This error occurs during reception when RFIG = 0 and an unexpected frame-synchronization pulse occurs. An unexpected frame-synchronization pulse is one that begins the next frame transfer before all the bits of the current frame have been received. Such a pulse causes data reception to abort and restart. If new data has been copied into the RBRs from the RSRs since the last RBR-to-DRR copy, this new data in the RBRs is lost. This is because no RBR-to-DRR copy occurs; the reception has been restarted. For more details about receive frame-synchronization errors, see Section 20.5.3.
- Transmitter data overwrite

  This error occurs when the CPU or DMA controller overwrites data in the DXRs before the data is copied to the XSRs. The overwritten data never reaches the DX pin. For more details about overwrite in the transmitter, see Section 20.5.4.
- Transmitter underflow ($\overline{\text{XEMPTY}}$ = 0)

  If a new frame-synchronization signal arrives before new data is loaded into DXR1, the previous data in the DXRs is sent again. This procedure continues for every new frame-synchronization pulse that arrives until DXR1 is loaded with new data. For more details about underflow in the transmitter, see Section 20.5.5.
- Unexpected transmit frame-synchronization pulse (XSYNCERR = 1)

  This error occurs during transmission when XFIG = 0 and an unexpected frame-synchronization pulse occurs. An unexpected frame-synchronization pulse is one that begins the next frame transfer before all the bits of the current frame have been transferred. Such a pulse causes the current data transmission to abort and restart. If new data has been written to the DXRs since the last DXR-to-XSR copy, the current value in the XSRs is lost. For more details about transmit frame-synchronization errors, see Section 20.5.6.

20.5.2 Overrun in the Receiver

RFULL = 1 in SPCR1 indicates that the receiver has experienced overrun and is in an error condition. RFULL is set when all of the following conditions are met:

1. DRR1 has not been read since the last RBR-to-DRR copy (RRDY = 1).
2. RBR1 is full and an RBR-to-DRR copy has not occurred.
3. RSR1 is full and an RSR1-to-RBR copy has not occurred.

As described in Section 20.3.5, data arriving on DR is continuously shifted into RSR1 (for word length of 16 bits or smaller) or RSR2 and RSR1 (for word length larger than 16 bits). Once a complete word is shifted into the RSR(s), an RSR-to-RBR copy can occur only if the previous data in RBR1 has been copied to DRR1. The RRDY bit is set when new data arrives in DRR1 and is cleared when that data is read from DRR1. Until RRDY = 0, the next RBR-to-DRR copy does not take place, and the data is held in the RSR(s). New data arriving on the DR pin is shifted into RSR(s), and the previous content of the RSR(s) is lost.

You can prevent the loss of data if DRR1 is read no later than 2.5 cycles before the end of the third word is shifted into the RSR1.

Note

If both DRRs are needed (word length larger than 16 bits), the CPU or the DMA controller must read from DRR2 first and then from DRR1. As soon as DRR1 is read, the next RBR-to-DRR copy is initiated. If DRR2 is not read first, the data in DRR2 is lost.

After the receiver starts running from reset, a minimum of three words must be received before RFULL is set. Either of the following events clears the RFULL bit and allows subsequent transfers to be read properly:

- The CPU or DMA controller reads DRR1.
- The receiver is reset individually (RRST = 0) or as part of a device reset.

Another frame-synchronization pulse is required to restart the receiver.

20.5.2.1 Example of Overrun Condition

Figure 20-21 shows the receive overrun condition. Because serial word A is not read from DRR1 before serial word B arrives in RBR1, B is not transferred to DRR1 yet. Another new word ©) arrives and RSR1 is full with this data. DRR1 is finally read, but not earlier than 2.5 cycles before the end of word C. Therefore, new data (D) overwrites word C in RSR1. If DRR1 is not read in time, the next word can overwrite D.

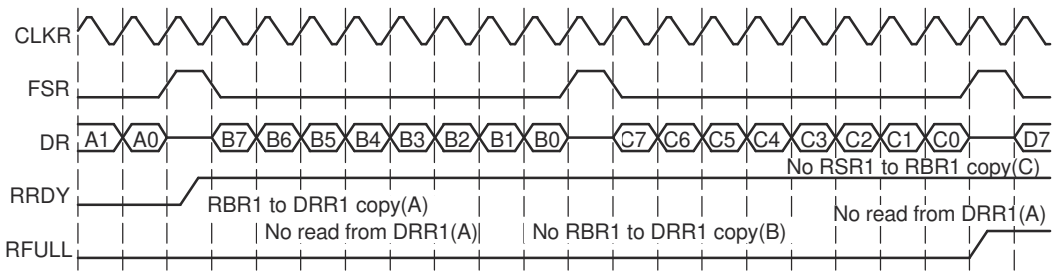

Figure 20-21. Overrun in the McBSP Receiver

20.5.2.2 Example of Preventing Overrun Condition

Figure 20-22 shows the case where RFULL is set, but the overrun condition is prevented by a read from DRR1 at least 2.5 cycles before the next serial word is completely shifted into RSR1. This makes sure that an RBR1-to-DRR1 copy of word B occurs before receiver attempts to transfer word C from RSR1 to RBR1.

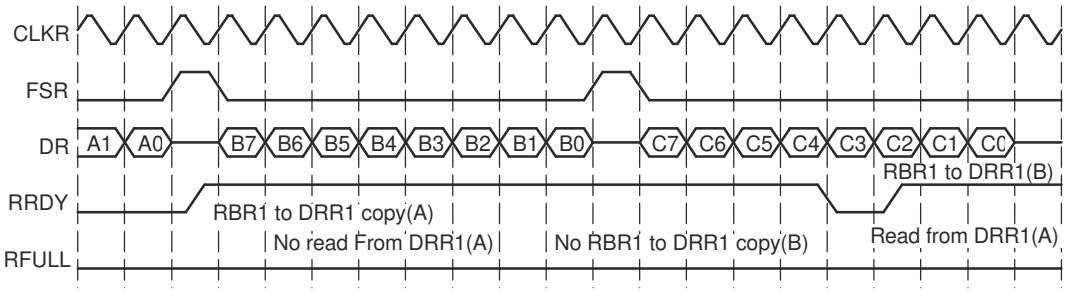

Figure 20-22. Overrun Prevented in the McBSP Receiver

20.5.3 Unexpected Receive Frame-Synchronization Pulse

Section 20.5.3.1 shows how the McBSP responds to any receive frame-synchronization pulses, including an unexpected pulse. Section 20.5.3.2 and Section 20.5.3.3 show an example of a frame-synchronization error and an example of how to prevent such an error, respectively.

20.5.3.1 Possible Responses to Receive Frame-Synchronization Pulses

Figure 20-23 shows the decision tree that the receiver uses to handle all incoming frame-synchronization pulses. The figure assumes that the receiver has been started (RRST = 1 in SPCR1). Case 3 shows where an error occurs.

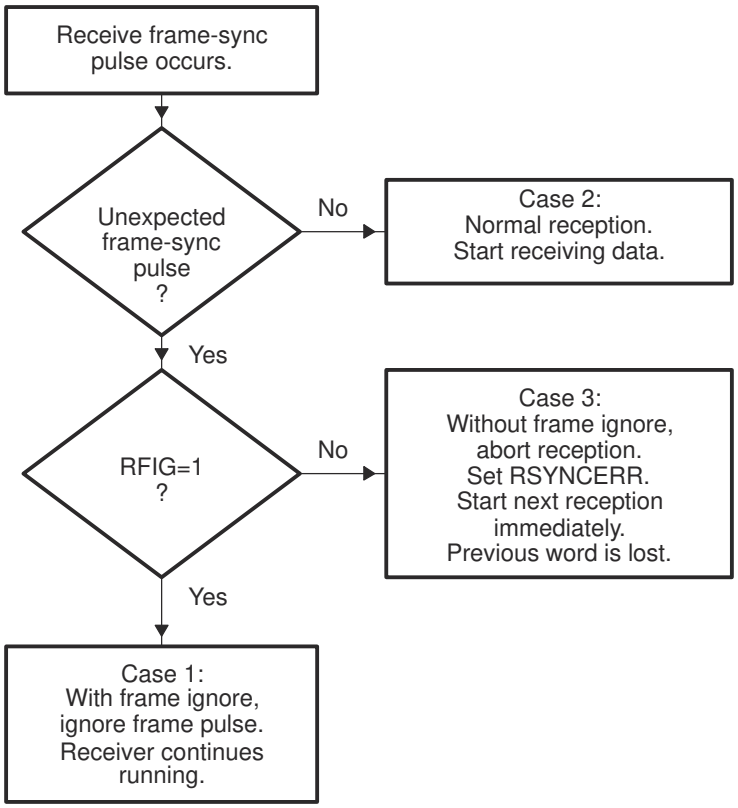

Figure 20-23. Possible Responses to Receive Frame-Synchronization Pulses

Any one of three cases can occur:

- Case 1: Unexpected internal FSR pulses with RFIG = 1 in RCR2. Receive frame-synchronization pulses are ignored, and the reception continues.
- Case 2: Normal serial port reception. Reception continues normally because the frame-synchronization pulse is not unexpected. There are three possible reasons why a receive operation might *not* be in progress when the pulse occurs:
  - The FSR pulse is the first after the receiver is enabled (RRST = 1 in SPCR1).
  - The FSR pulse is the first after DRR[1,2] is read, clearing a receiver full (RFULL = 1 in SPCR1) condition.
  - The serial port is in the interpacket intervals. The programmed data delay for reception (programmed with the RDATDLY bits in RCR2) may start during these interpacket intervals for the first bit of the next word to be received. Thus, at maximum frame frequency, frame synchronization can still be received 0 to 2 clock cycles before the first bit of the synchronized frame.
- Case 3: Unexpected receive frame synchronization with RFIG = 0 (frame-synchronization pulses not ignored). Unexpected frame-synchronization pulses can originate from an external source or from the internal sample rate generator.

  If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit (RSYNCERR) in SPCR1. RSYNCERR can be cleared only by a receiver reset or by a write of 0 to this bit.

  If you want the McBSP to notify the CPU of receive frame-synchronization errors, you can set a special receive interrupt mode with the RINTM bits of SPCR1. When RINTM = 11b, the McBSP sends a receive interrupt (RINT) request to the CPU each time that RSYNCERR is set.

20.5.3.2 Example of Unexpected Receive Frame-Synchronization Pulse

Figure 20-30 shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets. When the unexpected frame-synchronization pulse occurs, the RSYNCERR bit is set, the reception of data B is aborted, and the reception of data C begins. In addition, if RINTM = 11b, the McBSP sends a receive interrupt (RINT) request to the CPU.

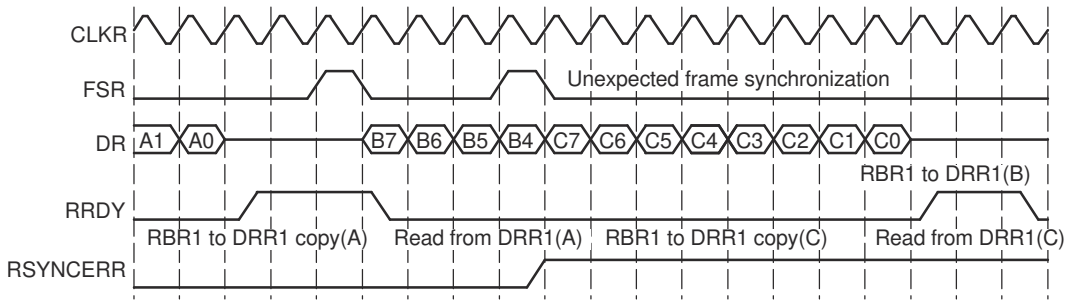

Figure 20-24. An Unexpected Frame-Synchronization Pulse During a McBSP Reception

20.5.3.3 Preventing Unexpected Receive Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 MCLKR cycles, depending on the value in the RDATDLY bits of RCR2. For each possible data delay, Figure 20-25 shows when a new frame-synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

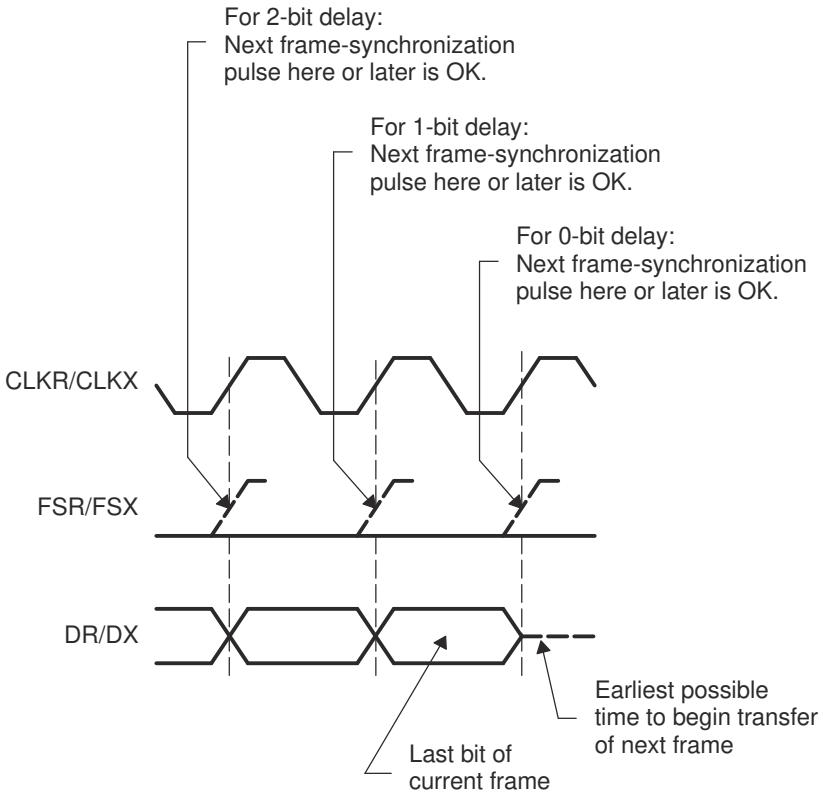

Figure 20-25. Proper Positioning of Frame-Synchronization Pulses

20.5.4 Overwrite in the Transmitter

As described in Section 20.3.6), the transmitter must copy the data previously written to the DXR(s) by the CPU or DMA controller into the XSR(s) and then shift each bit from the XSR(s) to the DX pin. If new data is written to the DXR(s) before the previous data is copied to the XSR(s), the previous data in the DXR(s) is overwritten and thus lost.

20.5.4.1 Example of Overwrite Condition

Figure 20-26 shows what happens if the data in DXR1 is overwritten before being transmitted. Initially, DXR1 is loaded with data C. A subsequent write to DXR1 overwrites C with D before C is copied to XSR1. Thus, C is never transmitted on DX.

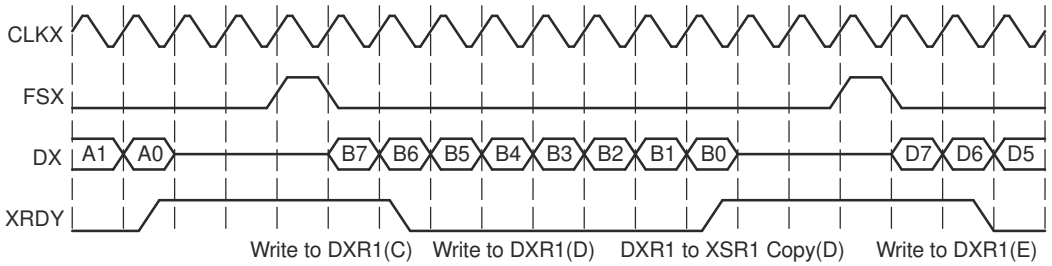

Figure 20-26. Data in the McBSP Transmitter Overwritten and Thus Not Transmitted

20.5.4.2 Preventing Overwrites

You can prevent CPU overwrites by making the CPU:

- Poll for XRDY = 1 in SPCR2 before writing to the DXRs. XRDY is set when data is copied from DXR1 to XSR1 and is cleared when new data is written to DXR1.

- Wait for a transmit interrupt (XINT) before writing to the DXRs. When XINTM = 00b in SPCR2, the transmitter sends XINT to the CPU each time XRDY is set.

You can prevent DMA overwrites by synchronizing DMA transfers to the transmit synchronization event XEVT. The transmitter sends an XEVT signal each time XRDY is set.

20.5.5 Underflow in the Transmitter

The McBSP indicates a transmitter empty (or underflow) condition by clearing the $\overline{\text{XEMPTY}}$ bit in SPCR2. Either of the following events activates $\overline{\text{XEMPTY}}$ ($\overline{\text{XEMPTY}}$ = 0):

- DXR1 has not been loaded since the last DXR-to-XSR copy, and all bits of the data word in the XSR(s) have been shifted out on the DX pin.
- The transmitter is reset (by forcing XRST = 0 in SPCR2, or by a device reset) and is then restarted.

In the underflow condition, the transmitter continues to transmit the old data that is in the DXR(s) for every new transmit frame-synchronization signal, until a new value is loaded into DXR1 by the CPU or the DMA controller.

Note

If both DXRs are needed (word length larger than 16 bits), the CPU or the DMA controller must load DXR2 first and then load DXR1. As soon as DXR1 is loaded, the contents of both DXRs are copied to the transmit shift registers (XSRs). If DXR2 is not loaded first, the previous content of DXR2 is passed to the XSR2.

XEMPTY is deactivated (XEMPTY = 1) when a new word in DXR1 is transferred to XSR1. If FSXM = 1 in PCR and FSGM = 0 in SRGR2, the transmitter generates a single internal FSX pulse in response to a DXR-to-XSR copy. Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on DX.

When the transmitter is taken out of reset (XRST = 1), it is in a transmitter ready (XRDY = 1 in SPCR2) and transmitter empty (XEMPTY = 0) state. If DXR1 is loaded by the CPU or the DMA controller before internal FSX goes active high, a valid DXR-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before DXR1 is loaded, zeros are output on DX.

20.5.5.1 Example of the Underflow Condition

Figure 20-27 shows an underflow condition. After B is transmitted, DXR1 is not reloaded before the subsequent frame-synchronization pulse. Thus, B is again transmitted on DX.

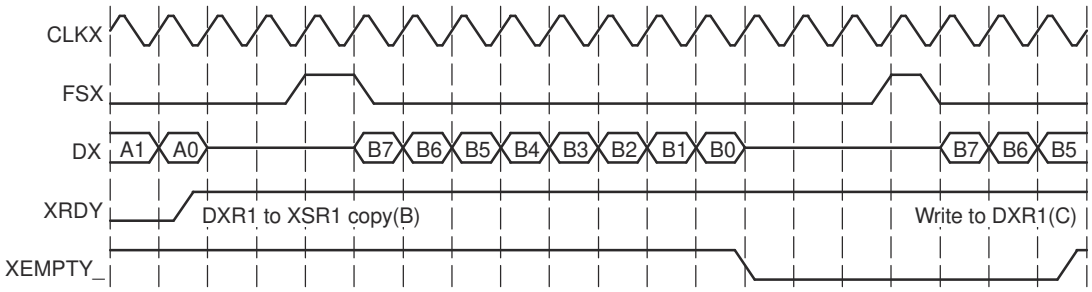

Figure 20-27. Underflow During McBSP Transmission

20.5.5.2 Example of Preventing Underflow Condition

Figure 20-28 shows the case of writing to DXR1 just before an underflow condition can otherwise occur. After B is transmitted, C is written to DXR1 before the next frame-synchronization pulse. As a result, there is no underflow; B is not transmitted twice.

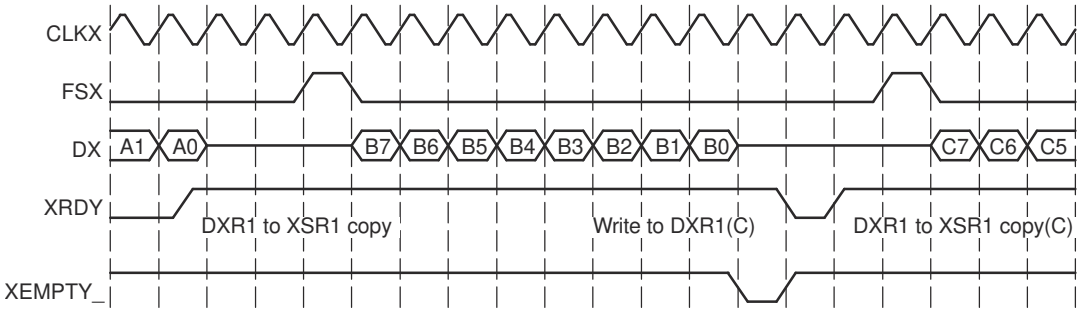

Figure 20-28. Underflow Prevented in the McBSP Transmitter

20.5.6 Unexpected Transmit Frame-Synchronization Pulse

Section 20.5.6.1 shows how the McBSP responds to any transmit frame-synchronization pulses, including an unexpected pulse. Section 20.5.6.2 and Section 20.5.6.3 show examples of a frame-synchronization error and an example of how to prevent such an error, respectively.

20.5.6.1 Possible Responses to Transmit Frame-Synchronization Pulses

Figure 20-29 shows the decision tree that the transmitter uses to handle all incoming frame-synchronization pulses. The figure assumes that the transmitter has been started (XRST = 1 in SPCR2). Case 3 shows where an error occurs.

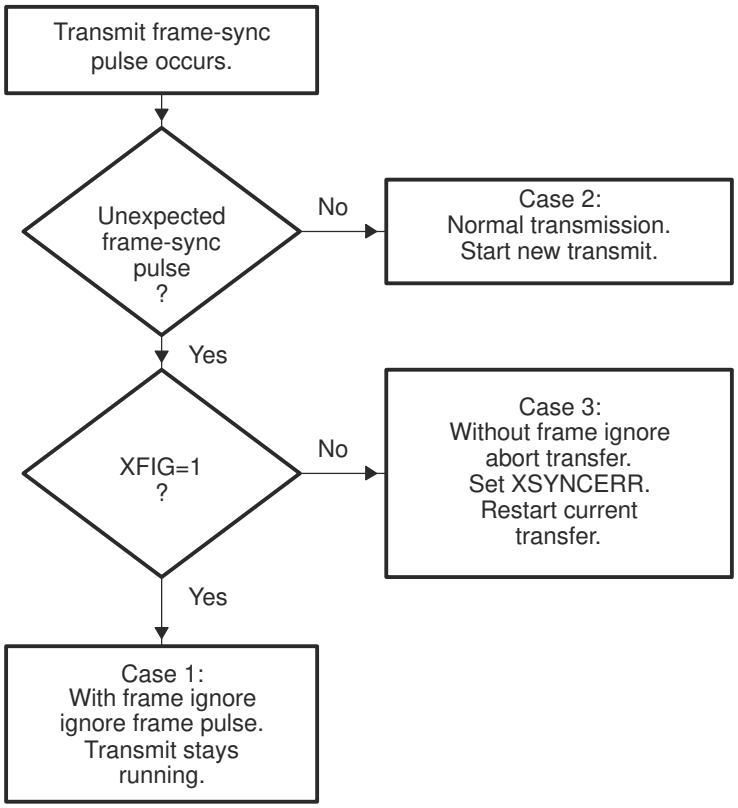

Figure 20-29. Possible Responses to Transmit Frame-Synchronization Pulses

Any one of three cases can occur:

- Case 1: Unexpected internal FSX pulses with XFIG = 1 in XCR2. Transmit frame-synchronization pulses are ignored, and the transmission continues.
- Case 2: Normal serial port transmission. Transmission continues normally because the frame-synchronization pulse is not unexpected. There are two possible reasons why a transmit operations might *not* be in progress when the pulse occurs:

  This FSX pulse is the first after the transmitter is enabled (XRST = 1).

  The serial port is in the interpacket intervals. The programmed data delay for transmission (programmed with the XDATDLY bits of XCR2) may start during these interpacket intervals before the first bit of the previous word is transmitted. Thus, at maximum packet frequency, frame synchronization can still be received 0 to 2 clock cycles before the first bit of the synchronized frame.
- Case 3: Unexpected transmit frame synchronization with XFIG = 0 (frame-synchronization pulses not ignored). Unexpected frame-synchronization pulses can originate from an external source or from the internal sample rate generator.

  If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit (XSYNCERR) in SPCR2. XSYNCERR can be cleared only by a transmitter reset or by a write of 0 to this bit.

  If you want the McBSP to notify the CPU of frame-synchronization errors, you can set a special transmit interrupt mode with the XINTM bits of SPCR2. When XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU each time that XSYNCERR is set.

20.5.6.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Section 20.5.3.2 shows an unexpected transmit frame-synchronization pulse during normal operation of the serial port with intervals between the data packets. When the unexpected frame-synchronization pulse occurs, the XSYNCERR bit is set and the transmission of data B is restarted because no new data has been passed to XSR1 yet. In addition, if XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU.

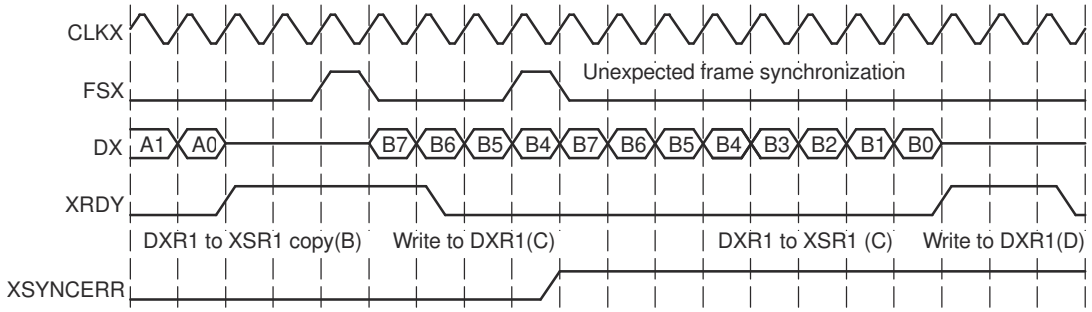

Figure 20-30. An Unexpected Frame-Synchronization Pulse During a McBSP Transmission

20.5.6.3 Preventing Unexpected Transmit Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the XDATDLY bits of XCR2. For each possible data delay, Figure 20-31 shows when a new frame-synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

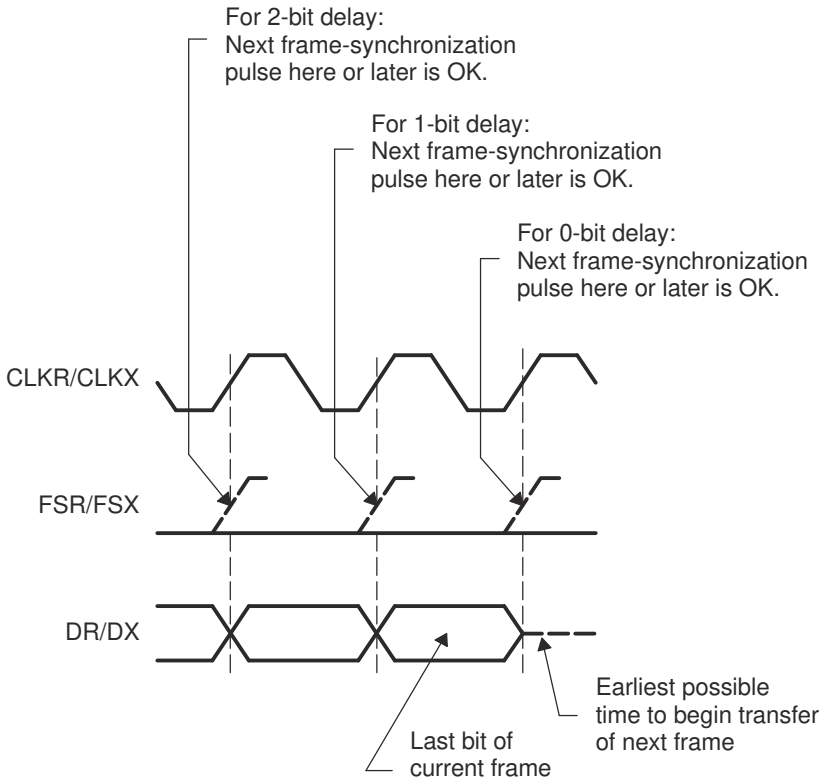

Figure 20-31. Proper Positioning of Frame-Synchronization Pulses

20.6 Multichannel Selection Modes

This section discusses the multichannel selection modes for the McBSP.

20.6.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. Each McBSP supports up to 128 channels for reception and 128 channels for transmission.

In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that each contain 16 contiguous channels (see Table 20-8 through Table 20-10):

- It is possible to have two receive partitions (A and B) and 8 transmit partitions (A to H).
- McBSP can transmit/receive on selected channels.
- Each channel partition has a dedicated channel-enable register. Each bit controls whether data flow is allowed or prevented in one of the channels assigned to that partition.
- There are three transmit multichannel modes and one receive multichannel mode.

The blocks are assigned to partitions according to the selected partition mode. In the two-partition mode (described in Section 20.6.4), you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode (described in Section 20.6.5), blocks 0 through 7 are automatically assigned to partitions, A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent. For example, using two receive partitions (A and B) and eight transmit partitions (A to H) is possible.

Table 20-8. Block - Channel Assignment

Block	Channels
0	0 -15
1	16 - 31
2	32 - 47
3	48 - 63
4	64 - 79
5	80 - 95
6	96 - 111
7	112 - 127

Table 20-9. 2-Partition Mode

Partition	Blocks
A	0, 2, 4, or 6
B	1, 3, 5, or 7

Table 20-10. 8-Partition Mode

Partition	Blocks	Channels
A	0	0 -15
B	1	16 - 31
C	2	32 - 47
D	3	48 - 63
E	4	64 - 79
F	5	80 - 95
G	6	96 - 111
H	7	112 - 127

20.6.2 Multichannel Selection

When a McBSP uses a time-division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices, the McBSP may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP has one receive multichannel selection mode (described in Section 20.6.6) and three transmit multichannel selection modes (described in Section 20.6.7).

20.6.3 Configuring a Frame for Multichannel Selection

Before you enable a multichannel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (RPHASE/XPHASE = 0). Each frame represents a TDM data stream.
- Set a frame length (in RFRLEN1/XFRLEN1) that includes the highest-numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). If XFRLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

20.6.4 Using Two Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions (described in Section 20.6.5). If you choose the 2-partition mode (RMCME = 0 for reception, XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

20.6.4.1 Assigning Blocks to Partitions A and B

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point in time. Similarly, any two of the eight transmit-channel blocks (up 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the RPABLK bits. In the receive multichannel selection mode (described in Section 20.6.6), the channels in this partition are controlled by receive channel enable register A (RCERA).
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the RPBBLK bits. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (RCERB).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the XPABLK bits. In one of the transmit multichannel selection modes (described in Section 20.6.7), the channels in this partition are controlled by transmit channel enable register A (XCERA).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the XPBBLK bits. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (XCERB).

Figure 20-32 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0-15 have been assigned to partition A, and channels 16-31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

As explained in Section 20.6.4.2, you can dynamically change which blocks of channels are assigned to the partitions.

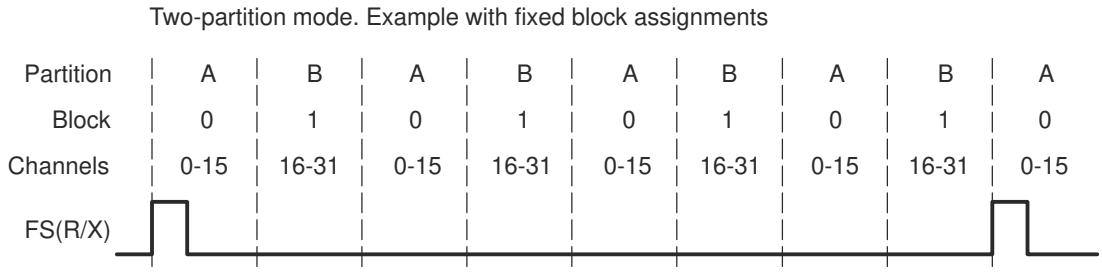

Figure 20-32. Alternating Between the Channels of Partition A and the Channels of Partition B

20.6.4.2 Reassigning Blocks During Reception/Transmission

If you want to use more than 32 channels, you can change which channel blocks are assigned to partitions A and B during the course of a data transfer. However, these changes must be carefully timed. While a partition is being transferred, the associated block assignment bits cannot be modified and the associated channel enable register cannot be modified. For example, if block 3 is being transferred and block 3 is assigned to partition A, you cannot modify (R/X)PABLK to assign different channels to partition A, nor (R/X)CERA to change the channel configuration for partition A.

Several features of the McBSP help you time the reassignment:

- The block of channels currently involved in reception and transmission (the current block) is reflected in the RCBLK/XCBLK bits. Your program can poll these bits to determine which partition is active. When a partition is not active, it is safe to change its block assignment and channel configuration.
- At the end of every block (at the boundary of two partitions), an interrupt can be sent to the CPU. In response to the interrupt, the CPU can then check the RCBLK/XCBLK bits and update the inactive partition. See Section 20.6.8.

Figure 20-33 shows an example of reassigning channels throughout a data transfer. In response to a frame-synchronization pulse, the McBSP alternates between partitions A and B. Whenever partition B is active, the CPU changes the block assignment for partition A. Whenever partition A is active, the CPU changes the block assignment for partition B.

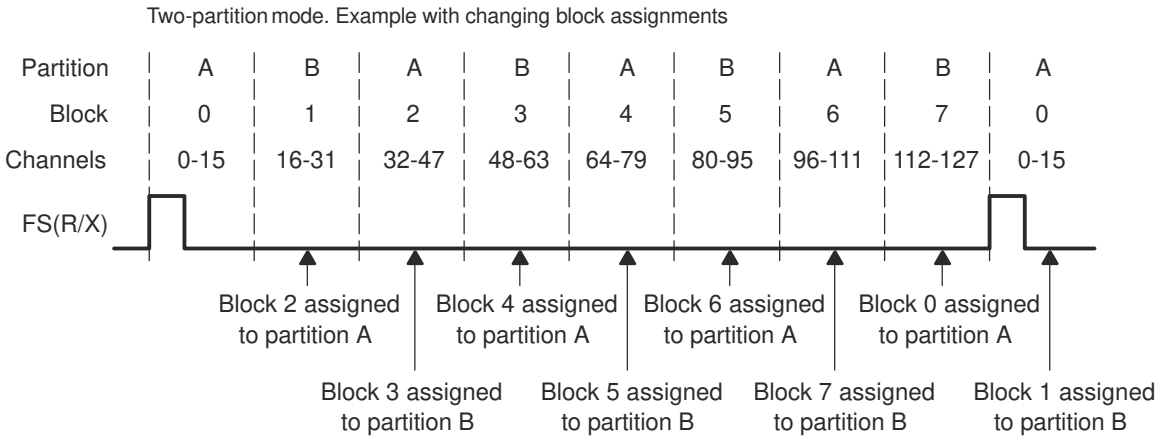

Figure 20-33. Reassigning Channel Blocks Throughout a McBSP Data Transfer

20.6.5 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions (described in Section 20.6.4). If you choose the 8-partition mode (RMCME = 1 for reception, XMCME = 1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the (R/X)PABLK and (R/X)PBBLK bits are ignored and the 16-channel blocks are assigned to the partitions as shown in Table 20-11 and Table 20-12. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Table 20-11. Receive Channel Assignment and Control With Eight Receive Partitions

Receive Partition	Assigned Block of Receive Channels	Register Used For Channel Control
A	Block 0: channels 0 through 15	RCERA
B	Block 1: channels 16 through 31	RCERB
C	Block 2: channels 32 through 47	RCERC
D	Block 3: channels 48 through 63	RCERD
E	Block 4: channels 64 through 79	RCERE
F	Block 5: channels 80 through 95	RCERF
G	Block 6: channels 96 through 111	RCERG
H	Block 7: channels 112 through 127	RCERH

Table 20-12. Transmit Channel Assignment and Control When Eight Transmit Partitions Are Used

Transmit Partition	Assigned Block of Transmit Channels	Register Used For Channel Control
A	Block 0: channels 0 through 15	XCERA
B	Block 1: channels 16 through 31	XCERB
C	Block 2: channels 32 through 47	XCERC
D	Block 3: channels 48 through 63	XCERD
E	Block 4: channels 64 through 79	XCERE
F	Block 5: channels 80 through 95	XCERF
G	Block 6: channels 96 through 111	XCERG
H	Block 7: channels 112 through 127	XCERH

Figure 20-34 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

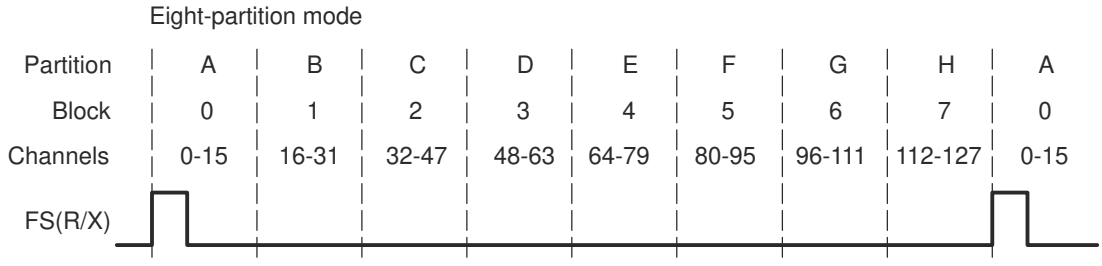

Figure 20-34. McBSP Data Transfer in the 8-Partition Mode

20.6.6 Receive Multichannel Selection Mode

The RMCM bit of MCR1 determines whether all channels or only selected channels are enabled for reception. When RMCM = 0, all 128 receive channels are enabled and cannot be disabled. When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:

- Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate receive channel enable registers (RCERs). The way channels are assigned to the RCERs depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit of MCR1.
- If a receive channel is disabled, any bits received in that channel are passed only as far as the receive buffer registers (RBRs). The receiver does not copy the content of the RBRs to the DRRs, and as a result, does not set the receiver ready bit (RRDY). Therefore, no DMA synchronization event (REVT) is generated and, if the receiver interrupt mode depends on RRDY (RINTM = 00b), no interrupt is generated.

As an example of how the McBSP behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP:

1. Accepts bits shifted in from the DR pin in channel 0
2. Ignores bits received in channels 1-14
3. Accepts bits shifted in from the DR pin in channel 15
4. Ignores bits received in channels 16-38
5. Accepts bits shifted in from the DR pin in channel 39

20.6.7 Transmit Multichannel Selection Modes

The XMCM bits of XCR2 determine whether all channels or only selected channels are enabled and unmasked for transmission. More details on enabling and masking are in Section 20.6.7.1. The McBSP has three transmit multichannel selection modes (XMCM = 01b, XMCM = 10b, and XMCM = 11b), which are described in Table 20-13.

Table 20-13. Selecting a Transmit Multichannel Selection Mode With the XMCM Bits

XMCM	Transmit Multichannel Selection Mode
00b	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
01b	All channels are disabled unless the channels are selected in the appropriate transmit channel enable registers (XCERs). If enabled, a channel in this mode is also unmasked. The XMCME bit of MCR2 determines whether 32 channels or 128 channels are selectable in XCERs.
10b	All channels are enabled, but the channels are masked unless the channels are selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit of MCR2 determines whether 32 channels or 128 channels are selectable in XCERs.
11b	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless the channels are enabled for reception in the appropriate receive channel enable registers (RCERs). Once enabled, the channels are masked unless the channels are also selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit of MCR2 determines whether 32 channels or 128 channels are selectable in RCERs and XCERs.

As an example of how the McBSP behaves in a transmit multichannel selection mode, suppose that XMCM = 01b (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP:

1. Shifts data to the DX pin in channel 0
2. Places the DX pin in the high impedance state in channels 1-14
3. Shifts data to the DX pin in channel 15
4. Places the DX pin in the high impedance state in channels 16-38
5. Shifts data to the DX pin in channel 39

20.6.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The following definitions explain the channel control options:

Enabled channel — A channel that can begin transmission by passing data from the data transmit registers (DXRs) to the transmit shift registers (XSRs).

Masked channel — A channel that cannot complete transmission. The DX pin is held in the high impedance state; data cannot be shifted out on the DX pin.

In systems where symmetric transmit and receive provides software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.

Disabled channel	A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XSR copy occurs, the XRDY bit of SPCR2 is not set. Therefore, no DMA synchronization event (XEVT) is generated, and if the transmit interrupt mode depends on XRDY (XINTM = 00b in SPCR2), no interrupt is generated. The XEMPTY bit of SPCR2 is not affected.
Unmasked channel	A channel that is not masked. Data in the XSRs is shifted out on the DX pin.

20.6.7.2 Activity on McBSP Pins for Different Values of XMCM

Figure 20-35 shows the activity on the McBSP pins for the various XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE = 0: Single-phase frame (required for multichannel selection modes)
- XFRLEN1 = 0000011b: 4 words per frame
- XWDLEN1 = 000b: 8 bits per word
- XMCME = 0: 2-partition mode (only partitions A and B used)

In the case where XMCM = 11b, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively.

In the figure, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

20.6.8 Using Interrupts Between Block Transfers

When a multichannel selection mode is used, an interrupt request can be sent to the CPU at the end of every 16-channel block (at the boundary between partitions and at the end of the frame). In the receive multichannel selection mode, a receive interrupt (RINT) request is generated at the end of each block transfer if RINTM = 01b. In any of the transmit multichannel selection modes, a transmit interrupt (XINT) request is generated at the end of each block transfer if XINTM = 01b. When RINTM/XINTM = 01b, no interrupt is generated unless a multichannel selection mode is on.

These interrupt pulses are active high and last for two CPU clock cycles.

This type of interrupt is especially helpful if you are using the two-partition mode (described in Section 20.6.4) and you want to know when you can assign a different block of channels to partition A or B.

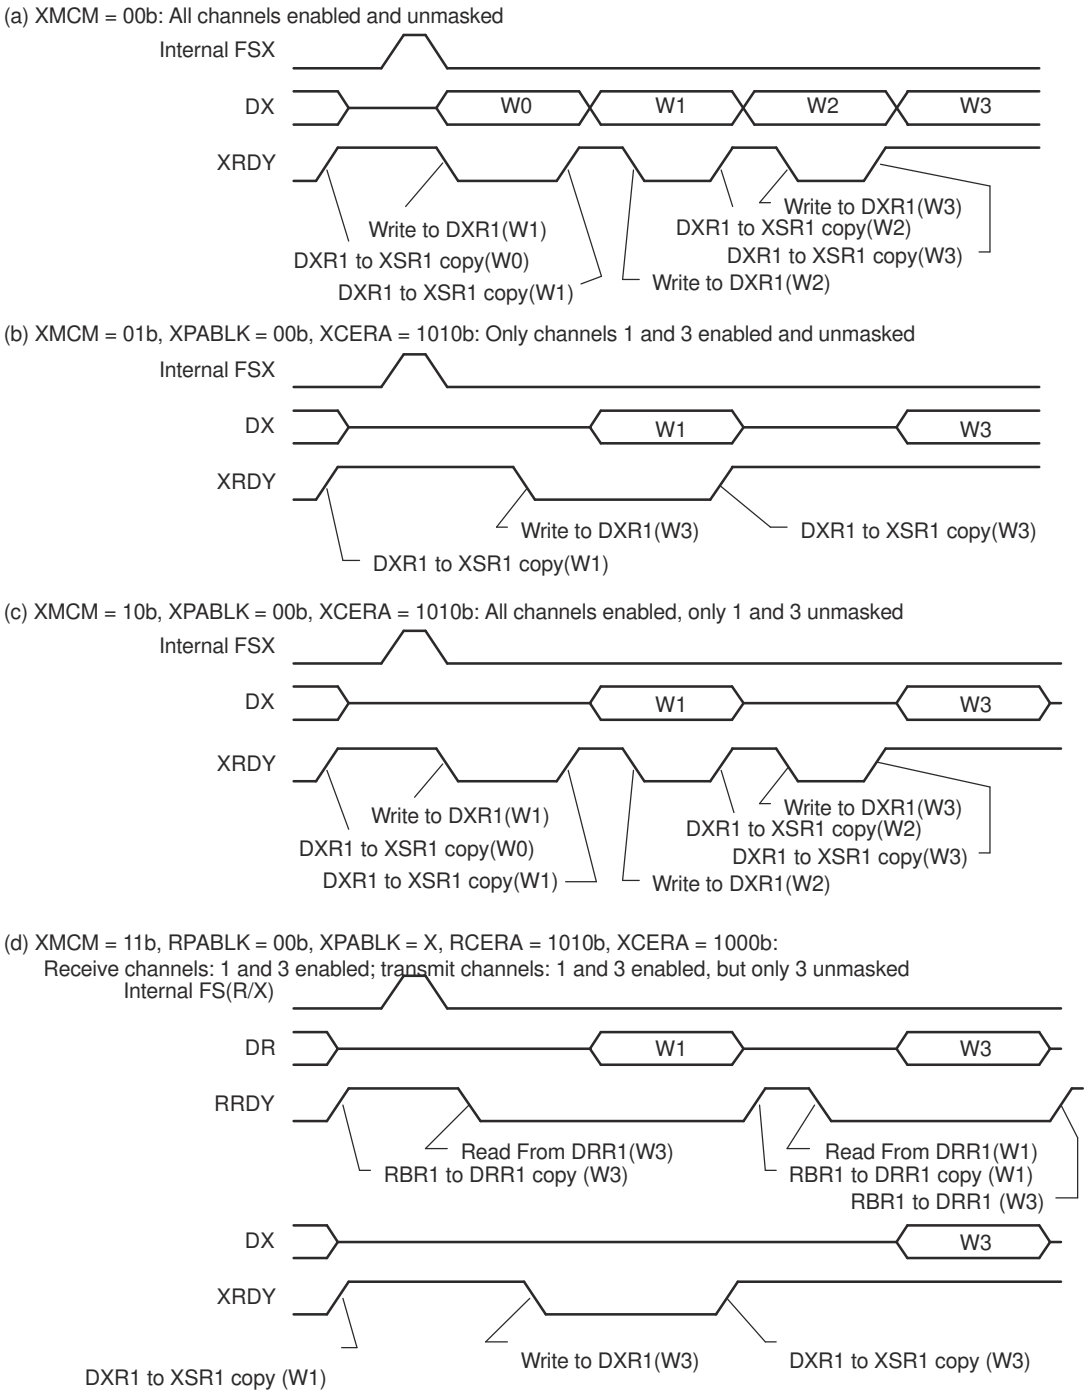

Figure 20-35. Activity on McBSP Pins for the Possible Values of XMCM

20.7 SPI Operation Using the Clock Stop Mode

This section explains how to use the McBSP in SPI mode.

20.7.1 SPI Protocol

The SPI protocol is a master-slave configuration with one master device and one or more slave devices. The interface consists of the following four signals:

- Serial data input (also referred to as master in/slave out, or SPISOMI)
- Serial data output (also referred to as master out/slave in, or SPISIMO)
- Shift-clock (also referred to as SPICLK)
- Slave-enable signal (also referred to as $\overline{\text{SPISTE}}$)

A typical SPI interface with a single slave device is shown in Figure 20-36.

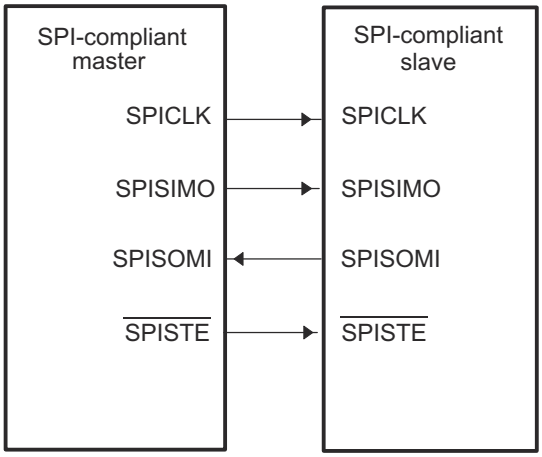

Figure 20-36. Typical SPI Interface

The master device controls the flow of communication by providing shift-clock and slave-enable signals. The slave-enable signal is an optional active-low signal that enables the serial data input and output of the slave device (device not sending out the clock).

In the absence of a dedicated slave-enable signal, communication between the master and slave is determined by the presence or absence of an active shift-clock. When the McBSP is operating in SPI master mode and the $\overline{\text{SPISTE}}$ signal is not used by the SPI slave port, the slave device must remain enabled at all times, and multiple slaves cannot be used.

20.7.2 Clock Stop Mode

The clock stop mode of the McBSP provides compatibility with the SPI protocol. When the McBSP is configured in clock stop mode, the transmitter and receiver are internally synchronized so that the McBSP functions as an SPI master or slave device. The transmit clock signal (CLKX) corresponds to the serial clock signal (SPICLK) of the SPI protocol, while the transmit frame-synchronization signal (FSX) is used as the slave-enable signal ($\overline{\text{SPISTE}}$).

The receive clock signal (MCLKR) and receive frame-synchronization signal (FSR) are not used in the clock stop mode because these signals are internally connected to their transmit counterparts, CLKX and FSX.

20.7.3 Enable and Configure the Clock Stop Mode

The bits required to configure the McBSP as an SPI device are introduced in Table 20-14. Table 20-15 shows how the various combinations of the CLKSTP bit and the polarity bits CLKXP and CLKRP create four possible clock stop mode configurations. The timing diagrams in Section 20.7.4 show the effects of CLKSTP, CLKXP, and CLKRP.

Table 20-14. Bits Used to Enable and Configure the Clock Stop Mode

Bit Field	Description
CLKSTP bits of SPCR1	Use these bits to enable the clock stop mode and to select one of two timing variations. (See also Table 20-15.)
CLKXP bit of PCR	This bit determines the polarity of the CLKX signal. (See also Table 20-15.)
CLKRP bit of PCR	This bit determines the polarity of the MCLKR signal. (See also Table 20-15.)
CLKXM bit of PCR	This bit determines whether CLKX is an input signal (McBSP as slave) or an output signal (McBSP as master).
XPHASE bit of XCR2	You must use a single-phase transmit frame (XPHASE = 0).
RPHASE bit of RCR2	You must use a single-phase receive frame (RPHASE = 0).
XFRLEN1 bits of XCR1	You must use a transmit frame length of 1 serial word (XFRLEN1 = 0).
RFRLEN1 bits of RCR1	You must use a receive frame length of 1 serial word (RFRLEN1 = 0).
XWDLEN1 bits of XCR1	The XWDLEN1 bits determine the transmit packet length. XWDLEN1 must be equal to RWDLEN1 because in the clock stop mode. The McBSP transmit and receive circuits are synchronized to a single clock.
RWDLEN1 bits of RCR1	The RWDLEN1 bits determine the receive packet length. RWDLEN1 must be equal to XWDLEN1 because in the clock stop mode. The McBSP transmit and receive circuits are synchronized to a single clock.

Table 20-15. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme

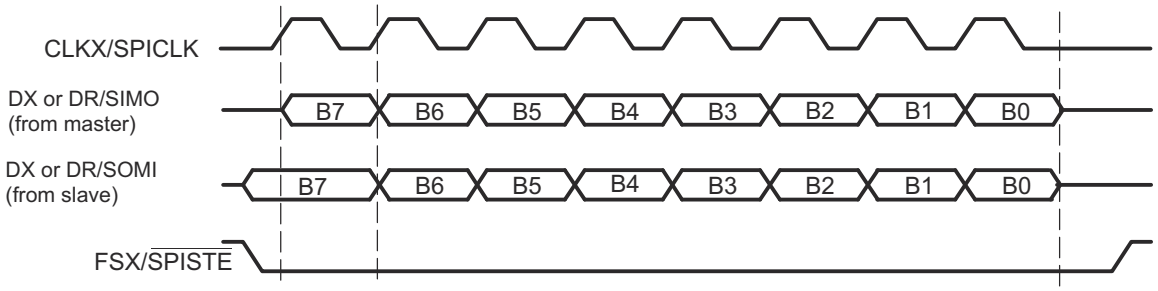
Bit Settings	Clock Scheme
CLKSTP = 00b or 01b CLKXP = 0 or 1 CLKRP = 0 or 1	Clock stop mode disabled. Clock enabled for non-SPI mode.
CLKSTP = 10b CLKXP = 0 CLKRP = 0	Low inactive state without delay: The McBSP transmits data on the rising edge of CLKX and receives data on the falling edge of MCLKR.
CLKSTP = 11b CLKXP = 0 CLKRP = 1	Low inactive state with delay: The McBSP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 10b CLKXP = 1 CLKRP = 0	High inactive state without delay: The McBSP transmits data on the falling edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 11b CLKXP = 1 CLKRP = 1	High inactive state with delay: The McBSP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of MCLKR.

20.7.4 Clock Stop Mode Timing Diagrams

The timing diagrams for the four possible clock stop mode configurations are shown here. Notice that the frame-synchronization signal used in clock stop mode is active throughout the entire transmission as a slave-enable signal. Although the timing diagrams show 8-bit transfers, the packet length can be set to 8, 12, 16, 20, 24, or 32 bits per packet. The receive packet length is selected with the RWDLEN1 bits of RCR1, and the transmit packet length is selected with the XWDLEN1 bits of XCR1. For clock stop mode, the values of RWDLEN1 and XWDLEN1 must be the same because the McBSP transmit and receive circuits are synchronized to a single clock.

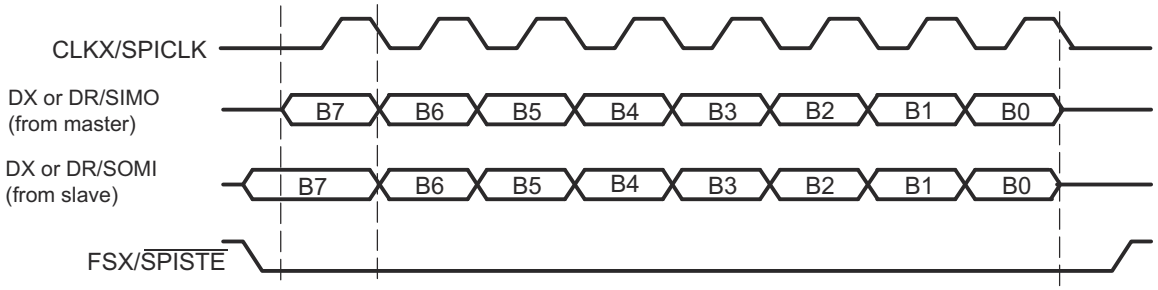
Note

Even if multiple words are consecutively transferred, the CLKX signal is always stopped and the FSX signal returns to the inactive state after a packet transfer. When consecutive packet transfers are performed, this leads to a minimum idle time of two bit-periods between each packet transfer.



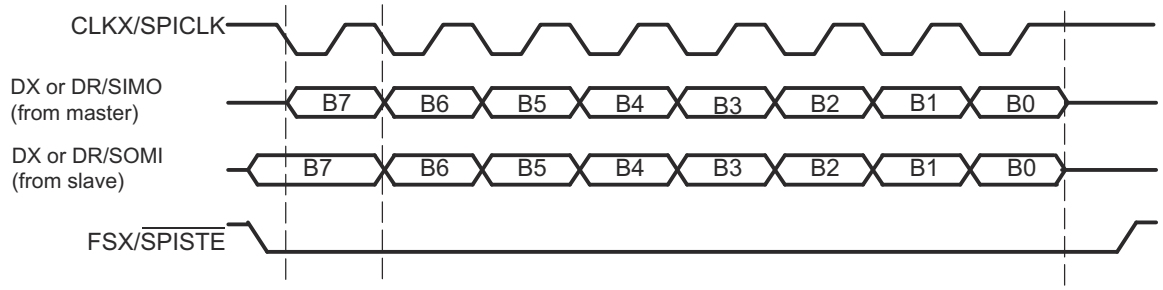
A. If the McBSP is the SPI master (CLKXM = 1), SIMO = DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.
B. If the McBSP is the SPI master (CLKXM = 1), SOMI = DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

Figure 20-37. SPI Transfer with CLKSTP = 10b (No Clock Delay), CLKXP = 0, and CLKRP = 0



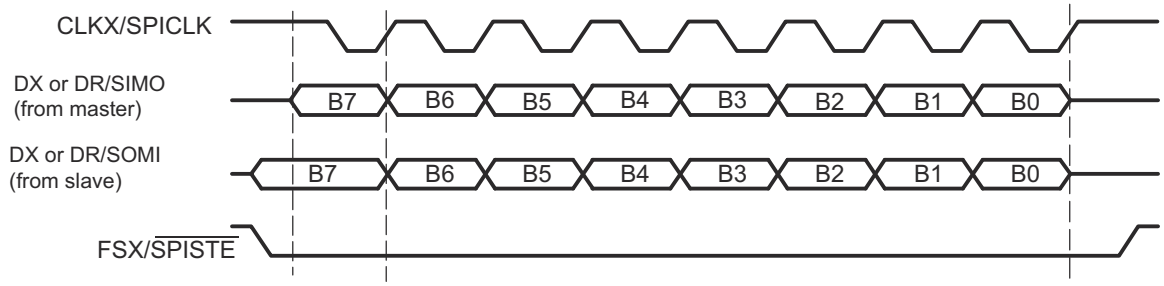
A. If the McBSP is the SPI master (CLKXM = 1), SIMO = DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.
B. If the McBSP is the SPI master (CLKXM = 1), SOMI = DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

Figure 20-38. SPI Transfer with CLKSTP = 11b (Clock Delay), CLKXP = 0, CLKRP = 1



A. If the McBSP is the SPI master (CLKXM = 1), SIMO = DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.
B. If the McBSP is the SPI master (CLKXM = 1), SOMI = DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

Figure 20-39. SPI Transfer with CLKSTP = 10b (No Clock Delay), CLKXP = 1, and CLKRP = 0



A. If the McBSP is the SPI master (CLKXM = 1), SIMO = DX. If the McBSP is the SPI slave (CLKXM = 0), SIMO = DR.
B. If the McBSP is the SPI master (CLKXM = 1), SOMI = DR. If the McBSP is the SPI slave (CLKXM = 0), SOMI = DX.

Figure 20-40. SPI Transfer with CLKSTP = 11b (Clock Delay), CLKXP = 1, CLKRP = 1

20.7.5 Procedure for Configuring a McBSP for SPI Operation

To configure the McBSP for SPI master or slave operation:

1. Place the transmitter and receiver in reset.
   Clear the transmitter reset bit (XRST = 0) in SPCR2 to reset the transmitter. Clear the receiver reset bit (RRST = 0) in SPCR1 to reset the receiver.
2. Place the sample rate generator in reset.
   Clear the sample rate generator reset bit (GRST = 0) in SPCR2 to reset the sample rate generator.
3. Program registers that affect SPI operation.
   Program the appropriate McBSP registers to configure the McBSP for proper operation as an SPI master or an SPI slave. For a list of important bits settings, see one of the following topics:
   - Section 20.7.6
   - Section 20.7.7
4. Enable the sample rate generator.
   To release the sample rate generator from reset, set the sample rate generator reset bit (GRST = 1) in SPCR2.
   Make sure that during the write to SPCR2, you only modify GRST. Otherwise, you modify the McBSP configuration you selected in the previous step.
5. Enable the transmitter and receiver.
   After the sample rate generator is released from reset, wait two sample rate generator clock periods for the McBSP logic to stabilize.
   If the CPU services the McBSP transmit and receive buffers, then you can immediately enable the transmitter (XRST = 1 in SPCR2) and enable the receiver (RRST = 1 in SPCR1).
   If the DMA controller services the McBSP transmit and receive buffers, then you must first configure the DMA controller (this includes enabling the channels that service the McBSP buffers). When the DMA controller is ready, make XRST = 1 and RRST = 1.
   In either case, make sure you only change XRST and RRST when you write to SPCR2 and SPCR1. Otherwise, you modify the bit settings you selected earlier in this procedure.
   After the transmitter and receiver are released from reset, wait two sample rate generator clock periods for the McBSP logic to stabilize.
6. If necessary, enable the frame-synchronization logic of the sample rate generator.
   After the required data acquisition setup is done (DXR[1,2] is loaded with data), set FRST = 1 if an internally generated frame-synchronization pulse is required (that is, if the McBSP is the SPI master).

20.7.6 McBSP as the SPI Master

An SPI interface with the McBSP used as the master is shown in Figure 20-41. When the McBSP is configured as a master, the transmit output signal (DX) is used as the SPISIMO signal of the SPI protocol and the receive input signal (DR) is used as the SPISOMI signal.

The register bit values required to configure the McBSP as a master are listed in Table 20-16. After Table 20-16 are more details about the configuration requirements.

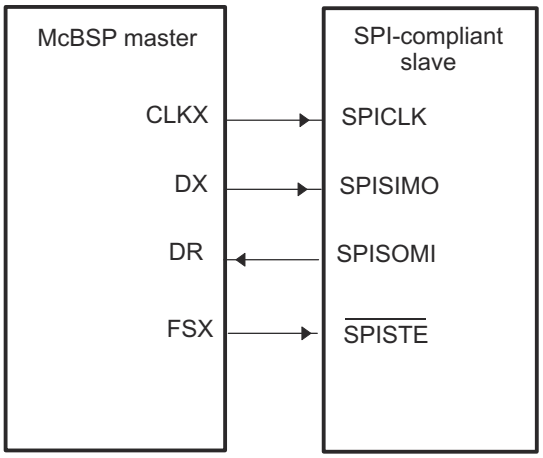


Figure 20-41. SPI Interface with McBSP Used as Master

Table 20-16. Bit Values Required to Configure the McBSP as an SPI Master

Required Bit Setting	Description
CLKSTP = 10b or 11b	The clock stop mode (without or with a clock delay) is selected.
CLKXP = 0 or 1	The polarity of CLKX as seen on the MCLKX pin is positive (CLKXP = 0) or negative (CLKXP = 1).
CLKRP = 0 or 1	The polarity of MCLKR as seen on the MCLKR pin is positive (CLKRP = 0) or negative (CLKRP = 1).
CLKXM = 1	The MCLKX pin is an output pin driven by the internal sample rate generator. Because CLKSTP is equal to 10b or 11b, MCLKR is driven internally by CLKX.
SCLKME = 0	The clock generated by the sample rate generator (CLKG) is derived from the CPU clock.
CLKSM = 1	
CLKGDV is a value from 1 to 255	CLKGDV defines the divide down value for CLKG.
FSXM = 1	The FSX pin is an output pin driven according to the FSGM bit.
FSGM = 0	The transmitter drives a frame-synchronization pulse on the FSX pin every time data is transferred from DXR1 to XSR1.
FSXP = 1	The FSX pin is active low.
XDATDLY = 01b	This setting provides the correct setup time on the FSX signal.
RDATDLY = 01b	

When the McBSP functions as the SPI master, the McBSP controls the transmission of data by producing the serial clock signal. The clock signal on the MCLKX pin is enabled only during packet transfers. When packets are not being transferred, the MCLKX pin remains high or low depending on the polarity used.

For SPI master operation, the MCLKX pin must be configured as an output. The sample rate generator is then used to derive the CLKX signal from the CPU clock. The clock stop mode internally connects the MCLKX pin to the MCLKR signal so that no external signal connection is required on the MCLKR pin and both the transmit and receive circuits are clocked by the master clock (CLKX).

The data delay parameters of the McBSP (XDATDLY and RDATDLY) must be set to 1 for proper SPI master operation. A data delay value of 0 or 2 is undefined in the clock stop mode.

The McBSP can also provide a slave-enable signal ($\overline{\text{SPISTE}}$) on the FSX pin. If a slave-enable signal is required, the FSX pin must be configured as an output and the transmitter must be configured so that a frame-synchronization pulse is generated automatically each time a packet is transmitted (FSGM = 0). The polarity of the FSX pin is programmable high or low; however, in most cases the pin must be configured active low.

When the McBSP is configured as described for SPI master operation, the bit fields for frame-synchronization pulse width (FWID) and frame-synchronization period (FPER) are overridden, and custom frame-synchronization

waveforms are not allowed. To see the resulting waveform produced on the FSX pin, see the timing diagrams in Section 20.7.4. The signal becomes active before the first bit of a packet transfer, and remains active until the last bit of the packet is transferred. After the packet transfer is complete, the FSX signal returns to the inactive state.

20.7.7 McBSP as an SPI Slave

An SPI with the McBSP used as a slave is shown in Figure 20-42. When the McBSP is configured as a slave, DX is used as the SPISOMI signal and DR is used as the SPISIMO signal.

The register bit values required to configure the McBSP as a slave are listed in Table 20-17. After Table 20-17 are more details about configuration requirements.

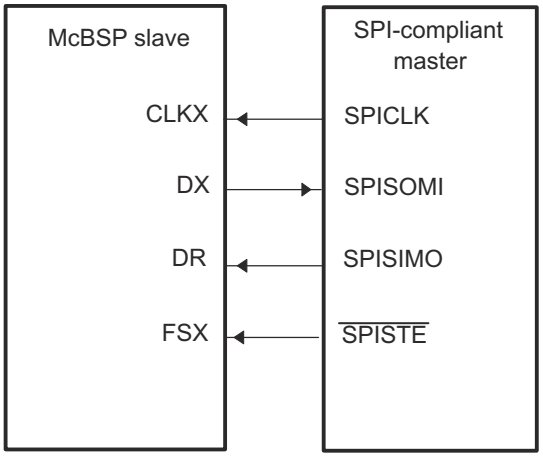

Figure 20-42. SPI Interface With McBSP Used as Slave

Table 20-17. Bit Values Required to Configure the McBSP as an SPI Slave

Required Bit Setting	Description
CLKSTP = 10b or 11b	The clock stop mode (without or with a clock delay) is selected.
CLKXP = 0 or 1	The polarity of CLKX as seen on the MCLKX pin is positive (CLKXP = 0) or negative (CLKXP = 1).
CLKRP = 0 or 1	The polarity of MCLKR as seen on the MCLKR pin is positive (CLKRP = 0) or negative (CLKRP = 1).
CLKXM = 0	The MCLKX pin is an input pin, so that the pin can be driven by the SPI master. Because CLKSTP = 10b or 11b, MCLKR is driven internally by CLKX.
SCLKME = 0 CLKSM = 1	The clock generated by the sample rate generator (CLKG) is derived from the CPU clock. (The sample rate generator is used to synchronize the McBSP logic with the externally-generated master clock.)
CLKGDV = 1	The sample rate generator divides the CPU clock before generating CLKG.
FSXM = 0	The FSX pin is an input pin, so that the pin can be driven by the SPI master.
FSXP = 1	The FSX pin is active low.
XDATDLY = 00b	These bits must be 0s for SPI slave operation.
RDATDLY = 00b	

When the McBSP is used as an SPI slave, the master clock and slave-enable signals are generated externally by a master device. Accordingly, the CLKX and FSX pins must be configured as inputs. The MCLKX pin is internally connected to the MCLKR signal, so that both the transmit and receive circuits of the McBSP are clocked by the external master clock. The FSX pin is also internally connected to the FSR signal, and no external signal connections are required on the MCLKR and FSR pins.

Although the CLKX signal is generated externally by the master and is asynchronous to the McBSP, the sample rate generator of the McBSP must be enabled for proper SPI slave operation. The sample rate generator must

be programmed to the maximum rate of half the CPU clock rate. The internal sample rate clock is then used to synchronize the McBSP logic to the external master clock and slave-enable signals.

The McBSP requires an active edge of the slave-enable signal on the FSX input for each transfer. This means that the master device must assert the slave-enable signal at the beginning of each transfer, and deassert the signal after the completion of each packet transfer; the slave-enable signal cannot remain active between transfers. Unlike the standard SPI, this pin cannot be tied low all the time.

The data delay parameters of the McBSP must be set to 0 for proper SPI slave operation. A value of 1 or 2 is undefined in the clock stop mode.

20.8 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP/receiver in reset (see Section 20.8.2).
2. Program McBSP registers for the desired receiver operation (see Section 20.8.1).
3. Take the receiver out of reset (see Section 20.8.2).

20.8.1 Programming the McBSP Registers for the Desired Receiver Operation

The following is a list of important tasks to be performed when you are configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields.

- Global behavior:
  - Set the receiver pins to operate as McBSP pins.
  - Enable/disable the digital loopback mode.
  - Enable/disable the clock stop mode.
  - Enable/disable the receive multichannel selection mode.
- Data behavior:
  - Choose 1 or 2 phases for the receive frame.
  - Set the receive word length(s).
  - Set the receive frame length.
  - Enable/disable the receive frame-synchronization ignore function.
  - Set the receive companding mode.
  - Set the receive data delay.
  - Set the receive sign-extension and justification mode.
  - Set the receive interrupt mode.
- Frame-synchronization behavior:
  - Set the receive frame-synchronization mode.
  - Set the receive frame-synchronization polarity.
  - Set the sample rate generator (SRG) frame-synchronization period and pulse width.
- Clock behavior:
  - Set the receive clock mode.
  - Set the receive clock polarity.
  - Set the SRG clock divide-down value.
  - Set the SRG clock synchronization mode.
  - Set the SRG clock mode (choose an input clock).
  - Set the SRG input clock polarity.

20.8.2 Resetting and Enabling the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take the receiver out of reset). Table 20-18 describes the bits used for both of these steps.

Table 20-18. Register Bits Used to Reset or Enable the McBSP Receiver Field Descriptions

Register	Bit	Field	Value	Description
SPCR2	7	FRST		Frame-synchronization logic reset
			0	Frame-synchronization logic is reset. The sample rate generator does not generate frame-synchronization signal FSG, even if GRST = 1.
			1	If GRST = 1, frame-synchronization signal FSG is generated after (FPER + 1) number of CLKG clock cycles; all frame counters are loaded with their programmed values.
SPCR2	6	GRST		Sample rate generator reset
			0	Sample rate generator is reset. If GRST = 0 due to a DSP reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven low (inactive). If GRST = 0 due to program code, CLKG and FSG are both driven low (inactive).
			1	Sample rate generator is enabled. CLKG is driven according to the configuration programmed in the sample rate generator registers (SRGR[1,2]). If FRST = 1, the generator also generates the frame-synchronization signal FSG as programmed in the sample rate generator registers.
SPCR1	0	RRST		Receiver reset
			0	The serial port receiver is disabled and in the reset state.
			1	The serial port receiver is enabled.

20.8.2.1 Reset Considerations

The serial port can be reset in the following two ways:

1. The DSP reset ($\overline{\text{XRS}}$ signal driven low) places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed ($\overline{\text{XRS}}$ signal released), GRST = FRST = RRST = XRST = 0 keep the entire serial port in the reset state, provided the McBSP clock is turned on.
2. The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the serial port control registers. The sample rate generator can be reset directly using the GRST bit in SPCR2.

Table 20-19 shows the state of McBSP pins when the serial port is reset due to a device reset and a direct receiver/transmitter reset.

For more details about McBSP reset conditions and effects, see Section 20.10.2.

Table 20-19. Reset State of Each McBSP Pin

Pin	Possible States[1]	State Forced By Device Reset	State Forced By Receiver Reset (RRST = 0 and GRST = 1)
MDRx	I	GPIO Input	Input
MCLKRx	I/O/Z	GPIO Input	Known state, if input; MCLKR running, if output
MFSRx	I/O/Z	GPIO Input	Known state, if input; FSRP inactive state, if output
			Transmitter reset (XRST = 0 and GRST = 1)
MDXx	O/Z	GPIO Input	Low impedance after transmit bit clock provided
MCLKXx	I/O/Z	GPIO Input	Known state, if input; CLKX running, if output
MFSXx	I/O/Z	GPIO Input	Known state, if input; FSXP inactive state, if output

(1) In Possible States column, I = input, O = output, Z = high impedance

20.8.3 Set the Receiver Pins to Operate as McBSP Pins

To configure a pin for McBSP functioning, configure the bits of the GPxMUXn register appropriately. In addition to this, bits 12 and 13 of the PCR register must be set to 0. These bits are defined as reserved.

20.8.4 Digital Loopback Mode

The DLB bit determines whether the digital loopback mode is on. DLB is described in Table 20-20.

Table 20-20. Register Bit Used to Enable/Disable the Digital Loopback Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	15	DLB	Digital loopback mode		R/W	0
			DLB = 0	Digital loopback mode is disabled.		
			DLB = 1	Digital loopback mode is enabled.		

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals, as shown in Table 20-21. This mode allows testing of serial port code with a single DSP device; the McBSP receives the data the McBSP transmits.

Table 20-21. Receive Signals Connected to Transmit Signals in Digital Loopback Mode

This Receive Signal	Is Fed Internally by This Transmit Signal
MDR (receive data)	MDX (transmit data)
MFSR (receive frame synchronization)	MFSX (transmit frame synchronization)
MCLKR (receive clock)	MCLKX (transmit clock)

20.8.5 Clock Stop Mode

The CLKSTP bits determine whether the clock stop mode is on. CLKSTP is described in Table 20-22.

Table 20-22. Register Bits Used to Enable/Disable the Clock Stop Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	12-11	CLKSTP	Clock stop mode		R/W	00
			CLKSTP = 0Xb	Clock stop mode disabled; normal clocking for non-SPI mode		
			CLKSTP = 10b	Clock stop mode enabled, without clock delay		
			CLKSTP = 11b	Clock stop mode enabled, with clock delay		

The clock stop mode supports the SPI master-slave protocol. If you do not plan to use the SPI protocol, you can clear CLKSTP to disable the clock stop mode.

In the clock stop mode, the clock stops at the end of each data transfer. At the beginning of each data transfer, the clock starts immediately (CLKSTP = 10b) or after a half-cycle delay (CLKSTP = 11b). The CLKXP bit determines whether the starting edge of the clock on the MCLKX pin is rising or falling. The CLKRP bit determines whether receive data is sampled on the rising or falling edge of the clock shown on the MCLKR pin.

Table 20-23 summarizes the impact of CLKSTP, CLKXP, and CLKRP on serial port operation. In the clock stop mode, the receive clock is tied internally to the transmit clock, and the receive frame-synchronization signal is tied internally to the transmit frame-synchronization signal.

Table 20-23. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme

Bit Settings	Clock Scheme
CLKSTP = 00b or 01b CLKXP = 0 or 1 CLKRP = 0 or 1	Clock stop mode disabled. Clock enabled for non-SPI mode.
CLKSTP = 10b CLKXP = 0 CLKRP = 0	Low inactive state without delay: The McBSP transmits data on the rising edge of CLKX and receives data on the falling edge of MCLKR.
CLKSTP = 11b CLKXP = 0 CLKRP = 1	Low inactive state with delay: The McBSP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 10b CLKXP = 1 CLKRP = 0	High inactive state without delay: The McBSP transmits data on the falling edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 11b CLKXP = 1 CLKRP = 1	High inactive state with delay: The McBSP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of MCLKR.

20.8.6 Receive Multichannel Selection Mode

The RMCM bit determines whether the receive multichannel selection mode is on. RMCM is described in Table 20-24. For more details, see Section 20.6.6.

Table 20-24. Register Bit Used to Enable/Disable the Receive Multichannel Selection Mode

Register	Bit	Name	Function		Type	Reset Value
MCR1	0	RMCM	Receive multichannel selection mode		R/W	0
			RMCM = 0	The mode is disabled. All 128 channels are enabled.		
			RMCM = 1	The mode is enabled. Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate receive channel enable registers (RCERs). The way channels are assigned to the RCERs depends on the number of receive channel partitions (2 or 8), as defined by the RMCME bit.		

20.8.7 Receive Frame Phases

The RPHASE bit (see Table 20-25) determines whether the receive data frame has one or two phases.

Table 20-25. Register Bit Used to Choose One or Two Phases for the Receive Frame

Register	Bit	Name	Function		Type	Reset Value
RCR2	15	RPHASE	Receive phase number		R/W	0
			Specifies whether the receive frame has 1 or 2 phases.			
			RPHASE = 0	Single-phase frame		
			RPHASE = 1	Dual-phase frame		

20.8.8 Receive Word Lengths

The RWDLEN1 and RWDLEN2 bit fields (see Table 20-26) determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

Table 20-26. Register Bits Used to Set the Receive Word Lengths

Register	Bit	Name	Function		Type	Reset Value
RCR1	7-5	RWDLEN1	Receive word length 1		R/W	000
			Specifies the length of every serial word in phase 1 of the receive frame.			
			RWDLEN1 = 000	8 bits		
			RWDLEN1 = 001	12 bits		
			RWDLEN1 = 010	16 bits		
			RWDLEN1 = 011	20 bits		
			RWDLEN1 = 100	24 bits		
			RWDLEN1 = 101	32 bits		
			RWDLEN1 = 11X	Reserved		
RCR2	7-5	RWDLEN2	Receive word length 2		R/W	000
			If a dual-phase frame is selected, RWDLEN2 specifies the length of every serial word in phase 2 of the frame.			
			RWDLEN2 = 000	8 bits		
			RWDLEN2 = 001	12 bits		
			RWDLEN2 = 010	16 bits		
			RWDLEN2 = 011	20 bits		
			RWDLEN2 = 100	24 bits		
			RWDLEN2 = 101	32 bits		
			RWDLEN2 = 11X	Reserved		

20.8.8.1 Word Length Bits

Each frame can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 determines the length of the serial words in phase 1 of the frame and RWDLEN2 determines the word length in phase 2 of the frame.

20.8.9 Receive Frame Length

The RFRLEN1 and RFRLEN2 bit fields (see Table 20-27) determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

Table 20-27. Register Bits Used to Set the Receive Frame Length

Register	Bit	Name	Function		Type	Reset Value
RCR1	14-8	RFRLEN1	Receive frame length 1		R/W	000 0000
			(RFRLEN1 + 1) is the number of serial words in phase 1 of the receive frame.			
			RFRLEN1 = 000 0000	1 word in phase 1		
			RFRLEN1 = 000 0001	2 words in phase 1		
			|	|		
			|	|		
			RFRLEN1 = 111 1111	128 words in phase 1		
RCR2	14-8	RFRLEN2	Receive frame length 2		R/W	000 0000
			If a dual-phase frame is selected, (RFRLEN2 + 1) is the number of serial words in phase 2 of the receive frame.			
			RFRLEN2 = 000 0000	1 word in phase 2		
			RFRLEN2 = 000 0001	2 words in phase 2		
			|	|		
			|	|		
			RFRLEN2 = 111 1111	128 words in phase 2		

20.8.9.1 Selected Frame Length

The receive frame length is the number of serial words in the receive frame. Each frame can have one or two phases, depending on value that you load into the RPHASE bit.

If a single-phase frame is selected (RPHASE = 0), the frame length is equal to the length of phase 1. If a dual-phase frame is selected (RPHASE = 1), the frame length is the length of phase 1 plus the length of phase 2.

The 7-bit RFRLEN fields allow up to 128 words per phase. See Table 20-28 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the RFRLEN fields with [*w minus 1*], where *w* represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into RFRLEN1.

Table 20-28. How to Calculate the Length of the Receive Frame

RPHASE	RFRLEN1	RFRLEN2	Frame Length
0	0 ≤ RFRLEN1 ≤ 127	Don't care	(RFRLEN1 + 1) words
1	0 ≤ RFRLEN1 ≤ 127	0 ≤ RFRLEN2 ≤ 127	(RFRLEN1 + 1) + (RFRLEN2 + 1) words

20.8.10 Receive Frame-Synchronization Ignore Function

The RFIG bit (see Table 20-29) controls the receive frame-synchronization ignore function.

Table 20-29. Register Bit Used to Enable/Disable the Receive Frame-Synchronization Ignore Function

Register	Bit	Name	Function		Type	Reset Value
RCR2	2	RFIG	Receive frame-synchronization ignore		R/W	0
			RFIG = 0	An unexpected receive frame-synchronization pulse causes the McBSP to restart the frame transfer.		
			RFIG = 1	The McBSP ignores unexpected receive frame-synchronization pulses.		

20.8.10.1 Unexpected Frame-Synchronization Pulses and the Frame-Synchronization Ignore Function

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse.

When RFIG = 1, reception continues, ignoring the unexpected frame-synchronization pulses.

When RFIG = 0, an unexpected FSR pulse causes the McBSP to discard the contents of RSR[1,2] in favor of the new incoming data. Therefore, if RFIG = 0 and an unexpected frame-synchronization pulse occurs, the serial port:

1. Aborts the current data transfer
2. Sets RSYNCERR in SPCR1 to 1
3. Begins the transfer of a new data word

For more details about the frame-synchronization error condition, see Section 20.5.3.

20.8.10.2 Examples of Effects of RFIG

Figure 20-43 shows an example in which word B is interrupted by an unexpected frame-synchronization pulse when (R/X)FIG = 0. In the case of reception, the reception of B is aborted (B is lost), and a new data word C in this example) is received after the appropriate data delay. This condition is a receive synchronization error, which sets the RSYNCERR bit.

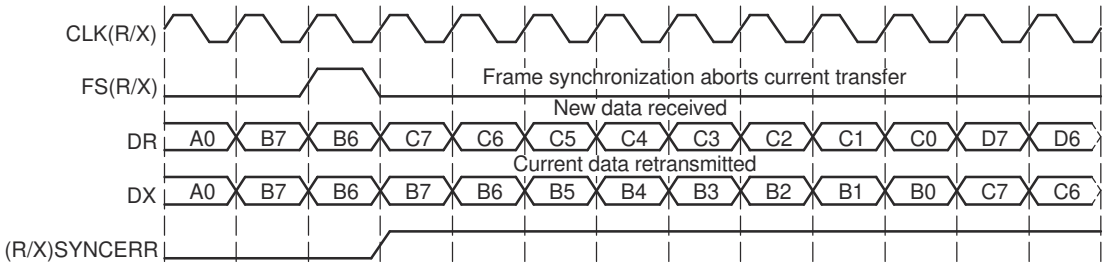

Figure 20-43. Unexpected Frame-Synchronization Pulse With (R/X)FIG = 0

In contrast with Figure 20-43, Figure 20-44 shows McBSP operation when unexpected frame-synchronization signals are ignored (when (R/X)FIG = 1). Here, the transfer of word B is not affected by an unexpected pulse.

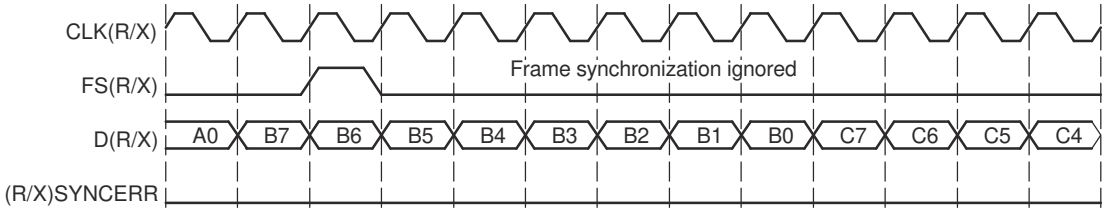

Figure 20-44. Unexpected Frame-Synchronization Pulse With (R/X)FIG = 1

20.8.11 Receive Companding Mode

The RCOMPAND bits (see Table 20-30) determine whether companding or another data transfer option is chosen for McBSP reception.

Table 20-30. Register Bits Used to Set the Receive Companding Mode

Register	Bit	Name	Function		Type	Reset Value
RCR2	4-3	RCOMPAND	Receive companding mode		R/W	00
			Modes other than 00b are enabled only when the appropriate RWDLEN is 000b, indicating 8-bit data.			
			RCOMPAND = 00	No companding, any size data, MSB received first		
			RCOMPAND = 01	No companding, 8-bit data, LSB received first (for details, see Section 20.8.11.4).		
			RCOMPAND = 10	µ-law companding, 8-bit data, MSB received first		
			RCOMPAND = 11	A-law companding, 8-bit data, MSB received first		

20.8.11.1 Companding

Companding (COMpressing and exPANDing) hardware allows compression and expansion of data in either μ-law or A-law format. The companding standard employed in the United States and Japan is μ-law. The European companding standard is referred to as A-law. The specifications for μ-law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and μ-law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

The μ-law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 20-45 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or μ-law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to 2's-complement format.

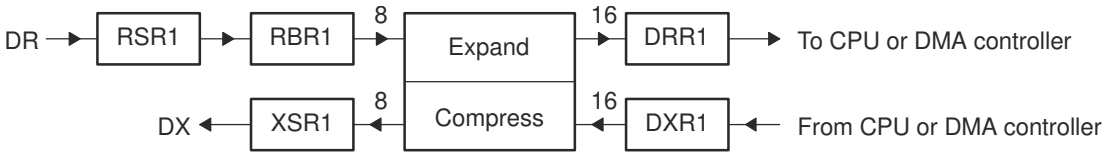

Figure 20-45. Companding Processes for Reception and for Transmission

20.8.11.2 Format of Expanded Data

For reception, the 8-bit compressed data in RBR1 is expanded to left-justified 16-bit data in DRR1. The RJUST bit of SPCR1 is ignored when companding is used.

20.8.11.3 Companding Internal Data

If the McBSP is otherwise unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. See Section 20.3.2.2.

20.8.11.4 Option to Receive LSB First

Normally, the McBSP transmits or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set RCOMPAND = 01b in RCR2, the bit ordering of 8-bit words is reversed during reception. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits and LSB-first ordering is done.

20.8.12 Receive Data Delay

The RDATDLY bits (see Table 20-31) determine the length of the data delay for the receive frame.

Table 20-31. Register Bits Used to Set the Receive Data Delay

Register	Bit	Name	Function		Type	Reset Value
RCR2	1-0	RDATDLY	Receive data delay		R/W	00
			RDATDLY = 00	0-bit data delay		
			RDATDLY = 01	1-bit data delay		
			RDATDLY = 10	2-bit data delay		
			RDATDLY = 11	Reserved		

20.8.12.1 Data Delay

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

RDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (RDATDLY = 00b-10b), as described in Table 20-31 and shown in Figure 20-46. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

20.8.12.2 0-Bit Data Delay

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of MCLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on DX. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the DX pin.

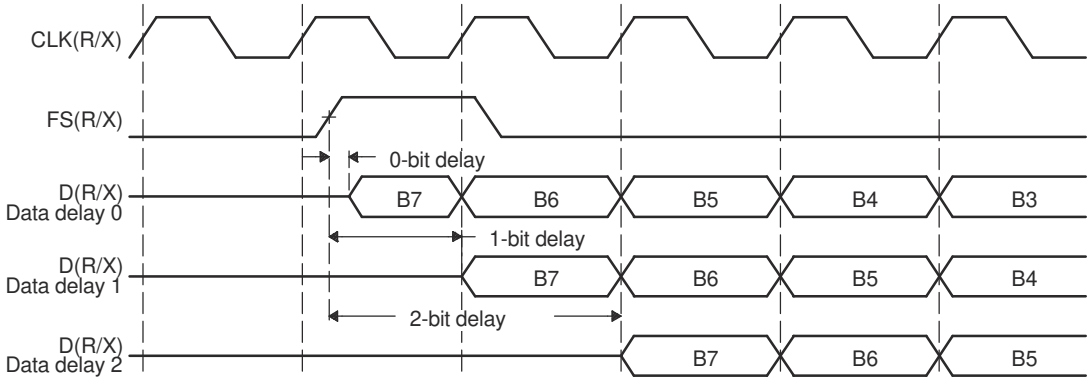

Figure 20-46. Range of Programmable Data Delay

20.8.12.3 2-Bit Data Delay

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 20-47. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

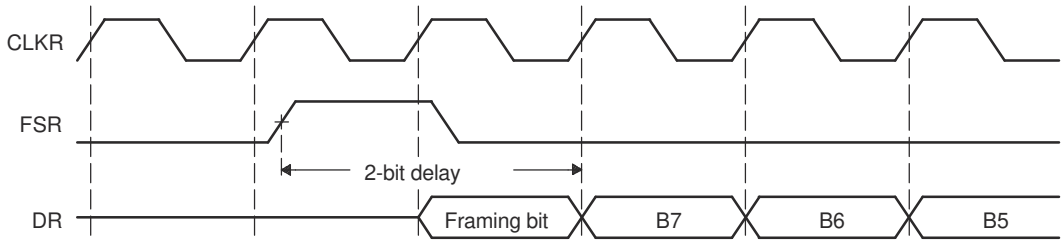

Figure 20-47. 2-Bit Data Delay Used to Skip a Framing Bit

20.8.13 Receive Sign-Extension and Justification Mode

The RJUST bits (see Table 20-32) determine whether data received by the McBSP is sign-extended and how the data is justified.

Table 20-32. Register Bits Used to Set the Receive Sign-Extension and Justification Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	14-13	RJUST	Receive sign-extension and justification mode		R/W	00
			RJUST = 00	Right justify data and zero fill MSBs in DRR[1,2]		
			RJUST = 01	Right justify data and sign extend the data into the MSBs in DRR[1,2]		
			RJUST = 10	Left justify data and zero fill LSBs in DRR[1,2]		
			RJUST = 11	Reserved		

20.8.13.1 Sign-Extension and the Justification

RJUST in SPCR1 selects whether data in RBR[1,2] is right- or left-justified (with respect to the MSB) in DRR[1,2] and whether unused bits in DRR[1,2] are filled with zeros or with sign bits.

Table 20-33 and Table 20-34 show the effects of various RJUST values. The first table shows the effect on an example 12-bit receive-data value ABCh. The second table shows the effect on an example 20-bit receive-data value ABCDEh.

Table 20-33. Example: Use of RJUST Field With 12-Bit Data Value ABCh

RJUST	Justification	Extension	Value in DRR2	Value in DRR1
00b	Right	Zero fill MSBs	0000h	0ABCh
01b	Right	Sign extend data into MSBs	FFFFh	FABCh
10b	Left	Zero fill LSBs	0000h	ABC0h
11b	Reserved	Reserved	Reserved	Reserved

Table 20-34. Example: Use of RJUST Field With 20-Bit Data Value ABCDEh

RJUST	Justification	Extension	Value in DRR2	Value in DRR1
00b	Right	Zero fill MSBs	000Ah	BCDEh
01b	Right	Sign extend data into MSBs	FFFAh	BCDEh
10b	Left	Zero fill LSBs	ABCDh	E000h
11b	Reserved	Reserved	Reserved	Reserved

20.8.14 Receive Interrupt Mode

The RINTM bits (see Table 20-35) determine which event generates a receive interrupt request to the CPU.

The receive interrupt (RINT) informs the CPU of changes to the serial port status. Four options exist for configuring this interrupt. The options are set by the receive interrupt mode bits, RINTM, in SPCR1.

Table 20-35. Register Bits Used to Set the Receive Interrupt Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	5-4	RINTM	Receive interrupt mode		R/W	00
			RINTM = 00	RINT generated when RRDY changes from 0 to 1. Interrupt on every serial word by tracking the RRDY bit in SPCR1. Regardless of the value of RINTM, RRDY can be read to detect the RRDY = 1 condition.		
			RINTM = 01	RINT generated by an end-of-block or end-of-frame condition in the receive multichannel selection mode. In the multichannel selection mode, interrupt after every 16-channel block boundary has been crossed within a frame and at the end of the frame. For details, see Section 20.6.8. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.		
			RINTM = 10	RINT generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in the reset state. This is done by synchronizing the incoming frame-synchronization pulse to the CPU clock and sending the pulse to the CPU using RINT.		
			RINTM = 11	RINT generated when RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see Section 20.5.3.		

20.8.15 Receive Frame-Synchronization Mode

The bits described in Table 20-36 determine the source for receive frame synchronization and the function of the FSR pin.

20.8.15.1 Receive Frame-Synchronization Modes

Table 20-37 shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the FSR pin. The polarity of the signal on the FSR pin is determined by the FSRP bit.

In digital loopback mode (DLB = 1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the clock stop mode, the internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

Table 20-36. Register Bits Used to Set the Receive Frame Synchronization Mode

Register	Bit	Name	Function		Type	Reset Value
PCR	10	FSRM	Receive frame-synchronization mode		R/W	0
			FSRM = 0	Receive frame synchronization is supplied by an external source via the FSR pin.		
			FSRM = 1	Receive frame synchronization is supplied by the sample rate generator. FSR is an output pin reflecting internal FSR, except when GSYNC = 1 in SRGR2.		
SRGR2	15	GSYNC	Sample rate generator clock synchronization mode		R/W	0
			If the sample rate generator creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the FSR pin.			
			GSYNC = 0	No clock synchronization is used: CLKG oscillates without adjustment, and FSG pulses every (FPER + 1) CLKG cycles.		
			GSYNC = 1	Clock synchronization is used. When a pulse is detected on the FSR pin: • CLKG is adjusted as necessary so that CLKG is synchronized with the input clock on the MCLKR pin. • FSG pulses FSG only pulses in response to a pulse on the FSR pin. The frame-synchronization period defined in FPER is ignored. For more details, see Section 20.4.3.		
SPCR1	15	DLB	Digital loopback mode		R/W	0
			DLB = 0	Digital loopback mode is disabled.		
			DLB = 1	Digital loopback mode is enabled. The receive signals, including the receive frame-synchronization signal, are connected internally through multiplexers to the corresponding transmit signals.		
SPCR1	12-11	CLKSTP	Clock stop mode		R/W	00
			CLKSTP = 0Xb	Clock stop mode disabled; normal clocking for non-SPI mode.		
			CLKSTP = 10b	Clock stop mode enabled without clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.		
			CLKSTP = 11b	Clock stop mode enabled with clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.		

Table 20-37. Select Sources to Provide the Receive Frame-Synchronization Signal and the Effect on the FSR Pin

DLB	FSRM	GSYNC	Source of Receive Frame Synchronization	FSR Pin Status
0	0	0 or 1	An external frame-synchronization signal enters the McBSP through the FSR pin. The signal is then inverted as determined by FSRP before being used as internal FSR.	Input
0	1	0	Internal FSR is driven by the sample rate generator frame-synchronization signal (FSG).	Output. FSG is inverted as determined by FSRP before being driven out on the FSR pin.
0	1	1	Internal FSR is driven by the sample rate generator frame-synchronization signal (FSG).	Input. The external frame-synchronization input on the FSR pin is used to synchronize CLKG and generate FSG pulses.
1	0	0	Internal FSX drives internal FSR.	High impedance
1	0 or 1	1	Internal FSX drives internal FSR.	Input. If the sample rate generator is running, external FSR is used to synchronize CLKG and generate FSG pulses.
1	1	0	Internal FSX drives internal FSR.	Output. Receive (same as transmit) frame synchronization is inverted as determined by FSRP before being driven out on the FSR pin.

20.8.16 Receive Frame-Synchronization Polarity

The FSRP bit (see Table 20-38) determines whether frame-synchronization pulses are active high or active low on the FSR pin.

Table 20-38. Register Bit Used to Set Receive Frame-Synchronization Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	2	FSRP	Receive frame-synchronization polarity		R/W	0
			FSRP = 0	Frame-synchronization pulse FSR is active high.		
			FSRP = 1	Frame-synchronization pulse FSR is active low.		

20.8.16.1 Frame-Synchronization Pulses, Clock Signals, and Their Polarities

Receive frame-synchronization pulses can be generated internally by the sample rate generator (see Section 20.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSRM, in PCR. FSR is also affected by the GSYNC bit in SRGR2. For information about the effects of FSRM and GSYNC, see Section 20.8.15. Similarly, receive clocks can be selected to be inputs or outputs by programming the mode bit, CLKRM, in the PCR (see Section 20.8.17).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that the outputs are driven by the sample rate generator, the outputs are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and MCLKR is an input pin), the external rising-edge triggered input clock on MCLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

MCLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to make sure of valid setup and hold of data around this edge. Figure 20-48 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

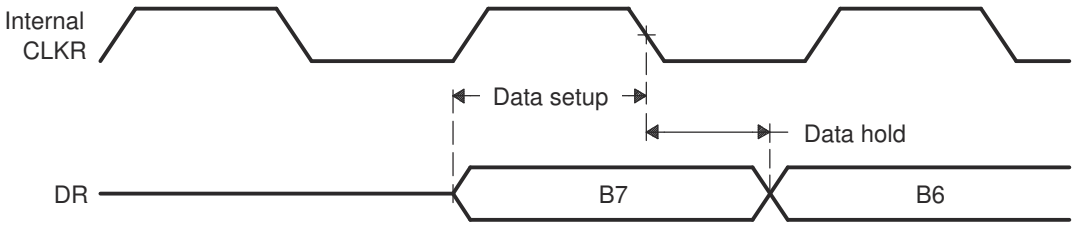

Figure 20-48. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge

Set the SRG Frame-Synchronization Period and Pulse Width.

20.8.16.2 Frame-Synchronization Period and the Frame-Synchronization Pulse Width

The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0. Table 20-39 shows settings for FPER and FWID.

Figure 20-49 shows a frame-synchronization period of 16 CLKG periods (FPER = 15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

Table 20-39. Register Bits Used to Set the SRG Frame-Synchronization Period and Pulse Width

Register	Bit	Name	Function	Type	Reset Value
SRGR2	11-0	FPER	Sample rate generator frame-synchronization period For the frame-synchronization signal FSG, (FPER + 1) determines the period from the start of a frame-synchronization pulse to the start of the next frame-synchronization pulse. Range for (FPER + 1): 1 to 4096 CLKG cycles	R/W	0000 0000 0000
SRGR1	15-8	FWID	Sample rate generator frame-synchronization pulse width This field plus 1 determines the width of each frame-synchronization pulse on FSG. Range for (FWID + 1): 1 to 256 CLKG cycles	R/W	0000 0000

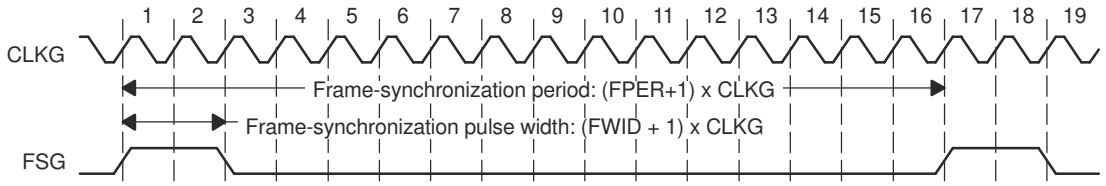

Figure 20-49. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods

When the sample rate generator comes out of reset, FSG is in the inactive state. Then, when GRST = 1 and FSGM = 1, a frame-synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until the value reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

20.8.17 Receive Clock Mode

Table 20-40 shows the settings for bits used to set receive clock mode.

Table 20-40. Register Bits Used to Set the Receive Clock Mode

Register	Bit	Name	Function		Type	Reset Value
PCR	8	CLKRM	Receive clock mode		R/W	0
			Case 1: Digital loopback mode not set (DLB = 0) in SPCR1.			
			CLKRM = 0	The MCLKR pin is an input pin that supplies the internal receive clock (MCLKR).		
			CLKRM = 1	Internal MCLKR is driven by the sample rate generator of the McBSP. The MCLKR pin is an output pin that reflects internal MCLKR.		
			Case 2: Digital loopback mode set (DLB = 1) in SPCR1.			
			CLKRM = 0	The MCLKR pin is in the high impedance state. The internal receive clock (MCLKR) is driven by the internal transmit clock (CLKX). Internal CLKX is derived according to the CLKXM bit of PCR.		
			CLKRM = 1	Internal MCLKR is driven by internal CLKX. The MCLKR pin is an output pin that reflects internal MCLKR. Internal CLKX is derived according to the CLKXM bit of PCR.		
SPCR1	15	DLB	Digital loopback mode		R/W	00
			DLB = 0	Digital loopback mode is disabled.		
			DLB = 1	Digital loopback mode is enabled. The receive signals, including the receive frame-synchronization signal, are connected internally through multiplexers to the corresponding transmit signals.		
SPCR1	12-11	CLKSTP	Clock stop mode		R/W	00
			CLKSTP = 0Xb	Clock stop mode disabled; normal clocking for non-SPI mode.		
			CLKSTP = 10b	Clock stop mode enabled without clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.		
			CLKSTP = 11b	Clock stop mode enabled with clock delay. The internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.		

20.8.17.1 Selecting a Source for the Receive Clock and a Data Direction for the MCLKR Pin

Table 20-41 shows how you can select various sources to provide the receive clock signal and affect the MCLKR pin. The polarity of the signal on the MCLKR pin is determined by the CLKRP bit.

In the digital loopback mode (DLB = 1), the transmit clock signal is used as the receive clock signal.

Also, in the clock stop mode, the internal receive clock signal (MCLKR) and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

Table 20-41. Receive Clock Signal Source Selection

DLB in SPCR1	CLKRM in PCR	Source of Receive Clock	MCLKR Pin Status
0	0	The MCLKR pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP before being used.	Input
0	1	The sample rate generator clock (CLKG) drives internal MCLKR.	Output. CLKG, inverted as determined by CLKRP, is driven out on the MCLKR pin.
1	0	Internal CLKX drives internal MCLKR. To configure CLKX, see Section 20.9.19.	High impedance
1	1	Internal CLKX drives internal MCLKR. To configure CLKX, see Section 20.9.19.	Output. Internal MCLKR (same as internal CLKX) is inverted as determined by CLKRP before being driven out on the MCLKR pin.

20.8.18 Receive Clock Polarity

Table 20-42 shows which register bits set the Receive Clock Polarity.

Table 20-42. Register Bit Used to Set Receive Clock Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	0	CLKRP	Receive clock polarity		R/W	0
			CLKRP = 0	Receive data sampled on falling edge of MCLKR		
			CLKRP = 1	Receive data sampled on rising edge of MCLKR		

20.8.18.1 Frame Synchronization Pulses, Clock Signals, and Their Polarities

Receive frame-synchronization pulses can be generated internally by the sample rate generator (see Section 20.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSRM, in PCR. FSR is also affected by the GSYNC bit in SRGR2. For information about the effects of FSRM and GSYNC, see Section 20.8.15. Similarly, receive clocks can be selected to be inputs or outputs by programming the mode bit, CLKRM, in the PCR (see Section 20.8.17).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that the outputs are driven by the sample rate generator, the outputs are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and MCLKR is an input pin), the external rising-edge triggered input clock on MCLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to make sure of valid setup and hold of data around this edge. Figure 20-50 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

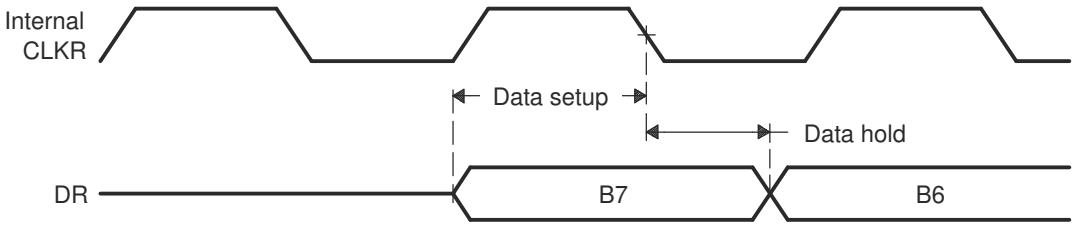

Figure 20-50. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge

20.8.19 SRG Clock Divide-Down Value

Table 20-43. Register Bits Used to Set the Sample Rate Generator (SRG) Clock Divide-Down Value

Register	Bit	Name	Function	Type	Reset Value
SRGR1	7-0	CLKGDV	Sample rate generator clock divide-down value The input clock of the sample rate generator is divided by (CLKGDV + 1) to generate the required sample rate generator clock frequency. The default value of CLKGDV is 1 (divide input clock by 2).	R/W	0000 0001

20.8.19.1 Sample Rate Generator Clock Divider

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to 1/(CLKGDV + 1) of sample rate generator input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. When CLKGDV is odd or equal to 0, the CLKG duty cycle is 50%. When CLKGDV is an even value, 2p, representing an odd divide-down, the high-state duration is p + 1 cycles and the low-state duration is p cycles.

20.8.20 SRG Clock Synchronization Mode

For more details on using the clock synchronization feature, see Section 20.4.3.

Table 20-44. Register Bit Used to Set the SRG Clock Synchronization Mode

Register	Bit	Name	Function	Type	Reset Value
SRGR2	15	GSYNC	Sample rate generator clock synchronization GSYNC is used only when the input clock source for the sample rate generator is external—on the MCLKR or MCLKX pin. GSYNC = 0: The sample rate generator clock (CLKG) is free running. CLKG oscillates without adjustment, and FSG pulses every (FPER + 1) CLKG cycles. GSYNC = 1: Clock synchronization is performed. When a pulse is detected on the FSR pin: • CLKG is adjusted as necessary so that CLKG is synchronized with the input clock on the MCLKR or MCLKX pin. • FSG pulses. FSG only pulses in response to a pulse on the FSR pin. The frame-synchronization period defined in FPER is ignored.	R/W	0

20.8.21 SRG Clock Mode (Choose an Input Clock)

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock. Table 20-45 shows the four possible sources of the input clock. For more details on generating CLKG, see Section 20.4.1.1.

Table 20-45. Register Bits Used to Set the SRG Clock Mode (Choose an Input Clock)

Register	Bit	Name	Function		Type	Reset Value
PCR	7	SCLKME	Sample rate generator clock mode		R/W	0
SRGR2	13	CLKSM			R/W	1
			SCLKME = 0 CLKSM = 0	Reserved		
			SCLKME = 0 CLKSM = 1	Sample rate generator clock derived from LSPCLK (default)		
			SCLKME = 1 CLKSM = 0	Sample rate generator clock derived from MCLKR pin		
			SCLKME = 1 CLKSM = 1	Sample rate generator clock derived from MCLKX pin		

20.8.22 SRG Input Clock Polarity

Table 20-46 shows which register bits set the SRG Input Clock Polarity.

Table 20-46. Register Bits Used to Set the SRG Input Clock Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	1	CLKXP	MCLKX pin polarity		R/W	0
			CLKXP determines the input clock polarity when the MCLKX pin supplies the input clock (SCLKME = 1 and CLKSM = 1).			
			CLKXP = 0	Rising edge on MCLKX pin generates transitions on CLKG and FSG.		
			CLKXP = 1	Falling edge on MCLKX pin generates transitions on CLKG and FSG.		
PCR	0	CLKRP	MCLKR pin polarity		R/W	0
			CLKRP determines the input clock polarity when the MCLKR pin supplies the input clock (SCLKME = 1 and CLKSM = 0).			
			CLKRP = 0	Falling edge on MCLKR pin generates transitions on CLKG and FSG.		
			CLKRP = 1	Rising edge on MCLKR pin generates transitions on CLKG and FSG.		

20.8.22.1 Using CLKXP/CLKRP to Choose an Input Clock Polarity

The sample rate generator can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the sample rate generator must be driven by an input clock signal derived from the CPU clock or from an external clock on the CLKX or MCLKR pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKXP for the MCLKX pin, CLKRP for the MCLKR pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

20.9 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP/transmitter in reset (see Section 20.9.2).
2. Program the McBSP registers for the desired transmitter operation (see Section 20.9.1).
3. Take the transmitter out of reset (see Section 20.9.2).

20.9.1 Programming the McBSP Registers for the Desired Transmitter Operation

The following is a list of important tasks to be performed when you are configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

- Global behavior:
  - Set the transmitter pins to operate as McBSP pins.
  - Enable/disable the digital loopback mode.
  - Enable/disable the clock stop mode.
  - Enable/disable transmit multichannel selection.
- Data behavior:
  - Choose 1 or 2 phases for the transmit frame.
  - Set the transmit word length(s).
  - Set the transmit frame length.
  - Enable/disable the transmit frame-synchronization ignore function.
  - Set the transmit companding mode.
  - Set the transmit data delay.
  - Set the transmit DXENA mode.
  - Set the transmit interrupt mode.
- Frame-synchronization behavior:
  - Set the transmit frame-synchronization mode.
  - Set the transmit frame-synchronization polarity.
  - Set the SRG frame-synchronization period and pulse width.
- Clock behavior:
  - Set the transmit clock mode.
  - Set the transmit clock polarity.
  - Set the SRG clock divide-down value.
  - Set the SRG clock synchronization mode.
  - Set the SRG clock mode (choose an input clock).
  - Set the SRG input clock polarity.

20.9.2 Resetting and Enabling the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take the transmitter out of reset). Table 20-47 describes the bits used for both of these steps.

Table 20-47. Register Bits Used to Place Transmitter in Reset Field Descriptions

Register	Bit	Field	Value	Description
SPCR2	7	FRST		Frame-synchronization logic reset
			0	Frame-synchronization logic is reset. The sample rate generator does not generate frame-synchronization signal FSG, even if GRST = 1.
			1	Frame-synchronization is enabled. If GRST = 1, frame-synchronization signal FSG is generated after (FPER + 1) number of CLKG clock cycles; all frame counters are loaded with their programmed values.
SPCR2	6	GRST		Sample rate generator reset
			0	Sample rate generator is reset. If GRST = 0 due to a device reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven low (inactive). If GRST = 0 due to program code, CLKG and FSG are both driven low (inactive).
			1	Sample rate generator is enabled. CLKG is driven according to the configuration programmed in the sample rate generator registers (SRGR[1,2]). If FRST = 1, the generator also generates the frame-synchronization signal FSG as programmed in the sample rate generator registers.
SPCR2	0	XRST		Transmitter reset
			0	The serial port transmitter is disabled and in the reset state.
			1	The serial port transmitter is enabled.

20.9.2.1 Reset Considerations

The serial port can be reset in the following two ways:

1. A DSP reset ($\overline{\text{XRS}}$ signal driven low) places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed, GRST = FRST = RRST = XRST = 0, keeping the entire serial port in the reset state.
2. The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the serial port control registers. The sample rate generator can be reset directly using the GRST bit in SPCR2.
3. When using the DMA, the order in which McBSP events must occur is important. DMA channel and peripheral interrupts must be configured prior to releasing the McBSP transmitter from reset.

   The reason for this is that an XRDY is fired when XRST = 1. The XRDY signals the DMA to start copying data from the buffer into the transmit register. If the McBSP transmitter is released from reset before the DMA channel and peripheral interrupts are configured, the XRDY signals before the DMA channel can receive the signal; therefore, the DMA does not move the data from the buffer to the transmit register. The DMA PERINTFLG is edge-sensitive and will fail to recognize the XRDY, which is continuously high.

For more details about McBSP reset conditions and effects, see Section 20.10.2.

20.9.3 Set the Transmitter Pins to Operate as McBSP Pins

To configure a pin for McBSP functioning, configure the bits of the GPxMUXn register appropriately. In addition to this, bits 12 and 13 of the PCR register must be set to 0. These bits are defined as reserved.

20.9.4 Digital Loopback Mode

The DLB bit determines whether the digital loopback mode is on. DLB is described in Table 20-48.

Table 20-48. Register Bit Used to Enable/Disable the Digital Loopback Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	15	DLB	Digital loopback mode		R/W	0
			DLB = 0	Digital loopback mode is disabled.		
			DLB = 1	Digital loopback mode is enabled.		

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals, as shown in Table 20-49. This mode allows testing of serial port code with a single DSP device; the McBSP receives the data it transmits.

Table 20-49. Receive Signals Connected to Transmit Signals in Digital Loopback Mode

This Receive Signal	Is Fed Internally by This Transmit Signal
DR (receive data)	DX (transmit data)
FSR (receive frame synchronization)	FSX (transmit frame synchronization)
MCLKR (receive clock)	CLKX (transmit clock)

20.9.5 Clock Stop Mode

The CLKSTP bits determine whether the clock stop mode is on. CLKSTP is described in Table 20-50.

Table 20-50. Register Bits Used to Enable/Disable the Clock Stop Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	12-11	CLKSTP	Clock stop mode		R/W	00
			CLKSTP = 0Xb	Clock stop mode disabled; normal clocking for non-SPI mode.		
			CLKSTP = 10b	Clock stop mode enabled without clock delay		
			CLKSTP = 11b	Clock stop mode enabled with clock delay		

The clock stop mode supports the SPI master-slave protocol. If you do not plan to use the SPI protocol, you can clear CLKSTP to disable the clock stop mode.

In the clock stop mode, the clock stops at the end of each data transfer. At the beginning of each data transfer, the clock starts immediately (CLKSTP = 10b) or after a half-cycle delay (CLKSTP = 11b). The CLKXP bit determines whether the starting edge of the clock on the MCLKX pin is rising or falling. The CLKRP bit determines whether receive data is sampled on the rising or falling edge of the clock shown on the MCLKR pin.

Table 20-51 summarizes the impact of CLKSTP, CLKXP, and CLKRP on serial port operation. In the clock stop mode, the receive clock is tied internally to the transmit clock, and the receive frame-synchronization signal is tied internally to the transmit frame-synchronization signal.

Table 20-51. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme

Bit Settings	Clock Scheme
CLKSTP = 00b or 01b CLKXP = 0 or 1 CLKRP = 0 or 1	Clock stop mode disabled. Clock enabled for non-SPI mode.
CLKSTP = 10b CLKXP = 0 CLKRP = 0	Low inactive state without delay: The McBSP transmits data on the rising edge of CLKX and receives data on the falling edge of MCLKR.
CLKSTP = 11b CLKXP = 0 CLKRP = 1	Low inactive state with delay: The McBSP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 10b CLKXP = 1 CLKRP = 0	High inactive state without delay: The McBSP transmits data on the falling edge of CLKX and receives data on the rising edge of MCLKR.
CLKSTP = 11b CLKXP = 1 CLKRP = 1	High inactive state with delay: The McBSP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of MCLKR.

20.9.6 Transmit Multichannel Selection Mode

For more details, see Section 20.6.7.

Table 20-52. Register Bits Used to Enable/Disable Transmit Multichannel Selection

Register	Bit	Name	Function		Type	Reset Value
MCR2	1-0	XMCM	Transmit multichannel selection		R/W	00
			XMCM = 00b	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.		
			XMCM = 01b	All channels are disabled unless the channels are selected in the appropriate transmit channel enable registers (XCERs). If enabled, a channel in this mode is also unmasked. The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs.		
			XMCM = 10b	All channels are enabled, but the channels are masked unless the channels are selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs.		
			XMCM = 11b	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless the channels are enabled for reception in the appropriate receive channel enable registers (RCERs). Once enabled, the channels are masked unless the channels are also selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit determines whether 32 channels or 128 channels are selectable in RCERs and XCERs.		

20.9.7 XCERs Used in the Transmit Multichannel Selection Mode

For multichannel selection operation, the assignment of channels to the XCERs depends on whether 32 or 128 channels are individually selectable by the XMCME bit, as shown in Table 20-53. The table shows which block of channels is assigned to each XCER that is used. For each XCER, the table shows which channel is assigned to each of the bits.

Note

When XMCM = 11b (for symmetric transmission and reception), the transmitter uses the receive channel enable registers (RCERs) to enable channels and uses the XCERs to unmask channels for transmission.

Table 20-53. Use of the Transmit Channel Enable Registers

Number of Selectable Channels	Block Assignments		Channel Assignments	
	XCERx	Block Assigned	Bit in XCERx	Channel Assigned
32 (XMCME = 0)	XCERA	Channels n to (n + 15)	XCE0	Channel n
			XCE1	Channel (n + 1)
			XCE2	Channel (n + 2)
			:	:
		When XMCM = 01b or 10b, the block of channels is chosen with the XPABLK bits. When XMCM = 11b, the block is chosen with the RPABLK bits.	XCE15	Channel (n + 15)
	XCERB	Channels m to (m + 15)	XCE0	Channel m
			XCE1	Channel (m + 1)
			XCE2	Channel (m + 2)
			:	:
		When XMCM = 01b or 10b, the block of channels is chosen with the XPBBLK bits. When XMCM = 11b, the block is chosen with the RPBBLK bits.	XCE15	Channel (m + 15)
128 (XMCME = 1)	XCERA	Block 0	XCE0	Channel 0
			XCE1	Channel 1
			XCE2	Channel 2
			:	:
			XCE15	Channel 15
	XCERB	Block 1	XCE0	Channel 16
			XCE1	Channel 17
			XCE2	Channel 18
			:	:
			XCE15	Channel 31
	XCERC	Block 2	XCE0	Channel 32
			XCE1	Channel 33
			XCE2	Channel 34
			:	:
			XCE15	Channel 47
	XCERD	Block 3	XCE0	Channel 48
			XCE1	Channel 49
			XCE2	Channel 50
			:	:
			XCE15	Channel 63

Table 20-53. Use of the Transmit Channel Enable Registers (continued)

Number of Selectable Channels	Block Assignments		Channel Assignments	
	XCERx	Block Assigned	Bit in XCERx	Channel Assigned
	XCERE	Block 4	XCE0	Channel 64
			XCE1	Channel 65
			XCE2	Channel 66
			:	:
			XCE15	Channel 79
	XCERF	Block 5	XCE0	Channel 80
			XCE1	Channel 81
			XCE2	Channel 82
			:	:
			XCE15	Channel 95
	XCERG	Block 6	XCE0	Channel 96
			XCE1	Channel 97
			XCE2	Channel 98
			:	:
			XCE15	Channel 111
	XCERH	Block 7	XCE0	Channel 112
			XCE1	Channel 113
			XCE2	Channel 114
			:	:
			XCE15	Channel 127

20.9.8 Transmit Frame Phases

The XPHASE bit (see Table 20-54) determines whether the transmit data frame has one or two phases.

Table 20-54. Register Bit Used to Choose 1 or 2 Phases for the Transmit Frame

Register	Bit	Name	Function		Type	Reset Value
XCR2	15	XPHASE	Transmit phase number		R/W	0
			Specifies whether the transmit frame has 1 or 2 phases.			
			XPHASE = 0	Single-phase frame		
			XPHASE = 1	Dual-phase frame		

20.9.9 Transmit Word Lengths

The XWDLEN1 and XWDLEN2 bit fields (see Table 20-55) determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

Table 20-55. Register Bits Used to Set the Transmit Word Lengths

Register	Bit	Name	Function		Type	Reset Value
XCR1	7-5	XWDLEN1	Transmit word length of frame phase 1		R/W	000
			XWDLEN1 = 000b	8 bits		
			XWDLEN1 = 001b	12 bits		
			XWDLEN1 = 010b	16 bits		
			XWDLEN1 = 011b	20 bits		
			XWDLEN1 = 100b	24 bits		
			XWDLEN1 = 101b	32 bits		
			XWDLEN1 = 11Xb	Reserved		
XCR2	7-5	XWDLEN2	Transmit word length of frame phase 2		R/W	000
			XWDLEN2 = 000b	8 bits		
			XWDLEN2 = 001b	12 bits		
			XWDLEN2 = 010b	16 bits		
			XWDLEN2 = 011b	20 bits		
			XWDLEN2 = 100b	24 bits		
			XWDLEN2 = 101b	32 bits		
			XWDLEN2 = 11Xb	Reserved		

20.9.9.1 Word Length Bits

Each frame can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, XWDLEN1 selects the length for every serial word transmitted in the frame. If a dual-phase frame is selected, XWDLEN1 determines the length of the serial words in phase 1 of the frame, and XWDLEN2 determines the word length in phase 2 of the frame.

20.9.10 Transmit Frame Length

The XFRLEN1 and XFRLEN2 bit fields (see Table 20-56) determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

Table 20-56. Register Bits Used to Set the Transmit Frame Length

Register	Bit	Name	Function		Type	Reset Value
XCR1	14-8	XFRLEN1	Transmit frame length 1		R/W	000 0000
			(XFRLEN1 + 1) is the number of serial words in phase 1 of the transmit frame.			
			XFRLEN1 = 000 0000	1 word in phase 1		
			XFRLEN1 = 000 0001	2 words in phase 1		
			|	|		
			|	|		
			XFRLEN1 = 111 1111	128 words in phase 1		
XCR2	14-8	XFRLEN2	Transmit frame length 2		R/W	000 0000
			If a dual-phase frame is selected, (XFRLEN2 + 1) is the number of serial words in phase 2 of the transmit frame.			
			XFRLEN2 = 000 0000	1 word in phase 2		
			XFRLEN2 = 000 0001	2 words in phase 2		
			|	|		
			|	|		
			XFRLEN2 = 111 1111	128 words in phase 2		

20.9.10.1 Selected Frame Length

The transmit frame length is the number of serial words in the transmit frame. Each frame can have one or two phases, depending on the value that you load into the XPHASE bit.

If a single-phase frame is selected (XPHASE = 0), the frame length is equal to the length of phase 1. If a dual-phase frame is selected (XPHASE = 1), the frame length is the length of phase 1 plus the length of phase 2.

The 7-bit XFRLEN fields allow up to 128 words per phase. See Table 20-57 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Note

Program the XFRLEN fields with [*w minus 1*], where w represents the number of words per phase. For example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

Table 20-57. How to Calculate Frame Length

XPHASE	XFRLEN1	XFRLEN2	Frame Length
0	0 ≤ XFRLEN1 ≤ 127	Don't care	(XFRLEN1 + 1) words
1	0 ≤ XFRLEN1 ≤ 127	0 ≤ XFRLEN2 ≤ 127	(XFRLEN1 + 1) + (XFRLEN2 + 1) words

20.9.11 Enable/Disable the Transmit Frame-Synchronization Ignore Function

Table 20-58. Register Bit Used to Enable/Disable the Transmit Frame-Synchronization Ignore Function

Register	Bit	Name	Function		Type	Reset Value
XCR2	2	XFIG	Transmit frame-synchronization ignore		R/W	0
			XFIG = 0	An unexpected transmit frame-synchronization pulse causes the McBSP to restart the frame transfer.		
			XFIG = 1	The McBSP ignores unexpected transmit frame-synchronization pulses.		

20.9.11.1 Unexpected Frame-Synchronization Pulses and Frame-Synchronization Ignore

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse.

When XFIG = 1, normal transmission continues with unexpected frame-synchronization signals ignored.

When XFIG = 0 and an unexpected frame-synchronization pulse occurs, the serial port:

1. Aborts the present transmission
2. Sets XSYNCERR to 1 in SPCR2
3. Reinitiates transmission of the current word that was aborted

For more details about the frame-synchronization error condition, see Section 20.5.6.

20.9.11.2 Examples Showing the Effects of XFIG

Figure 20-51 shows an example in which word B is interrupted by an unexpected frame-synchronization pulse when (R/X)FIG = 0. In the case of transmission, the transmission of B is aborted (B is lost). This condition is a transmit synchronization error, which sets the XSYNCERR bit. No new data has been written to DXR[1,2]; therefore, the McBSP transmits B again.

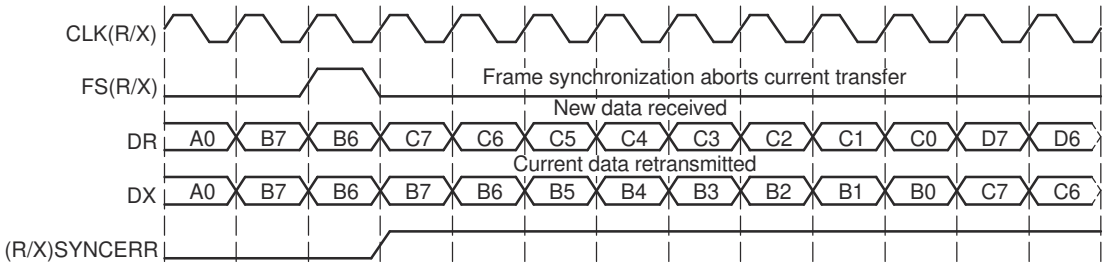

Figure 20-51. Unexpected Frame-Synchronization Pulse With (R/X) FIG = 0

In contrast with Figure 20-51, Figure 20-52 shows McBSP operation when unexpected frame-synchronization signals are ignored (when (R/X)FIG = 1). Here, the transfer of word B is not affected by an unexpected frame-synchronization pulse.

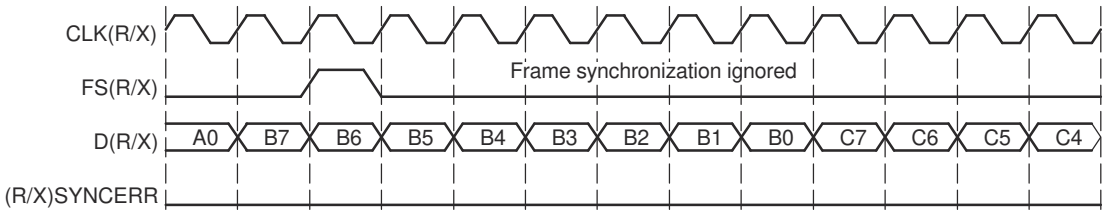

Figure 20-52. Unexpected Frame-Synchronization Pulse With (R/X) FIG = 1

20.9.12 Transmit Companding Mode

The XCOMPAND bits (see Table 20-59) determine whether companding or another data transfer option is chosen for McBSP transmission.

Table 20-59. Register Bits Used to Set the Transmit Companding Mode

Register	Bit	Name	Function		Type	Reset Value
XCR2	4-3	XCOMPAND	Transmit companding mode		R/W	00
			Modes other than 00b are enabled only when the appropriate XWDLEN is 000b, indicating 8-bit data.			
			XCOMPAND = 00b	No companding, any size data, MSB transmitted first		
			XCOMPAND = 01b	No companding, 8-bit data, LSB transmitted first (for details, see Section 20.8.11.4)		
			XCOMPAND = 10b	µ-law companding, 8-bit data, MSB transmitted first		
			XCOMPAND = 11b	A-law companding, 8-bit data, MSB transmitted first		

20.9.12.1 Companding

Companding (COMpressing and exPANDing) hardware allows compression and expansion of data in either µ-law or A-law format. The companding standard employed in the United States and Japan is µ-law. The European companding standard is referred to as A-law. The specifications for µ-law and A-law log PCM are part of the CCITT G.711 recommendation.

A-law and µ-law allow 13 bits and 14 bits of dynamic range, respectively. Any values outside this range are set to the most positive or most negative value. Thus, for companding to work best, the data transferred to and from the McBSP via the CPU or DMA controller must be at least 16 bits wide.

The µ-law and A-law formats both encode data into 8-bit code words. Companded data is always 8 bits wide; the appropriate word length bits (RWDLEN1, RWDLEN2, XWDLEN1, XWDLEN2) must therefore be set to 0, indicating an 8-bit wide serial data stream. If companding is enabled and either of the frame phases does not have an 8-bit word length, companding continues as if the word length is 8 bits.

Figure 20-53 illustrates the companding processes. When companding is chosen for the transmitter, compression occurs during the process of copying data from DXR1 to XSR1. The transmit data is encoded according to the specified companding law (A-law or µ-law). When companding is chosen for the receiver, expansion occurs during the process of copying data from RBR1 to DRR1. The receive data is decoded to twos-complement format.

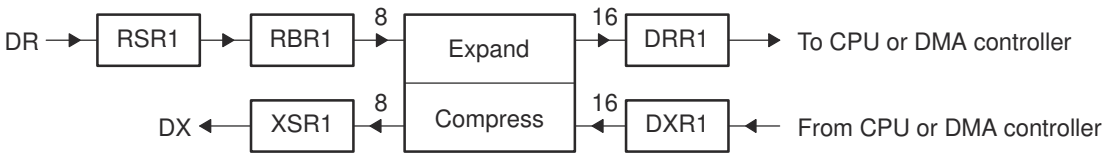

Figure 20-53. Companding Processes for Reception and for Transmission

20.9.12.2 Format for Data To Be Compressed

For transmission using μ-law compression, make sure the 14 data bits are left-justified in DXR1, with the remaining two low-order bits filled with 0s as shown in Figure 20-54.

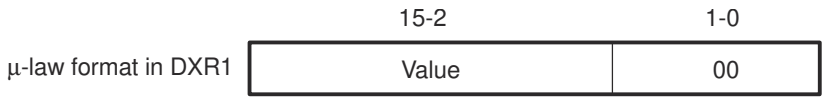

Figure 20-54. μ-Law Transmit Data Companding Format

For transmission using A-law compression, make sure the 13 data bits are left-justified in DXR1, with the remaining three low-order bits filled with 0s as shown in Figure 20-55.

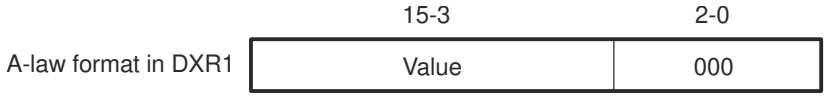

Figure 20-55. A-Law Transmit Data Companding Format

20.9.12.3 Capability to Compand Internal Data

If the McBSP is otherwise unused (the serial port transmit and receive sections are reset), the companding hardware can compand internal data. See Section 20.3.2.2.

20.9.12.4 Option to Transmit LSB First

Normally, the McBSP transmit or receives all data with the most significant bit (MSB) first. However, certain 8-bit data protocols (that do not use companded data) require the least significant bit (LSB) to be transferred first. If you set XCOMPAND = 01b in XCR2, the bit ordering of 8-bit words is reversed (LSB first) before being sent from the serial port. Similar to companding, this feature is enabled only if the appropriate word length bits are set to 0, indicating that 8-bit words are to be transferred serially. If either phase of the frame does not have an 8-bit word length, the McBSP assumes the word length is eight bits and LSB-first ordering is done.

20.9.13 Transmit Data Delay

The XDATDLY bits (see Table 20-60) determine the length of the data delay for the transmit frame.

Table 20-60. Register Bits Used to Set the Transmit Data Delay

Register	Bit	Name	Function		Type	Reset Value
XCR2	1-0	XDATDLY	Transmitter data delay		R/W	00
			XDATDLY = 00	0-bit data delay		
			XDATDLY = 01	1-bit data delay		
			XDATDLY = 10	2-bit data delay		
			XDATDLY = 11	Reserved		

20.9.13.1 Data Delay

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if necessary. This delay is called data delay.

XDATDLY specifies the data delay for transmission. The range of programmable data delay is zero to two bit-clocks (XDATDLY = 00b-10b), as described in Table 20-60 and Figure 20-56. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

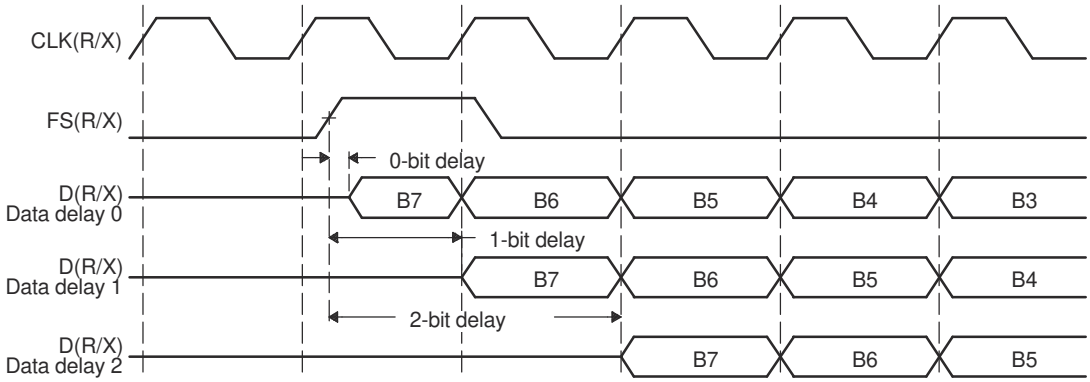

Figure 20-56. Range of Programmable Data Delay

20.9.13.2 0-Bit Data Delay

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of serial clock internal CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data can be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception this problem is solved because receive data is sampled on the first falling edge of MCLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus DX. The transmitter then asynchronously detects the frame synchronization, FSX, going active high and immediately starts driving the first bit to be transmitted on the DX pin.

20.9.13.3 2-Bit Data Delay

A data delay of two bit-periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 20-57. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

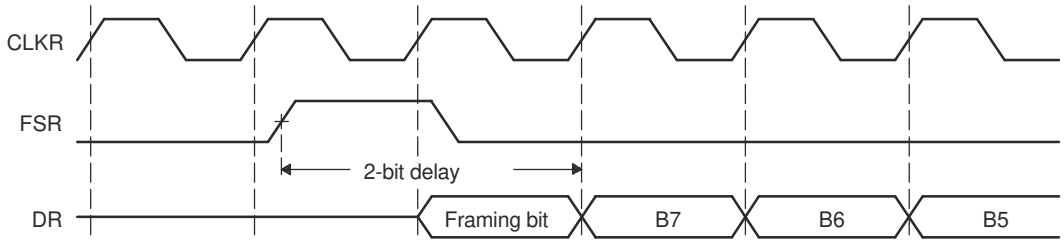

Figure 20-57. 2-Bit Data Delay Used to Skip a Framing Bit

20.9.14 Transmit DXENA Mode

Table 20-61 shows which register bit enables the Transmit DXENA (DX Delay Enabler) Mode.

Table 20-61. Register Bit Used to Set the Transmit DXENA (DX Delay Enabler) Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR1	7	DXENA	DX delay enabler mode		R/W	0
			DXENA = 0	DX delay enabler is off.		
			DXENA = 1	DX delay enabler is on.		

The DXENA bit controls the delay enabler on the DX pin. Set DXENA to enable an extra delay for turn-on time. This bit does not control the data itself, so only the first bit is delayed.

If you tie together the DX pins of multiple McBSPs, make sure DXENA = 1 to avoid having more than one McBSP transmit on the data line at one time.

20.9.15 Transmit Interrupt Mode

The transmitter interrupt (XINT) signals the CPU of changes to the serial port status. Four options exist for configuring this interrupt. The options are set by the transmit interrupt mode bits, XINTM, in SPCR2.

Table 20-62. Register Bits Used to Set the Transmit Interrupt Mode

Register	Bit	Name	Function		Type	Reset Value
SPCR2	5-4	XINTM	Transmit interrupt mode		R/W	00
			XINTM = 00	XINT generated when XRDY changes from 0 to 1.		
			XINTM = 01	XINT generated by an end-of-block or end-of-frame condition in a transmit multichannel selection mode. In any of the transmit multichannel selection modes, interrupt after every 16-channel block boundary has been crossed within a frame and at the end of the frame. For details, see Section 20.6.8. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.		
			XINTM = 10	XINT generated by a new transmit frame-synchronization pulse. Interrupt on detection of each transmit frame-synchronization pulse. This generates an interrupt even when the transmitter is in the reset state. This is done by synchronizing the incoming frame-synchronization pulse to the CPU clock and sending the pulse to the CPU using XINT.		
			XINTM = 11	XINT generated when XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR can be read to detect this condition. For more information on using XSYNCERR, see Section 20.5.6.		

20.9.16 Transmit Frame-Synchronization Mode

Table 20-63 shows which register bits enable the Transmit Frame-Synchronization Mode.

Table 20-63. Register Bits Used to Set the Transmit Frame-Synchronization Mode

Register	Bit	Name	Function		Type	Reset Value
PCR	11	FSXM	Transmit frame-synchronization mode		R/W	0
			FSXM = 0	Transmit frame synchronization is supplied by an external source via the FSX pin.		
			FSXM = 1	Transmit frame synchronization is supplied by the McBSP, as determined by the FSGM bit of SRGR2.		
SRGR2	12	FSGM	Sample rate generator transmit frame-synchronization mode		R/W	0
			Used when FSXM = 1 in PCR.			
			FSGM = 0	The McBSP generates a transmit frame-synchronization pulse when the content of DXR[1,2] is copied to XSR[1,2].		
			FSGM = 1	The transmitter uses frame-synchronization pulses generated by the sample rate generator. Program the FWID bits to set the width of each pulse. Program the FPER bits to set the frame-synchronization period.		

Table 20-64 shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

- External frame-synchronization input
- Sample rate generator frame-synchronization signal (FSG)
- Internal signal that indicates a DXR-to-XSR copy has been made

Table 20-64 also shows the effect of each bit setting on the FSX pin. The polarity of the signal on the FSX pin is determined by the FSXP bit.

Table 20-64. How FSXM and FSGM Select the Source of Transmit Frame-Synchronization Pulses

FSXM	FSGM	Source of Transmit Frame Synchronization	FSX Pin Status
0	0 or 1	An external frame-synchronization signal enters the McBSP through the FSX pin. The signal is then inverted by FSXP before being used as internal FSX.	Input
1	1	Internal FSX is driven by the sample rate generator frame-synchronization signal (FSG).	Output. FSG is inverted by FSXP before being driven out on FSX pin.
1	0	A DXR-to-XSR copy causes the McBSP to generate a transmit frame-synchronization pulse that is 1 cycle wide.	Output. The generated frame-synchronization pulse is inverted as determined by FSXP before being driven out on FSX pin.

20.9.16.1 Other Considerations

If the sample rate generator creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the FSR pin. For more details, see Section 20.4.3.

In the clock stop mode (CLKSTP = 10b or 11b), the McBSP can act as a master or as a slave in the SPI protocol. If the McBSP is a master and must provide a slave-enable signal ($\overline{\text{SPISTE}}$) on the FSX pin, make sure that FSXM = 1 and FSGM = 0 so that FSX is an output and is driven active for the duration of each transmission. If the McBSP is a slave, make sure that FSXM = 0 so that the McBSP can receive the slave-enable signal on the FSX pin.

20.9.17 Transmit Frame-Synchronization Polarity

Table 20-65 shows which register bits enable the Transmit Frame-Synchronization Polarity.

Table 20-65. Register Bit Used to Set Transmit Frame-Synchronization Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	3	FSXP	Transmit frame-synchronization polarity		R/W	0
			FSXP = 0	Frame-synchronization pulse FSX is active high.		
			FSXP = 1	Frame-synchronization pulse FSX is active low.		

20.9.17.1 Frame Synchronization Pulses, Clock Signals, and Their Polarities

Transmit frame-synchronization pulses can be generated internally by the sample rate generator (see Section 20.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSXM, in PCR. FSX is also affected by the FSGM bit in SRGR2. For information about the effects of FSXM and FSGM, see Section 20.9.16). Similarly, transmit clocks can be selected to be inputs or outputs by programming the mode bit, CLKXM, in the PCR (see Section 20.9.19).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that the outputs are driven by the sample rate generator, the outputs are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected and the polarity bit FS(R/X)P = 1, the internal active-high frame-synchronization signals are inverted before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and MCLKR is an input pin), the external rising-edge triggered input clock on MCLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to make sure of valid setup and hold of data around this edge. Figure 20-58 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

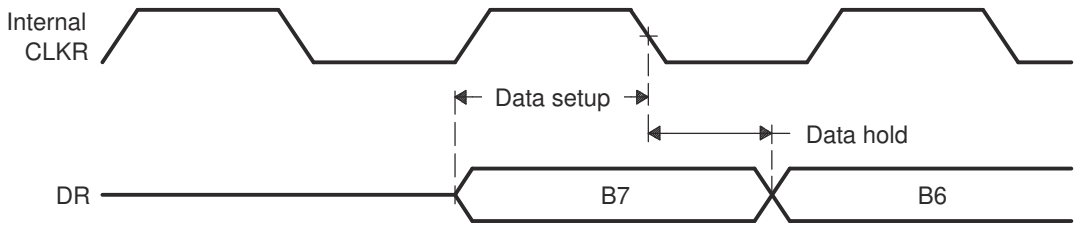

Figure 20-58. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge

20.9.18 SRG Frame-Synchronization Period and Pulse Width

Table 20-66 shows which register bits set the SRG Frame-Synchronization Period and Pulse Width.

Table 20-66. Register Bits Used to Set SRG Frame-Synchronization Period and Pulse Width

Register	Bit	Name	Function	Type	Reset Value
SRGR2	11-0	FPER	Sample rate generator frame-synchronization period For the frame-synchronization signal FSG, (FPER + 1) determines the period from the start of a frame-synchronization pulse to the start of the next frame-synchronization pulse. Range for (FPER + 1): 1 to 4096 CLKG cycles.	R/W	0000 0000 0000
SRGR1	15-8	FWID	Sample rate generator frame-synchronization pulse width This field plus 1 determines the width of each frame-synchronization pulse on FSG. Range for (FWID + 1): 1 to 256 CLKG cycles.	R/W	0000 0000

20.9.18.1 Frame-Synchronization Period and Frame-Synchronization Pulse Width

The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 20-59 shows a frame-synchronization period of 16 CLKG periods (FPER = 15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

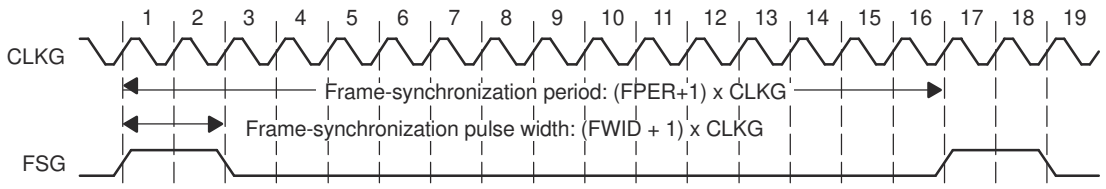

Figure 20-59. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods

When the sample rate generator comes out of reset, FSG is in the inactive state. Then, when GRST = 1 and FSGM = 1, a frame-synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until the value reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

20.9.19 Transmit Clock Mode

Table 20-67 shows which register bits can set the Transmit Clock Mode.

Table 20-67. Register Bit Used to Set the Transmit Clock Mode

Register	Bit	Name	Function		Type	Reset Value
PCR	9	CLKXM	Transmit clock mode		R/W	0
			CLKXM = 0	The transmitter gets the clock signal from an external source via the MCLKX pin.		
			CLKXM = 1	The MCLKX pin is an output pin driven by the sample rate generator of the McBSP.		

20.9.19.1 Selecting a Source for the Transmit Clock and a Data Direction for the MCLKX pin

Table 20-68 shows how the CLKXM bit selects the transmit clock and the corresponding status of the MCLKX pin. The polarity of the signal on the MCLKX pin is determined by the CLKXP bit.

Table 20-68. How the CLKXM Bit Selects the Transmit Clock and the Corresponding Status of the MCLKX pin

CLKXM in PCR	Source of Transmit Clock	MCLKX pin Status
0	Internal CLKX is driven by an external clock on the MCLKX pin. CLKX is inverted as determined by CLKXP before being used.	Input
1	Internal CLKX is driven by the sample rate generator clock, CLKG.	Output. CLKG, inverted as determined by CLKXP, is driven out on CLKX.

20.9.19.2 Other Considerations

If the sample rate generator creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the FSR pin. For more details, see Section 20.4.3.

In the clock stop mode (CLKSTP = 10b or 11b), the McBSP can act as a master or as a slave in the SPI protocol. If the McBSP is a master, make sure that CLKXM = 1 so that CLKX is an output to supply the master clock to any slave devices. If the McBSP is a slave, make sure that CLKXM = 0 so that CLKX is an input to accept the master clock signal.

20.9.20 Transmit Clock Polarity

Table 20-69 shows which register bits set the Transmit Clock Polarity.

Table 20-69. Register Bit Used to Set Transmit Clock Polarity

Register	Bit	Name	Function		Type	Reset Value
PCR	1	CLKXP	Transmit clock polarity		R/W	0
			CLKXP = 0	Transmit data sampled on rising edge of CLKX.		
			CLKXP = 1	Transmit data sampled on falling edge of CLKX.		

20.9.20.1 Frame Synchronization Pulses, Clock Signals, and Their Polarities

Transmit frame-synchronization pulses can be either generated internally by the sample rate generator (see Section 20.4.2) or driven by an external source. The source of frame synchronization is selected by programming the mode bit, FSXM, in PCR. FSX is also affected by the FSGM bit in SRGR2. For information about the effects of FSXM and FSGM, see Section 20.9.16). Similarly, transmit clocks can be selected to be inputs or outputs by programming the mode bit, CLKXM, in the PCR (see Section 20.9.19).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame-synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal MCLKR, and internal CLKX, respectively. The receive data arriving at the DR pin is also sampled on the falling edge of internal MCLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that the outputs are driven by the sample rate generator, the outputs are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR) configure the polarities of the FSR, FSX, MCLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the MCLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal MCLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the MCLKR pin.

CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to make sure of valid setup and hold of data around this edge (see Figure 20-58).

Figure 20-60 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

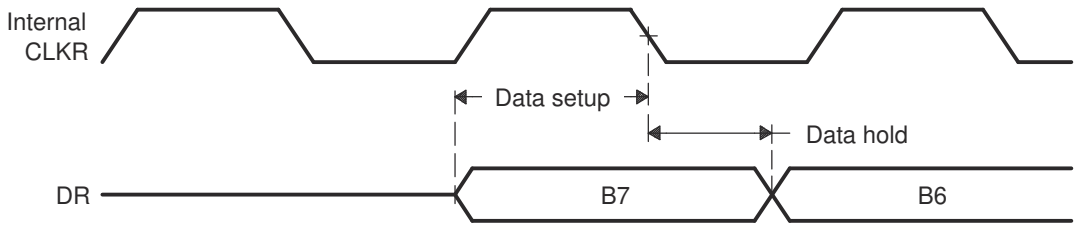

Figure 20-60. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge

20.10 Emulation and Reset Considerations

This section covers the following topics:

- How to program McBSP response to a breakpoint in the high-level language debugger (see Section 20.10.1)
- How to reset and initialize the various parts of the McBSP (see Section 20.10.2)

20.10.1 McBSP Emulation Mode

FREE and SOFT are special emulation bits in SPCR2 that determine the state of the McBSP when a breakpoint is encountered in the high-level language debugger. If FREE = 1, the clock continues to run upon a software breakpoint and data is still shifted out. When FREE = 1, the SOFT bit is a *don't care.*

If FREE = 0, the SOFT bit takes effect. If SOFT = 0 when breakpoint occurs, the clock stops immediately, aborting a transmission. If SOFT = 1 and a breakpoint occurs while transmission is in progress, the transmission continues until completion of the transfer and then the clock halts. These options are listed in Table 20-70.

The McBSP receiver functions in a similar fashion. If a mode other than the immediate stop mode (SOFT = FREE = 0) is chosen, the receiver continues running and an overrun error is possible.

Table 20-70. McBSP Emulation Modes Selectable with FREE and SOFT Bits of SPCR2

FREE	SOFT	McBSP Emulation Mode
0	0	Immediate stop mode (reset condition). The transmitter or receiver stops immediately in response to a breakpoint.
0	1	Soft stop mode When a breakpoint occurs, the transmitter stops after completion of the current word. The receiver is not affected.
1	0 or 1	Free run mode The transmitter and receiver continue to run when a breakpoint occurs.

20.10.2 Resetting and Initializing McBSPs

This section discusses in greater depth the MCBSP Reset and Initialization configurations.

20.10.2.1 McBSP Pin States: DSP Reset Versus Receiver/Transmitter Reset

Table 20-71 shows the state of McBSP pins when the serial port is reset due to direct receiver or transmitter reset on the 2833x device.

Table 20-71. Reset State of Each McBSP Pin

Pin	Possible States[1]	State Forced by Device Reset	State Forced by Receiver/Transmitter Reset
Receiver reset (RRST = 0 and GRST = 1)			
MDRx	I	GPIO-input	Input
MCLKRx	I/O/Z	GPIO-input	Known state if input; MCLKR running if output
MFSRx	I/O/Z	GPIO-input	Known state if input; FSRP inactive state if output
Transmitter reset (XRST = 0 and GRST = 1)			
MDXx	O/Z	GPIO Input	High impedance
MCLKXx	I/O/Z	GPIO-input	Known state if input; CLKX running if output
MFSXx	I/O/Z	GPIO-input	Known state if input; FSXP inactive state if output

(1) In Possible States column, I = Input, O = Output, Z = High impedance. In the C28x family, at device reset, all I/Os default to GPIO function and generally as inputs.

20.10.2.2 Device Reset, McBSP Reset, and Sample Rate Generator Reset

When the McBSP is reset in either of the above two ways, the machine is reset to its initial state, including reset of all counters and status bits. The receive status bits include RFULL, RRDY, and RSYNCERR. The transmit status bits include XEMPTY, XRDY, and XSYNCERR.

- Device reset. When the whole DSP is reset ($\overline{\text{XRS}}$ signal is driven low), all McBSP pins are in GPIO mode. When the device is pulled out of reset, the clock to the McBSP modules remains disabled.
- McBSP reset. When the receiver and transmitter reset bits, RRST and XRST, are loaded with 0s, the respective portions of the McBSP are reset and activity in the corresponding section of the serial port stops. Input-only pins such as MDRx, and all other pins that are configured as inputs are in a known state. The MFSRx and MFSXx pins are driven to their inactive state if they are not outputs. If the MCLKR and MCLKX pins are programmed as outputs, they are driven by CLKG, provided that GRST = 1. Lastly, the MDXx pin is in the high-impedance state when the transmitter and/or the device is reset.

  During normal operation, the sample rate generator is reset if the GRST bit is cleared. GRST must be 0 only when neither the transmitter nor the receiver is using the sample rate generator. In this case, the internal sample rate generator clock (CLKG) and its frame-synchronization signal (FSG) are driven inactive low.

  When the sample rate generator is not in the reset state (GRST = 1), pins MFSRx and MFSXx are in an inactive state when RRST = 0 and XRST = 0, respectively, even if they are outputs driven by FSG. This ensures that when only one portion of the McBSP is in reset, the other portion can continue operation when GRST = 1 and its frame synchronization is driven by FSG.
- Sample rate generator reset. The sample rate generator is reset when GRST is loaded with 0.

  When neither the transmitter nor the receiver is fed by CLKG and FSG, you can reset the sample rate generator by clearing GRST. In this case, CLKG and FSG are driven inactive low. If you then set GRST, CLKG starts and runs as programmed. Later, if GRST = 1, FSG pulses active high after the programmed number of CLKG cycles has elapsed.

20.10.2.3 McBSP Initialization Procedure

The serial port initialization procedure is as follows:

1. Make XRST = RRST = GRST = 0 in SPCR[1,2]. If coming out of a device reset, this step is not required.
2. While the serial port is in the reset state, program only the McBSP configuration registers (not the data registers) as required.
3. Wait for two clock cycles. This makes sure of proper internal synchronization.
4. Set up data acquisition as required (such as writing to DXR[1,2]).
5. Make XRST = RRST = 1 to enable the serial port. Make sure that as you set these reset bits, you do not modify any of the other bits in SPCR1 and SPCR2. Otherwise, you change the configuration you selected in step 2.
6. Set FRST = 1, if internally generated frame synchronization is required.
7. Wait two clock cycles for the receiver and transmitter to become active.

Alternatively, on either write (step 1 or 5), the transmitter and receiver can be placed in or taken out of reset individually by modifying the desired bit.

The previous procedure for reset/initialization can be applied in general when the receiver or transmitter must be reset during normal operation and when the sample rate generator is not used for either operation.

Note

1. The necessary duration of the active-low period of XRST or RRST is at least two MCLKR/CLKX cycles.
2. The appropriate bits in serial port configuration registers SPCR[1,2], PCR, RCR[1,2], XCR[1,2], and SRGR[1,2] must only be modified when the affected portion of the serial port is in the reset state.
3. In most cases, the data transmit registers (DXR[1,2]) must be loaded by the CPU or by the DMA controller only when the transmitter is enabled (XRST = 1). An exception to this rule is when these registers are used for companding internal data (see Section 20.3.2.2).
4. The bits of the channel control registers—MCR[1,2], RCER[A-H], XCER[A-H]—can be modified at any time as long as the bits are not being used by the current reception/transmission in a multichannel selection mode.

20.10.2.4 Resetting the Transmitter While the Receiver is Running

Example 20-1 shows values in the control registers that reset and configure the transmitter while the receiver is running.

Example 20-1. Resetting and Configuring McBSP Transmitter While McBSP Receiver Running

```
SPCR1 = 0001h SPCR2 = 0030h ;
The receiver is running with the receive interrupt (RINT) triggered by the receiver ready bit
(RRDY).;
The transmitter is in its reset state.;
The transmit interrupt (XINT) will be triggered by the transmit frame-sync error bit (XSYNCERR).;
PCR = 0900h ;
Transmit frame synchronization is generated internally according to the FSGM bit of SRGR2.;
The transmit clock is driven by an external source. ;
The receive clock continues to be driven by sample rate generator. The input clock ;
of the sample rate generator is supplied by the CPU clock. ;
SRGR1 = 0001h SRGR2 = 2000h ;
The CPU clock is the input clock for the sample rate generator. The sample ;
rate generator divides the CPU clock by 2 to generate its output clock (CLKG). ;
Transmit frame synchronization is tied to the automatic copying of data from ;
the DXR(s) to the XSR(s). ;
XCR1 = 0740h XCR2 = 8321h ;
The transmit frame has two phases. Phase 1 has eight 16-bit words. ;
Phase 2 has four 12-bit words. There is 1-bit data delay between the start of a ;
frame-sync pulse and the first data bit transmitted. ;
SPCR2 = 0031h ;
The transmitter is taken out of reset.
```

20.11 Data Packing Examples

This section shows two ways to implement data packing in the McBSP.

20.11.1 Data Packing Using Frame Length and Word Length

Frame length and word length can be manipulated to effectively pack data. For example, consider a situation where four 8-bit words are transferred in a single-phase frame as shown in Figure 20-61. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0000011b: 4-word frame
- (R/X)WDLEN1 = 000b: 8-bit words

Four 8-bit data words are transferred to and from the McBSP by the CPU or by the DMA controller. Thus, four reads from DRR1 and four writes to DXR1 are necessary for each frame.

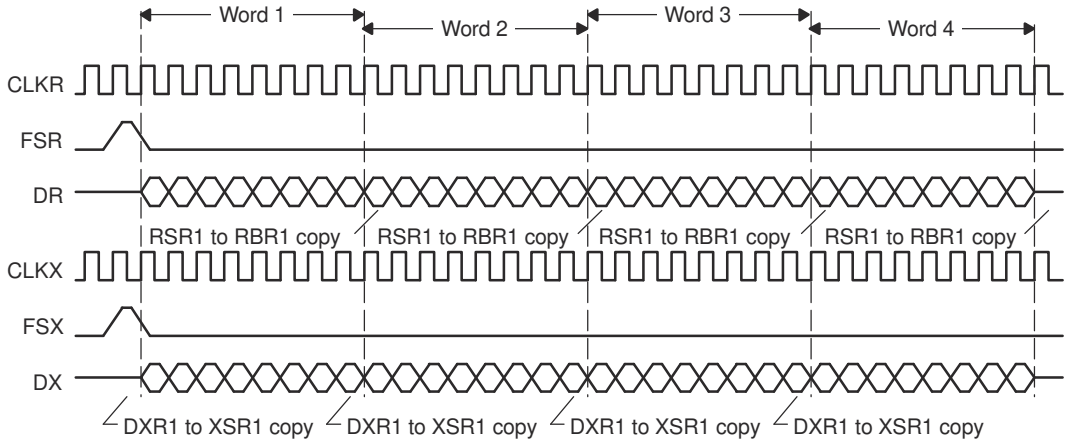

Figure 20-61. Four 8-Bit Data Words Transferred To/From the McBSP

This data can also be treated as a single-phase frame consisting of one 32-bit data word, as shown in Figure 20-62. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0000000b: 1-word frame
- (R/X)WDLEN1 = 101b: 32-bit word

Two 16-bit data words are transferred to and from the McBSP by the CPU or DMA controller. Thus, two reads, from DRR2 and DRR1, and two writes, to DXR2 and DXR1, are necessary for each frame. This results in only half the number of transfers compared to the previous case. This manipulation reduces the percentage of bus time required for serial port data movement.

Note

When the word length is larger than 16 bits, make sure you access DRR2/DXR2 before you access DRR1/DXR1. McBSP activity is tied to accesses of DRR1/DXR1. During the reception of 24-bit or 32-bit words, read DRR2 and then read DRR1. Otherwise, the next RBR[1,2]-to-DRR[1,2] copy occurs before DRR2 is read. Similarly, during the transmission of 24-bit or 32-bit words, write to DXR2 and then write to DXR1. Otherwise, the next DXR[1,2]-to-XSR[1,2] copy occurs before DXR2 is loaded with new data.

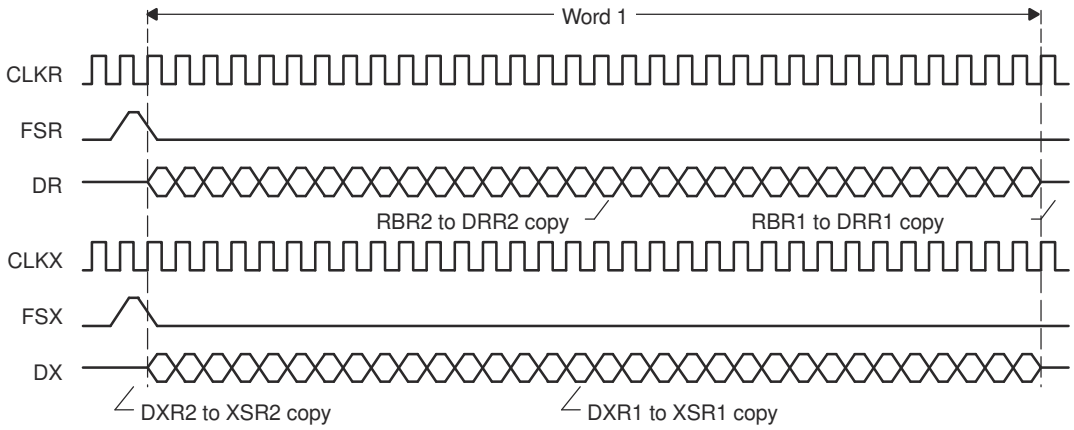

Figure 20-62. One 32-Bit Data Word Transferred To/From the McBSP

20.11.2 Data Packing Using Word Length and the Frame-Synchronization Ignore Function

When there are multiple words per frame, you can implement data packing by increasing the word length (defining a serial word with more bits) and by ignoring frame-synchronization pulses. First, consider Figure 20-63, which shows the McBSP operating at the maximum packet frequency. Here, each frame only has a single 8-bit word. Notice the frame-synchronization pulse that initiates each frame transfer for reception and for transmission. For reception, this configuration requires one read operation for each word. For transmission, this configuration requires one write operation for each word.

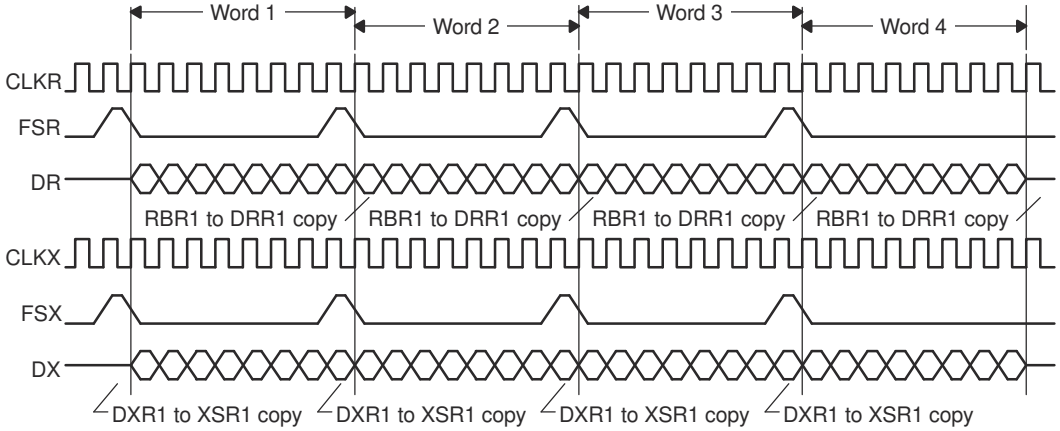

Figure 20-63. 8-Bit Data Words Transferred at Maximum Packet Frequency

Figure 20-64 shows the McBSP configured to treat this data stream as a continuous 32-bit word. In this example, the McBSP responds to an initial frame-synchronization pulse. However, (R/X)FIG = 1 so that the McBSP ignores subsequent pulses. Only two read transfers or two write transfers are needed every 32 bits. This configuration effectively reduces the required bus bandwidth to half the bandwidth needed to transfer four 8-bit words.

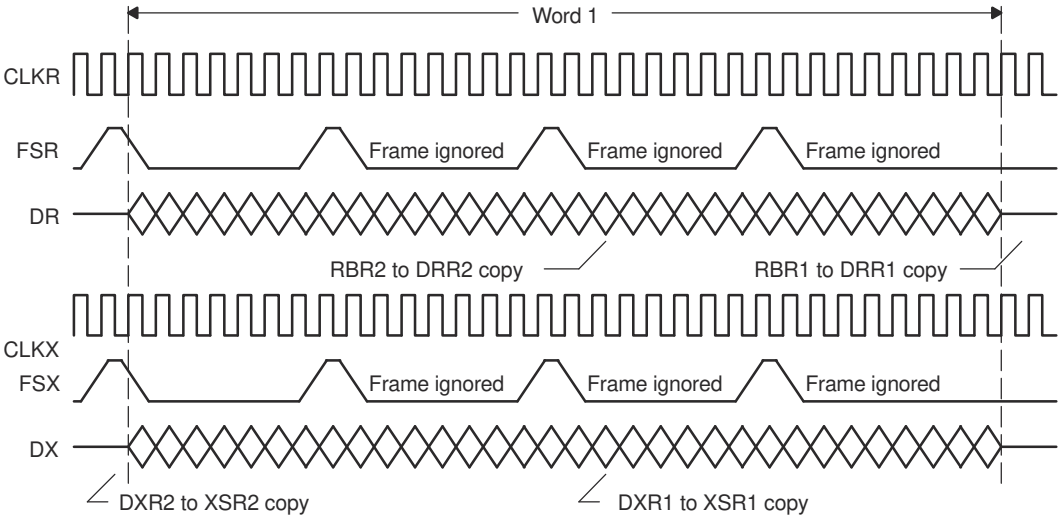

Figure 20-64. Configuring the Data Stream of Figure 20-63 as a Continuous 32-Bit Word

20.12 Interrupt Generation

McBSP registers can be programmed to receive and transmit data through DRR2/DRR1 and DXR2/DXR1 registers, respectively. The CPU can directly access these registers to move data from memory to these registers. Interrupt signals are based on these register pair contents and the related flags. MRINT/MXINT generates CPU interrupts for receive and transmit conditions.

20.12.1 McBSP Receive Interrupt Generation

In the McBSP module, data receive and error conditions generate two sets of interrupt signals. One set is used for the CPU and the other set is for DMA.

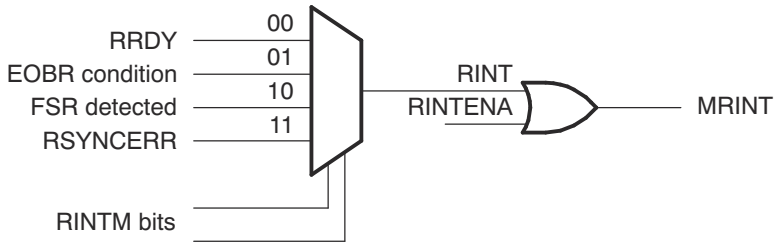

Figure 20-65. Receive Interrupt Generation

Table 20-72. Receive Interrupt Sources and Signals

McBSP Interrupt Signal	Interrupt Flags	Interrupt Enables in SPCR1 (RINTM Bits)	Interrupt Enables	Type of Interrupt	Interrupt Line
RINT	RRDY	00	RINTENA	Every word receive	MRINT
	EOBR	01	RINTENA	Every 16-channel block boundary	
	FSR	10	RINTENA	On every FSR	
	RSYNCERR	11	RINTENA	Frame sync error	

Note

Since X/RINT, X/REVTA, and X/RXFFINT share the same CPU interrupt, it is recommended that all applications use one of the above selections for interrupt generation. If multiple interrupt enables are selected at the same time, there is a likelihood of interrupts being masked or not recognized.

20.12.2 McBSP Transmit Interrupt Generation

McBSP module data transmit and error conditions generate two sets of interrupt signals. One set is used for the CPU and the other set is for DMA.

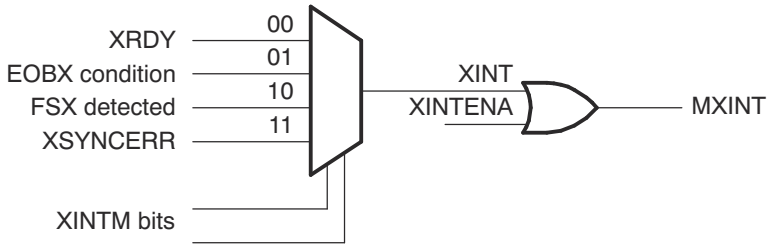

Figure 20-66. Transmit Interrupt Generation

Table 20-73. Transmit Interrupt Sources and Signals

McBSP Interrupt Signal	Interrupt Flags	Interrupt Enables in SPCR2 (XINTM Bits)	Interrupt Enables	Type of Interrupt	Interrupt Line
XINT	XRDY	00	XINTENA	Every word transmit	MXINT
	EOBX	01	XINTENA	Every 16-channel block boundary	
	FSX	10	XINTENA	On every FSX	
	XSYNCERR	11	XINTENA	Frame sync error	

20.12.3 Error Flags

The McBSP has several error flags both on receive and transmit channel. Table 20-74 explains the error flags and their meaning.

Table 20-74. Error Flags

Error Flags	Function
RFULL	Indicates DRR2/DRR1 are not read and RXR register is overwritten
RSYNCERR	Indicates unexpected frame-sync condition, current data reception will abort and restart. Use RINTM bit 11 for interrupt generation on this condition.
XSYNCERR	Indicates unexpected frame-sync condition, current data transmission will abort and restart. Use XINTM bit 11 for interrupt generation on this condition.

20.13 McBSP Modes

McBSP, in its normal mode, communicates with various types of Codecs with variable word size. Apart from this mode, the McBSP uses time-division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices. The multichannel mode provides flexibility while transmitting/receiving selected channels or all the channels in a TDM stream.

Table 20-75 provides a quick reference to McBSP mode selection.

Table 20-75. McBSP Mode Selection

No.	McBSP Word Size	Register Bits Used for Mode Selection				Mode and Function Description
		MCR1 bit 9,0		MCR2 bit 9,1,0		
		RMCME	RMCM	XMCME	XMCM	
						Normal Mode
1	8/12/16/20/24/32 bit words	0	0	0	0	All types of Codec interface will use this selection
						Multichannel Mode
2	8-bit words					2 Partition or 32-channel Mode
		0	1	0	1	All channels are disabled, unless selected in X/RCERA/B
		0	1	0	10	All channels are enabled,but masked unless selected in X/RCERA/B
		0	1	0	11	Symmetric transmit, receive
						8 Partition or 128 Channel Mode Transmit/Receive
						Channels selected by X/RCERA to X/RCERH bits
						Multichannel Mode is ON
		1	1	1	1	All channels are disabled, unless selected in XCERs
		1	1	1	10	All channels are enabled, but masked unless selected in XCERs
		1	1	1	11	Symmetric transmit, receive
						Continuous mode, transmit
		1	0	1	0	**Multi-Channel Mode is OFF**
						All 128 channels are active and enabled

20.14 Special Case: External Device is the Transmit Frame Master

Care must be taken if the transmitter expects a frame sync from an external device. After the transmitter comes out of reset (XRST = 1), the transmitter waits for a frame sync from the external device. If the first frame sync arrives very shortly after the transmitter is enabled, the CPU or DMA controller cannot have a chance to service DXR. In this case, the transmitter shifts out the default data in XSR instead of the desired value, which has not yet arrived in DXR. This causes problems in some applications, as the first data element in the frame is invalid. The data stream appears element-shifted (the first data word can appear in the second channel instead of the first).

To make sure of proper operation when the external device is the frame master, you must verify that DXR is already serviced with the first word when a frame sync occurs. To do so, you can keep the transmitter in reset until the first frame sync is detected. Upon detection of the first frame sync, the McBSP generates an interrupt to the CPU. Within the interrupt service routine, the transmitter is taken out of reset (XRST = 1). This verifies that the transmitter does not begin data transfers at the data pin during the first frame sync period. This also provides almost an entire frame period for the DSP to service DXR with the first word before the second frame sync occurs. The transmitter only begins data transfers upon receiving the second frame sync. At this point, DXR is already serviced with the first word.

The interrupt service routine must first be setup, then follow this modified procedure for proper initialization:

1. Make sure that no portion of the McBSP is using the internal sample rate generator signal CLKG and the internal frame sync generator signal FSG (GRST = FRST = 0). The respective portion of the McBSP needs to be in reset (XRST = 0 and/or RRST = 0).
2. Program SRGR and other control registers as required. Make sure the internal sample rate generator and the internal frame sync generator are still in reset (GRST = FRST = 0). Also make sure the respective portion of the McBSP is still in reset in this step (XRST = 0 and/or RRST = 0).
3. Program the XINTM bits to 2h in SPCR to generate an interrupt to the CPU upon detection of a transmit frame sync. Do not enable the XINT interrupt in the interrupt enable register (IER) in this step.
4. Wait for proper internal synchronization. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a master clock, wait for two CLKSRG cycles. In this case, the clock source to the sample rate generator (CLKSRG) is selected by the CLKSM bit in SRGR.
5. Skip this step if the bit clock is provided by the external device. This step only applies if the McBSP is the bit master clock and the internal sample rate generator is used.
   a. Start the sample rate generator by setting the GRST bit to 1. Wait two CLKG bit clocks for synchronization. CLKG is the output of the sample rate generator.
   b. On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to 1/(CLKGDV + 1) of the sample rate generator source clock CLKSRG.
6. A transmit sync error (XSYNCERR) can occur when enabled for the first time after device reset. The purpose of this step is to clear any potential XSYNCERR that occurs on the transmitter at this time:
   a. Set the XRST bit to 1 to enable the transmitter.
   b. Wait for any unexpected frame sync error to occur. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the McBSP generates the bit clock as a master clock, wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
   c. Disable the transmitter (XRST = 0). This clears any outstanding XSYNCERR.
7. Setup data acquisition as required:
   a. If the DMA controller is used to service the McBSP, setup data acquisition as desired and start the DMA controller in this step, before the McBSP is taken out of reset.
   b. If CPU interrupt is used to service the McBSP, no action is required in this step.
   c. If CPU polling is used to service the McBSP, no action is required in this step.
8. Enable the XINT interrupt by setting the corresponding bit in the interrupt enable register (IER). In this step, the McBSP transmitter is still in reset. Upon detection of the first transmit frame sync from the external device, the McBSP generates an interrupt to the CPU and the DSP enters the interrupt service routine (ISR). The ISR needs to perform these tasks in this order:
   a. Modify the XINTM bits to the value desired for normal McBSP operations. If CPU interrupt is used to service the McBSP in normal operations, make sure that the XINTM bits are modified to 0 to detect the McBSP XRDY event. If no McBSP interrupt is desired in normal operations, disable future McBSP-to-CPU interrupt in the interrupt enable register (IER).
   b. Set the XRST bit and/or the RRST bit to 1 to enable the respective portion of the McBSP. The McBSP is now ready to transmit and/or receive.
9. Service the McBSP:
   a. If CPU polling is used to service the McBSP in normal operations, CPU polling can do so upon exit from the ISR.
   b. If CPU interrupt is used to service the McBSP in normal operations, upon XRDY interrupt service routine is entered. The ISR must be setup to verify that XRDY = 1 and service the McBSP accordingly.
   c. If DMA controller is used to service the McBSP in normal operations, the DMA controller services the McBSP automatically upon receiving the XEVT and/or REVT.
10. Upon detection of the second frame sync, DXR is already serviced and the transmitter is ready to transmit the valid data. The receiver is also serviced properly by the DSP.

20.15 Software

20.15.1 MCBSP Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/mcbsp

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

20.16 McBSP Registers

This section describes the McBSP registers.

20.16.1 McBSP Base Addresses

Table 20-76. McBSP Base Address Table

Device Registers	Register Name	Start Address	End Address
McbspaRegs	MCBSP_REGS	0x0000_6000	0x0000_603F
McbspbRegs	MCBSP_REGS	0x0000_6040	0x0000_607F

20.16.2 McBSP_REGS Registers

Table 20-77 lists the memory-mapped registers for the McBSP_REGS registers. All register offset addresses not listed in Table 20-77 should be considered as reserved locations and the register contents should not be modified.

Table 20-77. MCBSP_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	DRR2	Data receive register bits 31-16		Go
1h	DRR1	Data receive register bits 15-0		Go
2h	DXR2	Data transmit register bits 31-16		Go
3h	DXR1	Data transmit register bits 15-0		Go
4h	SPCR2	Serial port control register 2		Go
5h	SPCR1	Serial port control register 1		Go
6h	RCR2	Receive Control register 2		Go
7h	RCR1	Receive Control register 1		Go

23h	MFFINT	Interrupt enable		Go

Complex bit access types are encoded to fit into small table cells. Table 20-78 shows the codes that are used for access types in this section.

Table 20-78. McBSP_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		

Table 20-78. McBSP_REGS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.16.2.1 DRR2 Register (Offset = 0h) [Reset = 0000h]

DRR2 is shown in Figure 20-67 and described in Table 20-79.

Return to the Summary Table.

DRR2 contains the upper 16 bits of the received data to be read by the CPU or DMA. DRR2 is only used if the word length is greater than 16 bits.

Figure 20-67. DRR2 Register

20.16.2.2 DRR1 Register (Offset = 1h) [Reset = 0000h]

DRR1 is shown in Figure 20-68 and described in Table 20-80.

Return to the Summary Table.

DRR1 contains the lower 16 bits of the received data to be read by either the CPU or DMA.

Figure 20-68. DRR1 Register

20.16.2.3 DXR2 Register (Offset = 2h) [Reset = 0000h]

DXR2 is shown in Figure 20-69 and described in Table 20-81.

Return to the Summary Table.

DXR2 contains the upper 16 bits of the data to be transmitted after being written by the CPU or DMA. DXR2 is only used if the word length is greater than 16 bits.

Figure 20-69. DXR2 Register

20.16.2.5 SPCR2 Register (Offset = 4h) [Reset = 0000h]

SPCR2 is shown in Figure 20-71 and described in Table 20-83.

Return to the Summary Table.

SPCR2 conatins control and status bits for various McBSP functions such as emulation modes, transmit interrupt mode control, transmitter status bits, and transmitter and other internal reset controls.

Figure 20-71. SPCR2 Register

15-10	RESERVED	R	0h	Reserved
9	FREE	R/W	0h	Free run bit. When a breakpoint is encountered in the high-level language debugger, FREE determines whether the McBSP transmit and receive clocks continue to run or whether they are affected as determined by the SOFT bit. When one of the clocks stops, the corresponding data transfer (transmission or reception) stops. Reset type: SYSRSn
8	SOFT	R/W	0h	Soft stop bit. When FREE = 0, SOFT determines the response of the McBSP transmit and receive clocks when a breakpoint is encountered in the high-level language debugger. When one of the clocks stops, the corresponding data transfer (transmission or reception) stops. Reset type: SYSRSn
7	FRST	R/W	0h	Frame-synchronization logic reset bit. The sample rate generator of the McBSP includes framesynchronization logic to generate an internal frame-synchronization signal. You can use FRST to take the frame-synchronization logic into and out of its reset state. This bit has a negative polarity FRST = 0 indicates the reset state. Reset type: SYSRSn 0h (R/W) = If you read a 0, the frame-synchronization logic is in its reset state. If you write a 0, you reset the frame-synchronization logic. In the reset state, the frame-synchronization logic does not generate a frame-synchronization signal (FSG). 1h (R/W) = If you read a 1, the frame-synchronization logic is enabled. If you write a 1, you enable the frame-synchronization logic by taking it out of its reset state. When the frame-synchronization logic is enabled (FRST = 1) and the sample rate generator as a whole is enabled (GRST = 1), the frame-synchronization logic generates the frame-synchronization signal FSG as programmed.

Table 20-83. SPCR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	GRST	R/W	0h	Sample rate generator reset bit. You can use GRST to take the McBSP sample rate generator into and out of its reset state. This bit has a negative polarity GRST = 0 indicates the reset state. Reset type: SYSRSn 0h (R/W) = If you read a 0, the sample rate generator is in its reset state. If you write a 0, you reset the sample rate generator. If GRST = 0 due to a reset, CLKG is driven by the CPU clock divided by 2, and FSG is driven low (inactive). If GRST = 0 due to program code, CLKG and FSG are both driven low (inactive). 1h (R/W) = If you read a 1, the sample rate generator is enabled. If you write a 1, you enable the sample rate generator by taking it out of its reset state. When enabled, the sample rate generator generates the clock signal CLKG as programmed in the sample rate generator registers. If FRST = 1, the generator also generates the frame-synchronization signal FSG as programmed in the sample rate generator registers.
5-4	XINTM	R/W	0h	Transmit interrupt mode bits. XINTM determines which event in the McBSP transmitter generates a transmit interrupt (XINT) request. If XINT is properly enabled, the CPU services the interrupt request otherwise, the CPU ignores the request. Reset type: SYSRSn 0h (R/W) = The McBSP sends a transmit interrupt (XINT) request to the CPU when the XRDY bit changes from 0 to 1, indicating that transmitter is ready to accept new data (the content of DXR[1,2] has been copied to XSR[1,2]). Regardless of the value of XINTM, you can check XRDY to determine whether a word transfer is complete. The McBSP sends an XINT request to the CPU when 16 enabled bits have been transmitted on the DX pin. 1h (R/W) = In the multichannel selection mode, the McBSP sends an XINT request to the CPU after every 16- channel block is transmitted in a frame. Outside of the multichannel selection mode, no interrupt request is sent. 2h (R/W) = The McBSP sends an XINT request to the CPU when each transmit frame-synchronization pulse is detected. The interrupt request is sent even if the transmitter is in its reset state. 3h (R/W) = The McBSP sends an XINT request to the CPU when the XSYNCERR bit is set, indicating a transmit frame-synchronization error. Regardless of the value of XINTM, you can check XSYNCERR to determine whether a transmit framesynchronization error occurred.
3	XSYNCERR	R/W	0h	Transmit frame-synchronization error bit. XSYNCERR is set when a transmit frame-synchronization error is detected by the McBSP. If XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU when XSYNCERR is set. The flag remains set until you write a 0 to it or reset the transmitter. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Transmit frame-synchronization error

Table 20-83. SPCR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	XEMPTY	R	0h	Transmitter empty bit. XEMPTY is cleared when the transmitter is ready to send new data but no new data is available (transmitter-empty condition). This bit has a negative polarity a transmitter-empty condition is indicated by XEMPTY = 0. Reset type: SYSRSn 0h (R/W) = Transmitter-empty condition Typically this indicates that all the bits of the current word have been transmitted but there is no new data in DXR1. XEMPTY is also cleared if the transmitter is reset and then restarted. 1h (R/W) = No transmitter-empty condition
1	XRDY	R	0h	Transmitter ready bit. XRDY is set when the transmitter is ready to accept new data in DXR[1,2]. Specifically, XRDY is set in response to a copy from DXR1 to XSR1. If the transmit interrupt mode is XINTM = 00b, the McBSP sends a transmit interrupt (XINT) request to the CPU when XRDY changes from 0 to 1. Also, when XRDY changes from 0 to 1, the McBSP sends a transmit synchronization event (XEVT) signal to the DMA controller. Reset type: SYSRSn 0h (R/W) = Transmitter not ready When DXR1 is loaded, XRDY is automatically cleared. 1h (R/W) = Transmitter ready: DXR[1,2] is ready to accept new data. If both DXRs are needed (word length larger than 16 bits), the CPU or the DMA controller must load DXR2 first and then load DXR1. As soon as DXR1 is loaded, the contents of both DXRs are copied to the transmit shift registers (XSRs), as described in the next step. If DXR2 is not loaded first, the previous content of DXR2 is passed to the XSR2
0	XRST	R/W	0h	Transmitter reset bit. You can use XRST to take the McBSP transmitter into and out of its reset state. This bit has a negative polarity XRST = 0 indicates the reset state. To read about the effects of a transmitter reset, see Section 15.10.2, Resetting and Initializing a McBSP. Reset type: SYSRSn 0h (R/W) = If you read a 0, the transmitter is in its reset state. If you write a 0, you reset the transmitter. 1h (R/W) = If you read a 1, the transmitter is enabled. If you write a 1, you enable the transmitter by taking it out of its reset state.

20.16.2.6 SPCR1 Register (Offset = 5h) [Reset = 0000h]

SPCR1 is shown in Figure 20-72 and described in Table 20-84.

Return to the Summary Table.

SPCR1 contains control and status bits for various McBSP functions such as digital loopback, receive data justification, clock stop mode, receive interrupt mode, DX pin delay enabler, receiver status bits, and receiver reset control.

Figure 20-72. SPCR1 Register

15	14	13	12	11	10	9	8
DLB	RJUST		CLKSTP		RESERVED		
R/W-0h	R/W-0h		R/W-0h		R-0h		
7	6	5	4	3	2	1	0
DXENA	RESERVED	RINTM		RSYNCERR	RFULL	RRDY	RRST
R/W-0h	R/W-0h	R/W-0h		R/W-0h	R-0h	R-0h	R/W-0h

Table 20-84. SPCR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	DLB	R/W	0h	Digital loopback mode bit. DLB disables or enables the digital loopback mode of the McBSP: Reset type: SYSRSn 0h (R/W) = Disabled Internal DR is supplied by the MDRx pin. Internal FSR and internal MCLKR can be supplied by their respective pins or by the sample rate generator, depending on the mode bits FSRM and CLKRM. Internal DX is supplied by the MDXx pin. Internal FSX and internal CLKX are supplied by their respective pins or are generated internally, depending on the mode bits FSXM and CLKXM. 1h (R/W) = Enabled Internal receive signals are supplied by internal transmit signals: MDRx connected to MDXx MFSRx connected to MFSXx MCLKR connected to MCLKXx This mode allows you to test serial port code with a single DSP. The McBSP transmitter directly supplies data, frame synchronization, and clocking to the McBSP receiver.
14-13	RJUST	R/W	0h	Receive sign-extension and justification mode bits. During reception, RJUST determines how data is justified and bit filled before being passed to the data receive registers (DRR1, DRR2). RJUST is ignored if you enable a companding mode with the RCOMPAND bits. In a companding mode, the 8-bit compressed data in RBR1 is expanded to left-justified 16-bit data in DRR1. Reset type: SYSRSn 0h (R/W) = Right justify the data and zero fill the MSBs 1h (R/W) = Right justify the data and sign-extend the data into the MSBs 2h (R/W) = Left justify the data and zero fill the LSBs 3h (R/W) = Reserved (do not use)

Table 20-84. SPCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12-11	CLKSTP	R/W	0h	Clock stop mode bits. CLKSTP allows you to use the clock stop mode to support the SPI masterslave protocol. If you will not be using the SPI protocol, you can clear CLKSTP to disable the clock stop mode. In the clock stop mode, the clock stops at the end of each data transfer. At the beginning of eachdata transfer, the clock starts immediately (CLKSTP = 10b) or after a half-cycle delay (CLKSTP = 11b). Reset type: SYSRSn 0h (R/W) = Clock stop mode is disabled. 1h (R/W) = Clock stop mode is disabled. 2h (R/W) = Clock stop mode, without clock delay 3h (R/W) = Clock stop mode, with half-cycle clock delay
10-8	RESERVED	R	0h	Reserved
7	DXENA	R/W	0h	DX delay enabler mode bit. DXENA controls the delay enabler for the DX pin. The enabler creates an extra delay for turn-on time (for the length of the delay, see the device-specific data sheet). Reset type: SYSRSn 0h (R/W) = DX delay enabler off 1h (R/W) = DX delay enabler on
6	RESERVED	R/W	0h	Reserved
5-4	RINTM	R/W	0h	Receive interrupt mode bits. RINTM determines which event in the McBSP receiver generates areceive interrupt (RINT) request. If RINT is properly enabled inside the CPU, the CPU services the interrupt request otherwise, the CPU ignores the request. Reset type: SYSRSn 0h (R/W) = The McBSP sends a receive interrupt (RINT) request to the CPU when the RRDY bit changes from 0 to 1, indicating that receive data is ready to be read (the content of RBR[1,2] has been copied to DRR[1,2]): Regardless of the value of RINTM, you can check RRDY to determine whether a word transfer is complete. The McBSP sends a RINT request to the CPU when 16 enabled bits have been received on the DR pin. 1h (R/W) = In the multichannel selection mode, the McBSP sends a RINT request to the CPU after every 16- channel block is received in a frame. Outside of the multichannel selection mode, no interrupt request is sent. 2h (R/W) = The McBSP sends a RINT request to the CPU when each receive frame-synchronization pulse is detected. The interrupt request is sent even if the receiver is in its reset state. 3h (R/W) = The McBSP sends a RINT request to the CPU when the RSYNCERR bit is set, indicating a receive frame-synchronization error. Regardless of the value of RINTM, you can check RSYNCERR to determine whether a receive frame-synchronization error occurred.
3	RSYNCERR	R/W	0h	Receive frame-sync error bit. RSYNCERR is set when a receive frame-sync error is detected by the McBSP. If RINTM = 11b, the McBSP sends a receive interrupt (RINT) request to the CPU when RSYNCERR is set. The flag remains set until you write a 0 to it or reset the receiver. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Receive frame-synchronization error.

Table 20-84. SPCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	RFULL	R	0h	Receiver full bit. RFULL is set when the receiver is full with new data and the previously received data has not been read (receiver-full condition). For more details about this condition, Reset type: SYSRSn 0h (R/W) = No receiver-full condition 1h (R/W) = Receiver-full condition: RSR[1,2] and RBR[1,2] are full with new data, but the previous data in DRR[1,2] has not been read
1	RRDY	R	0h	Receiver ready bit. RRDY is set when data is ready to be read from DRR[1,2]. Specifically, RRDY is set in response to a copy from RBR1 to DRR1. If the receive interrupt mode is RINTM = 00b, the McBSP sends a receive interrupt request to the CPU when RRDY changes from 0 to 1. Also, when RRDY changes from 0 to 1, the McBSP sends a receive synchronization event (REVT) signal to the DMA controller. Reset type: SYSRSn 0h (R/W) = Receiver not ready When the content of DRR1 is read, RRDY is automatically cleared. 1h (R/W) = Receiver ready: New data can be read from DRR[1,2]. Important: If both DRRs are required (word length larger than 16 bits), the CPU or the DMA controller must read from DRR2 first and then from DRR1. As soon as DRR1 is read, the next RBR-to-DRR copy is initiated. If DRR2 is not read first, the data in DRR2 is lost.
0	RRST	R/W	0h	Receiver reset bit. You can use RRST to take the McBSP receiver into and out of its reset state. This bit has a negative polarity RRST = 0 indicates the reset state. Reset type: SYSRSn 0h (R/W) = If you read a 0, the receiver is in its reset state. If you write a 0, you reset the receiver. 1h (R/W) = If you read a 1, the receiver is enabled. If you write a 1, you enable the receiver by taking it out of its reset state.

20.16.2.7 RCR2 Register (Offset = 6h) [Reset = 0000h]

RCR2 is shown in Figure 20-73 and described in Table 20-85.

Return to the Summary Table.

RCR2 contains control bits for the receiver such as number of phases in each frame, the serial word length and number of words for phase 2 of dual phase frames, receive companding mode, receive frame synchronization ignore function, and the receive data delay.

Figure 20-73. RCR2 Register

15	14	13	12	11	10	9	8
RPHASE	RFRLEN2						
R/W-0h	R/W-0h						
7	6	5	4	3	2	1	0

R/W-0h			R/W-0h		R/W-0h	R/W-0h	

Table 20-85. RCR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RPHASE	R/W	0h	Receive phase number bit. RPHASE determines whether the receive frame has one phase or two phases. For each phase you can define the serial word length and the number of serial words in the phase. To set up phase 1, program RWDLEN1 (word length) and RFRLEN1 (number of words). To set up phase 2 (if there are two phases), program RWDLEN2 and RFRLEN2. Reset type: SYSRSn 0h (R/W) = Single-phase frame The receive frame has only one phase, phase 1. 1h (R/W) = Dual-phase frame The receive frame has two phases, phase 1 and phase 2.
14-8	RFRLEN2	R/W	0h	Receive frame length 2 (1 to 128 words). Each frame of receive data can have one or two phases, depending on value that you load into the RPHASE bit. If a single-phase frame is selected, RFRLEN1 in RCR1 selects the number of serial words (8, 12, 16, 20, 24, or 32 bits per word) in the frame. If a dual-phase frame is selected, RFRLEN1 determines the number of serial words in phase 1 of the frame, and RFRLEN2 in RCR2 determines the number of words in phase 2 of the frame. The 7-bit RFRLEN fields allow up to 128 words per phase. See Table 15-77 for a summary of how to determine the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization period. Program the RFRLEN fields with [w minus 1], where w represents the number of words per phase. For example, if you want a phase length of 128 words in phase 2, load 127 into RFRLEN2. Reset type: SYSRSn

Table 20-85. RCR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-5	RWDLEN2	R/W	0h	Receive word length 2. Each frame of receive data can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, RWDLEN1 in RCR1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 determines the length of the serial words in phase 1 of the frame, and RWDLEN2 in RCR2 determines the word length in phase 2 of the frame. Reset type: SYSRSn 0h (R/W) = 8 bits 1h (R/W) = 12 bits 2h (R/W) = 16 bits 3h (R/W) = 20 bits 4h (R/W) = 24 bits 5h (R/W) = 32 bits 6h (R/W) = Reserved (do not use) 7h (R/W) = Reserved (do not use)
4-3	RCOMPAND	R/W	0h	Receive companding mode bits. Companding (COMpress and exPAND) hardware allows compression and expansion of data in either u-law or A-law format. RCOMPAND allows you to choose one of the following companding modes for the McBSP receiver: For more details about these companding modes, see Section 15.1.5, Companding (Compressing and Expanding) Data. Reset type: SYSRSn 0h (R/W) = No companding, any size data, MSB received first 1h (R/W) = No companding, 8-bit data, LSB received first 2h (R/W) = u-law companding, 8-bit data, MSB received first 3h (R/W) = A-law companding, 8-bit data, MSB received first
2	RFIG	R/W	0h	Receive frame-synchronization ignore bit. If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected framesynchronization pulse. Unexpected Receive Frame-Synchronization Pulse. Setting RFIG causes the serial port to ignore unexpected frame-synchronization signals during reception. Reset type: SYSRSn 0h (R/W) = Frame-synchronization detect. An unexpected FSR pulse causes the receiver to discard the contents of RSR[1,2] in favor of the new incoming data. The receiver: 1. Aborts the current data transfer 2. Sets RSYNCERR in SPCR1 3. Begins the transfer of a new data word 1h (R/W) = Frame-synchronization ignore. An unexpected FSR pulse is ignored. Reception continues uninterrupted.
1-0	RDATDLY	R/W	0h	Receive data delay bits. RDATDLY specifies a data delay of 0, 1, or 2 receive clock cycles after framesynchronization and before the reception of the first bit of the frame. Reset type: SYSRSn 0h (R/W) = 0-bit data delay 1h (R/W) = 1-bit data delay 2h (R/W) = 2-bit data delay 3h (R/W) = Reserved (do not use)

20.16.2.8 RCR1 Register (Offset = 7h) [Reset = 0000h]

RCR1 is shown in Figure 20-74 and described in Table 20-86.

Return to the Summary Table.

RCR1 contains control bits for the receiver such as the serial word length and number of words for single phase transmissions, or phase 1 if dual phase frames are used.

Figure 20-74. RCR1 Register

15	14	13	12	11	10	9	8

Table 20-86. RCR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14-8	RFRLEN1	R/W	0h	Receive frame length 1 (1 to 128 words). Each frame of receive data can have one or two phases,depending on value that you load into the RPHASE bit. If a single-phase frame is selected, RFRLEN1 inRCR1 selects the number of serial words (8, 12, 16, 20, 24, or 32 bits per word) in the frame. If a dualphase frame is selected, RFRLEN1 determines the number of serial words in phase 1 of the frame, and RFRLEN2 in RCR2 determines the number of words in phase 2 of the frame. The 7-bit RFRLEN fields allow up to 128 words per phase. See Table 15-75 for a summary of how you determine the frame length. This length corresponds to the number of words or logical time slots or channels per framesynchronization period. Program the RFRLEN fields with [w minus 1], where w represents the number of words per phase. For example, if you want a phase length of 128 words in phase 1, load 127 into RFRLEN1. Note: When operating in SPI mode, the frame length can only be 1 word. Reset type: SYSRSn
7-5	RWDLEN1	R/W	0h	Receive word length 1. Each frame of receive data can have one or two phases, depending on the value that you load into the RPHASE bit. If a single-phase frame is selected, RWDLEN1 in RCR1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 determines the length of the serial words in phase 1 of the frame, and RWDLEN2 in RCR2 determines the word length in phase 2 of the frame. Reset type: SYSRSn 0h (R/W) = 8 bits 1h (R/W) = 12 bits 2h (R/W) = 16 bits 3h (R/W) = 20 bits 4h (R/W) = 24 bits 5h (R/W) = 32 bits 6h (R/W) = Reserved (do not use) 7h (R/W) = Reserved (do not use)
4-0	RESERVED	R	0h	Reserved

20.16.2.9 XCR2 Register (Offset = 8h) [Reset = 0000h]

XCR2 is shown in Figure 20-75 and described in Table 20-87.

Return to the Summary Table.

XCR2 contains control bits for the transmitter such as number of phases in each frame, the serial word length and number of words for phase 2 of dual phase frames, transmit companding mode, transmit frame synchronization ignore function, and the transmit data delay control.

Figure 20-75. XCR2 Register

R/W-0h			R/W-0h		R/W-0h	R/W-0h	

Table 20-87. XCR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	XPHASE	R/W	0h	Transmit phase number bit. XPHASE determines whether the transmit frame has one phase or two phases. For each phase you can define the serial word length and the number of serial words in the phase. To set up phase 1, program XWDLEN1 (word length) and XFRLEN1 (number of words). To set up phase 2 (if there are two phases), program XWDLEN2 and XFRLEN2. Reset type: SYSRSn
14-8	XFRLEN2	R/W	0h	Transmit frame length 2 (1 to 128 words). Each frame of transmit data can have one or two phases, depending on value that you load into the XPHASE bit. If a single-phase frame is selected, XFRLEN1 in XCR1 selects the number of serial words (8, 12, 16, 20, 24, or 32 bits per word) in the frame. If a dualphase frame is selected, XFRLEN1 determines the number of serial words in phase 1 of the frame and XFRLEN2 in XCR2 determines the number of words in phase 2 of the frame. The 7-bit XFRLEN fields allow up to 128 words per phase. See Table 15-81 for a summary of how to determine the frame length. This length corresponds to the number of words or logical time slots or channels per framesynchronization period. Program the XFRLEN fields with [w minus 1], where w represents the number of words per phase. For example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1. Reset type: SYSRSn
7-5	XWDLEN2	R/W	0h	Transmit word length 2. Each frame of transmit data can have one or two phases, depending on the value that you load into the XPHASE bit. If a single-phase frame is selected, XWDLEN1 in XCR1 selects the length for every serial word transmitted in the frame. If a dual-phase frame is selected, XWDLEN1 determines the length of the serial words in phase 1 of the frame and XWDLEN2 in XCR2 determines the word length in phase 2 of the frame. Reset type: SYSRSn 0h (R/W) = 8 bits 1h (R/W) = 12 bits 2h (R/W) = 16 bits 3h (R/W) = 20 bits 4h (R/W) = 24 bits 5h (R/W) = 32 bits 6h (R/W) = Reserved (do not use) 7h (R/W) = Reserved (do not use)

Table 20-87. XCR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-3	XCOMPAND	R/W	0h	Transmit companding mode bits. Companding (COMpress and exPAND) hardware allows compression and expansion of data in either u-law or A-law format. Reset type: SYSRSn 0h (R/W) = No companding, any size data, MSB received first 1h (R/W) = No companding, 8-bit data, LSB received first 2h (R/W) = u-law companding, 8-bit data, MSB received first 3h (R/W) = A-law companding, 8-bit data, MSB received first
2	XFIG	R/W	0h	Transmit frame-synchronization ignore bit. If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected framesynchronization pulse. Setting XFIG causes the serial port to ignore unexpected frame-synchronization pulses during transmission. Reset type: SYSRSn 0h (R/W) = Frame-synchronization detect. An unexpected FSX pulse causes the transmitter to discard the content of XSR[1,2]. The transmitter: 1. Aborts the present transmission 2. Sets XSYNCERR in SPCR2 3. Begins a new transmission from DXR[1,2]. If new data was written to DXR[1,2] since the last DXR[1,2]-to-XSR[1,2] copy, the current value in XSR[1,2] is lost. Otherwise, the same data is transmitted. 1h (R/W) = Frame-synchronization ignore. An unexpected FSX pulse is ignored. Transmission continues uninterrupted.
1-0	XDATDLY	R/W	0h	Transmit data delay bits. XDATDLY specifies a data delay of 0, 1, or 2 transmit clock cycles after frame synchronization and before the transmission of the first bit of the frame. Reset type: SYSRSn 0h (R/W) = 0-bit data delay 1h (R/W) = 1-bit data delay 2h (R/W) = 2-bit data delay 3h (R/W) = Reserved (do not use)

20.16.2.10 XCR1 Register (Offset = 9h) [Reset = 0000h]

XCR1 is shown in Figure 20-76 and described in Table 20-88.

Return to the Summary Table.

XCR1 contains control bits for the transmitter such as the serial word length and number of words for single phase transmissions, or phase 1 if dual phase frames are used.

Figure 20-76. XCR1 Register

Table 20-88. XCR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14-8	XFRLEN1	R/W	0h	Transmit frame length 1 (1 to 128 words). Each frame of transmit data can have one or two phases, depending on value that you load into the XPHASE bit. If a single-phase frame is selected, XFRLEN1 in XCR1 selects the number of serial words (8, 12, 16, 20, 24, or 32 bits per word) in the frame. If a dual-phase frame is selected, XFRLEN1 determines the number of serial words in phase 1 of the frame and XFRLEN2 in XCR2 determines the number of words in phase 2 of the frame. The 7-bit XFRLEN fields allow up to 128 words per phase. See Table 15-79 for a summary of how you determine the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization period. Program the XFRLEN fields with [w minus 1], where w represents the number of words per phase. For example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1. Note: When operating in SPI mode, the frame length can only be 1 word. Reset type: SYSRSn
7-5	XWDLEN1	R/W	0h	Transmit word length 1. Each frame of transmit data can have one or two phases, depending on the value that you load into the XPHASE bit. If a single-phase frame is selected, XWDLEN1 in XCR1 selects the length for every serial word transmitted in the frame. If a dual-phase frame is selected, XWDLEN1 determines the length of the serial words in phase 1 of the frame and XWDLEN2 in XCR2 determines the word length in phase 2 of the frame. Reset type: SYSRSn 0h (R/W) = 8 bits 1h (R/W) = 12 bits 2h (R/W) = 16 bits 3h (R/W) = 20 bits 4h (R/W) = 24 bits 5h (R/W) = 32 bits 6h (R/W) = Reserved (do not use) 7h (R/W) = Reserved (do not use)
4-0	RESERVED	R	0h	Reserved

20.16.2.11 SRGR2 Register (Offset = Ah) [Reset = 0000h]

SRGR2 is shown in Figure 20-77 and described in Table 20-89.

Return to the Summary Table.

SRGR2 contains control bits for the sample rate generator such as input clock selection, internal tranmist frame-synchronization source selection, and the period between frame-synchronization pulses.
If an external source provides the input clock source for the sample rate generator, a control bit is provided to make the CLKG synchronized to an external frame synchronization pulse on the FSR pin so that CLKG is kept in phase with the input clock.

Table 20-89. SRGR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15	GSYNC	R/W	0h	Clock synchronization mode bit for CLKG. GSYNC is used only when the input clock source for the sample rate generator is external?on the MCLKR pin. When GSYNC = 1, the clock signal (CLKG) and the frame-synchronization signal (FSG) generated by the sample rate generator are made dependent on pulses on the FSR pin. Reset type: SYSRSn 0h (R/W) = No clock synchronization CLKG oscillates without adjustment, and FSG pulses every (FPER + 1) CLKG cycles. 1h (R/W) = Clock synchronization - CLKG is adjusted as necessary so that it is synchronized with the input clock on the MCLKR pin. - FSG pulses. FSG only pulses in response to a pulse on the FSR pin. The frame-synchronization period defined in FPER is ignored.
14	RESERVED	R/W	0h	Reserved

Table 20-89. SRGR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	CLKSM	R/W	0h	Sample rate generator mode Reset type: SYSRSn 0h (R/W) = Sample rate generator input clock mode bit. The sample rate generator can accept an input clock signal and divide it down according to CLKGDV to produce an output clock signal, CLKG. The frequency of CLKG is:) CLKG frequency = (input clock frequency)/ (CLKGDV + 1 CLKSM is used in conjunction with the SCLKME bit to determine the source for the input clock. A reset selects the CPU clock as the input clock and forces the CLKG frequency to half the LSPCLK frequency. The input clock for the sample rate generator is taken from the MCLKR pin, depending on the value of the SCLKME bit of PCR: SCLKME CLKSM Input Clock For Sample Rate Generator 0 0 Reserved 1 0 Signal on MCLKR pin 1h (R/W) = The input clock for the sample rate generator is taken from the LSPCLK or from the MCLKX pin, depending on the value of the SCLKME bit of PCR: SCLKME CLKSM Input Clock For Sample Rate Generator 0 1 LSPCLK 1 1 Signal on MCLKX pin
12	FSGM	R/W	0h	Sample rate generator transmit frame-synchronization mode bit. The transmitter can get frame synchronization from the FSX pin (FSXM = 0) or from inside the McBSP (FSXM = 1). When FSXM = 1, the FSGM bit determines how the McBSP supplies frame-synchronization pulses. Reset type: SYSRSn 0h (R/W) = If FSXM = 1, the McBSP generates a transmit frame-synchronization pulse when the content of DXR[1,2] is copied to XSR[1,2]. 1h (R/W) = If FSXM = 1, the transmitter uses frame-synchronization pulses generated by the sample rate generator. Program the FWID bits to set the width of each pulse. Program the FPER bits to set the period between pulses.
11-0	FPER	R/W	0h	Frame-synchronization period bits for FSG. The sample rate generator can produce a clock signal, CLKG, and a frame-synchronization signal, FSG. The period between framesynchronization pulses on FSG is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles: Reset type: SYSRSn

20.16.2.12 SRGR1 Register (Offset = Bh) [Reset = 0001h]

SRGR1 is shown in Figure 20-78 and described in Table 20-90.

Return to the Summary Table.

SRGR1 contains control bits for the sample rate generator functions such as the divide down frequency, and the width fo the frame-synchronization pulses on FSG.

7	6	5	4	3	2	1	0
XPBBLK	XPABLK		XCBLK			XMCM	
R/W-0h	R/W-0h		R-0h			R/W-0h	

Table 20-91. MCR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9	XMCME	R/W	0h	Transmit multichannel partition mode bit. XMCME determines whether only 32 channels or all 128 channels are to be individually selectable. XMCME is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero). Reset type: SYSRSn
8-7	XPBBLK	R/W	0h	Transmit partition B block bits XPBBLK is only applicable if channels can be individually disabled/ enabled and masked/unmasked (XMCM is nonzero) and the 2-partition mode is selected (XMCME = 0). Under these conditions, the McBSP transmitter can transmit or withhold data in any of the 32 channels that are assigned to partitions A and B of the transmitter. The 128 transmit channels of the McBSP are divided equally among 8 blocks (0 through 7). When XPBBLK is applicable, use XPBBLK to assign one of the odd-numbered blocks (1, 3, 5, or 7) to partition B, as shown in the following table. Use the PABLK bit to assign one of the evennumbered blocks (0, 2, 4, or 6) to partition A. If you want to use more than 32 channels, you can change block assignments dynamically. You can assign a new block to one partition while the transmitter is handling activity in the other partition. For example, while the block in partition A is active, you can change which block is assigned to partition B. The XCBLK bits are regularly pdated to indicate which block is active. When XMCM = 11b (for symmetric transmission and reception), the transmitter uses the receive block bits (RPABLK and RPBBLK) rather than the transmit block bits (XPABLK and XPBBLK). Reset type: SYSRSn 0h (R/W) = Block 1: channels 16 through 31 1h (R/W) = Block 3: channels 48 through 63 2h (R/W) = Block 5: channels 80 through 95 3h (R/W) = Block 7: channels 112 through 127

Table 20-91. MCR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6-5	XPABLK	R/W	0h	Transmit partition A block bits. XPABLK is only applicable if channels can be individually disabled/enabled and masked/unmasked (XMCM is nonzero) and the 2-partition mode is selected (XMCME = 0). Under these conditions, the McBSP transmitter can transmit or withhold data in any of the 32 channels that are assigned to artitions A and B of the transmitter. See the Descriptionfor XPBBLK (bits 8-7) for more information about assigning blocks to partitions A and B. Reset type: SYSRSn 0h (R/W) = Block 0: channels 0 through 15 1h (R/W) = Block 2: channels 32 through 47 2h (R/W) = Block 4: channels 64 through 79 3h (R/W) = Block 6: channels 96 through 111
4-2	XCBLK	R	0h	Transmit current block indicator. XCBLK indicates which block of 16 channels is involved in the current McBSP transmission: Reset type: SYSRSn 0h (R/W) = Block 0: channels 0 through 15 1h (R/W) = Block 1: channels 16 through 31 2h (R/W) = Block 2: channels 32 through 47 3h (R/W) = Block 3: channels 48 through 63 4h (R/W) = Block 4: channels 64 through 79 5h (R/W) = Block 5: channels 80 through 95 6h (R/W) = Block 6: channels 96 through 111 7h (R/W) = Block 7: channels 112 through 127
1-0	XMCM	R/W	0h	Transmit multichannel selection mode bits. XMCM determines whether all channels or only selected channels are enabled and unmasked for transmission. Reset type: SYSRSn 0h (R/W) = No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked 1h (R/W) = All channels are disabled unless they are selected in the appropriate transmit channel enable registers (XCERs). If enabled, a channel in this mode is also unmasked. The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs. 2h (R/W) = All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit determines whether 32 channels or 128 channels are selectable in XCERs. 3h (R/W) = This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (RCERs). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (XCERs). The XMCME bit determines whether 32 channels or 128 channels are selectable in RCERs and XCERs.

20.16.2.14 MCR1 Register (Offset = Dh) [Reset = 0000h]

MCR1 is shown in Figure 20-80 and described in Table 20-92.

Return to the Summary Table.

MCR1 contains control bits for the receiver multi-channel functions such as channel enable mode selection, channel partition modes, channel block assignments, and active channel status bits.

15-12	RESERVED	R	0h	Reserved
11	FSXM	R/W	0h	Transmit frame-synchronization mode bit. FSXM determines whether transmit framesynchronization pulses are supplied externally or internally. The polarity of the signal on the FSX pin is determined by the FSXP bit. Reset type: SYSRSn 0h (R/W) = Transmit frame synchronization is supplied by an external source via the FSX pin. 1h (R/W) = Transmit frame synchronization is generated internally by the Sample Rate generator, as determined by the FSGM bit of SRGR2
10	FSRM	R/W	0h	Receive frame-synchronization mode bit. FSRM determines whether receive framesynchronization pulses are supplied externally or internally. The polarity of the signal on the FSR pin is determined by the FSRP bit. Reset type: SYSRSn 0h (R/W) = Receive frame synchronization is supplied by an external source via the FSR pin. 1h (R/W) = Receive frame synchronization is supplied by the sample rate generator. FSR is an output pin reflecting internal FSR, except when GSYNC = 1 in SRGR2

Table 20-97. PCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	CLKXM	R/W	0h	Transmit clock mode bit. CLKXM determines whether the source for the transmit clock is external or internal, and whether the MCLKX pin is an input or an output. The polarity of the signal on the MCLKX pin is determined by the CLKXP bit. In the clock stop mode (CLKSTP = 10b or 11b), the McBSP can act as a master or as a slave in the SPI protocol. If the McBSP is a master, make sure that CLKX is an output. If the McBSP is a slave, make sure that CLKX is an input. Reset type: SYSRSn 0h (R/W) = Not in clock stop mode (CLKSTP = 00b or 01b): The transmitter gets its clock signal from an external source via the MCLKX pin. In clock stop mode (CLKSTP = 10b or 11b): The McBSP is a slave in the SPI protocol. The internal transmit clock (CLKX) is driven by the SPI master via the MCLKX pin. The internal receive clock (MCLKR) is driven internally by CLKX, so that both the transmitter and the receiver are controlled by the external master clock. 1h (R/W) = Not in clock stop mode (CLKSTP = 00b or 01b): Internal CLKX is driven by the sample rate generator of the McBSP. The MCLKX pin is an output pin that reflects internal CLKX. In clock stop mode (CLKSTP = 10b or 11b): The McBSP is a master in the SPI protocol. The sample rate generator drives the internal transmit clock (CLKX). Internal CLKX is reflected on the MCLKX pin to drive the shift clock of the SPI-compliant slaves in the system. Internal CLKX also drives the internal receive clock (MCLKR), so that both the transmitter and the receiver are controlled by the internal master clock
8	CLKRM	R/W	0h	Receive clock mode bit. The role of CLKRM and the resulting effect on the MCLKR pin depend on whether the McBSP is in the digital loopback mode (DLB = 1). The polarity of the signal on the MCLKR pin is determined by the CLKRP bit. Reset type: SYSRSn 0h (R/W) = Not in digital loopback mode (DLB = 0): The MCLKR pin is an input pin that supplies the internal receive clock (MCLKR). In digital loopback mode (DLB = 1): The MCLKR pin is in the high impedance state. The internal receive clock (MCLKR) is driven by the internal transmit clock (CLKX). CLKX is derived according to the CLKXM bit. 1h (R/W) = Not in digital loopback mode (DLB = 0): Internal MCLKR is driven by the sample rate generator of the McBSP. The MCLKR pin is an output pin that reflects internal MCLKR. In digital loopback mode (DLB = 1): Internal MCLKR is driven by internal CLKX. The MCLKR pin is an output pin that reflects internal MCLKR. CLKX is derived according to the CLKXM bit.

Table 20-97. PCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	SCLKME	R/W	0h	Sample rate generator input clock mode bit. The sample rate generator can produce a clock signal, CLKG. The frequency of CLKG is: CLKG freq. = (Input clock frequency) / (CLKGDV + 1) SCLKME is used in conjunction with the CLKSM bit to select the input clock. SCLKME CLKSM Input Clock For Sample Rate Generator 0 0 Reserved 0 1 LSPCLK The input clock for the sample rate generator is taken from the MCLKR pin or from the MCLKX pin, depending on the value of the CLKSM bit of SRGR2: SCLKME CLKSM Input Clock For Sample Rate Generator 1 0 Signal on MCLKR pin 1 1 Signal on MCLKX pin Reset type: SYSRSn
6	RESERVED	R	0h	Reserved
5	RESERVED	R	0h	Reserved
4	RESERVED	R	0h	Reserved
3	FSXP	R/W	0h	Transmit frame-synchronization polarity bit. FSXP determines the polarity of FSX as seen on the FSX pin. Reset type: SYSRSn 0h (R/W) = Transmit frame-synchronization pulses are active high. 1h (R/W) = Transmit frame-synchronization pulses are active low.
2	FSRP	R	0h	Receive frame-synchronization polarity bit. FSRP determines the polarity of FSR as seen on the FSR pin. Reset type: SYSRSn 0h (R/W) = Receive frame-synchronization pulses are active high. 1h (R/W) = Receive frame-synchronization pulses are active low.
1	CLKXP	R	0h	Transmit clock polarity bit. CLKXP determines the polarity of CLKX as seen on the MCLKX pin. Reset type: SYSRSn 0h (R/W) = Transmit data is sampled on the rising edge of CLKX. 1h (R/W) = Transmit data is sampled on the falling edge of CLKX.
0	CLKRP	R/W	0h	Receive clock polarity bit. CLKRP determines the polarity of CLKR as seen on the MCLKR pin. Reset type: SYSRSn 0h (R/W) = Receive data is sampled on the falling edge of MCLKR. 1h (R/W) = Receive data is sampled on the rising edge of MCLKR.

20.16.2.20 RCERC Register (Offset = 13h) [Reset = 0000h]

RCERC is shown in Figure 20-86 and described in Table 20-98.

Return to the Summary Table.

RCERC contains the receive channel enable registers for the C partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

Figure 20-86. RCERC Register

15-0	RCEC	R/W	0h	Receive channel enable bit. For receive multichannel selection mode (RMCM = 1): Reset type: SYSRSn 0h (R/W) = Disable the channel that is mapped to RCEx. 1h (R/W) = Enable the channel that is mapped to RCEx.

20.16.2.21 RCERD Register (Offset = 14h) [Reset = 0000h]

RCERD is shown in Figure 20-87 and described in Table 20-99.

Return to the Summary Table.

RCERD contains the receive channel enable registers for the D partition. This register is only used when the receiver is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. RMCM is nonzero).

15-0	RCED	R/W	0h	Receive channel enable bit. For receive multichannel selection mode (RMCM = 1): Reset type: SYSRSn 0h (R/W) = Disable the channel that is mapped to RCEx. 1h (R/W) = Enable the channel that is mapped to RCEx.

20.16.2.22 XCERC Register (Offset = 15h) [Reset = 0000h]

XCERC is shown in Figure 20-88 and described in Table 20-100.

Return to the Summary Table.

XCERC contains the transmit channel enable registers for the C partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

Figure 20-88. XCERC Register

Table 20-100. XCERC Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	XCERC	R/W	0h	Transmit channel enable bit. The role of this bit depends on which transmit multichannel selection mode is selected with the XMCM bits. Reset type: SYSRSn 0h (R/W) = For multichannel selection when XMCM = 01b (all channels disabled unless selected): Disable and mask the channel that is mapped to XCEx. For multichannel selection when XMCM = 10b (all channels enabled but masked unless selected): Mask the channel that is mapped to XCEx. For multichannel selection when XMCM = 11b (all channels masked unless selected): Mask the channel that is mapped to XCEx. Even if the channel is enabled by the corresponding receive channel enable bit, this channel's data cannot appear on the DX pin. 1h (R/W) = For multichannel selection when XMCM = 01b (all channels disabled unless selected): Enable and unmask the channel that is mapped to XCEx. For multichannel selection when XMCM = 10b (all channels enabled but masked unless selected): Unmask the channel that is mapped to XCEx. For multichannel selection when XMCM = 11b (all channels masked unless selected): Unmask the channel that is mapped to XCEx. If the channel is also enabled by the corresponding receive channel enable bit, full transmission can occur.

20.16.2.23 XCERD Register (Offset = 16h) [Reset = 0000h]

XCERD is shown in Figure 20-89 and described in Table 20-101.

Return to the Summary Table.

XCERD contains the transmit channel enable registers for the D partition. This register is only used when the transmitter is configured to allow individual disabling/enabling and masking/unmasking of the channels (e.g. XMCM is nonzero).

Chapter 21

Controller Area Network (CAN)

This chapter describes the Controller Area Network (CAN) module. CAN is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. The CAN module supports bit rates up to 1 Mbit/s and is compliant with the ISO11898-1 (CAN 2.0B) protocol specification.

Further information can be found in:

21.1.2 Features

The CAN module implements the following features:

- Complies with ISO11898-1 (Bosch® CAN protocol specification 2.0 A and B)
- Bit rates up to 1Mbps
- Multiple clock sources
- 32 message objects (“message objects” are also referred to as “mailboxes” in this document; the two terms are used interchangeably), each with the following properties:
  - Configurable as receive or transmit
  - Configurable with standard (11-bit) or extended (29-bit) identifier
  - Supports programmable identifier receive mask
  - Supports data and remote frames
  - Holds 0 to 8 bytes of data
  - Parity-checked configuration and data RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus-on, after bus-off state by a programmable 32-bit timer
- Message-RAM parity-check mechanism
- Two interrupt lines

Note

For a CAN bit clock of 200MHz, the smallest bit rate possible is 7.8125kbps.

Depending on the timing settings used, the accuracy of the on-chip zero-pin oscillator (specified in the data sheet) may not meet the requirements of the CAN protocol. In this situation, an external clock source must be used.

21.1.3 Block Diagram

Figure 21-1 shows a block diagram of the CAN module. Following is a description of some of the main blocks.

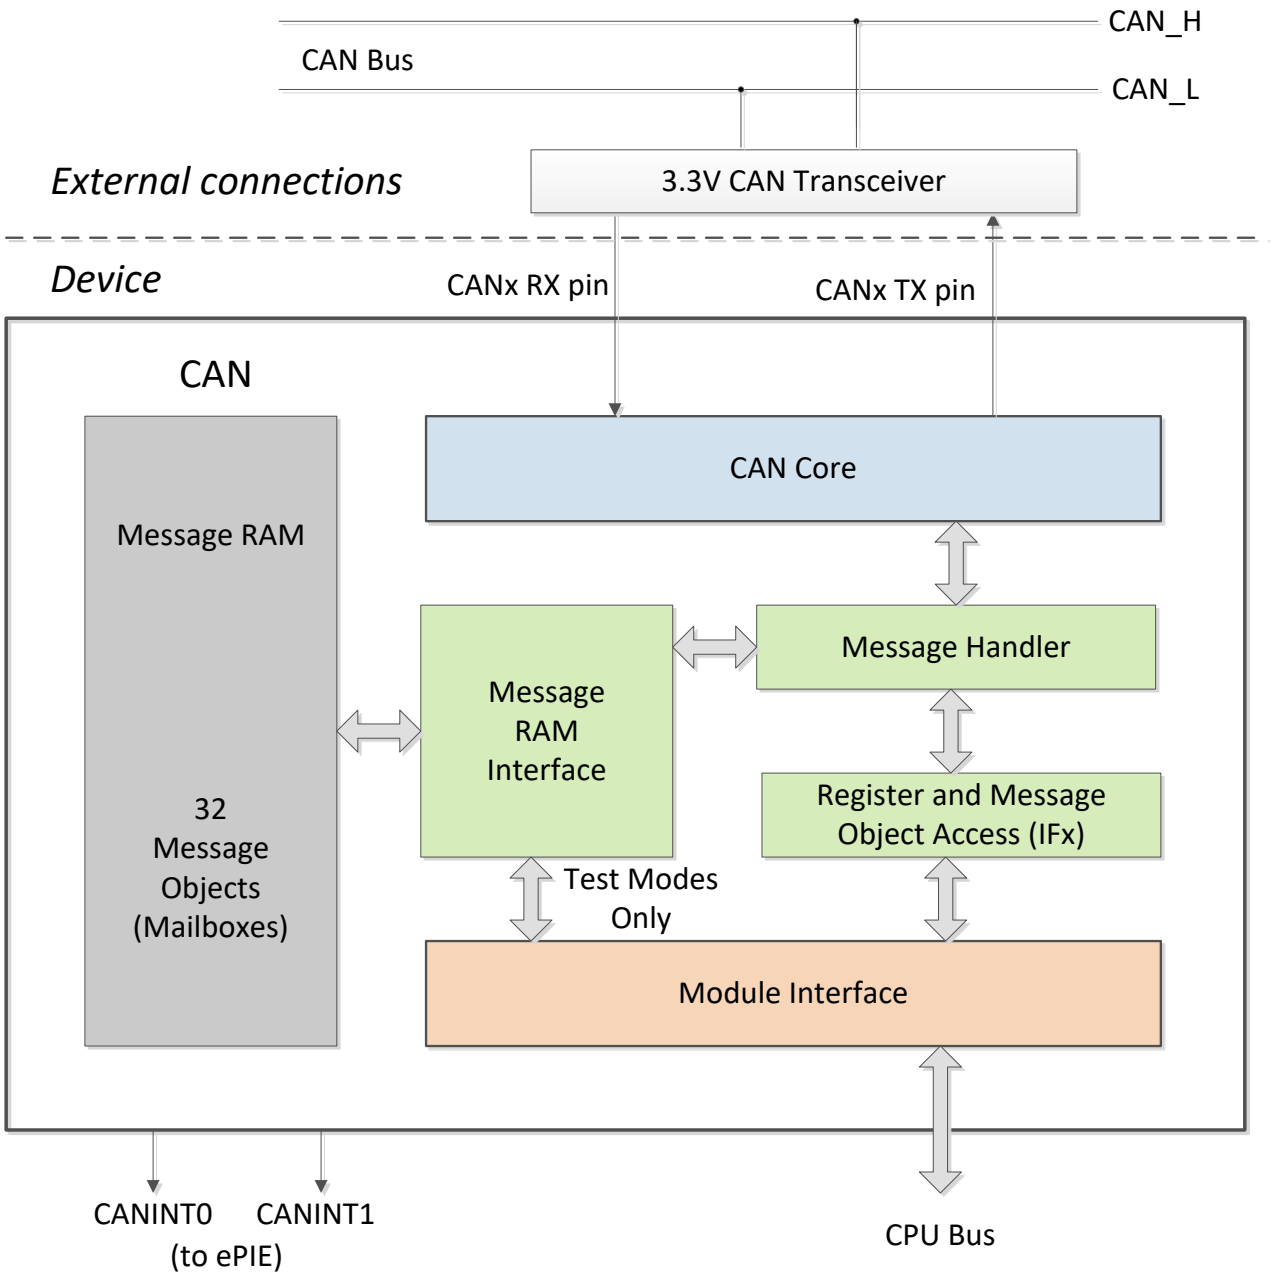

Figure 21-1. CAN Block Diagram

21.1.3.1 CAN Core

The CAN core consists of the CAN Protocol Controller and the Rx/Tx Shift register. It handles all ISO 11898-1 protocol functions.

21.1.3.2 Message Handler

The message handler is a state machine which controls the data transfer between the single-port Message RAM and the CAN Core's Rx/Tx Shift register. It also handles acceptance filtering and the interrupt request generation as programmed in the control registers.

21.1.3.3 Message RAM

The CAN message RAM enables the storage of 32 CAN messages.

21.1.3.4 Registers and Message Object Access (IFx)

Data consistency is provided by indirect accesses to the message objects. During normal operation, all CPU accesses to the message RAM are done through Interface registers. The IFx registers can be thought of as a "window" through which the message objects (mailboxes) are accessed.

Three Interface register sets control the CPU read and write accesses to the Message RAM, see Figure 21-2. There are two Interface register sets for read/write access (IF1 and IF2) and one Interface register set for read access only (IF3). See also Section 21.12. The Interface registers have the same word length as the message RAM.

In a dedicated test mode, the message RAM is memory-mapped and can be directly accessed.

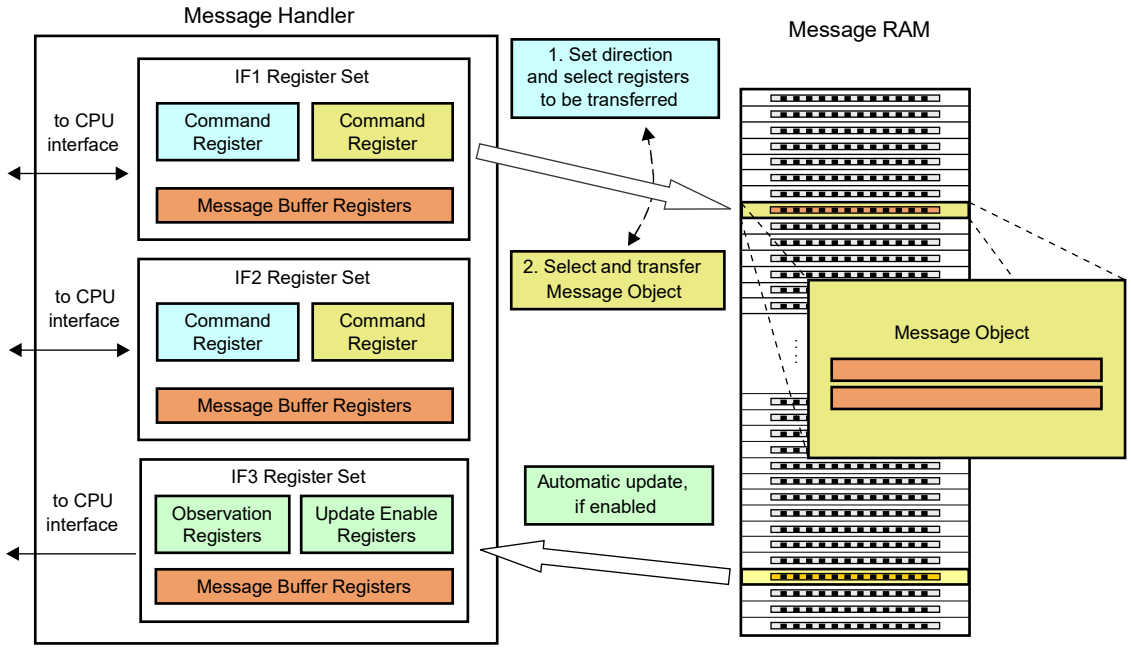

Figure 21-2. Accessing Message Objects Through IFx Registers

21.2 Functional Description

The CAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1Mbps. A CAN transceiver chip is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the message handler. These functions are: acceptance filtering; the transfer of messages between the CAN Core and the Message RAM; and the handling of transmission requests .

The register set of the CAN can be accessed directly by the CPU through the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

21.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some I/O functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pull-ups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

21.2.2 Address/Data Bus Bridge

The CAN module uses a special addressing scheme to support byte accesses.This is the same addressing scheme that is used on the USB module. It is recommended to only use 32-bit accesses to the CAN registers using the *HWREG_BP()* macro that uses the *__byte_peripheral_32()* intrinsic. If 16-bit accesses are to be used, the lower 16-bits must be written to the register's address, and the upper 16-bits must be written to the register's address plus 2.

Because of the bus bridge, the view of the CAN module's register space through the Code Composer Studio™ (CCS) IDE memory window does not always match the actual addressing. When the view mode is 32-bit or 16-bit, even addresses are effectively duplicated; odd addresses can be ignored. When the view mode is 8-bit, even addresses from within the CAN module are duplicated into the odd addresses in the CCS memory view; odd addresses from the module are not displayed.

Table 21-1. CAN Register Access from Software

CAN Register Space			C28x 8-Bit		C28x 16-Bit		C28x 32-Bit	
Address	Name	Data	Access	Data	Access	Data	Address	Data

21.3 Operating Modes

21.3.1 Initialization

The initialization mode is entered either by software (by setting the **Init** bit in the CAN_CTL register), by hardware reset, or by going bus-off. While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high). The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

To initialize the CAN controller, the CPU has to configure the CAN bit timing and those message objects that are used for CAN communication. Message objects that are not needed, can be deactivated with the MsgVal bits cleared.

The access to the Bit Timing Register for the configuration of the bit timing is enabled when both **Init** and CCE bits in the CAN Control register are set.

Clearing the Init bit finishes the software initialization. Afterwards, the bit stream processor (BSP) synchronizes to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus Idle) before the BSP can take part in bus activities and start the message transfer. For more details, see Section 21.11.

The initialization of the message objects is independent of the Init bit; however, all message objects must be configured with particular identifiers or set to "not-valid" before the message transfer is started.

It is possible to change the configuration of message objects during normal operation by the CPU. After setup and subsequent transfer of message object from interface registers to message RAM, the acceptance filtering is applied to it when the modified message object number is same or smaller than the previously found message object. This makes sure of data consistency even when changing message objects; for example, while there is a pending CAN frame reception.

21.3.2 CAN Message Transfer (Normal Operation)

Once the CAN is initialized and the Init bit is reset to zero, the CAN Core synchronizes to the CAN bus and is ready for communication.

Received messages are stored into the appropriate message objects, if the messages pass acceptance filtering. The whole message (MSGID, DLC, and up to 8 data bytes) is stored into the message object. As a consequence, for example, if the identifier mask is used, the MSGID bits that are masked to "don't care" can change in the message object when a received message is stored.

The CPU can read or write each message at any time using the interface registers, as the message handler provides data consistency in case of concurrent accesses.

Messages to be transmitted can be updated by the CPU. If a permanent message object (MSGID, control bits set up during configuration, and setup for multiple CAN transfers) exists for the message, it is possible to only update the data bytes. If several transmit messages must be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects can be requested at the same time. The message objects are subsequently transmitted, according to the internal priority. Messages can be updated or set to "not valid" at any time, even if a requested transmission is still pending. However, the data bytes are discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission can be automatically requested by the reception of a remote frame with a matching identifier.

21.3.2.1 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898, 6.3.3 Recovery Management), the CAN provides a mechanism to automatically retransmit frames that have lost arbitration or have been disturbed by errors during transmission. The frame transmission service is not confirmed to the user before the transmission is successfully completed

By default, this automatic retransmission is enabled and can be disabled by setting the DAR bit in the CAN control register. Further details to this mode are provided in Section 21.10.3.

21.3.2.2 Auto-Bus-On

After the CAN has entered the bus-off state, the CPU can start a bus-off-recovery sequence by resetting the *Init* bit. If this is not done, the module stays in the bus-off state.

The CAN provides an automatic auto-bus-on feature that is enabled by the ABO bit. If set, the CAN automatically starts the bus-off-recovery sequence. The sequence can be delayed by a user-defined number of clock cycles.

Note

If the CAN module goes Bus-Off due to multiple CAN bus errors, the CAN module stops all bus activities and automatically sets the Init bit. Once the Init bit is cleared by the application (or due to the auto-bus-on feature), the device waits for 129 occurrences of Bus Idle (equal to 129 * 11 consecutive recessive bits) before resuming normal operation. The Bus-Off recovery sequence cannot be shortened by setting or resetting the Init bit. At the end of the bus-off recovery sequence, the error counters reset. After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 Error code is written to the Error and Status Register. This enables the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.

21.3.3 Test Modes

The CAN module provides several test modes that are mainly intended for self-test purposes. Figure 21-3 aids in understanding the various test modes. Figure 21-3 must be viewed as representative of the module behavior, and not as a gate-accurate implementation of the module. Figure 21-3 does not include the GPIO muxing or the I/O buffers.

For all test modes, the Test bit in the CAN control register needs to be set to 1 to enable write access to the CAN_TEST register.

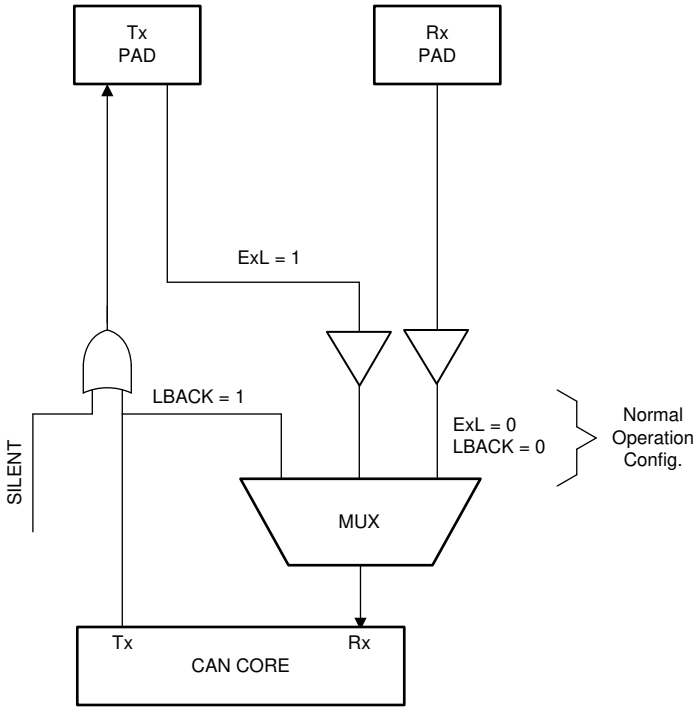

Figure 21-3. CAN_MUX

21.3.3.1 Silent Mode

The silent mode can be used to analyze the traffic on the CAN bus without affecting the CAN by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The CAN is still able to receive valid data frames and valid remote frames, but the CAN does not send any dominant bits. However, the received frames are internally routed to the CAN Core.

Figure 21-4 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the Silent bit in test register (CAN_TEST), to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

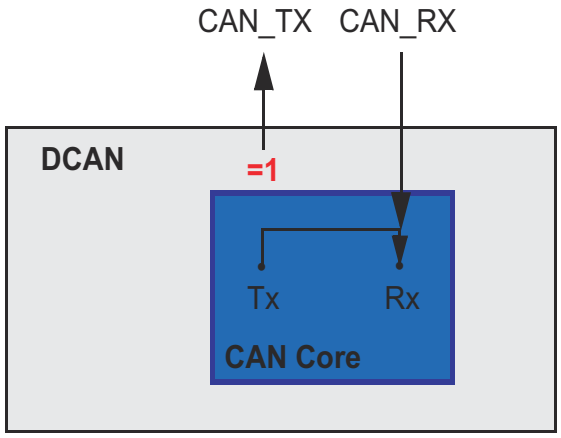

Figure 21-4. CAN Core in Silent Mode

21.3.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if the messages pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages still can be monitored at the CAN_TX pin.

To be independent from external stimulation, the CAN core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loopback mode.

Figure 21-5 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode. Loopback mode can be activated by setting the LBack bit in the CAN_TEST register to 1.

Note

In loopback mode, the signal path from the CAN core to the Tx pin, and the signal path from the Tx pin back to the CAN core are disregarded. For including these into the testing, see Section 21.3.3.3.

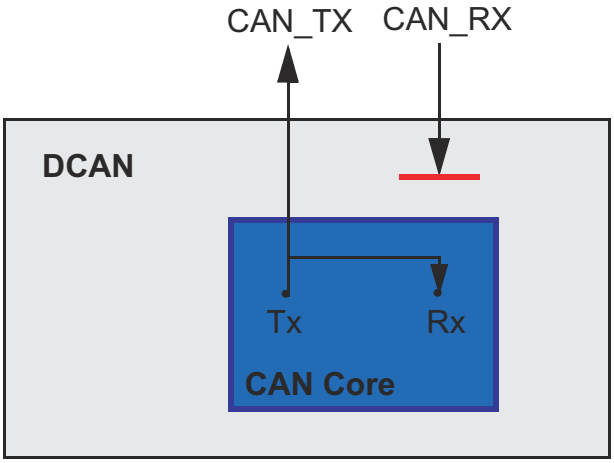

Figure 21-5. CAN Core in Loopback Mode

21.3.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, the external loopback mode includes the signal path from the CAN core to the Tx pin, and the signal path from the Tx pin back to the CAN core. When the external loopback mode is selected, the CAN core is connected to the input buffer of the Tx pin. With this configuration, the Tx pin IO circuit can be tested. External loopback mode can be activated by setting the ExL bit in Test Register to 1.

Figure 21-6 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in external loopback mode.

Note

When loopback mode is active (LBack bit set), the ExL bit is ignored.

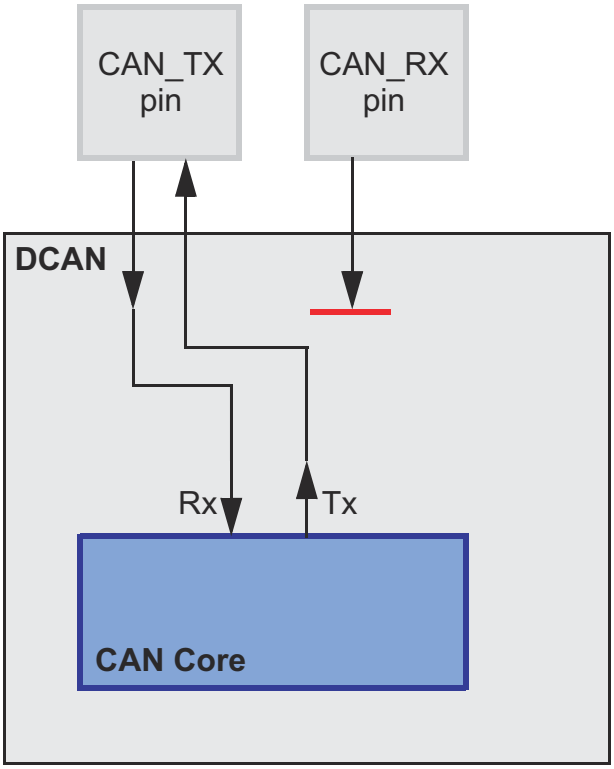

Figure 21-6. CAN Core in External Loopback Mode

21.3.3.4 Loopback Combined with Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. The CAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits are sent on the CAN_TX pin.

Figure 21-7 shows the connection of the signals CAN_TX and CAN_RX to the CAN Core in case of the combination of loopback mode with silent mode.

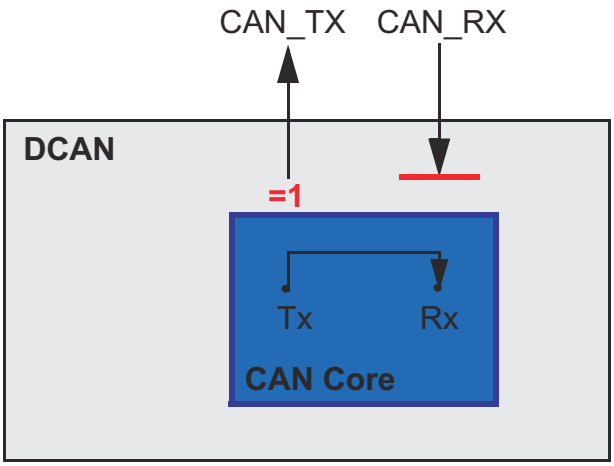

Figure 21-7. CAN Core in Loopback Combined with Silent Mode

21.4 Multiple Clock Source

Three clock domains are provided to the CAN module for generating the CAN bit timing: the external clock (X1/X2), the system clock (SYSCLK), and the GPIO_AUXCLKIN.

The *System Control and Interrupts* chapter and the device data sheet provide more information on how to configure the relevant clock source registers in the system module.

Note

The CAN core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1Mbps an oscillator frequency of 8MHz or higher has to be used.

21.5 Interrupt Functionality

Interrupts can be generated on two interrupt lines: CAN0INT and CAN1INT. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN Control register.

The CAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts. The source of an interrupt can be determined by the interrupt identifiers Int0ID and Int1ID in the CAN_INT Interrupt register. When no interrupt is pending, the register holds the value zero. Each interrupt line remains active until the dedicated field in the Interrupt register (Int0ID or Int1ID) again reaches zero (this means the cause of the interrupt is reset), or until IE0 and IE1 are reset. The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits RxOk, TxOk, and LEC by reading the Error and Status Register, but a write access of the CPU never generates or resets an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects. INT0ID and INT1ID point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine that reads the message from the interrupt source can also read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1 or IF2 Command register). When IntPnd is cleared, the Interrupt register points to the next message object with a pending interrupt.

The CAN module features a module-level interrupt enable and acknowledge mechanism. To enable the CAN0 and CAN1 interrupts, you must set the appropriate bits in the CAN_GLB_INT_EN register. When handling an interrupt, the individual message or status change flag must be cleared prior to acknowledging the interrupt using CAN_GLB_INT_CLR and PIEACK.

21.5.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE which are described in Section 21.13.1. Message object interrupts can be routed to the CAN0INT or CAN1INT line, which is controlled by the Interrupt Multiplexer register.

Note that writing to the IntPnd bit in the CAN_IFnMCTL registers can force an interrupt.

21.5.2 Status Change Interrupts

The events RxOk, TxOk, and LEC in the Error and Status register belong to the status change interrupts. The status change interrupt group can be enabled by the SIE bit in the CAN Control Register. If SIE is set, a status change interrupt is generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration. Status Change interrupts can only be routed to interrupt line CAN0INT which has to be enabled by setting IE0 in the CAN_CTL Register.

21.5.3 Error Interrupts

The events PER, BOff and EWarn, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE. Also, error interrupts can only be routed to interrupt line CAN0INT, which has to be enabled by setting IE0 in the CAN_CTL register.

21.5.4 Peripheral Interrupt Expansion (PIE) Module Nomenclature for DCAN Interrupts

Table 21-3 shows the Peripheral Interrupt Expansion (PIE) module nomenclature for the interrupts.

Table 21-3. PIE Module Nomenclature for Interrupts

Interrupt	CANA	CANB
CANINT0	CANA_0	CANB_0
CANINT1	CANA_1	CANB_1

21.5.5 Interrupt Topologies

Interrupt topologies for CAN are illustrated in Figure 21-8 and Figure 21-9. Mailbox interrupts for transmit and receive operations can be routed to both CANINT0 and CANINT1. However, error and status interrupts can only be routed to CANINT0.

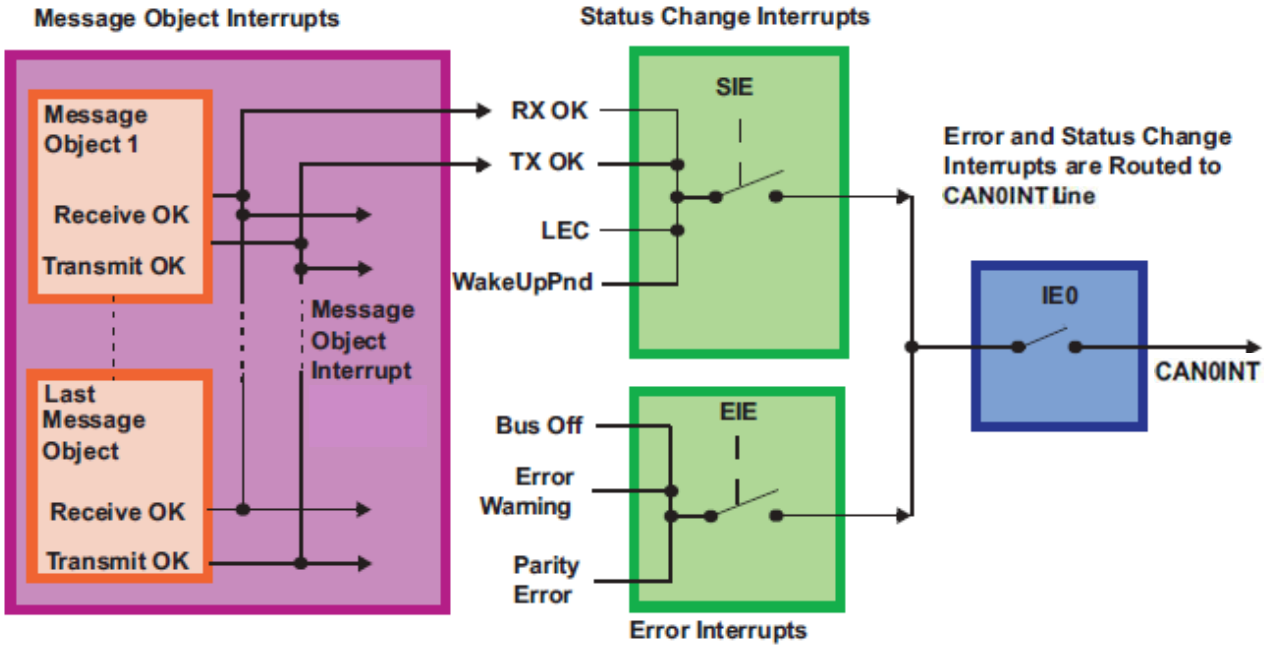

Figure 21-8. CAN Interrupt Topology 1

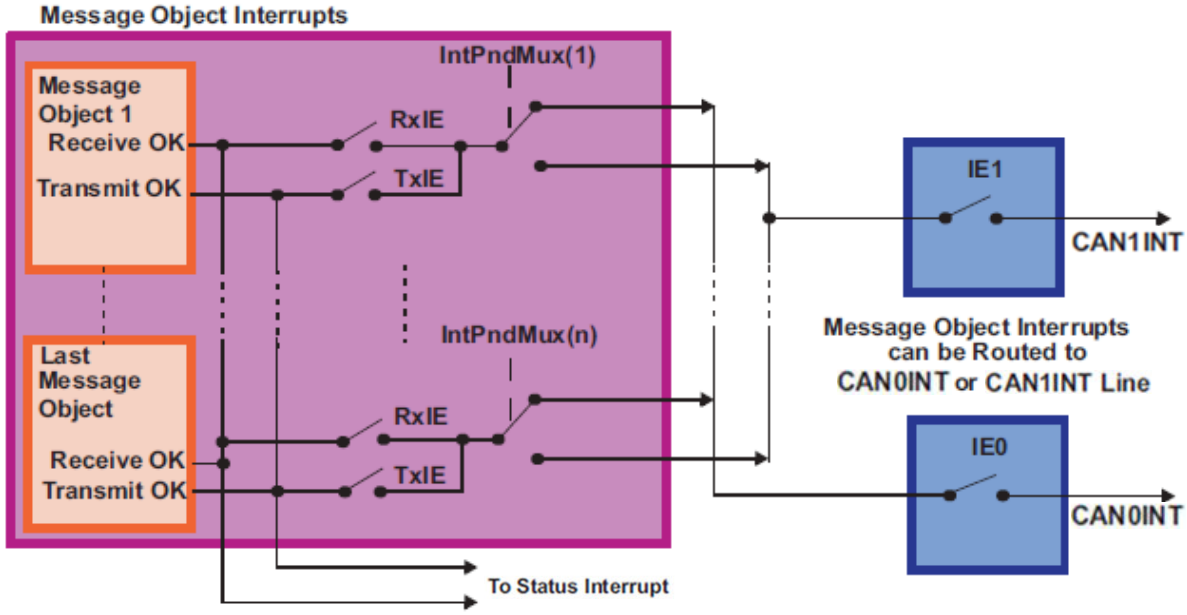

Figure 21-9. CAN Interrupt Topology 2

21.6 Parity Check Mechanism

The CAN provides a parity check mechanism to make sure data integrity of the message RAM data. For each word (32 bits) in Message RAM, one parity bit is calculated.

Parity information is stored in the Message RAM on write accesses and is checked against the stored parity bit from Message RAM on read accesses.

The parity check functionality can be enabled or disabled by the PMD bit field in the CAN control register. In case of a disabled parity check, the parity bits in message RAM are left unchanged on write access to the data area and no check is done on read access.

If parity checking is enabled, parity bits are automatically generated and checked by the CAN. A parity bit is set if the modulo-2-sum of the data bits is 1. This means that if the parity bit is set, then there are an odd number of 1 bits in the data.

21.6.1 Behavior on Parity Error

On any read access to Message RAM, for example, during the start of a CAN frame transmission, the parity of the message object is checked. If a parity error is detected, the PER bit in the Error and Status register is set. If error interrupts are enabled, an interrupt can also be generated. To avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object is reset.

The message object data can be read by the CPU, independently of parity errors. Thus, the application has to make sure that the read data is valid, for example, by immediately checking the Parity Error Code register on parity error interrupt.

21.7 Debug Mode

The module supports the usage of an external debug unit by providing functions like pausing CAN activities and making message RAM content accessible from the debugger. Debug mode is entered automatically when an external debugger is connected and the core is halted.

Before entering Debug mode, the circuit waits until a transmission is started, a reception is finished, or the Bus idle state is recognized. If the IDS bit is set, the debugger immediately interrupts the current transmission or reception. Afterwards, the CAN enters Debug mode, indicated by the InitDbg flag, in the CAN Control register. During debug mode, all CAN registers can be accessed. Reading reserved bits returns a 0; writing to reserved bits has no effect. Also, the message RAM is memory-mapped, so this allows the external debug unit to read the message RAM. For the memory organization (see Section 21.13.3).

Note

During debug mode, the Message RAM cannot be accessed using the IFx register sets.

Writing to control registers in Debug mode can influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following CAN registers is disabled:

- Error and Status register (clear of status flags by read)
- IF1/IF2 Command registers

21.8 Module Initialization

After hardware reset, the Init bit in the CAN Control register is set and all CAN protocol functions are disabled. The configuration of the bit timing and of the message objects must be completed before the CAN protocol functions are enabled.

For the configuration of the message objects, see Section 21.9.

For the configuration of the Bit Timing, see Section 21.11.2.

The bits MsgVal, NewDat, IntPnd, and TxRqst of the message objects are reset to 0 by a hardware reset. The configuration of a message object is done by programming Mask, Arbitration, Control and Data bits of one of the IF1/IF2 Interface register sets to the desired values. By writing the message object number to bits [7:0] of the corresponding IF1/IF2 Command register, the IF1/IF2 Interface Register content is loaded into the addressed message object in the Message RAM.

The configuration of the bit timing requires that the CCE bit in the CAN Control register is set additionally to Init. This is not required for the configuration of the message objects.

When the Init bit in the CAN Control register is cleared, the CAN Protocol Controller state machine of the CAN Core and the message handler State Machine start to control the CAN's internal data flow. Received messages which pass the acceptance filtering are stored into the Message RAM; messages with pending transmission request are loaded into the CAN Core's Shift register and are transmitted using the CAN bus.

The CPU can enable the interrupt lines (setting IE0 and IE1 to 1) at the same time when the CPU clears Init and CCE. The status interrupts EIE and SIE can be enabled simultaneously.

The CAN communication can be controlled interrupt-driven or in polling mode. The Interrupt Register points to those message objects with IntPnd = 1. The register is updated even if the interrupt lines to the CPU are disabled (IE0 and IE1 are 0).

The CPU can poll all MessageObject's NewDat and TxRqst bits in parallel from the NewData registers and the Transmission Request registers. Polling can be made easier if all Transmit Objects are grouped at the low numbers; all Receive Objects are grouped at the high numbers.

21.9 Configuration of Message Objects

The entire Message RAM must be configured before the end of the initialization; however, it is also possible to change the configuration of message objects during CAN communication.

21.9.1 Configuration of a Transmit Object for Data Frames

Figure 21-10 shows how a transmit object can be initialized.

Figure 21-10. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. The arbitration bits define the identifier and type of the outgoing message. If an 11-bit Identifier (standard frame) is used (Xtd = 0), the Identifier is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.
- The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn must not be set before the data is valid.
- If the TxIE bit is set, the IntPnd bit is set after a successful transmission of the message object.
- If the RmtEn bit is set, a matching received remote frame causes the TxRqst bit to be set; the remote frame is autonomously answered by a data frame.
- The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) can be used (UMask = 1) to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit must not be masked. For details, see Section 21.10.8. Identifier masking must be disabled (UMask = 0) if no remote frames are allowed to set the TxRqst bit (RmtEn = 0).

21.9.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

21.9.3 Configuration of a Single Receive Object for Data Frames

Figure 21-11 shows how a receive object for data frames can be initialized.

Figure 21-11. Initialization of a Single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. The arbitration bits define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (Xtd = 0), the Identifier is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to 0.
- When the message handler stores a data frame in the message object, the message handler stores the received data length code and the corresponding number of data bytes. If the data length code is less than 8, the remaining bytes of the message object can be overwritten by non-specified values.
- The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) can be used (UMask = 1) to allow groups of data frames with similar identifiers to be accepted. The Dir bit must not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register are overwritten by the bits of the stored data frame.
- If the RxIE bit is set, the IntPnd bit is set when a received data frame is accepted and stored in the message object.
- If the TxRqst bit is set, the transmission of a remote frame with the same identifier as stored in the Arbitration bits is triggered. The content of the Arbitration bits can change if the Mask bits are used (UMask = 1) for acceptance filtering.

21.9.4 Configuration of a Single Receive Object for Remote Frames

Figure 21-12 shows how a receive object for remote frames can be initialized.

Figure 21-12. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

- Receive objects for remote frames can be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object does not trigger the transmission of a data frame. Receive objects for remote frames can be expanded to a FIFO buffer, see Section 21.9.5.
- UMask must be set to 1. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) can be set to "must-match" or to "don't care", to allow groups of remote frames with similar identifiers to be accepted. The Dir bit must not be masked in typical applications. For details, see Section 21.10.8.
- The arbitration bits (ID[28:0] and Xtd bit) can be given by the application. The arbitration bits define the identifier and type of accepted received remote frames. If some bits of the Mask bits are set to "don't care", the corresponding bits of the arbitration bits are overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = 0), the Identifier is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] is set to 0.
- The data length code (DLC[3:0]) can be given by the application. When the message handler stores a remote frame in the message object, the message handler stores the received data length code. The data bytes of the message object remain unchanged.
- If the RxIE bit is set, the IntPnd bit is set when a received remote frame is accepted and stored in the message object.

21.9.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to form a FIFO , the identifiers and masks (if used) of these message objects are programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number is the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one must be programmed to 0. The EoB bit of the last message object of a FIFO buffer is set to 1, configuring the last message object as the end of the block.

21.10 Message Handling

When initialization is finished, the CAN module synchronizes to the traffic on the CAN bus. The CAN module does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application must update the data of the messages to be transmitted and to enable and request the transmission. The transmission is requested automatically when a matching remote frame is received.

The application can read messages that are received and accepted. Messages that are not read before the next messages are accepted for the same message object are overwritten. Messages can be read interrupt-driven or after polling of NewDat.

21.10.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. The message handler state machine performs the following tasks:

- Data transfer from Message RAM to CAN Core (messages to be transmitted).
- Data transfer from CAN Core to the Message RAM (received messages).
- Data transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission request flags
- New data flags
- Interrupt pending flags
- Message valid registers

Instead of collecting above listed status information of each message object using IFx registers separately, these message handler registers provide a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

21.10.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the requests are serviced according to the priority of the corresponding message object, so for example, messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object can be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

21.10.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx registers and Message RAM, the MsgVal bits in the Message Valid register and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = 0) since the start of the transmission, the TxRqst bit is reset. If TxIE is set, IntPnd is set after a successful transmission. If the CAN has lost the arbitration or if an error occurred during the transmission, the message is retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages are transmitted in the order of the priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CAN control register, the behavior of bits TxRqst and NewDat in the Message Control register of the Interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object for storage. The remote frames automatically trigger the transmission of a data frame, if the *RmtEn* bit is set in the matching Transmit Object.

21.10.4 Updating a Transmit Object

The CPU can update the data bytes of a transmit object any time using the IF1 and IF2 interface registers; neither MsgVal nor TxRqst need to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register or IF1/IF2 Data B register must be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command register and then the number of the message object is written to bits [7:0] of the Command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that can already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details see Section 21.10.3.

When NewDat is set together with TxRqst, NewDat is reset as soon as the new transmission has started.

21.10.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects can be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the Interface register. The bits [23:16] of the Command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither MsgVal nor TxRqst need to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, the transmission is continued; however, the transmission is not repeated if the transmission is disturbed.

To update only the data bytes of a message being transmitted, set bits [23:16] of the Command register to 0x87.

Note

After the update of the transmit object, the interface register set contains a copy of the actual contents of the object, including the part that had not been updated.

21.10.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the message handler starts to scan the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

21.10.7 Reception of Data Frames

The message handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This makes sure that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU must reset the NewDat bit when the CPU reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

21.10.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object are considered:

1. Dir = 1 (direction = transmit), RmtEn = 1, UMask = 1 or 0
   The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
2. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 0
   The remote frame is ignored, this message object remains unchanged.
3. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 1
   The remote frame is treated similar to a received data frame. At the reception of a matching remote frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged

21.10.9 Reading Received Messages

The CPU can read a received message any time using the IFx interface registers, the data consistency is provided by the message handler state machine.

Typically the CPU writes 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination transfers the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since the last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst is not automatically reset.

21.10.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU can request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame can be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

21.10.11 Storing Received Messages in FIFO Buffers

Several message objects can be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifiers. Arbitration and Mask registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are 0, in the last bit the EoB bit is 1.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is 0, the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to 0, all further messages for this FIFO Buffer are written into the last message object of the FIFO Buffer (EoB = 1) and therefore overwrite previous messages in this message object.

21.10.12 Reading from a FIFO Buffer

Several messages can be accumulated in a set of message objects that are concatenated to form a FIFO buffer before the application program is required (to avoid the loss of data) to empty the buffer. A FIFO buffer of length N stores N-1 plus the last received message since the last time the FIFO buffer was cleared. A FIFO buffer is cleared by reading and resetting the NewDat bits of all the message objects, starting at the FIFO object with the lowest message number. This can be done in a subroutine following the example shown in Figure 21-13.

Note

All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality cannot be maintained, since the message objects of a partly read buffer are refilled according to the normal (descending) priority.

Reading from a FIFO Buffer message object and resetting the NewDat bit is handled the same way as reading from a single message object.

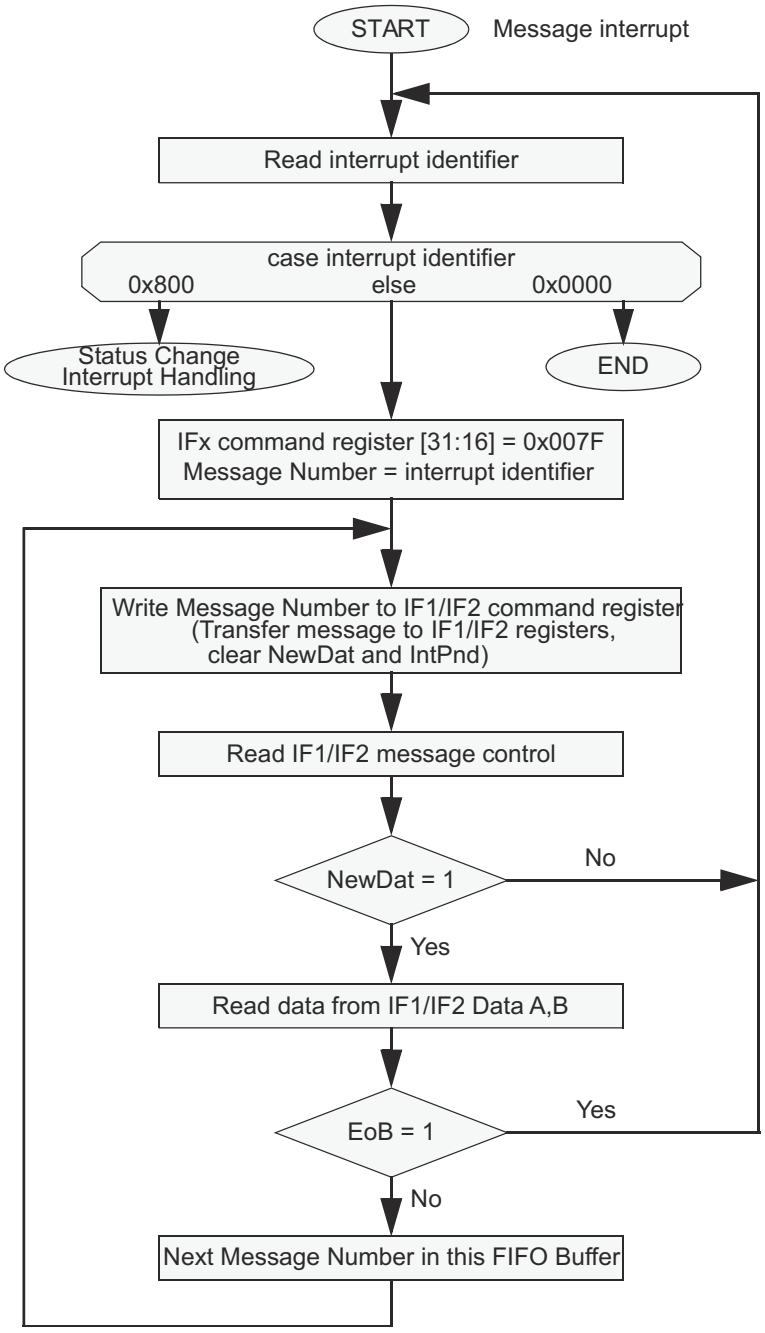

Figure 21-13. CPU Handling of a FIFO Buffer (Interrupt Driven)

21.11 CAN Bit Timing

The CAN supports bit rates up to 1000kBit/s.

Each CAN node has a clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods (F_{osc}) can be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point can cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

21.11.1 Bit Time and Bit Rate

According to the CAN specification, the Bit time is divided into four segments (see Figure 21-14):

- Synchronization Segment (Sync_Seg)
- Propagation Time Segment (Prop_Seg)
- Phase Buffer Segment 1 (Phase_Seg1)
- Phase Buffer Segment 2 (Phase_Seg2)

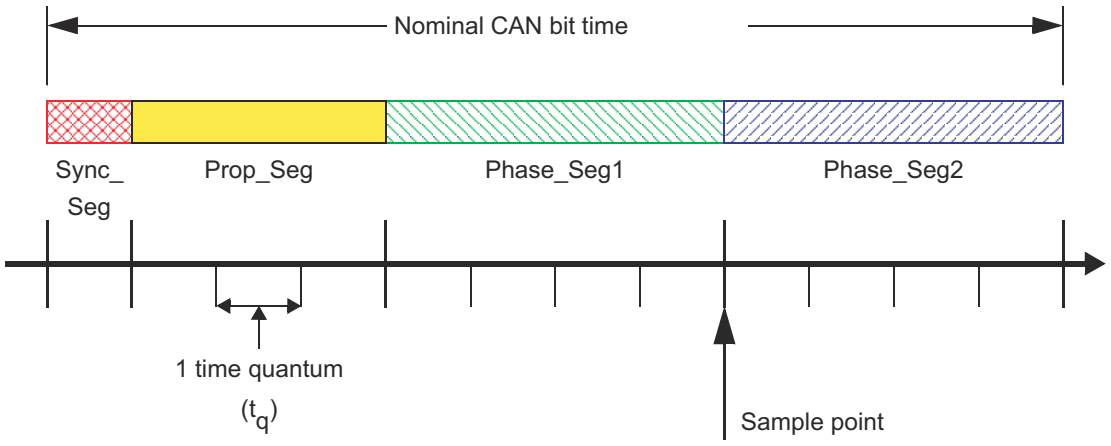

Figure 21-14. Bit Timing

Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the CAN_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler/CAN_CLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 21-4 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate can be met by different bit time configurations.

Table 21-4. Programmable Ranges Required by CAN Protocol

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	Can be lengthened temporarily by synchronization
Phase_Seg2	[1 … 8] t_q	Can be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	Cannot be longer than either phase buffer segment

Note

For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range must be considered.

21.11.1.1 Synchronization Segment

The Synchronization Segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, the distance to the Sync_Seg is called the phase error of this edge.

21.11.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 21-15 shows the phase shift and propagation times between two CAN nodes.

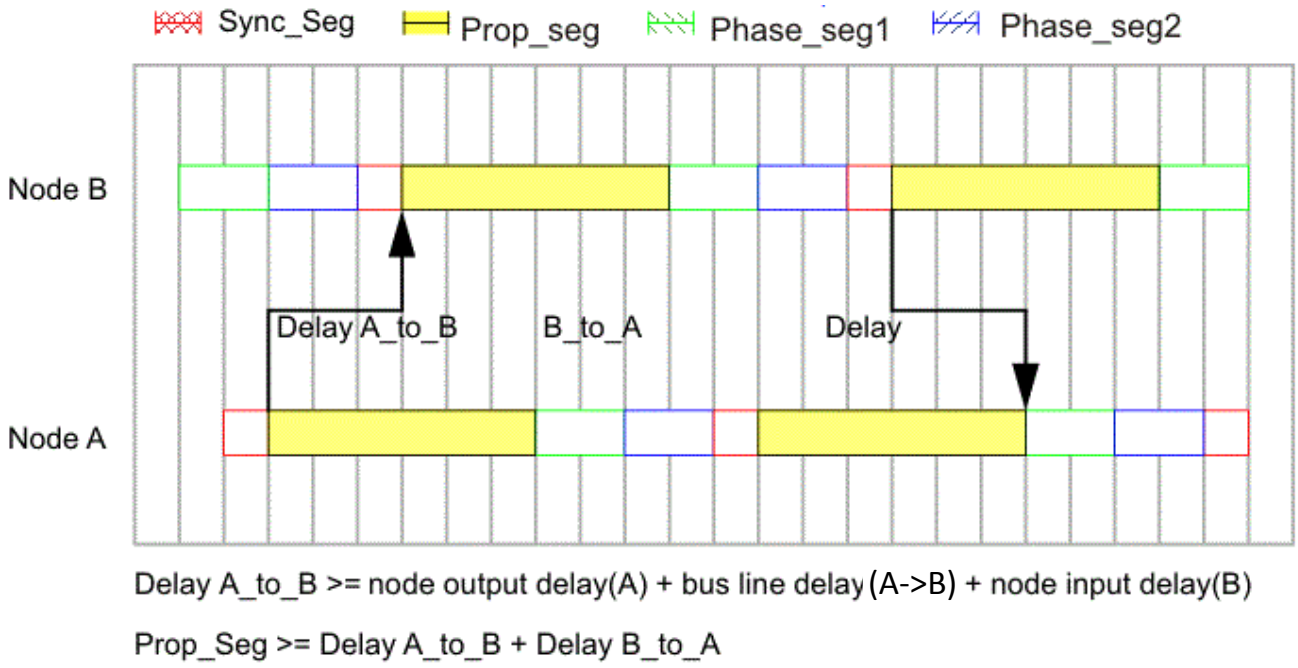

Figure 21-15. Propagation Time Segment

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. Node A has sent a Start of Frame bit less than one bit time earlier than node B, therefore node B has synchronized to the received edge from recessive to dominant. Since node B has received this edge delay (A_to_B) after the bit has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority, so node B wins the arbitration at a specific identifier bit when node B transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B arrives at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's Sample Point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B arrives at node A after the start of Phase_Seg1, node A can potentially sample a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus, which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The CAN module on this device does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

21.11.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point. The phase buffer segments can be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism can move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. The purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing the sample with the bus level at the previous sample point. A synchronization can be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if the edge occurs inside of Sync_Seg; otherwise, the distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative; else, the phase error is positive.

Two types of synchronization exist: hard synchronization and resynchronization. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- **Hard Synchronization:** After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization to lie within the synchronization segment of the restarted bit time.
- **Bit Resynchronization:** Resynchronization leads to a shortening or lengthening of the bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge that causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error; else, Phase_Seg1 is lengthened by SJW.

  When the phase error of the edge that causes resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error; else, Phase_Seg2 is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

Only one synchronization can be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize "hard" on the edge transmitted by the "leading" transceiver that started transmitting first, but due to propagation delay times, the nodes cannot become completely synchronized. The "leading" transmitter does not necessarily win the arbitration; therefore, the receivers must synchronize themselves to different transmitters that subsequently "take the lead" and that are differently synchronized to the previously "leading" transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers must synchronize to the receiver that "takes the lead" in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration are caused by oscillator tolerance, when the differences in the oscillator's clock periods of transmitter and receivers sum up during the time between synchronizations (at most 10 bits). These summarized differences cannot be longer than the SJW, limiting the oscillator's tolerance range.

The examples in Figure 21-16 show how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a "late" edge, the lower drawing shows the synchronization on an "early" edge, and the middle drawing is the reference without synchronization.

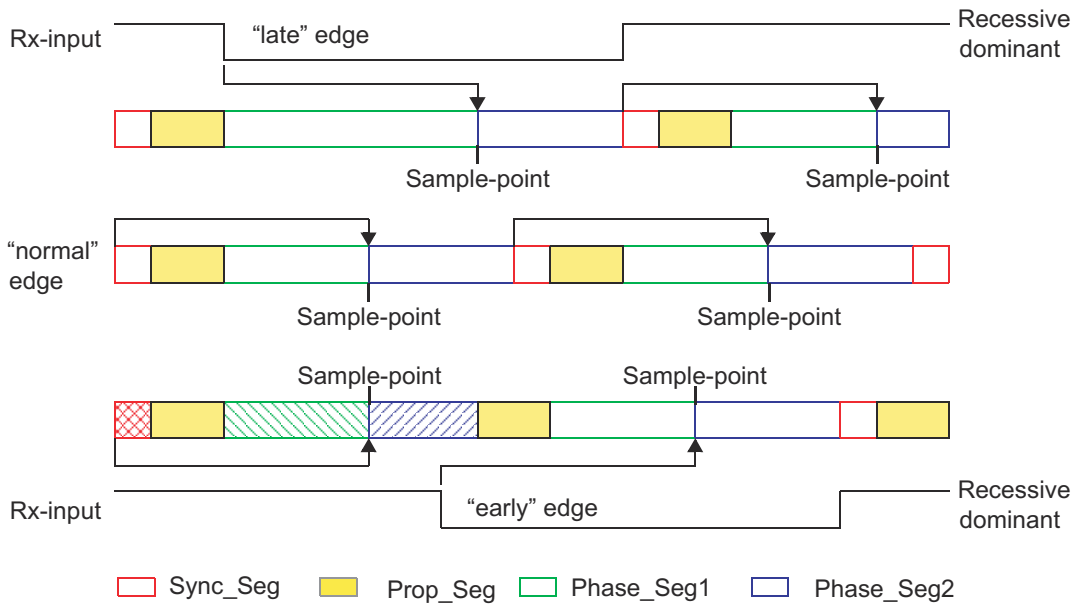

Figure 21-16. Synchronization on Late and Early Edges

In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since the edge occurs after the Sync_Seg. Reacting to the "late" edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as from the Sync_Seg to the sample point if no edge had occurred. The phase error of this "late" edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the "early" edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this "early" edge's phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to the nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an "*early*" edge because the state machine cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

The examples in Figure 21-17 show how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

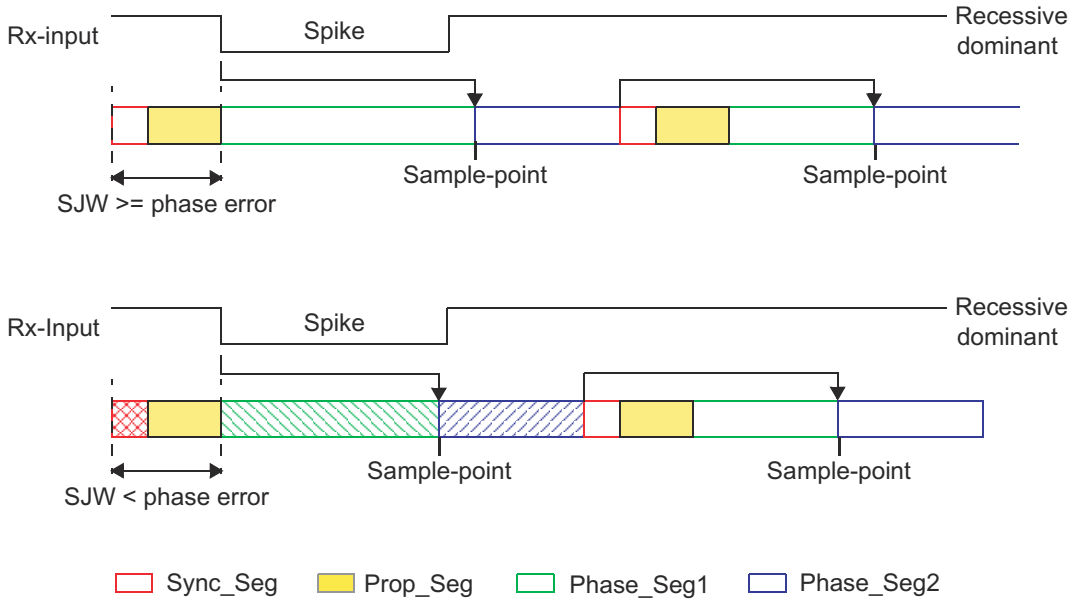

Figure 21-17. Filtering of Short Dominant Spikes

21.11.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) * f_{nom} \leq f_{osc} \leq (1 + df) * f_{nom}$$

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is defined by two conditions (both must be met):

$$df \leq \frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$$

$$df \leq \frac{SJW}{20 \times bit\_time}$$

You must consider that SJW cannot be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that can be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not for short bit times; the combination can be used for bit rates of up to 125kBit/s (bit time = 8µs) with a bus length of 40 meters.

21.11.2 Configuration of the CAN Bit Timing

In the CAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BRPE) is provided. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see Figure 21-18).

In this bit timing register, the components TSEG1, TSEG2, SJW, and BRP are programmed to a numerical value that is one less than the functional value; so instead of values in the range of [1…n], values in the range of [0…n-1] are programmed. That way, for example, SJW (functional range of [1…4]) is represented by only two bits.

Therefore the length of the bit time is either:

- (programmed values) [TSEG1 + TSEG2 + 3] t_q
- (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q

The data in the Bit Timing Register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the Bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the Bit Stream Processor (BSP) state machine, is evaluated once each bit time, at the Sample Point.

The Shift register serializes the messages to be sent and parallelizes received messages. Loading and shifting is controlled by the BSP.

The BSP translates messages into frames and conversely. The BSP generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT), which is 0 t_q for the CAN.

Generally, the IPT is CAN controller specific, but cannot be longer than 2 t_q. The IPT length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 can be shortened to a value less than IPT, which does not affect bus timing.

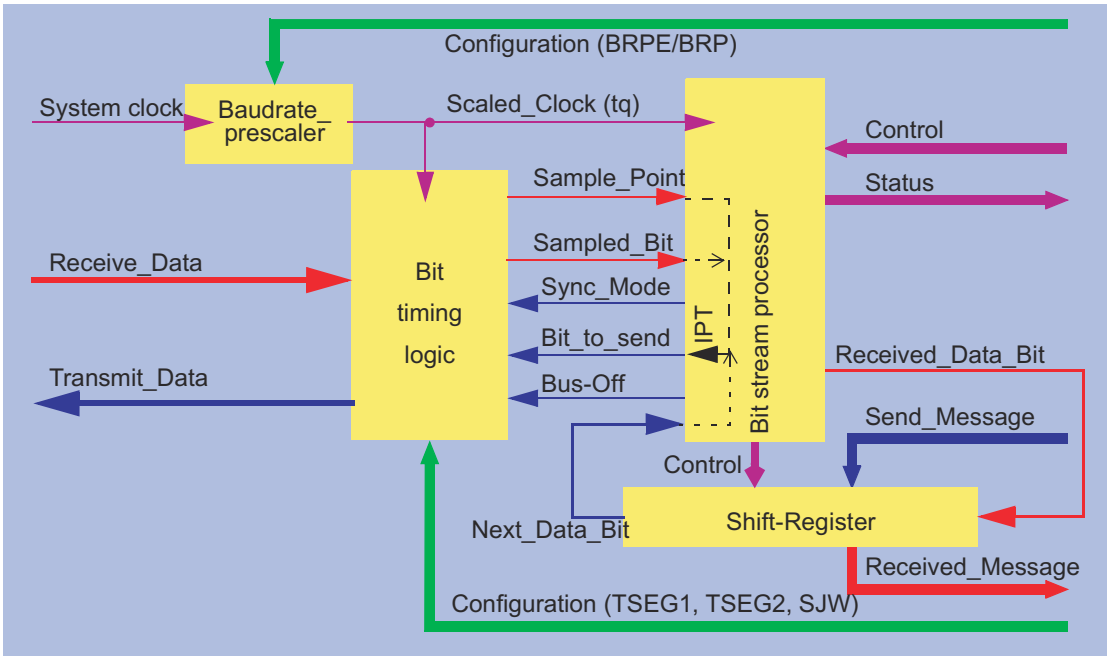

Figure 21-18. Structure of the CAN Core's CAN Protocol Controller

21.11.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time (1/Bit rate) must be an integer multiple of the CAN clock period.

Note

8MHz is the minimum CAN clock frequency required to operate the CAN at a bit rate of 1MBit/s.

The bit time can consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the Baud Rate Prescaler with t_q = (Baud Rate Prescaler) / CAN_CLK. Several combinations can lead to the desired bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the Prop_Seg. The length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time - Prop_Seg - 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1; else, Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 cannot be shorter than the Information Processing Time of any node in the network, which is device dependent and can be in the range of [0 to 2] t_q.

The length of the synchronization jump width is set to the maximum value, which is the minimum of 4 and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Section 21.11.1.4.

If more than one configurations are possible to reach a certain bit rate, choose the configuration that allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation can show that bus length or bit rate has to be decreased or that the oscillator frequency stability has to be increased to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the Bit Timing register:

(Phase_Seg2-1)&(Phase_Seg1+Prop_Seg-1)&(SynchronizationJumpWidth-1)&(Prescaler-1)

21.11.2.2 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN_CLK is 10MHz, BRP is 0, the bit rate is 1MBit/s.

t_q	100ns	=	t_{CAN_CLK}
delay of bus driver	90ns	=	
delay of receiver circuit	40ns	=	
delay of bus line (40m)	220ns	=	
t_{Prop}	700ns	=	2*delays = 7 • t_q
t_{SJW}	100ns	=	1 • t_q
t_{TSeg1}	800ns	=	t_{Prop} + t_{SJW}
t_{TSeg2}	100ns	=	Information Processing Time + 1 • t_q
$t_{Sync-Seg}$	100ns	=	1 • t_q
bit time	1000ns	=	$t_{Sync-Seg}$ + t_{TSeg1} + t_{TSeg2}
tolerance for CAN_CLK	0.35%	=	$\frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$ $= \frac{0.1\,\mu s}{2((13 \times 1\,\mu s) - 0.1\,\mu s)}$

In this example, the concatenated bit time parameters are $(1\text{-}1)_3$&$(8\text{-}1)_4$&$(1\text{-}1)_2$&$(1\text{-}1)_6$, so the Bit Timing Register is programmed to = 0x0000 0700.

21.11.2.3 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN_CLK is 2MHz, BRP is 1, the bit rate is 100KBit/s.

t_q	1µs	=	2 • t_{CAN_CLK}
delay of bus driver	200ns	=	
delay of receiver circuit	80ns	=	
delay of bus line (40m)	220ns	=	
t_{Prop}	1µs	=	1 • t_q
t_{SJW}	4µs	=	4 • t_q
t_{TSeg1}	5µs	=	t_{Prop} + t_{SJW}
t_{TSeg2}	4µs	=	Information Processing Time + 4 • t_q
$t_{Sync-Seg}$	1µs	=	1 • t_q
bit time	10µs	=	$t_{Sync-Seg}$ + t_{TSeg1} + t_{TSeg2}
tolerance for CAN_CLK	1.58%	=	$\frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$ $= \frac{4\,\mu s}{2((13 \times 10\,\mu s) - 4\,\mu s)}$

In this example, the concatenated bit time parameters are $(4\text{-}1)_3$&$(5\text{-}1)_4$&$(4\text{-}1)_2$&$(2\text{-}1)_6$, so the Bit Timing register is programmed to = 0x0000 34C1.

21.12 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the Message RAM. There are two interface register sets for read and write access (IF1 and IF2) and one Interface Register Set for read access only (IF3).

Due to the structure of the Message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the Message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the Message RAM requires the message handler to perform a read-modifywrite cycle. First those parts of the message object that are not to be changed are read from the Message RAM into the Interface Register set, and after the update the whole content of the Interface Register set is written into the message object.

After the partial write of a message object, those parts of the Interface Register set that are not selected in the Command Register are set to the actual contents of the selected message object. After the partial read of a message object, those parts of the Interface Register set that are not selected in the Command Register are left unchanged.

By buffering the data to be transferred, the Interface Register sets avoid conflicts between concurrent CPU accesses to the Message RAM and CAN message reception and transmission. A complete message object (see Section 21.13.1) or parts of the message object can be transferred between the Message RAM and the IF1/IF2 Register set in one single transfer. This transfer, performed in parallel on all selected parts of the message object, maintains the data consistency of the CAN message.

There is one condition that can cause a write access to the message RAM to be lost. If MsgVal = 1 for the message object that is accessed and CAN communication is ongoing, a transfer from the IFx register to message RAM can be lost. The reason this can happen is that the IFx register write to the message RAM occurs in between a read-modify-write access of the Host Message Handler when in the process of receiving a message for the same message object.

To avoid this issue with receive mail boxes, reset MsgVal before changing any of the following: Id28-0, Xtd, Dir, DLC3-0, RxIE, TxIE, RmtEn, EoB, Umask, Msk28-0, MXtd, and MDir.

To avoid this issue with transmit mail boxes, reset MsgVal before changing any of the following: Dir, RxIE, TxIE, RmtEn, EoB, Umask, Msk28-0, MXtd, and MDir. Other fields not listed above, like Data, can be changed without fear of losing a write to the message RAM.

21.12.1 Message Interface Register Sets 1 and 2 (IF1 and IF2)

The IF1 and IF2 register sets allow data transfers to and from the message objects. The IFxCMD register for an interface control the direction of the data transfer. If the IFxCMD register is set to write, then the message object fields selected by the IFxCMD register are overwritten by values taken from the other IFx registers. If the IFxCMD register is set to read, then the message object fields selected by the IFxCMD register is copied from the message object to the other IFx registers. The interfaces allow for transfers of a complete message object as well as individual parts. The transfer begins with the desired message object number is written to bits 7:0 of the IFxCMD register.

When the CPU initiates a data transfer between the IF1/IF2 registers and Message RAM, the message handler sets the Busy bit in the respective Command Register to 1. After the transfer has completed, the Busy bit is set back to 0 (see Figure 21-19).

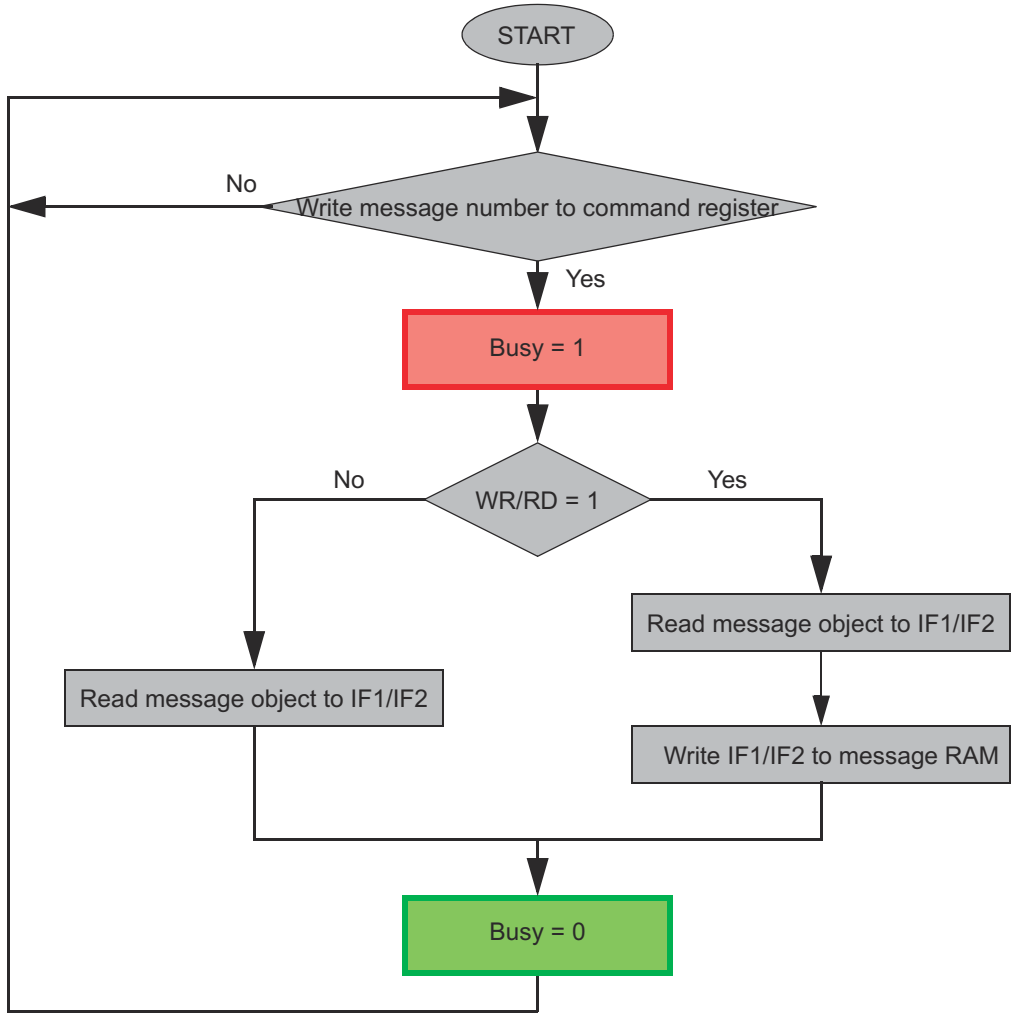

Figure 21-19. Data Transfer Between IF1 / IF2 Registers and Message RAM

21.12.2 Message Interface Register Set 3 (IF3)

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The automatic update functionality can be programmed for each message object (see the IF3 Update Enable register).

All valid message objects in Message RAM that are configured for automatic update are checked for active NewDat flags. If such a message object is found, the message objects are transferred to the IF3 register, controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object is reset by a transfer to IF3.

If DCAN internal IF3 update is complete, an IF3 interrupt can also be generated.

Note

The IF3 register set cannot be used for transferring data into message objects.

21.13 Message RAM

The CAN Message RAM contains message objects and parity bits for the message objects. There are 32 message objects in the Message RAM.

During normal operation, accesses to the Message RAM are performed using the Interface Register sets, and the CPU cannot directly access the Message RAM.

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third Interface Register set IF3 can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 Register set.

The message handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

The message RAM can only be accessed in debug mode. The message RAM base address is 0x1000 above the base address of the CAN peripheral.

21.13.1 Structure of Message Objects

Figure 21-20 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Figure 21-20. Structure of a Message Object

Message Object												
UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 21-5. Message Object Field Descriptions

Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit can be kept at level 1 even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code DLC[3:0] are changed.
UMask		Use Acceptance Mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to 1, the message object's mask bits are programmed during initialization of the message object before MsgVal is set to 1. Note: The bit functionality in the DCAN module is the opposite of the Local Acceptance Mask bit functionality in the eCAN module found in older C28x devices, where a 1 means the corresponding bit is not used for filtering and a 0 means the bit is used.
ID[28:0]		Message Identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits

Table 21-5. Message Object Field Descriptions (continued)

Name	Value	Description
Msk[28:0]		Identifier Mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
		Note: The bit functionality in the DCAN module is the opposite of the Local Acceptance Mask bit functionality in the eCAN module found in older C28x devices, where a 1 means the corresponding bit is not used for filtering, and a 0 means the bit is used.
Xtd		Extended Identifier
	0	The 11-bit ("standard") identifier is used for this message object.
	1	The 29-bit ("extended") identifier is used for this message object.
MXtd		Mask Extended Identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message Direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).
MDir		Mask Message Direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of Block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to 1.
NewDat		New Data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU.
	1	The message handler or the CPU has written new data into the data bytes of this message object.
MsgLst		Message Lost (only valid for Message Objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the CPU.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive Interrupt Enable
	0	IntPnd is not triggered after the successful reception of a frame.
	1	IntPnd is triggered after the successful reception of a frame.
TxIE		Transmit Interrupt Enable
	0	IntPnd is not triggered after the successful transmission of a frame.
	1	IntPnd is triggered after the successful transmission of a frame.
IntPnd		Interrupt Pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register point to this message object, if there is no other interrupt source with higher priority.

Table 21-5. Message Object Field Descriptions (continued)

Name	Value	Description
RmtEn		Remote Enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
		Note: See Section 21.10.8 for details on the setup of RmtEn and UMask for remote frames.
TxRqst		Transmit Request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0-8	Data frame has 0-8 data bytes.
	9-15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, the message handler writes the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, the message handler writes all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object can be overwritten by undefined values.

21.13.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

Message RAM base address + (message object number) * 0x20

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

Note

A 0 is not a valid message object number. At address 0x0000, the last message object (32) (with the lowest priority) is located. Writing to the address of an unimplemented message object can overwrite an implemented message object.

Message Object number 1 has the highest priority.

Table 21-6. Message RAM Addressing in Debug Mode

Message Object Number	Offset From Base Address	Word Number	Debug Mode(1)
last implemented (here:32)	0x0000	1	Parity
	0x0004	2	MXtd,MDir,Mask
	0x0008	3	Xtd,Dir,ID
	0x000C	4	Ctrl
	0x0010	5	Data Bytes 3-0
	0x0014	6	Data Bytes 7-4
1	0x0020	1	Parity
	0x0024	2	MXtd,MDir,Mask
	0x0028	3	Xtd,Dir,ID
	0x002C	4	Ctrl
	0x0030	5	Data Bytes 3-0
	0x0034	6	Data Bytes 7-4
2	0x0040	1	Parity
	0x0044	2	MXtd,MDir,Mask
	0x0048	3	Xtd,Dir,ID
	0x004C	4	Ctrl
	0x0050	5	Data Bytes 3-0
	0x0054	6	Data Bytes 7-4
…	…	…	…
31	0x03E0	1	Parity
	0x03E4	2	MXtd,MDir,Mask
	0x03E8	3	Xtd,Dir,ID
	0x03EC	4	Ctrl
	0x03F0	5	Data Bytes 3-0
	0x03F4	6	Data Bytes 7-4

(1) See Section 21.13.3.

21.13.3 Message RAM Representation in Debug Mode

In debug mode, the Message RAM is memory-mapped. This allows the external debug unit to access the Message RAM.

Note

During debug mode, the Message RAM cannot be accessed using the IFx register sets.

21.14.1 CAN Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/can

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

21.15 CAN Registers

This section describes the Controller Area Network registers.

21.15.1 CAN Base Addresses

Table 21-7. CAN Base Address Table

Device Registers	Register Name	Start Address	End Address
CanaRegs	CAN_REGS	0x0004_8000	0x0004_87FF
CanbRegs	CAN_REGS	0x0004_A000	0x0004_A7FF

21.15.2 CAN_REGS Registers

Table 21-8 lists the memory-mapped registers for the CAN_REGS registers. All register offset addresses not listed in Table 21-8 should be considered as reserved locations and the register contents should not be modified.

Table 21-8. CAN_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CAN_CTL	CAN Control Register		Go
4h	CAN_ES	Error and Status Register		Go
8h	CAN_ERRC	Error Counter Register		Go
Ch	CAN_BTR	Bit Timing Register		Go

Complex bit access types are encoded to fit into small table cells. Table 21-9 shows the codes that are used for access types in this section.

Table 21-9. CAN_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

21.15.2.1 CAN_CTL Register (Offset = 0h) [Reset = 00001401h]

CAN_CTL is shown in Figure 21-22 and described in Table 21-10.

Return to the Summary Table.

This register is used for configuring the CAN module in terms of interrupts, parity, debug-mode behavior etc.

Figure 21-22. CAN_CTL Register

7	Test	R/W	0h	Test Mode Enable 0 Disable Test Mode (Normal operation) 1 Enable Test Mode Reset type: SYSRSn
6	CCE	R/W	0h	Configuration Change Enable 0 The CPU has no write access to the configuration registers. 1 The CPU has write access to the configuration registers (when Init bit is set). Reset type: SYSRSn
5	DAR	R/W	0h	Disable Automatic Retransmission 0 Automatic Retransmission of 'not successful' messages enabled. 1 Automatic Retransmission disabled. Reset type: SYSRSn
4	RESERVED	R	0h	Reserved
3	EIE	R/W	0h	Error Interrupt Enable 0 Disabled - PER, BOff and EWarn bits cannot generate an interrupt. 1 Enabled - PER, BOff and EWarn bits can generate an interrupt at CANINT0 line and affect the Interrupt Register. Reset type: SYSRSn
2	SIE	R/W	0h	Status Change Interrupt Enable 0 Disabled - RxOk, TxOk and LEC bits cannot generate an interrupt. 1 Enabled - RxOk, TxOk and LEC can generate an interrupt on the CANINT0 line Reset type: SYSRSn

Table 21-10. CAN_CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	IE0	R/W	0h	Interrupt line 0 Enable 0 CANINT0 is disabled. 1 CANINT0 is enabled. Interrupts will assert CANINT0 line to 1 line remains active until pending interrupts are processed. Reset type: SYSRSn
0	Init	R/W	1h	Initialization Mode This bit is used to keep the CAN module inactive during bit timing configuration and message RAM initialization. It is set automatically during a bus off event. Clearing this bit will not shorten the bus recovery time. 0 CAN module processes messages normally 1 CAN module ignores bus activity Reset type: SYSRSn

21.15.2.2 CAN_ES Register (Offset = 4h) [Reset = 00000007h]

CAN_ES is shown in Figure 21-23 and described in Table 21-11.

Return to the Summary Table.

This register indicates error conditions, if any, of the CAN module. Interrupts are generated by PER, BOff and EWarn bits (if EIE bit in CAN Control Register is set) and by RxOk, TxOk, and LEC bits (if SIE bit in CAN Control Register is set). A change of bit EPass will not generate an Interrupt.
Reading the Error and Status Register clears the PER, RxOk and TxOk bits and sets the LEC to value '7'. Additionally, the Status Interrupt value (0x8000) in the Interrupt Register will be replaced by the next lower priority interrupt value.
For debug support, the auto clear functionality of Error and Status Register (clear of status flags by read) is disabled when in Debug/Suspend mode.

31-11	RESERVED	R	0h	Reserved
10	RESERVED	R	0h	Reserved
9	RESERVED	R	0h	Reserved
8	PER	R	0h	Parity Error Detected: This bit will be reset after the CPU reads the register. 0 No parity error has been detected since last read access. 1 The parity check mechanism has detected a parity error in the Message RAM. Reset type: SYSRSn
7	BOff	R	0h	Bus-off Status Bit: 0 The CAN module is not in Bus-Off state. 1 The CAN module is in Bus-Off state. Reset type: SYSRSn
6	EWarn	R	0h	Warning State Bit: 0 Both error counters are below the error warning limit of 96. 1 At least one of the error counters has reached the error warning limit of 96. Reset type: SYSRSn
5	EPass	R	0h	Error Passive State 0 On CAN Bus error, the CAN could send active error frames. 1 The CAN Core is in the error passive state as defined in the CAN Specification. Reset type: SYSRSn

Table 21-11. CAN_ES Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	RxOk	R	0h	Reception status Bit: This bit indicates the status of reception. The bit will be reset after the CPU reads the register. 0 No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events. 1 A message has been successfully received since the last time when this bit was reset by a read access of the CPU. This bit will be set independent of the result of acceptance filtering. Reset type: SYSRSn
3	TxOk	R	0h	Transmission status Bit: This bit indicates the status of transmission. The bit will be reset after the CPU reads the register. 0 No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events. 1 A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was cleared by a read access of the CPU. Reset type: SYSRSn
2-0	LEC	R	7h	Last Error Code The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. This field will be reset to '7' whenever the CPU reads the register. 0 No Error 1 Stuff Error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed. 2 Form Error: A fixed format part of a received frame has the wrong format. 3 Ack Error: The message this CAN Core transmitted was not acknowledged by another node. 4 Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 5 Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 6 CRC Error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). 7 No CAN bus event was detected since the last time when CPU has read the Error and Status Register. Any read access to the Error and Status Register re-initializes the LEC to value '7'. Reset type: SYSRSn

21.15.2.3 CAN_ERRC Register (Offset = 8h) [Reset = 00000000h]

CAN_ERRC is shown in Figure 21-24 and described in Table 21-12.

Return to the Summary Table.

This register reflects the value of the Transmit and Receive error counters

Figure 21-24. CAN_ERRC Register

21.15.2.4 CAN_BTR Register (Offset = Ch) [Reset = 00002301h]

CAN_BTR is shown in Figure 21-25 and described in Table 21-13.

Return to the Summary Table.

This register is used to configure the bit-timing parameters for the CAN module. This register is only writable if CCE and Init bits in the CAN Control Register are set.
The CAN bit time may be programmed in the range of 8 to 25 time quanta.
The CAN time quantum may be programmed in the range of 1 to1024 CAN_CLK periods.

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	INT1ID	R	0h	Interrupt 1 Cause 0x00 No interrupt is pending. 0x01-0x20 Number of message object (mailbox) which caused the interrupt. 0x21-0xFF Unused. If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority. Note: The CANINT1 interrupt line remains active until INT1ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. A message interrupt is cleared by clearing the mailbox's IntPnd bit. Among the message interrupts, the mailbox's interrupt priority decreases with increasing message number. Reset type: SYSRSn
15-0	INT0ID	R	0h	Interrupt 0 Cause 0x0000 - No interrupt is pending. 0x0001 - 0x0020 - Number of message object which caused the interrupt. 0x0021 - 0x7FFF - Unused. 0x8000 - Error and Status Register value is not 0x07. 0x8001 - 0xFFFF - Unused. If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority. Note: The CANINT0 interrupt line remains active until INT0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. The Status Interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. Reset type: SYSRSn

21.15.2.6 CAN_TEST Register (Offset = 14h) [Reset = 00000000h]

CAN_TEST is shown in Figure 21-27 and described in Table 21-15.

Return to the Summary Table.

This register is used to configure the various test options supported. For all test modes, the Test bit in CAN Control Register needs to be set to one. If Test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of CANRX pin and therefore is only readable. All Test Register functions are disabled when Test bit is cleared.
Note: Setting Tx[1:0] other than '00' will disturb message transfer.
Note: When the internal loop back mode is active (bit LBack is set), bit EXL will be ignored.

21.15.2.7 CAN_PERR Register (Offset = 1Ch) [Reset = 00000XXXh]

CAN_PERR is shown in Figure 21-28 and described in Table 21-16.

Return to the Summary Table.

This register indicates the Word/Mailbox number where a parity error has been detected. If a parity error is detected, the PER flag will be set in the Error and Status Register. This bit is not reset by the parity check mechanism
it must be reset by reading the Error and Status Register. In addition to the PER flag, the Parity Error Code Register will indicate the memory area where the parity error has been detected. If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

ABO_Time																															
R/W-0h																															

Table 21-21. CAN_ABOTR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ABO_Time	R/W	0h	Auto-Bus-On Timer Number of clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit. 'Clock' refers to the input clock to the CAN module. This function has to be enabled by setting bit ABO in CAN Control Register. The Auto-Bus-On timer is realized by a 32-bit counter which starts to count down to zero when the module goes Bus-Off. The counter will be reloaded with the preload value of the ABO Time register after this phase. NOTE: On write access to the CAN Control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted. NOTE: During Debug mode, running Auto-Bus-On timer will be paused. Reset type: SYSRSn

21.15.2.13 CAN_TXRQ_X Register (Offset = 84h) [Reset = 00000000h]

CAN_TXRQ_X is shown in Figure 21-34 and described in Table 21-22.

Return to the Summary Table.

With these bits, the CPU can detect if one or more bits in the CAN Transmission Request 21 Register (CAN_TXRQ_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the TxRqst bits of these message objects is set, the corresponding bit in this register will be set.

1-0	TxRqstReg1	R	0h	Transmit Request Register 1 flag: Bit 0 represents byte 0 of CAN_TXRQ_21 Register. If one or more bits in that byte are set, then bit 0 will be set. Bit 1 represents byte 1 of CAN_TXRQ_21 Register. If one or more bits in that byte are set, then bit 1 will be set. Reset type: SYSRSn

21.15.2.14 CAN_TXRQ_21 Register (Offset = 88h) [Reset = 00000000h]

CAN_TXRQ_21 is shown in Figure 21-35 and described in Table 21-23.

Return to the Summary Table.

This register holds the TxRqst bits of the mailboxes. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific mailbox can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

Figure 21-35. CAN_TXRQ_21 Register

21.15.2.15 CAN_NDAT_X Register (Offset = 98h) [Reset = 00000000h]

CAN_NDAT_X is shown in Figure 21-36 and described in Table 21-24.

Return to the Summary Table.

With these bits, the CPU can detect if one or more bits in the CAN New Data 21 Register (CAN_NDAT _21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the NewDat bits of these mailboxes are set, the corresponding bit in this register will be set.

21.15.2.16 CAN_NDAT_21 Register (Offset = 9Ch) [Reset = 00000000h]

CAN_NDAT_21 is shown in Figure 21-37 and described in Table 21-25.

Return to the Summary Table.

This register holds the NewDat bits of all mailboxes. By reading out the NewDat bits, the CPU can check for which mailboxes the data portion was updated. The NewDat bit of a specific mailbox can be set/reset by the CPU via the IFx 'Message Interface' Registers or by the Message Handler after reception of a Data Frame or after a successful transmission.

21.15.2.21 CAN_IP_MUX21 Register (Offset = D8h) [Reset = 00000000h]

CAN_IP_MUX21 is shown in Figure 21-42 and described in Table 21-30.

Return to the Summary Table.

The IntMux bit determines for each mailbox, which of the two interrupt lines (CANINT0 or CANINT1) will be asserted when the IntPnd bit of that mailbox is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN Control Register. This will also affect the INT0ID or INT1ID flags in the Interrupt Register.

21.15.2.22 CAN_IF1CMD Register (Offset = 100h) [Reset = 00000001h]

CAN_IF1CMD is shown in Figure 21-43 and described in Table 21-31.

Return to the Summary Table.

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.
If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16- bits.
Note: While Busy bit is one, IF1/IF2 Register sets are write protected.
Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAactive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.
Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

Note: This bit is write protected by Busy bit. Reset type: SYSRSn

21.15.2.24 CAN_IF1ARB Register (Offset = 108h) [Reset = 00000000h]

CAN_IF1ARB is shown in Figure 21-45 and described in Table 21-33.

Return to the Summary Table.

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.
A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).
Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.
If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.
Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

13	IntPnd	R/W	0h	Interrupt Pending 0 This message object is not the source of an interrupt. 1 This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register will point to this message object if there is no other interrupt source with higher priority. Note: This bit is write protected by Busy bit. Reset type: SYSRSn
12	UMask	R/W	0h	Use Acceptance Mask 0 Mask ignored 1 Use Mask (Msk[28:0], MXtd, and MDir) for acceptance filtering If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one. Note: This bit is write protected by Busy bit. Reset type: SYSRSn

Table 21-34. CAN_IF1MCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	TxIE	R/W	0h	Transmit Interrupt Enable 0 IntPnd will not be triggered after the successful transmission of a frame. 1 IntPnd will be triggered after the successful transmission of a frame. Note: This bit is write protected by Busy bit. Reset type: SYSRSn
10	RxIE	R/W	0h	Receive Interrupt Enable 0 IntPnd will not be triggered after the successful reception of a frame. 1 IntPnd will be triggered after the successful reception of a frame. Note: This bit is write protected by Busy bit. Reset type: SYSRSn
9	RmtEn	R/W	0h	Remote Enable 0 At the reception of a remote frame, TxRqst is not changed. 1 At the reception of a remote frame, TxRqst is set. Note: This bit is write protected by Busy bit. Reset type: SYSRSn
8	TxRqst	R/W	0h	Transmit Request 0 This message object is not waiting for a transmission. 1 The transmission of this message object is requested and is not yet done. Note: This bit is write protected by Busy bit. Reset type: SYSRSn
7	EoB	R/W	0h	End of Block 0 The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block. 1 The message object is a single message object or the last message object in a FIFO Buffer Block. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one. Note: This bit is write protected by Busy bit. Reset type: SYSRSn
6-4	RESERVED	R	0h	Reserved
3-0	DLC	R/W	0h	Data length code 0-8 Data frame has 0-8 data bytes. 9-15 Data frame has 8 data bytes. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message. Note: This bit is write protected by Busy bit. Reset type: SYSRSn

21.15.2.26 CAN_IF1DATA Register (Offset = 110h) [Reset = 00000000h]

CAN_IF1DATA is shown in Figure 21-47 and described in Table 21-35.

Return to the Summary Table.

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

21.15.2.28 CAN_IF2CMD Register (Offset = 120h) [Reset = 00000001h]

CAN_IF2CMD is shown in Figure 21-49 and described in Table 21-37.

Return to the Summary Table.

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.
If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16- bits.
Note: While Busy bit is one, IF1/IF2 Register sets are write protected.
Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAactive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.
Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

Note: This bit is write protected by Busy bit. Reset type: SYSRSn

21.15.2.30 CAN_IF2ARB Register (Offset = 128h) [Reset = 00000000h]

CAN_IF2ARB is shown in Figure 21-51 and described in Table 21-39.

Return to the Summary Table.

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.
A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).
Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.
If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.
Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

21.15.2.34 CAN_IF3OBS Register (Offset = 140h) [Reset = 00000000h]

CAN_IF3OBS is shown in Figure 21-55 and described in Table 21-43.

Return to the Summary Table.

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU.
The observation flags (Bits [4:0]) in the IF3 Observation register are used to determine, which data sections of the IF3 Interface Register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 Interface Register set with new data.
Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.
Note: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.
A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 Interface Register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).
With this, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode

Chapter 22

Universal Serial Bus (USB) Controller

This chapter discusses the features and functions of the universal serial bus (USB) controller.

22.1 Introduction

The USB controller operates as a full-speed function controller during point-to-point communications with the USB host. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. The USB controller has thirty-two endpoints, one-half of them being for IN transactions and one-half of them being for OUT transactions. One IN and one OUT endpoint are fixed-function endpoints used for control transfers; the others are defined by firmware. A dynamically sizeable FIFO supports queuing multiple packets. Software-controlled connect and disconnect allow flexibility during USB device startup.

22.1.1 Features

The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12Mbps) operation in host and device modes as well as low-speed (1.5Mbps) operation in host mode
- Integrated PHY
- Three transfer types: Control, Interrupt, and Bulk
- 32 endpoints
  - One dedicated control IN endpoint and one dedicated control OUT endpoint
  - Fifteen configurable IN endpoints and fifteen configurable OUT endpoints
- 4KB dedicated endpoint memory

22.1.3 Block Diagram

The USB block diagram is shown in Figure 22-1.

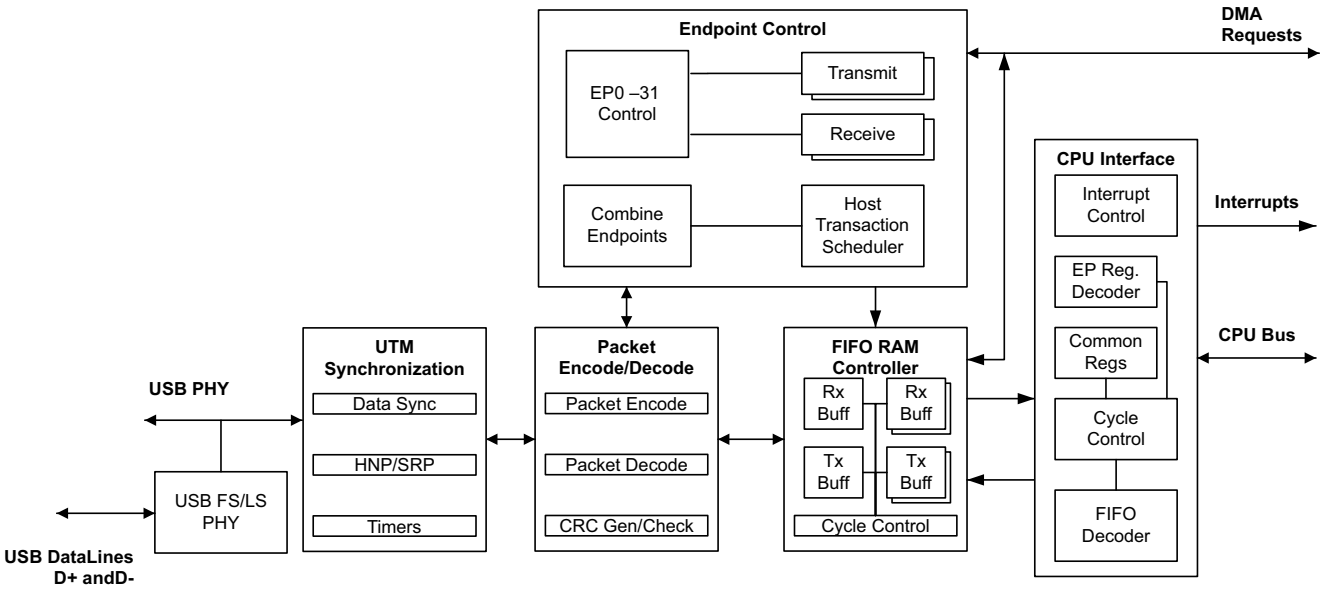

Figure 22-1. USB Block Diagram

22.1.3.1 Signal Description

The USB controller requires a total of three signals (D+, D-, and V_{Bus}) to operate in device mode and two signals (D+, D-) to operate in embedded host mode. Because of the differential signaling needed for USB, the D+ and D- pins have special buffers to support USB. As such, the position on the chip is not user-selectable. The D+ and D- pins at reset are, by default, GPIOs and must be configured before being used as USB function pins. Bits 10 and 11 in the GPIO B Analog Mode Select register (GPBAMSEL) must be set to choose the USB function. The signals USB bus voltage (V_{BUS}), external power enable (EPEN), and power fault (PFLT) are not hardwired to any pin and some applications require these signals be implemented in software using a GPIO. Software that implements these signals is available in the USB software library.

22.1.3.2 VBus Recommendations

Most applications do not need to monitor V_{Bus}. Because of this, a dedicated V_{Bus} monitoring pin was not included on this microcontroller. If you are designing a bus-powered device application or an embedded host application, you do not need to monitor V_{Bus}. If you are designing a self-powered device, you need to actively monitor the state of the V_{Bus} pin to make sure compliance with the USB specification. In Section 7.1.5 and Section 7.2.1 of the USB Specification Revision 2.0™:

- "The voltage source on the [speed identification] pull-up resistor must be derived from or controlled by the power supplied on the USB cable such that when V_{BUS} is removed, the pull-up resistor does not supply current on the data line to which it is attached.
- When V_{BUS} is removed, the device must remove power from the D+/D- pull-up resistor within 10 seconds.
- Later in the timing tables (Section 7.3.2) of the USB Specification 2.0, it is also stated that the D+/D- pull-up resistor must be applied within 100 ms of V_{Bus} reaching a valid level."

Meeting the above specification is easy because of the slow timing requirements. The hardware part of the V_{Bus} monitoring is discussed in this chapter. The corresponding software is discussed briefly, but for examples and an explanation, consult the USB software guide.

The pins of this microcontroller are not 5V tolerant, and because of this, the V_{Bus} signal cannot be directly connected to a GPIO pin. Directly connecting 5V to a pin of the microcontroller destroys the I/O buffer of the pin and possibly more of the chip. The most cost-effective way of making any pin capable of reading a 5V input is to use a series resistance in conjunction with the ESD diode clamps already present inside the device on every pin. Also, use a 100kΩ series resistor between the V_{Bus} signal and the pin chosen to monitor the pin. A diagram of this setup is shown in Figure 22-2.

In Figure 22-2, if V_{Bus} is above 3.3V or below 0V, one of the ESD clamp diodes is forward-biased, allowing current to flow through the 100kΩ resistor. The purpose of the diode clamps is to protect the pins of the microcontroller from very short over voltage spikes of a high magnitude. The diode clamps do this by clamping the voltage excursion to one of the supply rails. We are effectively requiring the ESD clamps to do the same thing the clamps were designed to do, but instead of a short high magnitude pulse, we are giving the clamps a long low magnitude static value using the 100kΩ resistor.

Any pin that has digital input and output functionality can potentially be used to monitor V_{Bus}, but the use of an interrupt-capable GPIO is recommended. A pin that does not have external interrupt capability can also be used, but the input state of the pin must be polled periodically by the application software to make sure appropriate action is taken whenever V_{Bus} is applied or removed. If an interrupt-capable GPIO is chosen, the GPIO can be configured to generate an interrupt on both the rising and falling edge. More information on external interrupts can be found in the *System Control and Interrupts* chapter. Example code that implements V_{Bus} monitoring using external interrupts and takes the appropriate actions is documented in the USB Software Guide and can be found in the associated USB software package.

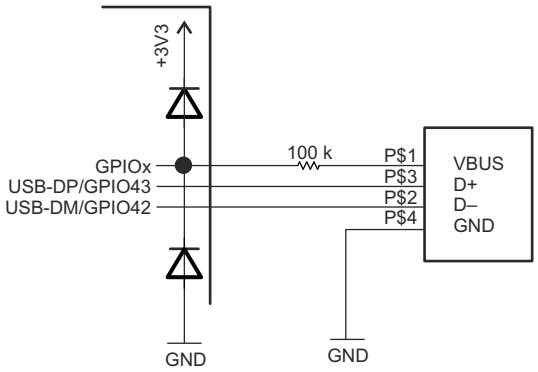

Figure 22-2. USB Scheme

22.2 Functional Description

The USB controller can be configured to act as either a dedicated host or device. However, when the USB controller is acting as a self-powered device, a GPIO input or analog comparator input must be connected to V_{BUS} and configured to generate an interrupt when the V_{BUS} level drops. This interrupt is used to disable the pullup resistor on the USB0DP signal.

Note

When a USB is used in the system, the minimum system frequency is 30MHz.

22.2.1 Operation as a Device

This section describes how the USB controller performs when the USB controller is being used as a USB device. IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of start of frame (SOF) are all described.

When in device mode, IN transactions are controlled by the endpoint transmit interface and uses the transmit endpoint registers for the given endpoint. OUT transactions are handled with the endpoints receive interface and use the receive endpoint registers for the given endpoint. When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint. Note the following:

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint for a USB device. However, in most cases the USB device must use the dedicated control endpoint on the USB controller’s endpoint 0.

22.2.1.1 Control and Configurable Endpoints

When operating as a device, the USB controller provides two dedicated control endpoints (IN and OUT). The remaining available configurable endpoints (one-half IN and one-half OUT) can be used for communications with a host controller. The endpoint number and direction associated with an endpoint is directly related to the register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface. Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions.
The remaining six endpoints can be configured as control, bulk, or interrupt endpoints. The six endpoints can be treated as three configurable IN and three configurable OUT endpoints. The endpoint pairs are not required to have the same type for the IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair can be a bulk endpoint, while the IN portion of that endpoint pair can be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

22.2.1.1.1 IN Transactions as a Device

When operating as a USB device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the configurable IN endpoints are determined by the USB Transmit FIFO Start Address (USBTXFIFOADD) register. The maximum size of a data packet that can be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the USB Maximum Transmit Data Endpoint n (USBTXMAXPn) register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

Note

The maximum packet size set for any endpoint must not exceed the FIFO size. The USBTXMAXPn register cannot be written to while data is in the FIFO as unexpected results can occur.

Single-Packet Buffering

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ) register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the USB Transmit Control and Status Endpoint n Low (USBTXCSRLn) register must be set. If the AUTOSET bit in the USB Transmit Control and Status Endpoint n High (USBTXCSRHn) register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

Double-Packet Buffering

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the USBTXCSRLn register must be set. If the AUTOSET bit in the USBTXCSRHn register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the USBTXCSRLn register at this point indicates how many packets can be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

Note

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

22.2.1.1.2 Out Transactions as a Device

When in device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the configurable OUT endpoints are determined by the USB Receive FIFO Start Address (USBRXFIFOADD) register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the USB Maximum Receive Data Endpoint n (USBRXMAXPn) register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

Note

In all cases, the maximum packet size must not exceed the FIFO size.

Single-Packet Buffering

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the USB Receive Control and Status Endpoint n Low (USBRXCSRL[*n*]) register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the USB Receive Control and Status Endpoint n High (USBRXCSRH[*n*]) register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

Double-Packet Buffering

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the USBRXCSRL[*n*] register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

Note

The FULL bit in USBRXCSRL[*n*] is not set when the first packet is received. The FULL bit is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the USBRXCSRH[*n*] register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

Note

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

22.2.1.1.3 Scheduling

The device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if it was terminated due to some error. If the Host controller makes a request and the device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

22.2.1.1.4 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

Stalled Control Transfer

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the USB Control and Status Endpoint 0 Low (USBCSRL0) register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what must have been the last packet.
3. The Host sends more than USBRXMAXPn bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

Zero Length OUT Data Packets

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets must only be received after the entire length of the device request has been transferred. However, if the Host sends a zero-length OUT data packet before the entire length of device request has been transferred, the Host is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the USBCSRL0 register.

Setting the Device Address

When a Host is attempting to enumerate the USB device, the Host requests that the device change the address from zero to some other value. The address is changed by writing the value that the Host requested to the USB Device Functional Address (USBFADDR) register. However, care must be taken when writing to USBFADDR to avoid changing the address before the transaction is complete. This register must only be set after the SET_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the device has left the STATUS phase. In the case of a SET_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the device has responded to the IN request, the USBFADDR register must be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

Note

If the USBFADDR register is set to the new value as soon as the device receives the OUT transaction with the SET_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the device.

22.2.1.1.5 Device Mode Suspend

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the USB Interrupt Enable (USBIE) register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the USB Power (USBPOWER) register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10 ms (a maximum of 15 ms) to end RESUME signaling. To meet USB power requirements, the controller can be put into Deep Sleep mode which keeps the controller in a static state.

22.2.1.1.6 Start of Frame

When the USB controller is operating in device mode, it receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the USB Frame Value (USBFRAME) register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, the packet is assumed to have been lost, and the USBFRAME register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

22.2.1.1.7 USB Reset

When the USB controller is in device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the USBFADDR register
- Clears the USB Endpoint Index (USBEPIDX) register
- Flushes all endpoint FIFOs
- Clears all control/status registers
- Enables all endpoint interrupts
- Generates a RESET interrupt

22.2.1.1.8 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the SOFTCONN bit of the USBPOWER register. When the SOFTCONN bit is set, the PHY is placed in the normal mode, and the USB0DP/USB0DM lines of the USB bus are enabled. At the same time, the USB controller is placed into a state that does not respond to any USB signaling except a USB RESET. When the SOFTCONN bit is cleared, the PHY is put into non-driving mode, USB0DP and USB0DM are tristated, and the USB controller appears to other devices on the USB bus as if the USB controller has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the SOFTCONN bit has been set. The application software can then choose when to set the PHY into the normal mode. Systems with a lengthy initialization procedure can use this to make sure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the SOFTCONN bit has been set, the USB controller can be disconnected by clearing this bit.

Note

The USB controller does not generate an interrupt when the device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

22.2.2 Operation as a Host

When the USB controller is operating in Host mode, the USB controller can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub. Control, bulk, and interrupt transactions are supported. This section describes the USB controller's actions when the USB controller is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in device mode, the FIFOs for endpoints must take into account the maximum packet size for an endpoint.

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint to communicate with a device. However, in most cases the USB controller must use the dedicated control endpoint to communicate with a device's endpoint 0.

22.2.2.1 Endpoint Registers

The endpoint registers are used to control the USB endpoint interfaces which communicate with devices that are connected. The endpoints consist of a dedicated control IN endpoint and a dedicated control OUT endpoint. The remaining available endpoints are configurable, with one-half of them being OUT endpoints, and one-half of them being IN endpoints. See Section 22.1.1 for the number of available endpoints on this device.

The dedicated control interface can only be used for control transactions to endpoint 0 of devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, or interrupt endpoints.

These USB interfaces can be used to simultaneously schedule as many as 15 independent OUT and 15 independent IN transactions to any endpoints on any device. The IN and OUT controls are paired together in the same set of registers for the respective endpoints. However, the IN and OUT controls can be configured to communicate with different types of endpoints and different endpoints on devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a device's bulk OUT endpoint 1, while the IN portion is communicating with a device's interrupt IN endpoint 2.

Before accessing any device, whether for point-to-point communications or for communications using a hub, the relevant USB Receive Functional Address Endpoint n (USBRXFUNCADDRn) or USB Transmit Functional Address Endpoint n (USBTXFUNCADDRn) registers must be set for each receive or transmit endpoint to record the address of the device being accessed.

The USB controller also supports connections to devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

22.2.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in device mode except that the transaction first must be initiated by setting the REQPKT bit in the USBCSRL0 register, indicating to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the USBCSRL0 register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the USBRXCSRHn register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in USBRXCSRHn causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. When the RXRDY bit is cleared, the controller sends an acknowledge to the device. When there is a known number of packets to be transferred, the USB Request Packet Count in Block Transfer Endpoint n (USBRQPKTCOUNTn) register associated with the endpoint must be configured to the number of packets to be transferred. The USB controller decrements the value in the USBRQPKTCOUNTn register following each request. When the USBRQPKTCOUNTn value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, USBRQPKTCOUNTn must be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the USBRXMAXPn register) such as can occur at the end of a bulk transfer.

If the device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the USBCSRL0 register. If the target device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the USBCSRL0 register.

22.2.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in device mode. The TXRDY bit in the USBTXCSRLn register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the USBTXCSRHn register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO.

If the target device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the USBTXCSRLn register. If the target device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the USBTXCSRLn register.

22.2.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every 255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a device is not responding.

The USB controller maintains a frame counter. If the target device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target device is a low-speed device, a K state is transmitted on the bus to act as a keep-alive to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt transaction occurs per endpoint every n frames, where n is the interval set using the USB Host Transmit Interval Endpoint n (USBTXINTERVAL[*n*]) or USB Host Receive Interval Endpoint n (USBRXINTERVAL[*n*]) register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process makes sure that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target device before the endpoint times out.

22.2.2.5 USB Hubs

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed device is connected to the USB controller using a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding USB Receive Hub Address Endpoint n (USBRXHUBADDRn) and USB Receive Hub Port Endpoint n (USBRXHUBPORTn) or the USB Transmit Hub Address Endpoint n (USBTXHUBADDRn) and USB Transmit Hub Port Endpoint n (USBTXHUBPORTn) registers. In addition, the speed at which the device operates (full or low) must be recorded in the USB Type Endpoint 0 (USBTYPE0) (endpoint 0), USB Host Configure Transmit Type Endpoint n (USBTXTYPEn), or USB Host Configure Receive Type Endpoint n (USBRXTYPEn) registers for each endpoint that is accessed by the device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB devices. To maximize the number of devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to device functions must be made following the completion of any on-going transactions on the endpoints affected.

22.2.2.6 Babble

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

22.2.2.7 Host SUSPEND

If the SUSPEND bit in the USBPOWER register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

22.2.2.8 USB RESET

If the RESET bit in the USBPOWER register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20 ms to make sure of correct resetting of the target device. After the CPU has cleared the bit, the USB Host controller starts the frame counter and transaction scheduler.

22.2.2.9 Connect/Disconnect

A session is started by setting the SESSION bit in the USB device Control (USBDEVCTL) register, enabling the USB controller to wait for a device to be connected. When a device is detected, a connect interrupt is generated. The speed of the device that has been connected can be determined by reading the USBDEVCTL register where the FSDEV bit is set for a full-speed device, and the LSDEV bit is set for a low-speed device. The USB controller must generate a RESET to the device, and then the USB Host controller can begin device enumeration. If the device is disconnected while a session is in progress, a disconnect interrupt is generated.

22.2.3 DMA Operation

The USB module DMA trigger signals are not supported on this device. The DMA controller can be used to read and write the USB FIFOs using software triggering. See the *Direct Memory Access (DMA)* chapter for more details about programming the DMA controller. See the *USB DMA Event Trigger* advisory in the device errata for more information.

22.2.4 Address/Data Bus Bridge

This USB controller was originally designed to connect to an ARM AHB bus, but has been modified to function with the C28x device bus architecture. The modifications made are largely invisible to the user application, but there are some things to note.

- The USB memory space is 8 bits wide, while the C28x memory space is 16 bits wide.
- 32- and 16-bit accesses (r/w) are completely transparent to the user application code, no changes need be made.
- The C28x core only supports 8 bit accesses through a byte intrinsic type. This can be used to perform 8 bit reads or writes to the USB controller.
  - int &__byte(int *array, unsigned int byte_index);
  - *array = ptr to address to access, byte_index = always 0 (for USB)
    See Table 22-1 for example.
  - See the *TMS320C28x Optimizing C/C++ Compiler User's Guide* and the *TMS320C28x Assembly Language Tools User's Guide*
- Because of the bridge, the memory view of the USB controller memory space in CCS is not a 1:1 representation of what is in the controller
  - When the view mode is
    - 32 bit or 16 bit, even address are effectively duplicated, ignore odd addresses.
    - 8 bit, even addresses from within the controller are duplicated into odd address in the view window; old addresses from within the controller are not displayed.
      See Table 22-2 for example.

Table 22-1. USB Memory Access from Software

USB Controller Memory			C28x 8 Bit

22.3 Initialization and Configuration

To use the USB controller, the peripheral clock must be enabled using the System Control module PCLKCR11 register. In addition, the USB PHY signals must be connected to the respective pins using the GPIO module GPBAMSEL register. Set bits 10 and 11 for USB0DM (GPIO42) and USB0DP (GPIO43).

Set up the auxiliary PLL so a 60MHz output clock is provided to the USB module. This fixed frequency is required for all USB operations. See the *System Control and Interrupts* chapter for more details.

In host mode, the USB controller is responsible for supplying power to the bus. To avoid incorrectly supplying voltage to the bus, the external power control signal, USB0EPEN, must be kept inactive on start-up. This can be done by connecting the USB0EPEN and USB0PFLT pins to the USB controller as soon as possible.

22.3.1 Pin Configuration

To give more flexibility, the signals External Power Enable (EPEN) and Power Fault (PFLT) were not implemented in hardware and the user must implement these signals in software. Examples of how to implement these signals in software can be found in the USB Software Guide located in C2000Ware in the \libraries\communications\usb\ directory.

When using the device controller portion of the USB controller in a system that also provides host functionality, the power to V_{BUS} must be disabled to allow the external host controller to supply power. Usually, the EPEN signal is used to control the external regulator and must be negated to avoid having two devices driving the V_{BUS} power pin on the USB connector.

When the USB controller is acting as a host, the USB controller is in control of two signals that are attached to an external voltage supply that provides power to V_{BUS}. The Host controller uses the EPEN signal to enable or disable power to the V_{BUS} pin on the USB connector. An input pin, PFLT, provides feedback when there has been a power fault on V_{BUS}. The PFLT signal can be configured to either automatically negate the EPEN signal to disable power, or the PFLT signal can generate an interrupt to the interrupt controller to allow software to handle the power fault condition. The polarity and actions related to both EPEN and PFLT are fully configurable in the USB controller. The controller also provides interrupts on device insertion and removal to allow the Host controller code to respond to these external events.

22.3.2 Endpoint Configuration

To start communication in Host or device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a device. In device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because the endpoint is a fixed-function, fixed-FIFO-size endpoint. In device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, or interrupt mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. The maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 4 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a device, the USB device controller's soft connect must be enabled when the device is ready to start communications, indicating to the host controller that the device is ready to start the enumeration process. If operating as a Host controller, the device soft connect must be disabled and power must be provided to V_{BUS} using the USB0EPEN signal.

22.4 USB Global Interrupts

Global interrupt enable, flag, and clear registers have been added to make sure that no interrupt is missed. The USB interrupt can be enabled or blocked using the INTEN bit. The INTFLG bit indicates whether an interrupt has occurred or not. Finally, the INTFLGCLR bit clears the INTFLG when a value of 1 is written to the field.

22.5 Software

22.5.1 USB Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/usb

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

22.6 USB Registers

This section describes the Universal Serial Bus (USB) Controller registers.

22.6.1 USB Base Address

Table 22-3. USB Base Address Table (C28)

DriverLib Name	Base Address	CPU1	CPU2	DMA	CLA	Pipeline Protected
USB_BASE	0x0004_0000	YES	-	-	-	YES

22.6.2 USB Register Map

Table 22-4 lists the registers. All addresses given are relative to the USB base address of 0x0000_5E00.

Note

The USB controller clock must be enabled before the registers can be programmed (see the *System Control and Interrupt* chapter).

(1) This register is used in Device mode. Some registers are used for both Host and Device mode and can have different bit definitions depending on the mode.

(2) This register is used in Host mode. Some registers are used for both Host and Device mode and can have different bit definitions depending on the mode. The USB controller is in Device mode upon reset, so the reset values shown for these registers apply to the Device mode definition.

22.6.3 Register Descriptions

22.6.3.1 USB Device Functional Address Register (USBFADDR), offset 0x000

The USB function address 8-bit register (USBFADDR) contains the 7-bit address of the device part of the transaction.

When the USB controller is being used in device mode (the HOST bit in the USBDEVCTL register is clear), this register must be written with the address received through a SET_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

Mode(s): Device

For special considerations when writing this register, see the *Setting the Device Address* in Section 22.2.1.1.4.

USBFADDR is shown in Figure 22-3 and described in Table 22-5.

Figure 22-3. USB Device Functional Address Register (USBFADDR)

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	FUNCADDR	0-7Fh	Function Address of Device as received through SET_ADDRESS.

22.6.3.2 USB Power Management Register (USBPOWER), offset 0x001

The power management 8-bit register (USBPOWER) is used for controlling SUSPEND and RESUME signaling, and some basic operational aspects of the USB controller.

Mode(s): Host Device

USBPOWER in Host Mode is shown in Figure 22-4 and described in Table 22-6.

Figure 22-4. USB Power Management Register (USBPOWER) in Host Mode

7	4	3	2	1	0
Reserved		RESET	RESUME	SUSPEND	PWRDNPHY

Table 22-7. USB Power Management Register (USBPOWER) in Device Mode Field Descriptions

Bit	Field	Value	Description
7	Reserved		Reserved
6	SOFTCONN		Soft Connect/Disconnect
		0	The USB D+/D- lines are tri-stated.
		1	The USB D+/D- lines are enabled.
5-4	Reserved	0	Reserved
3	RESET		RESET signaling
		0	Ends RESET signaling on the bus.
		1	Enables RESET signaling on the bus.
2	RESUME		RESUME signaling. The bit can be cleared by software 10 ms (a maximum of 15 ms) after being set.
		0	Ends RESUME signaling on the bus.
		1	Enables RESUME signaling when the Device is in SUSPEND mode.
1	SUSPEND		SUSPEND mode.
		0	This bit is cleared when software reads the interrupt register or sets the RESUME bit above.
		1	The USB controller is in SUSPEND mode.
0	PWRDNPHY		Power Down PHY
		0	No effect
		1	Powers down the internal USB PHY.

22.6.3.3 USB Transmit Interrupt Status Register (USBTXIS), offset 0x002

Note

Use caution when reading this register. Performing a read may change bit status.

The USB transmit interrupt status 16-bit read-only register (USBTXIS) indicates which interrupts are currently active for control endpoint 0 and the transmit endpoints 1–15. The meaning of the EPn bits in this register is based on the mode of the device. The EP1 through EP15 bits always indicate that the USB controller is sending data; however, in Host mode, the bits refer to OUT endpoints; while in Device mode, the bits refer to IN endpoints.

Note: The EP0 bit is special in Host and Device modes and indicates that either a control IN or control OUT endpoint has generated an interrupt. Both the control IN and control OUT endpoints are captured in the EP0 bit of the USBTXIS register.

Mode(s): Host Device

USBTXIS is shown in Figure 22-6 and described in Table 22-8.

Figure 22-6. USB Transmit Interrupt Status Register (USBTXIS)

15	14	13	12	11	10	9	8

		0	No interrupt
		1	The Endpoint 1 transmit interrupt is asserted.
0	EP0		TX and RX Endpoint 0 Interrupt
		0	No interrupt
		1	The Endpoint 0 transmit and receive interrupt is asserted.

22.6.3.4 USB Receive Interrupt Status Register

(USBRXIS), offset 0x004

Note

Use caution when reading this register. Performing a read may change bit status.

The USB receive interrupt status 16-bit read-only register (USBRXIS) indicates which interrupts are currently active for receive endpoints 1–15.

Note: The USBRXIS register does not have a bit for EP0. See the USBTXIS register for EP0 use.

Note: Bits relating to endpoints that have not been configured always return 0. All active interrupts are cleared when this register is read.

Mode(s): Host Device

USBRXIS is shown in Figure 22-7 and described in Table 22-9.

Figure 22-7. USB Transmit Interrupt Status Register (USBRXIS)

		1	The Endpoint 1 receive interrupt is asserted.
0	Reserved		Reserved

22.6.3.5 USB Transmit Interrupt Enable Register

(USBTXIE), offset 0x006

The USB transmit interrupt enable 16-bit register (USBTXIE) provides interrupt enable bits for the interrupts in the USBTXIS register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the USBTXIS register is set. When a bit is cleared, the interrupt in the USBTXIS register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

Note: The EP0 bit is special in Host and Device modes. Both the control IN and control OUT endpoints are captured in the EP0 bit of the USBTXIE register.

Mode(s): Host Device

USBTXIS is shown in Figure 22-8 and described in Table 22-10.

Figure 22-8. USB Transmit Interrupt Status Enable Register (USBTXIE)

15	14	13	12	11	10	9	8

Table 22-10. USB Transmit Interrupt Status Register (USBTXIE) Field Descriptions

Bit	Field	Value	Description
15	EP15		TX Endpoint 15 Interrupt Enable
		0	The EP15 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP15 bit in the USBTXIS register is set.
14	EP14		TX Endpoint 14 Interrupt Enable
		0	The EP14 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP14 bit in the USBTXIS register is set.
13	EP13		TX Endpoint 13 Interrupt Enable
		0	The EP13 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP13 bit in the USBTXIS register is set.
12	EP12		TX Endpoint 12 Interrupt Enable
		0	The EP12 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP12 bit in the USBTXIS register is set.
11	EP11		TX Endpoint 11 Interrupt Enable
		0	The EP11 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP11 bit in the USBTXIS register is set.
10	EP10		TX Endpoint 10 Interrupt Enable
		0	The EP10 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP10 bit in the USBTXIS register is set.
9	EP9		TX Endpoint 9 Interrupt Enable
		0	The EP9 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP9 bit in the USBTXIS register is set.
8	EP8		TX Endpoint 8 Interrupt Enable
		0	The EP8 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP8 bit in the USBTXIS register is set.

Table 22-10. USB Transmit Interrupt Status Register (USBTXIE) Field Descriptions (continued)

Bit	Field	Value	Description
7	EP7		TX Endpoint 7 Interrupt Enable
		0	The EP7 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP7 bit in the USBTXIS register is set.
6	EP6		TX Endpoint 6 Interrupt Enable
		0	The EP6 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP6 bit in the USBTXIS register is set.
5	EP5		TX Endpoint 5 Interrupt Enable
		0	The EP5 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP5 bit in the USBTXIS register is set.
4	EP4		TX Endpoint 4 Interrupt Enable
		0	The EP4 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP4 bit in the USBTXIS register is set.
3	EP3		TX Endpoint 3 Interrupt Enable
		0	The EP3 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP3 bit in the USBTXIS register is set.
2	EP2		TX Endpoint 2 Interrupt Enable
		0	The EP2 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP2 bit in the USBTXIS register is set.
1	EP1		TX Endpoint 1 Interrupt Enable
		0	The EP1 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP1 bit in the USBTXIS register is set.
0	EP0		TX and RX Endpoint 0 Interrupt Enable
		0	The EP0 transmit and receive interrupt is suppressed and not sent to the interupt controller.
		1	An interrupt is sent to the interrupt controller when the EP0 bit in the USBTXIS register is set.

22.6.3.6 USB Receive Interrupt Enable Register

(USBRXIE), offset 0x008

The USB receive interrupt enable 16-bit register (USBRXIE) provides interrupt enable bits for the interrupts in the USBRXIS register. When a bit is set, the USB interrupt is asserted to the interrupt controller when the corresponding interrupt bit in the USBRXIS register is set. When a bit is cleared, the interrupt in the USBRXIS register is still set but the USB interrupt to the interrupt controller is not asserted. On reset, all interrupts are enabled.

Note: The USBRXIE register does not have a bit for EP0. See the USBTXIE register for EP0 use.

Mode(s): Host Device

USBRXIE is shown in Figure 22-9 and described in Table 22-11.

Figure 22-9. USB Transmit Interrupt Status Enable Register (USBRXIE)

15	EP15		RX Endpoint 15 Interrupt Enable
		0	The EP15 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP15 bit in the USBRXIS register is set.
14	EP14		RX Endpoint 14 Interrupt Enable
		0	The EP14 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP14 bit in the USBRXIS register is set.
13	EP13		RX Endpoint 13 Interrupt Enable
		0	The EP13 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP13 bit in the USBRXIS register is set.
12	EP12		RX Endpoint 12 Interrupt Enable
		0	The EP12 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP12 bit in the USBRXIS register is set.
11	EP11		RX Endpoint 11 Interrupt Enable
		0	The EP11 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP11 bit in the USBRXIS register is set.
10	EP10		RX Endpoint 10 Interrupt Enable
		0	The EP10 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP10 bit in the USBRXIS register is set.
9	EP9		RX Endpoint 9 Interrupt Enable
		0	The EP9 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP9 bit in the USBRXIS register is set.
8	EP8		RX Endpoint 8 Interrupt Enable
		0	The EP8 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP8 bit in the USBRXIS register is set.

Table 22-11. USB Transmit Interrupt Status Register (USBRXIE) Field Descriptions (continued)

Bit	Field	Value	Description
7	EP7		RX Endpoint 7 Interrupt Enable
		0	The EP7 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP7 bit in the USBRXIS register is set.
6	EP6		RX Endpoint 6 Interrupt Enable
		0	The EP6 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP6 bit in the USBRXIS register is set.
5	EP5		RX Endpoint 5 Interrupt Enable
		0	The EP5 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP5 bit in the USBRXIS register is set.
4	EP4		RX Endpoint 4 Interrupt Enable
		0	The EP4 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP4 bit in the USBRXIS register is set.
3	EP3		RX Endpoint 3 Interrupt Enable
		0	The EP3 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP3 bit in the USBRXIS register is set.
2	EP2		RX Endpoint 2 Interrupt Enable
		0	The EP2 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP2 bit in the USBRXIS register is set.
1	EP1		RX Endpoint 1 Interrupt Enable
		0	The EP1 transmit interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the EP1 bit in the USBRXIS register is set.
0	Reserved	0	Reserved

22.6.3.7 USB General Interrupt Status Register (USBIS), offset 0x00A

CAUTION
Use caution when reading this register. Performing a read may change bit status.

The USB general interrupt status 8-bit read-only register (USBIS) indicates which USB interrupts are currently active. All active interrupts are cleared when this register is read.

Mode(s): Host Device

USBIS in Host Mode is shown in Figure 22-10 and described in Table 22-12.

Figure 22-10. USB General Interrupt Status Register (USBIS) in Host Mode

7	6	5	4	3	2	1	0
VBUSERR	SESREQ	DISCON	CONN	SOF	BABBLE	RESUME	Reserved
R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0

Table 22-12. USB General Interrupt Status Register (USBIS) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	VBUSERR		VBUS Error
		0	No interrupt
		1	VBUS has dropped below the VBUS Valid threshold during a session.
6	SESREQ		Session Request
		0	No interrupt
		1	SESSION REQUEST signaling has been detected.
5	DISCON		Session Disconnect
		0	No interrupt
		1	A Device disconnect has been detected.
4	CONN		Session Connect
		0	No interrupt
		1	A Device connection has been detected.
3	SOF		Start of Frame
		0	No interrupt
		1	A new frame has started.
2	BABBLE		Babble Detected
		0	No interrupt
		1	Babble has been detected. This interrupt is active only after the first SOF has been sent.
1	RESUME		RESUME Signaling Detected. This interrupt can only be used if the USB controller's system clock is enabled. If the user disables the clock programming, the USBDRRIS, USBDRIM, and USBDRISC registers should be used.
		0	No effect
		1	RESUME signaling has been detected on the bus while the USB controller is in SUSPEND mode.
0	Reserved	0	Reserved

USBIS in Device Mode is shown in Figure 22-11 and described in Table 22-13.

Figure 22-11. USB General Interrupt Status Register (USBIS) in Device Mode

Bit	Field	Value	Description
7-6	Reserved	0	Reserved
5	DISCON		Session Disconnect
		0	No interrupt
		1	The device has been disconnected from the host.
4	Reserved	0	Reserved
3	SOF		Start of frame
		0	No interrupt
		1	A new frame has started.
2	RESET		RESET Signaling Detected
		0	No interrupt
		1	RESET signaling has been detected on the bus.
1	RESUME		RESUME Signaling Detected. This interrupt can only be used if the USB controller's system clock is enabled. If the user disables the clock programming, the USBDRRIS, USBDRIM, and USBDRISC registers should be used.
		0	No interrupt
		1	RESUME signaling has been detected on the bus while the USB controller is in SUSPEND mode.
0	SUSPEND		SUSPEND Signaling Detected
		0	No interrupt
		1	SUSPEND signaling has been detected on the bus.

22.6.3.8 USB Interrupt Enable Register (USBIE), offset 0x00B

CAUTION
Use caution when reading this register. Performing a read may change bit status.

The USB interrupt enable 8-bit register (USBIE) provides interrupt enable bits for each of the interrupts in USBIS. At reset interrupts 1 and 2 are enabled in device mode.

Mode(s): Host Device

USBIE in Host Mode is shown in Figure 22-12 and described in Table 22-14.

Figure 22-12. USB Interrupt Enable Register (USBIE) in Host Mode

7	6	5	4	3	2	1	0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-14. USB Interrupt Enable Register (USBIE) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	VBUSERR		Enable VBUS Error Interrupt
		0	The VBUSERR interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the VBUSERR bit in the USBIS register is set.
6	SESREQ		Enable Session Request
		0	The SESREQ interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the SESREEQ bit in the USBIS register is set.
5	DISCON		Enable Disconnect Interrupt
		0	The DISCON interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the DISCON bit in the USBIS register is set.
4	CONN		Enable Connect Interrupt
		0	The CONN interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the CONN bit in the USBIS register is set.
3	SOF		Start of Frame
		0	The SOF interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the SOF bit in the USBIS register is set.
2	BABBLE		Babble Detected
		0	The BABBLE interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the BABBLE bit in the USBIS register is set.
1	RESUME		RESUME Signaling Detected. This interrupt can only be used if the USB controller's system clock is enabled. If the user disables the clock programming, the USBDRRIS, USBDRIM, and USBDRISC registers should be used.
		0	The RESUME interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the RESUME bit in the USBIS register is set.
0	Reserved	0	Reserved

USBIE in Device Mode is shown in Figure 22-11 and described in Table 22-13.

Figure 22-13. USB Interrupt Enable Register (USBIE) in Device Mode

7	6	5	4	3	2	1	0

Table 22-15. USB Interrupt Enable Register (USBIE) in Device Mode Field Descriptions

Bit	Field	Value	Description
7-6	Reserved	0	Reserved
5	DISCON		Enable Disconnect Interrupt
		0	The DISCON interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the DISCON bit in the USBIS register is set.
4	Reserved	0	Reserved
3	SOF		Start of frame
		0	The SOF interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the SOF bit in the USBIS register is set.
2	RESET		RESET Signaling Detected
		0	The RESET interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the RESET bit in the USBIS register is set.
1	RESUME		RESUME Signaling Detected. This interrupt can only be used if the USB controller's system clock is enabled. If the user disables the clock programming, the USBDRRIS, USBDRIM, and USBDRISC registers should be used.
		0	The RESUME interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the RESUME bit in the USBIS register is set.
0	SUSPEND		SUSPEND Signaling Detected
		0	The SUSPEND interrupt is suppressed and not sent to the interrupt controller.
		1	An interrupt is sent to the interrupt controller when the DISCON bit in the USBIS register is set.

22.6.3.9 USB Frame Value Register (USBFRAME), offset 0x00C

The frame number 16-bit read-only register (USBFRAME) holds the last received frame number.

Mode(s): Host Device

USBFRAME is shown in Figure 22-14 and described in Table 22-16.

Figure 22-14. USB Frame Value Register (USBFRAME)

15	11	10	0
Reserved		FRAME	
R-0		R-0	

LEGEND: R = Read only; *-n* = value after reset

Bit	Field	Value	Description
15-11	Reserved	0	Reserved
10-0	FRAME	0-7FFh	Last received frame number

22.6.3.10 USB Endpoint Index Register (USBEPIDX), offset 0x00E

Each endpoint buffer can be accessed by configuring a FIFO size and starting address. The endpoint index 16-bit register (USBEPIDX) is used with the USBTXFIFOSZ, USBRXFIFOSZ, USBTXFIFOADD, and USBRXFIFOADD registers.

Mode(s): Host Device

USBEPIDX is shown in Figure 22-15 and described in Table 22-17.

Figure 22-15. USB Endpoint Index Register (USBEPIDX)

7	4	3	0
Reserved		EPIDX	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 22-17. USB Endpoint Index Register (USBEPIDX) Field Descriptions

Bit	Field	Value	Description
7-4	Reserved	0	Reserved
3-0	EPIDX	0-4h	Endpoint Index. This bit field configures which endpoint is accessed when reading or writing to one of the USB controller's indexed registers. A value of 0x0 corresponds to Endpoint 0 and a value of 0xF corresponds to Endpoint 15.

22.6.3.11 USB Test Mode Register (USBTEST), offset 0x00F

The USB test mode 8-bit register (USBTEST) is primarily used to put the USB controller into one of the four test modes for operation described in the USB Specification 2.0 , in response to a SET FEATURE: USBTESTMODE command. This register is not used in normal operation.

Note: Only one of these bits should be set at any time.

Mode(s): Host Device

USBTEST in Host Mode is shown in Figure 22-16 and described in Table 22-18.

Figure 22-16. USB Test Mode Register (USBTEST) in Host Mode

7	6	5	4	0
FORCEH	FIFOACC	FORCEFS	Reserved	
R/W-0	R/W1S-0	R/W-0	R-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 22-18. USB Test Mode Register (USBTEST) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	FORCEH		Force Host Mode. While in this mode, status of the bus connection may be read using the DEV bit of the USBDEVCTL register. The operating speed is determined from the FORCEFS bit.
		0	No effect
		1	Forces the USB controller to enter Host mode when the SESSION bit is set, regardless of whether the USB controller is connected to any peripheral. The state of the USB0DP and USB0DM signals is ignored. The USB controller then remains in Host mode until the SESSION bit is cleared, even if a Device is disconnected. If the FORCEH bit remains set, the USB controller re-enters Host mode the next time the SESSION bit is set.
6	FIFOACC		FIFO Access
		0	No effect
		1	Transfers the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO.
5	FORCEFS		Force Full-Speed Mode
		0	The USB controller operates at Low Speed.
		1	Forces the USB controller into Full-Speed mode upon receiving a USB RESET.
4-0	Reserved	0	Reserved

USBTEST in Device Mode is shown in Figure 22-17 and described in Table 22-19.

Figure 22-17. USB Test Mode Register (USBTEST) in Device Mode

Bit	Field	Value	Description
7	Reserved		Force Host Mode. While in this mode, status of the bus connection may be read using the DEV bit of the USBDEVCTL register. The operating speed is determined from the FORCEFS bit.
6	FIFOACC		FIFO Access
		0	No effect
		1	Transfers the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO.
5	FORCEFS		Force Full-Speed Mode
		0	The USB controller operates at Low Speed.
		1	Forces the USB controller into Full-Speed mode upon receiving a USB RESET.
4-0	Reserved	0	Reserved

22.6.3.12 USB FIFO Endpoint n Register (USBFIFO[0]-USBFIFO[3])

Note

Use caution when reading these registers. Performing a read may change bit status.

The USB FIFO endpoint *n* 32-bit registers (USBFIFO[*n*]) provide an address for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

Transfers to and from FIFOs can be 8-bit, 16-bit or 32-bit as required, and any combination of accesses is allowed provided the data accessed is contiguous. All transfers associated with one packet must be of the same width so that the data is consistently byte-, halfword- or word-aligned. However, the last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

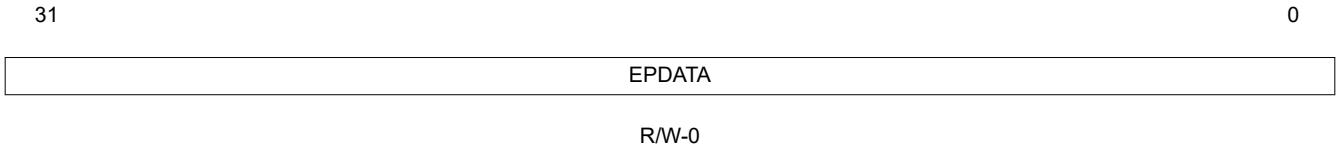
Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering (see *Single-Packet Buffering* in Section 22.2.1.1.2). Burst writing of multiple packets is not supported as flags must be set after each packet is written.

Following a STALL response or a transmit error on endpoint 1–3, the associated FIFO is completely flushed.

Mode(s): Host Device

USBFIFO0-3 are shown in Figure 22-18 and described in Table 22-20.

Figure 22-18. USB FIFO Endpoint *n* Register (USBFIFO[*n*])



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 22-20. USB FIFO Endpoint *n* Register (USBFIFO[*n*]) Field Descriptions

Bit	Field	Reset	Description
31-0	EPDATA	0x0000.0000	Endpoint Data. Writing to this register loads the data into the Transmit FIFO and reading unloads data from the Receive FIFO.

22.6.3.13 USB Device Control Register (USBDEVCTL), offset 0x060

The USB device control 8-bit register (USBDEVCTL) is used for controlling and monitoring the USB VBUS line. If the PHY is suspended, no PHY clock is received and the VBUS is not sampled. In addition, in Host mode, USBDEVCTL provides the status information for the current operating mode (Host or Device) of the USB controller. If the USB controller is in Host mode, this register also indicates if a full- or low-speed Device has been connected.

Mode(s): Host Device

USBDEVCTL is shown in Figure 22-19 and described in Table 22-21.

Figure 22-19. USB Device Control Register (USBDEVCTL)

7	6	5	4	3	2	1	0
DEV	FSDEV	LSDEV	VBUS		HOSTMODE	HOSTREQ	SESSION
R-1	R-0	R-0	R-0		R-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 22-21. USB Device Control Register (USBDEVCTL) Field Descriptions

Bit	Field	Value	Description
7	DEV		Device mode
		0	The USB controller is operating on the OTG A side of the cable.
		1	The USB controller is operating on the OTG B side of the cable.
			Only valid while a session is in progress.
6	FSDEV		Full-Speed Device Detected
		0	A full-speed Device has not been detected on the port.
		1	A full-speed Device has been detected on the port.
5	LSDEV		Low-Speed Device Detected
		0	A low-speed Device has not been detected on the port.
		1	A low-speed Device has been detected on the port.
4-3	VBUS	0-3h	These read-only bits encode the current VBus level as follows:
		0	Below Session End. VBUS is detected as under 0.5 V.
		1h	Above Session End, below AValid. VBUS is detected as above 0.5 V and under 1.5 V.
		2h	Above AValid, below VBusValid. VBUS is detected as above 1.5 V and below 4.75 V.
		3h	Above VBusValid. VBUS is detected as above 4.75 V.
2	HOSTMODE		This read-only bit is set when the USB controller is acting as a Host.
		0	The USB controller is acting as a Device.
		1	The USB controller is acting as a Host.
			Only valid while a session is in progress.
1	HOSTREQ		When set, the USB controller will initiate the Host Negotiation when Suspend mode is entered. It is cleared when Host Negotiation is completed.
		0	No effect
		1	Initiates the Host Negotiation when SUSPENDmode is entered.

Table 22-21. USB Device Control Register (USBDEVCTL) Field Descriptions (continued)

Bit	Field	Value	Description
0	SESSION		Session Start/End When operating as a Host:
		0	When cleared by software, this bit ends a session.
		1	When set by software, this bit starts a session.
			When operating as a Device:
		0	The USB controller has ended a session. When the USB controller is in SUSPEND mode, this bit may be cleared by software to perform a software disconnect.
		1	The USB controller has started a session. When set by software, the Session Request Protocol is initiated.
			Clearing this bit when the USB controller is not suspended results in undefined behavior.

22.6.3.14 USB Transmit Dynamic FIFO Sizing Register (USBTXFIFOSZ), offset 0x062

The USB transmit dynamic FIFO sizing 8-bit register (USBTXFIFOSZ) allows the selected TX endpoint FIFOs to be dynamically sized. USBEPIDX is used to configure each transmit endpoint's FIFO size.

Mode(s): Host Device

USBTXFIFOSZ is shown in Figure 22-20 and described in Table 22-22.

Figure 22-20. USB Transmit Dynamic FIFO Sizing Register (USBTXFIFOSZ)

Bit	Field	Value	Description
7-4	WTCON	5h	The connect wait field configures the wait required to allow for the user's connect/disconnect filter, in units of 533.3 ns. The default corresponds to 2.667 µs.
3-0	WTID	Ch	The wait ID field configures the delay required from the enable of the ID detection to when the ID value is valid, in units of 4.369 ms. The default corresponds to 52.43 ms.

22.6.3.19 USB Full-Speed Last Transaction to End of Frame Timing Register (USBFSEOF), offset 0x07D

USB full-speed last transaction to end of frame timing 8-bit configuration register (USBFSEOF) specifies the minimum time gap allowed between the start of the last transaction and the EOF for full-speed transactions.

Mode(s): Host Device

USBFSEOF is shown in Figure 22-25 and described in Table 22-27.

Figure 22-25. USB Full-Speed Last Transaction to End of Frame Timing Register (USBFSEOF)

Bit	Field	Reset	Description
7-0	FSEOFG	77h	The full-speed end-of-frame gap field is used during full-speed transactions to configure the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. The default corresponds to 63.46 µs.

22.6.3.20 USB Low-Speed Last Transaction to End of Frame Timing Register (USBLSEOF), offset 0x07E

The USB low-speed last transaction to end of frame timing 8-bit configuration register (USBLSEOF) specifies the minimum time gap that is to be allowed between the start of the last transaction and the EOF for low-speed transactions.

Mode(s): Host Device

USBLSEOF is shown in Figure 22-26 and described in Table 22-28.

Figure 22-26. USB Low-Speed Last Transaction to End of Frame Timing Register (USBLSEOF)

Bit	Field	Reset	Description
7-0	LSEOFG	72h	The low-speed end-of-frame gap field is used during low-speed transactions to set the gap between the last transaction and the End-of-Frame (EOF), in units of 1.067 µs. The default corresponds to 121.6 µs.

22.6.3.21 USB Transmit Functional Address Endpoint n Registers (USBTXFUNCADDR[0]-USBTXFUNCADDR[*n*])

The transmit functional address endpoint *n* 8-bit registers (USBTXFUNCADDR[*n*]) record the address of the target function to be accessed through the associated endpoint (EP*n*). USBTXFUNCADDRx must be defined for each transmit endpoint that is used.

Note: USBTXFUNCADDR0 is used for both receive and transmit for endpoint 0.

Mode(s): Host

The USBTXFUNCADDR[*n*] registers are shown in Figure 22-27 and described in Table 22-29.

Figure 22-27. USB Transmit Functional Address Endpoint *n* Registers (USBTXFUNCADDR[*n*])

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	ADDR	0	Device Address specifies the USB bus address for the target Device.

22.6.3.22 USB Transmit Hub Address Endpoint n Registers (USBTXHUBADDR[0]-USBTXHUBADDR[*n*])

The transmit hub address endpoint *n* 8-bit read/write registers (USBTXHUBADDR[*n*]), like USBTXHUBPORT[*n*], must be written only when a USB device is connected to transmit endpoint EP*n* via a USB 2.0 hub. This register records the address of the USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: USBTXHUBADDR0 is used for both receive and transmit for endpoint 0.

Mode(s): Host

The USBTXHUBADDR[*n*] registers are shown in Figure 22-27 and described in Table 22-29.

Figure 22-28. USB Transmit Hub Address Endpoint *n* Registers (USBTXHUBADDR[*n*])

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	ADDR	0	Device Address specifies the USB bus address for the target Device.

22.6.3.23 USB Transmit Hub Port Endpoint n Registers (USBTXHUBPORT[0]-USBTXHUBPORT[*n*])

The transmit hub port endpoint *n* 8-bit read/write registers (USBTXHUBPORT[*n*]), like USBTXHUBADDR[*n*], must be written only when a full- or low-speed Device is connected to transmit endpoint EP*n* with a USB 2.0 hub. This register records the port of the USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: USBTXHUBPORT0 is used for both receive and transmit for endpoint 0.

Mode(s): Host

The USBTXHUBPORT*n* registers are shown in Figure 22-29 and described in Table 22-31.

Figure 22-29. USB Transmit Hub Port Endpoint *n* Registers (USBTXHUBPORT[*n*])

7	Reserved	0	Reserved
6-0	PORT	0	Hub Port specifies the USB hub port number.

22.6.3.24 USB Receive Functional Address Endpoint n Registers (USBRXFUNCADDR[1]-USBRXFUNCADDR[*n*])

The receive functional address endpoint *n* 8-bit read/write registers (USBRXFUNCADDR[*n*]) record the address of the target function to be accessed through the associated endpoint (EP*n*). USBRXFUNCADDRx must be defined for each receive endpoint that is used.

Note: USBTXFUNCADDR0 is used for both receive and transmit for endpoint 0.

Mode(s): Host

The USBRXFUNCADDR[*n*] registers are shown in Figure 22-30 and described in Table 22-32.

Figure 22-30. USB Receive Functional Address Endpoint *n* Registers (USBFIFO[*n*])

6-0	ADDR	0	Device Address specifies the USB bus address for the target Device.

22.6.3.25 USB Receive Hub Address Endpoint n Registers (USBRXHUBADDR[1]-USBRXHUBADDR[*n*])

The receive hub address endpoint *n* 8-bit read/write registers (USBRXHUBADDR[*n*]), like [*n*], must be written only when a full- or low-speed Device is connected to receive endpoint EP*n* with a USB 2.0 hub. Each register records the address of the USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: USBTXHUBADDR0 is used for both receive and transmit for endpoint 0.

Mode(s): Host

The USBRXHUBADDR[*n*] registers are shown in Figure 22-31 and described in Table 22-33.

Figure 22-31. USB Receive Hub Address Endpoint *n* Registers (USBRXHUBADDR[*n*])

		0	Clear to indicate that the hub has a single transaction translator.
		1	Set to indicate that the hub has multiple transaction translators.
6-0	ADDR	0	Device Address specifies the USB bus address for the target Device.

22.6.3.26 USB Receive Hub Port Endpoint n Register (USBRXHUBPORT[1]-USBRXHUBPORT[*n*])

The receive hub port endpoint *n* 8-bit read/write registers (USBRXHUBPORT[*n*]), like USBRXHUBADDR[*n*], must be written only when a full- or low-speed device is connected to receive endpoint EP*n* with a USB 2.0 hub. Each register records the port of the USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: USBTXHUBPORT0 is used for both receive and transmit for endpoint 0.

Mode(s): Host

The USBRXHUBPORT*n* registers are shown in Figure 22-32 and described in Table 22-34.

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	PORT	0	Hub Port specifies the USB hub port number.

22.6.3.27 USB Maximum Transmit Data Endpoint n Registers (USBTXMAXP[1]-USBTXMAXP[*n*])

The USB maximum transmit data endpoint *n* 16-bit registers (USBTXMAXP[*n*]) define the maximum amount of data that can be transferred through the selected transmit endpoint in a single operation.

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the USB Specification on packet sizes for bulk and interrupt transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

If this register is changed after packets have been sent from the endpoint, the transmit endpoint FIFO must be completely flushed (using the FLUSH bit in USBTXCSRLn) after writing the new value to this register.

Note: USBTXMAXP[*n*] must be set to an even number of bytes for proper interrupt generation in DMA Basic Mode.

Mode(s): Host Device

The USBTXMAXP[*n*] registers are shown in Figure 22-33 and described in Table 22-35.

Figure 22-33. USB Maximum Transmit Data Endpoint *n* Registers (USBTXMAXP[*n*])

15-11	Reserved	0	Reserved
10-0	MAXLOAD		Maximum Payload specifies the maximum payload in bytes per transaction.

22.6.3.28 USB Control and Status Endpoint 0 Low Register (USBCSRL0), offset 0x102

The USB control and status endpoint 0 low 8-bit register (USBCSRL0) provides control and status bits for endpoint 0.

Mode(s): Host Device

USBCSRL0 in Host mode is shown in Figure 22-34 and described in Table 22-36.

Figure 22-34. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Host Mode

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 22-36. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	NAKTO		NAK Timeout. Software must clear this bit to allow the endpoint to continue.
		0	No timeout
		1	Indicates that endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the USBNAKLMT register.
6	STATUS		Status Packet. Setting this bit ensures that the DT bit is set in the USBCSRH0 register so that a DATA1 packet is used for the STATUS stage transaction.
		0	No transaction
		1	Initiates a STATUS stage transaction. This bit must be set at the same time as the TXRDY or REQPKT bit is set.
			This bit is automatically cleared when the STATUS stage is over.
5	REQPKT		Request Packet. This bit is cleared when the RXRDY bit is set.
		0	No request
		1	Requests an IN transaction.
4	ERROR		Error. Software must clear this bit.
		0	No error
		1	Three attempts have been made to perform a transaction with no response from the peripheral. The EP0 bit in the USBTXIS register is also set in this situation.
3	SETUP		Setup Packet. Setting this bit always clears the DT bit in the USBCSRH0 register to send a DATA0 packet.
		0	Sends an OUT token.
		1	Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set.
2	STALLED		Endpoint Stalled. Software must clear this bit.
		0	No handshake has been received.
		1	A STALL handshake has been received.
1	TXRDY		Transmit Packet Ready. If both the TXRDY and SETUP bits are set, a setup packet is sent. If just TXRDY is set, an OUT packet is sent.
		0	No transmit packet is ready.
		1	Software sets this bit after loading a data packet into the TX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.

Table 22-36. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Host Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	RXRDY		Receive Packet Ready. Software must clear this bit after the packet has been read from the FIFO to acknowledge that the data has been read from the FIFO.
		0	No receive packet has been received.
		1	Indicates that a data packet has been received in the RX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.

USBCSRL0 in Device mode is shown in Figure 22-35 and described in Table 22-37.

Figure 22-35. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Device Mode

Table 22-37. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Device Mode Field Descriptions

Bit	Field	Value	Description
7	SETENDC		Setup End Clear
		0	No effect
		1	Writing a 1 to this bit clears the SETEND bit.
6	RXRDYC		RXRDY Clear
		0	No effect
		1	Writing a 1 to this bit clears the RXRDY bit.
5	STALL		Send Stall.
		0	No effect
		1	Terminates the current transaction and transmits the STALL handshake.
			This bit is cleared automatically after the STALL handshake is transmitted.
4	SETEND		Setup end.
		0	A control transaction has not ended or ended after the DATAEND bit was set.
		1	A control transaction has ended before the DATAEND bit has been set. The EP0 bit in the USBTXIS register is also set in this situation.
			This bit is cleared by writing a 1 to the SETENDC bit.
3	DATAEND		Data end.
		0	No effect
		1	Set this bit in the following situations: • When setting TXRDY for the last data packet • When clearing RXRDY after unloading the last data packet • When setting TXRDY for a zero-length data packet This bit is cleared automatically.
2	STALLED		Endpoint Stalled. Software must clear this bit.
		0	A STALL handshake has not been transmitted.
		1	A STALL handshake has been transmitted.

Table 22-37. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Device Mode Field Descriptions (continued)

Bit	Field	Value	Description
1	TXRDY		Transmit Packet Ready. If both the TXRDY and SETUP bits are set, a setup packet is sent. If just TXRDY is set, an OUT packet is sent.
		0	No transmit packet is ready.
		1	Software sets this bit after loading an IN data packet into the TX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.
0	RXRDY		Receive Packet Ready.
		0	No receive packet has been received.
		1	A data packet has been received. The EP0 bit in the USBTXIS register is also set in this situation.
			This bit is cleared by writing a 1 to the RXRDYC bit.

22.6.3.29 USB Control and Status Endpoint 0 High Register (USBCSRH0), offset 0x103

The USB control and status endpoint 0 high 8-bit register (USBCSRH0) provides control and status bits for endpoint 0.

Mode(s): Host Device

USBCSRH0 in Host mode is shown in Figure 22-36 and described in Table 22-38.

Figure 22-36. USB Control and Status Endpoint 0 High Register (USBCSRH0) in Host Mode

Bit	Field	Value	Description
7-3	Reserved	0	Reserved
2	DTWE		Data Toggle Write Enable. This bit is automatically cleared once the new value is written.
		0	The DT bit cannot be written.
		1	Enables the current state of the endpoint 0 data toggle to be written (see DT bit).
1	DT		Data Toggle. When read, this bit indicates the current state of the endpoint 0 data toggle. If DTWE is set, this bit may be written with the required setting of the data toggle. If DTWE is Low, this bit cannot be written. Care should be taken when writing to this bit as it should only be changed to RESET USB endpoint 0.
0	FLUSH		Flush FIFO. This bit is automatically cleared after the flush is performed.
		0	No effect
		1	Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared. **Note:** This bit should only be set when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted.

USBCSRH0 in Device mode is shown in Figure 22-37 and described in Table 22-39.

Figure 22-37. USB Control and Status Endpoint 0 High Register (USBCSRH0) in Device Mode

Bit	Field	Value	Description
7-1	Reserved	0	Reserved
0	FLUSH		Flush FIFO. This bit is automatically cleared after the flush is performed.
		0	No effect
		1	Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared.
			Note: This bit should only be set when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted.

22.6.3.30 USB Receive Byte Count Endpoint 0 Register (USBCOUNT0), offset 0x108

The USB receive byte count endpoint 0 8-bit read-only register (USBCOUNT0) indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the RXRDY bit is set.

Mode(s): Host Device

USBCOUNT0 is shown in Figure 22-38 and described in Table 22-40 .

Figure 22-38. USB Receive Byte Count Endpoint 0 Register (USBCOUNT0)

7	6	0
Reserved	COUNT	
R-0	R/W-0

Table 22-40. USB Receive Byte Count Endpoint 0 Register (USBCOUNT0) Field Descriptions

Bit	Field	Value	Description
7	Reserved	0	Reserved
6-0	COUNT	0	FIFO Count. COUNT is a read-only value that indicates the number of received data bytes in the endpoint 0 FIFO.

22.6.3.31 USB Type Endpoint 0 Register (USBTYPE0), offset 0x10A

The USB type endpoint 0 8-bit register (USBTYPE0) must be written with the operating speed of the targeted Device being communicated with using endpoint 0.

Mode(s): Host

USBTYPE0 is shown in Figure 22-39 and described in Table 22-41.

Figure 22-39. USB Type Endpoint 0 Register (USBTYPE0)

7	6	5	0

Table 22-41. USB Type Endpoint 0 Register (USBTYPE0) Field Descriptions

Bit	Field	Value	Description
7-6	SPEED	0	Operating Speed specifies the operating speed of the target Device. If selected, the target is assumed to have the same connection speed as the USB controller.
		0-1h	Reserved
		2h	Full
		3h	Low
5-0	Reserved	0	Reserved

22.6.3.32 USB NAK Limit Register (USBNAKLMT), offset 0x10B

The USB NAK limit 8-bit read-only register (USBNAKLMT) sets the number of frames after which endpoint 0 should time out on receiving a stream of NAK responses. (Equivalent settings for other endpoints can be made through their USBTXINTERVAL[*n*] and USBRXINTERVAL[*n*] registers.)

The number of frames selected is 2(m-1) (where m is the value set in the register, with valid values of 2–16). If the Host receives NAK responses from the target for more frames than the number represented by the limit set in this register, the endpoint is halted.

Note: A value of 0 or 1 disables the NAK timeout function.

Mode(s): Host

USBNAKLMT is shown in Figure 22-40 and described in Table 22-42.

Figure 22-40. USB NAK Limit Register (USBNAKLMT)

7	5	4	0
Reserved		NAKLMT

Bit	Field	Value	Description
7-5	Reserved	0	Reserved
4-0	NAKLMT	0	EP0 NAK Limit specifies the number of frames after receiving a stream of NAK responses.

22.6.3.33 USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[1]-USBTXCSRL[*n*])

The USB transmit control and status endpoint *n* low 8-bit registers (USBTXCSRL[*n*]) provide control and status bits for transfers through the currently selected transmit endpoint.

Mode(s): Host Device

The USBTXCSRL[*n*] registers in Host Mode are shown in Figure 22-41 and described in Table 22-43.

Figure 22-41. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Host Mode

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	SETUP	FLUSH	ERROR	FIFONE	TXRDY

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 22-43. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	NAKTO		NAK Timeout. Software must clear this bit to allow the endpoint to continue.
		0	No timeout
		1	Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[*n*] register.
6	CLRDT		Clear DataToggle
		0	No effect
		1	Writing a 1 to this bit clears the DT bit in the USBTXCSRH[*n*] register.
5	STALLED		Endpoint Stalled. Software must clear this bit.
		0	A STALL handshake has not been received
		1	Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	SETUP		Setup Packet.
		0	No SETUP token is sent.
		1	Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set.
			Note: Setting this bit also clears the DT bit in the USBTXCSRH[*n*] register.
3	FLUSH		Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO.
		0	No effect
		1	Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation.
			Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	ERROR		Error. Software must clear this bit.
		0	No error
		1	Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed in this situation.
			Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONE		FIFO Not Empty
		0	The FIFO is empty
		1	At least one packet is in the transmit FIFO.

Table 22-43. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Host Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	TXRDY		Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EP*n* bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO.
		0	No transmit packet is ready.
		1	Software sets this bit after loading a data packet into the TX FIFO.

The USBTXCSRL[*n*] registers in Device Mode are shown in Figure 22-42 and described in Table 22-44.

Bit	Field	Value	Description
7	Reserved	0	Reserved
6	CLRDT		Clear Data Toggle
		0	No effect
		1	Writing a 1 to this bit clears the DT bit in the USBTXCSRH[*n*] register.
5	STALLED		Endpoint Stalled. Software must clear this bit.
		0	A STALL handshake has not been transmitted.
		1	A STALL handshake has been transmitted. The FIFO is flushed and the TXRDY bit is cleared.
4	STALL		Send Stall. Software clears this bit to terminate the STALL condition.
		0	No effect
		1	Issues a STALL handshake to an IN token.
3	FLUSH		Flush FIFO. This bit may be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. **Note:** This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
		0	No effect
		1	Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. This bit is cleared automatically.
2	UNDRN		Underrun. Software must clear this bit.
		0	No underrun
		1	An IN token has been received when TXRDY is not set.
1	FIFONE		FIFO Not Empty
		0	The FIFO is empty.
		1	At least one packet is in the transmit FIFO.

Table 22-44. USB Transmit Control and Status Endpoint n Low Register (USBTXCSRL[*n*]) in Device Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	TXRDY		Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO.
		0	No transmit packet is ready.
		1	Software sets this bit after loading a data packet into the TX FIFO. This bit is cleared by writing a 1 to the RXRDYC bit.

22.6.3.34 USB Transmit Control and Status Endpoint n High Register (USBTXCSRH[1]-USBTXCSRH[*n*])

The USB transmit control and status endpoint *n* high 8-bit registers (USBTXCSRH[*n*]) provide additional control for transfers through the currently selected transmit endpoint.

Mode(s): Host Device

The USBTXCSRH[*n*] registers in Host Mode are shown in Figure 22-43 and described in Table 22-45.

Figure 22-43. USB Transmit Control and Status Endpoint n High Register (USBTXCSRH[*n*]) in Host Mode

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 22-45. USB Transmit Control and Status Endpoint n High Register (USBTXCSRH[*n*]) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	AUTOSET		Auto Set
		0	The TXRDY bit must be set manually.
		1	Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[*n*]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	Reserved	0	Reserved. Any writes to these bit(s) must always have a value of 0.
5	MODE		Mode **Note:** This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions.
		0	Enables the endpoint direction as RX.
		1	Enables the endpoint direction as TX.
4	DMAEN		DMA Request Enable **Note:** Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly.
		0	Disables the DMA request for the transmit endpoint.
		1	Enables the DMA request for the transmit endpoint.
3	FDT		Force Data Toggle
		0	No effect
		1	Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. **Note:** This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD		DMA Request Mode **Note:** This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared.
		0	An interrupt is generated after every DMA packet transfer.
		1	An interrupt is generated only after the entire DMA transfer is complete. **Note:** This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	DTWE		Data Toggle Write Enable. This bit is automatically cleared once the new value is written.
		0	The DT bit cannot be written.
		1	Enables the current state of the transmit endpoint data to be written (see DT bit).

Table 22-45. USB Transmit Control and Status Endpoint n High Register (USBTXCSRH[*n*]) in Host Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	DT		Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint.

The USBTXCSRH[*n*] registers in Device Mode are shown in Figure 22-44 and described in Table 22-46.

7	AUTOSET		Auto Set
		0	The TXRDY bit must be set manually.
		1	Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[*n*]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	Reserved		Reserved. Should always have a value of 0.
5	MODE		Mode **Note:** This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions.
		0	Enables the endpoint direction as RX.
		1	Enables the endpoint direction as TX.
4	DMAEN		DMA Request Enable **Note:** Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly.
		0	Disables the DMA request for the transmit endpoint.
		1	Enables the DMA request for the transmit endpoint.
3	FDT		Force Data Toggle
		0	No effect
		1	Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received.
2	DMAMOD		DMA Request Mode **Note:** This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared.
		0	An interrupt is generated after every DMA packet transfer.
		1	An interrupt is generated only after the entire DMA transfer is complete.
0	Reserved	0	Reserved

22.6.3.35 USB Maximum Receive Data Endpoint n Registers (USBRXMAXP[1]-USBRXMAXP[*n*])

The USB maximum receive data endpoint *n* 16-bit registers (USBRXMAXP[*n*]) define the maximum amount of data that can be transferred through the selected receive endpoint in a single operation.

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the USB Specification on packet sizes for bulk and interrupt transfers in full-speed operation.

The total amount of data represented by the value written to this register must not exceed the FIFO size for the transmit endpoint, and must not exceed half the FIFO size if double-buffering is required.

Note: USBRXMAXP[*n*] must be set to an even number of bytes for proper interrupt generation in DMA Basic Mode.

Mode(s): Host Device

The USBRXMAXP[*n*] registers are shown in Figure 22-45 and described in Table 22-47.

Figure 22-45. USB Maximum Receive Data Endpoint *n* Registers (USBRXMAXP[*n*])

15	11	10	0
Reserved		MAXLOAD	
R-0		R/W-000	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-47. USB Maximum Receive Data Endpoint *n* Registers (USBRXMAXP[*n*]) Field Descriptions

Bit	Field	Value	Description
15-11	Reserved	0	Reserved
10-0	MAXLOAD		Maximum Payload specifies the maximum payload in bytes per transaction.

22.6.3.36 USB Receive Control and Status Endpoint n Low Register (USBRXCSRL[1]-USBRXCSRL[*n*])

The USB receive control and status endpoint *n* low 8-bit register (USBRXCSRL[*n*]) provides control and status bits for transfers through the currently selected receive endpoint.

Mode(s): Host Device

The USBCSRL[*n*] registers in Host mode are shown in Figure 22-46 and described in Table 22-48.

Figure 22-46. USB Receive Control and Status Endpoint n Low Register (USBRXCSRL[*n*]) in Host Mode

7	6	5	4	3	2	1	0

LEGEND: R/W = Read/Write; W = Write only; -*n* = value after reset

Table 22-48. USB Receive Control and Status Endpoint n Low Register (USBRXCSRL[*n*]) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	NAKTO		Clear Data Toggle.
		0	No effect
		1	Writing a 1 to this bit clears the DT bit in the USBRXCSRH[*n*] register.
6	STALLED		Endpoint Stalled. Software must clear this bit.
		0	No handshake has been received.
		1	A STALL handshake has been received. The EP*n* bit in the USBRXIS register is also set.
5	REQPKT		Request Packet. This bit is cleared when the RXRDY bit is set.
		0	No request
		1	Requests an IN transaction.
4	FLUSH		Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. **Note:**This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted.
		0	No effect
		1	Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared.
3	DATAERR / NAKTO		Data Error / NAK Timeout
		0	Normal operation
		1	Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[*n*] register. Software must clear this bit to allow the endpoint to continue.
2	ERROR		Error. Software must clear this bit. **Note:** This bit is only valid when the receive endpoint is operating in Bulk or Interrupt mode.
		0	No error
		1	Three attempts have been made to receive a packet and no data packet has been received. The EP*n* bit in the USBRXIS register is set in this situation.
1	FULL		FIFO Full
		0	The receive FIFO is not full.
		1	No more packets can be loaded into the receive FIFO.

Table 22-48. USB Receive Control and Status Endpoint n Low Register (USBRXCSRL[*n*]) in Host Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	RXRDY		Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[*n*] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[*n*] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO.
		0	No data packet has been received.
		1	Indicates that a data packet has been received. The EP*n* bit in the USBTXIS register is also set in this situation.

USBCSRL0 in Device mode is shown in Figure 22-47 and described in Table 22-49.

Figure 22-47. USB Receive Control and Status Endpoint n Low Register (USBRXCSRL[*n*]) in Device Mode

Table 22-49. USB Receive Control and Status Endpoint n Low Register (USBRX CSRL[*n*]) in Device Mode Field Descriptions

Bit	Field	Value	Description
7	CLRDT		Clear Data Toggle
		0	No effect
		1	Writing a 1 to this bit clears the DT bit in the USBRXCSRH[*n*] register.
6	STALLED		Endpoint Stalled. Software must clear this bit.
		0	A STALL handshake has been transmitted.
		1	A STALL handshake has been transmitted.
5	STALL		Send Stall. Software must clear this bit to terminate the STALL condition.
		0	No effect
		1	Issues a STALL handshake.
4	FLUSH		Flush FIFO. The CPU writes a 1 to this bit to flush the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO.
		0	No effect
		1	Flushes the next packet from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared. **Note:** This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted.
3-2	Reserved		Reserved
1	FULL		FIFO Full
		0	The receive FIFO is not full.
		1	No more packets can be loaded into the receive FIFO.

Table 22-49. USB Receive Control and Status Endpoint n Low Register (USBRX CSRL[*n*]) in Device Mode Field Descriptions (continued)

Bit	Field	Value	Description
0	RXRDY		Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[*n*] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[*n*] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO.
		0	No data packet has been received.
		1	A data packet has been received. The EP*n* bit in the USBTXIS register is also set in this situation. This bit is cleared by writing a 1 to the RXRDYC bit.

22.6.3.37 USB Receive Control and Status Endpoint n High Register (USBRXCSRH[1]-USBRXCSRH[*n*])

The USB receive control and status endpoint *n* high 8-bit register (USBRXCSRL[*n*]) provides additional control and status bits for transfers through the currently selected receive endpoint.

Mode(s): Host Device

The USBCSRH[*n*] registers in OTG A/Host mode are shown in Figure 22-48 and described in Table 22-50.

Figure 22-48. USB Receive Control and Status Endpoint n High Register (USBRXCSRH[*n*]) in Host Mode

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 22-50. USB Receive Control and Status Endpoint n High Register (USBRXCSRH[*n*]) in Host Mode Field Descriptions

Bit	Field	Value	Description
7	AUTOCL		Auto Clear
		0	No effect
		1	Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[*n*] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[*n*] register, see Section 22.2.3.
6	AUTORQ		Auto Request **Note:** This bit is automatically cleared when a short packet is received.
		0	No effect
		1	Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared.
5	DMAEN		DMA Request Enable **Note:** Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly.
		0	Disables the DMA request for the receive endpoint.
		1	Enables the DMA request for the receive endpoint.
4	Reserved		Reserved
3	DMAMOD		DMAMOD **Note:** This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared.
		0	An interrupt is generated after every DMA packet transfer.
		1	An interrupt is generated only after the entire DMA transfer is complete.
2	DTWE		Data Toggle Write Enable. This bit is automatically cleared once the new value is written.
		0	The DT bit cannot be written.
		1	Enables the current state of the receive endpoint data to be written (see DT bit).
1	DT		Data Toggle. When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint.
0	Reserved	0	Reserved

The USBCSRH[*n*] registers in Device mode are shown in Figure 22-49 and described in Table 22-51.

Figure 22-49. USB Receive Control and Status Endpoint n High Register (USBRXCSRH[*n*]) in Device Mode

Table 22-51. USB Receive Control and Status Endpoint n High Register (USBRXCSRH[*n*]) in Device Mode Field Descriptions

Bit	Field	Value	Description
7	AUTOCL		Auto Clear
		0	No effect
		1	Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[*n*] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[*n*] register, see Section 22.2.3.
6	Reserved		Reserved
5	DMAEN		DMA Request Enable **Note:** Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly.
		0	Disables the DMA request for the receive endpoint.
		1	Enables the DMA request for the receive endpoint.
4	DISNYET/ PIDERR		Disable NYET / PID Error
		0	No effect
		1	For bulk or interrupt transactions: Disables the sending of NYET handshakes. When this bit is set, all successfully received packets are acknowledged, including at the point at which the FIFO becomes full.
3	DMAMOD		DMA Request Mode **Note:** This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared.
		0	An interrupt is generated after every DMA packet transfer.
		1	An interrupt is generated only after the entire DMA transfer is complete.
0	Reserved	0	Reserved

22.6.3.38 USB Receive Byte Count Endpoint n Register (USBRXCOUNT[1]-USBRXCOUNT[*n*])

The USB receive byte count endpoint *n* 16-bit read-only registers hold the number of data bytes in the packet currently in line to be read from the receive FIFO. If the packet is transmitted as multiple bulk packets, the number given is for the combined packet.

Note: The value returned changes as the FIFO is unloaded and is only valid while the RXRDY bit in the USBRXCSRLn register is set.

Mode(s): Host Device

The USBRXCOUNT[*n*] registers are shown in Figure 22-50 and described in Table 22-52.

Figure 22-50. USB Receive Byte Count Endpoint n Register (USBRXCOUNT[*n*])

15 13	12 0
Reserved	COUNT
R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 22-52. USB Receive Byte Count Endpoint n Register (USBRXCOUNT[*n*]) Field Descriptions

Bit	Field	Value	Description
15-13	Reserved	0	Reserved
12-0	COUNT		Receive Packet Count indicates the number of bytes in the receive packet.

22.6.3.39 USB Host Transmit Configure Type Endpoint n Registers (USBTXTYPE[1]-USBTXTYPE[*n*])

The USB host transmit configure type endpoint *n* 8-bit registers (USBTXTYPE[*n*]) must be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently selected transmit endpoint, and its operating speed.

Mode(s): Host

The USBTXTYPE[*n*] registers are shown in Figure 22-51 and described in Table 22-53.

Figure 22-51. USB Host Transmit Configure Type Endpoint n Registers (USBTXTYPE[*n*])

7	6	5	4	3	0
SPEED		PROTO		TEP	
R/W-0		R/W-0		R/W-0

Table 22-53. USB Host Transmit Configure Type Endpoint n Registers (USBTXTYPE[*n*]) Field Descriptions

Bit	Field	Value	Description
7-6	SPEED		Operating Speed. This bit field specifies the operating speed of the target Device:
		0h	Default. The target is assumed to be using the same connection speed as the USB controller.
		1h	Reserved
		2h	Full
		3h	Low
5-4	PROTO		Protocol. Software must configure this bit field to select the required protocol for the transmit endpoint:
		0h	Control
		1h	Reserved
		2h	Bulk
		3h	Interrupt
3-0	TEP	0	Target Endpoint Number. Software must configure this value to the endpoint number contained in the transmit endpoint descriptor returned to the USB controller during Device enumeration.

22.6.3.40 USB Host Transmit Interval Endpoint n Registers (USBTXINTERVAL[1]-USBTXINTERVAL[*n*])

The USB host transmit interval endpoint *n* 8-bit registers (USBTXINTERVAL[*n*]), for interrupt transfers, define the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The USBTXINTERVAL[*n*] registers values define a number of frames, as follows:

Table 22-54. USB Host Transmit Interval Endpoint *n* Registers (USBTXINTERVAL[*n*]) Frame Numbers

Transfer Type	Speed	Valid Values (m)	Interpretation
Interrupt	Low-speed or Full-speed	0x01-0xFF	The polling interval is *m* frames.
Bulk	Full-speed	0x02-0x10	The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function.

Mode(s): Host

The USBTXINTERVAL[*n*] registers are shown in Figure 22-51 and described in Table 22-53.

Figure 22-52. USB Host Transmit Interval Endpoint *n* Registers (USBTXINTERVAL[*n*])

Bit	Field	Value	Description
7-6	SPEED		Operating Speed. This bit field specifies the operating speed of the target Device:
		0h	Default. The target is assumed to be using the same connection speed as the USB controller.
		1h	Reserved
		2h	Full
		3h	Low
5-4	PROTO		Protocol. Software must configure this bit field to select the required protocol for the receive endpoint:
		0h	Control
		1h	Reserved
		2h	Bulk
		3h	Interrupt
3-0	TEP	0	Target Endpoint Number. Software must configure this value to the endpoint number contained in the transmit endpoint descriptor returned to the USB controller during Device enumeration.

22.6.3.42 USB Host Receive Polling Interval Endpoint n Registers (USBRXINTERVAL[1]-USBRXINTERVAL[*n*])

The USB host receive polling interval endpoint *n* 8-bit registers (USBRXINTERVAL[*n*]), for interrupt transfers, define the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register defines the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The USBRXINTERVAL[*n*] registers values define a number of frames, as follows:

Table 22-57. USB Host Receive Polling Interval Endpoint *n* Registers (USBRXINTERVAL[*n*]) Frame Numbers

Transfer Type	Speed	Valid Values (m)	Interpretation
Interrupt	Low-speed or Full-speed	0x01-0xFF	The polling interval is *m* frames.
Bulk	Full-speed	0x02-0x10	The NAK Limit is $2^{(m-1)}$ frames. A value of 0 or 1 disables the NAK timeout function.

Mode(s): Host

The USBRXINTERVAL[*n*] registers are shown in Figure 22-51 and described in Table 22-53.

Figure 22-54. USB Host Receive Polling Interval Endpoint *n* Registers (USBRXINTERVAL[*n*])

7	0

Bit	Field	Value	Description
7-0	TXPOLL / NAKLMT	0	TX Polling / NAK Limit The polling interval for interrupt transfers; the NAK limit for bulk transfers. See Table 22-57 for valid entries; other values are reserved.

22.6.3.43 USB Request Packet Count in Block Transfer Endpoint n Registers (USBRQPKTCOUNT[1]-USBRQPKTCOUNT[*n*])

The USB receive packet count in block transfer endpoint *n* 16-bit read/writer registers are used in Host mode to specify the number of packets that are to be transferred in a block transfer of one or more bulk packets to receive endpoint *n*. The USB controller uses the value recorded in this register to determine the number of requests to issue where the AUTORQ bit in the USBRXCSRH[*n*] register has been set. For more information about IN transactions as a host, see Section 22.2.2.2.

Note: Multiple packets combined into a single bulk packet within the FIFO count as one packet.

Mode(s): Host

The USBRQPKTCOUNT[*n*] registers are shown in Figure 22-55 and described in Table 22-59.

Figure 22-55. USB Request Packet Count in Block Transfer Endpoint *n* Registers (USBRQPKTCOUNT[*n*])

15 13	12 0
Reserved	COUNT
R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-59. USB Request Packet Count in Block Transfer Endpoint *n* Registers (USBRQPKTCOUNT[*n*]) Field Descriptions

Bit	Field	Value	Description
15-13	Reserved	0	Reserved
12-0	COUNT		Block Transfer Packet Count sets the number of packets of the size defined by the MAXLOAD bit field that are to be transferred in a block transfer. **Note:** This is only used in Host mode when AUTORQ is set. The bit has no effect in Device mode or when AUTORQ is not set.

22.6.3.44 USB Receive Double Packet Buffer Disable Register (USBRXDPKTBUFDIS), offset 0x340

The USB receive double packet buffer disable 16-bit register (USBRXDPKTBUFDIS) indicates which of the receive endpoints have disabled the double-packet buffer functionality (see *Double-Packet Buffering* in Section 22.2.1.1.1).

Note: The USBRXDPKTBUFDIS register is not applicable to the control IN and control OUT endpoints, therefore the EP0 bit does not exist for the USBRXDPKTBUFDIS register.

Mode(s): Host Device

USBRXDPKTBUFDIS is shown in Figure 22-56 and described in Table 22-60.

Figure 22-56. USB Receive Double Packet Buffer Disable Register (USBRXDPKTBUFDIS)

0	Reserved	0	Reserved

22.6.3.45 USB Transmit Double Packet Buffer Disable Register (USBTXDPKTBUFDIS), offset 0x342

The USB transmit double packet buffer disable 16-bit register (USBTXDPKTBUFDIS) indicates which of the transmit endpoints have disabled the double-packet buffer functionality (see *Double-Packet Buffering* in Section 22.2.1.1.1).

Note: The USBTXDPKTBUFDIS register is not applicable to the control IN and control OUT endpoints, therefore the EP0 bit does not exist for the USBTXDPKTBUFDIS register.

Mode(s): Host Device

USBTXDPKTBUFDIS is shown in Figure 22-57 and described in Table 22-61.

Figure 22-57. USB Transmit Double Packet Buffer Disable Register (USBTXDPKTBUFDIS)

Bit	Field	Value	Description
15-4	Reserved		Reserved
3	EP3		EP3 RX Double-Packet Buffer Disable
		0	Disables double-packet buffering.
		1	Enables double-packet buffering.
2	EP2		EP2 RX Double-Packet Buffer Disable
		0	Disables double-packet buffering.
		1	Enables double-packet buffering.
1	EP1		EP1 RX Double-Packet Buffer Disable
		0	Disables double-packet buffering.
		1	Enables double-packet buffering.
0	Reserved	0	Reserved

22.6.3.46 USB External Power Control Register (USBEPC), offset 0x400

The USB external power control 32-bit register (USBEPC) specifies the function of the two-pin external power interface (USB0EPEN and USB0PFLT). The assertion of the power fault input may generate an automatic action, as controlled by the hardware configuration registers. The automatic action is necessary because the fault condition may require a response faster than one provided by firmware.

Mode(s): Host Device

USBEPC is shown in Figure 22-58 and described in Table 22-62.

Figure 22-58. USB External Power Control Register (USBEPC)

31	10	9	8
Reserved		PFLTACT	
R-0		R/W-0	

7	6	5	4	3	2	1	0
Reserved	PFLTAEN	PFLTSEN	PFLTEN	Reserved	EPENDE	EPEN	
R-0	R/W-0	R/W-0	R/W-0	R-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 22-62. USB External Power Control Register (USBEPC) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-8	PFLTACT		Power Fault Action. This bit field specifies how the USB0EPEN signal is changed when detecting a USB power fault.
		0h	Unchanged. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits.
		1h	Tristate. USB0EPEN is undriven (tristate).
		2h	Low. USB0EPEN is driven Low.
		3h	High. USB0EPEN is driven High.
7	Reserved	0	Reserved
6	PFLTAEN		Power Fault Action Enable. This bit specifies whether a USB power fault triggers any automatic corrective action regarding the driven state of the USB0EPEN signal.
		0	Disabled. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits.
		1	Enabled. The USB0EPEN output is automatically changed to the state specified by the PFLTACT field.
5	PFLTSEN		Power Fault Sense. This bit specifies the logical sense of the USB0PFLT input signal that indicates an error condition. The complementary state is the inactive state.
		0	Low Fault. If USB0PFLT is driven Low, the power fault is signaled internally (if enabled by the PFLTEN bit).
		1	High Fault. If USB0PFLT is driven High, the power fault is signaled internally (if enabled by the PFLTEN bit).
4	PFLTEN		Power Fault Input Enable. This bit specifies whether the USB0PFLT input signal is used in internal logic.
		0	Not Used. The USB0PFLT signal is ignored.
		1	Used. The USB0PFLT signal is used internally
3	Reserved	0	Reserved

Table 22-62. USB External Power Control Register (USBEPC) Field Descriptions (continued)

Bit	Field	Value	Description
2	EPENDE		EPEN Drive Enable. This bit specifies whether the USB0EPEN signal is driven or undriven (tristate). When driven, the signal value is specified by the EPEN field. When not driven, the EPEN field is ignored and the USB0EPEN signal is placed in a high-impedance state. The USB0EPEN signal is undriven at reset because the sense of the external power supply enable is unknown. By adding the high-impedance state, system designers can bias the power supply enable to the disabled state using a large resistor (100 kΩ) and later configure and drive the output signal to enable the power supply.
		0	Not Driven. The USB0EPEN signal is high impedance.
		1	Driven. The USB0EPEN signal is driven to the logical value specified by the value of the EPEN field.
1-0	EPEN		External Power Supply Enable Configuration. This bit field specifies and controls the logical value driven on the USB0EPEN signal.
		0h	Power Enable Active Low. The USB0EPEN signal is driven Low if the EPENDE bit is set.
		1h	Power Enable Active High. The USB0EPEN signal is driven High if the EPENDE bit is set.
		2h	Power Enable High if VBUS Low. The USB0EPEN signal is driven High when the A device is not recognized.
		3h	Power Enable High if VBUS High. The USB0EPEN signal is driven High when the A device is recognized.

22.6.3.47 USB External Power Control Raw Interrupt Status Register (USBEPCRIS), offset 0x404

The USB external power control raw interrupt status 32-bit register (USBEPCRIS) specifies the unmasked interrupt status of the two-pin external power interface.

Mode(s): Host Device

USBEPCRIS is shown in Figure 22-59 and described in Table 22-63.

Figure 22-59. USB External Power Control Raw Interrupt Status Register (USBEPCRIS)

31	1	0
Reserved		PF
R-0		R-0

LEGEND: R = Read only; *-n* = value after reset

Table 22-63. USB External Power Control Raw Interrupt Status Register (USBEPCRIS) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	PF		USB Power Fault Interrupt Status. This bit is cleared by writing a 1 to the PF bit in the USBEPCISC register.
		0	A Power Fault status has been detected.
		1	An interrupt has not occurred.

22.6.3.48 USB External Power Control Interrupt Mask Register (USBEPCIM), offset 0x408

The USB external power control interrupt mask 32-bit register (USBEPCIM) specifies the interrupt mask of the two-pin external power interface.

Mode(s): Host Device

USBEPCIM is shown in Figure 22-60 and described in Table 22-64.

Figure 22-60. USB External Power Control Interrupt Mask Register (USBEPCIM)

31	1	0
Reserved		PF
R-0		R-0

LEGEND: R = Read only; *-n* = value after reset

Table 22-64. USB External Power Control Interrupt Mask Register (USBEPCIM) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	PF		USB Power Fault Interrupt Mask.
		0	The raw interrupt signal from a detected power fault is sent to the interrupt controller.
		1	A detected power fault does not affect the interrupt status.

22.6.3.49 USB External Power Control Interrupt Status and Clear Register (USBEPCISC), offset 0x40C

The USB external power control interrupt status and clear 32-bit register (USBEPCISC) specifies the unmasked interrupt status of the two-pin external power interface.

Mode(s): Host Device

USBEPCISC is shown in Figure 22-61 and described in Table 22-65.

Figure 22-61. USB External Power Control Interrupt Status and Clear Register (USBEPCISC)

31	1	0
Reserved		PF
R-0		R-0

LEGEND: R = Read only; *-n* = value after reset

Table 22-65. USB External Power Control Interrupt Status and Clear Register (USBEPCISC) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Reset is 0x0000.000.
0	PF		USB Power Fault Interrupt Status and Clear. This bit is cleared by writing a 1. Clearing this bit also clears the PF bit in the USBEPCISC register.
		0	The PF bits in the USBEPCRIS and USBEPCIM registers are set, providing an interrupt to the interrupt controller.
		1	No interrupt has occurred or the interrupt is masked.

22.6.3.50 USB Device RESUME Raw Interrupt Status Register (USBDRRIS), offset 0x410

The USB device RESUME raw interrupt status register (USBDRRIS) is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

Mode(s): Host Device

USBDRRIS is shown in Figure 22-62 and described in Table 22-66.

Figure 22-62. USB Device RESUME Raw Interrupt Status Register (USBDRRIS)

31	1	0
Reserved		RESUME
R-0		R-0

LEGEND: R = Read only; *-n* = value after reset

Table 22-66. USB Device RESUME Raw Interrupt Status Register (USBDRRIS) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Reset is 0x0000.000.
0	PF		RESUME Interrupt Status This bit is cleared by writing a 1 to the RESUME bit in the USBDRISC register.
		0	A RESUME status has been detected.
		1	An interrupt has not occurred.

22.6.3.51 USB Device RESUME Raw Interrupt Mask Register (USBDRIM), offset 0x414

The USB device RESUME raw interrupt status register (USBDRIM) is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

Mode(s): Host Device

USBDRIM is shown in Figure 22-63 and described in Table 22-67.

Figure 22-63. USB Device RESUME Raw Interrupt Status Register (USBDRRIS)

31	1	0
Reserved		RESUME
R-0		R-0

LEGEND: R = Read only; *-n* = value after reset

Table 22-67. USB Device RESUME Raw Interrupt Status Register (USBDRRIS) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Reset is 0x0000.000.
0	PF		RESUME Interrupt Mask
		0	The raw interrupt signal from a detected RESUME is sent to the interrupt controller. This bit should only be set when a SUSPEND has been detected (the SUSPEND bit in the USBIS register is set).
		1	A detected RESUME does not affect the interrupt status.

22.6.3.52 USB Device RESUME Interrupt Status and Clear Register (USBDRISC), offset 0x418

The USB device RESUME interrupt status and clear register (USBDRRIS) is the raw interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

Mode(s): Host Device

USBDRISC is shown in Figure 22-64 and described in Table 22-68.

Figure 22-64. USB Device RESUME Interrupt Status and Clear Register (USBDRISC)

31	1	0
Reserved		RESUME
R-0		R/W1C

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 22-68. USB Device RESUME Interrupt Status and Clear Register (USBDRISC) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Reset is 0x0000.000.
0	RESUME		RESUME Interrupt Status and Clear. This bit is cleared by writing a 1. Clearing this bit also clears the RESUME bit in the USBDRCRIS register.
		0	The RESUME bits in the USBDRRIS and USBDRCIM registers are set, providing an interrupt to the interrupt controller.
		1	No interrupt has occurred or the interrupt is masked.

22.6.3.53 USB General-Purpose Control and Status Register (USBGPCS), offset 0x41C

The USB general-purpose control and status register (USBGPCS) provides the state of the internal ID signal.

When the USB controller is used as either a dedicated Host or Device, the DEVMODOTG and DEVMOD bits in the USB General-Purpose Control and Status (USBGPCS) register should be used to connect the ID inputs to fixed levels internally. For proper self-powered Device operation, the VBUS value must be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

Mode(s): Host Device

USBGPCS is shown in Figure 22-65 and described in Table 22-69.

Figure 22-65. USB General-Purpose Control and Status Register (USBGPCS)

31	2	1	0
Reserved		DEVMODOTG	DEVMOD

Bit	Field	Value	Description
31-2	Reserved	0	Reserved. Reset is 0x0000.000.
1	DEVMODOTG		Enable Device Mode. This bit enables the DEVMOD bit to control the state of the internal ID signal in OTG mode.
		0	The mode is specified by the state of the internal ID signal.
		1	This bit enables the DEVMOD bit to control the internal ID signal.
0	DEVMOD		Device Mode This bit specifies the state of the internal ID signal in Host mode and in OTG mode when the DEVMODOTG bit is set. In Device mode this bit is ignored (assumed set).
		0	Host mode
		1	Device mode

22.6.3.54 USB DMA Select Register (USBDMASEL), offset 0x450

The USB DMA select 32-bit register (USBDMASEL) specifies whether the unmasked interrupt status of the ID value is valid.

Mode(s): Host Device

USBDMASEL is shown in Figure 22-66 and described in Table 22-70.

Figure 22-66. USB DMA Select Register (USBDMASEL)

Chapter 23

External Memory Interface (EMIF)

This chapter describes the external memory interface (EMIF).

Further information can be found in the following documents:

Accessing External SDRAM on the TMS320F2837x/2807x Microcontrollers Using C/C++ Application Report

Design and Usage Guidelines for the C2000™ External Memory Interface (EMIF) Application Report

23.1 Introduction

This device supports one EMIF module — EMIF1, as shown in Figure 23-1.

Table 23-1 gives the configuration for the EMIF module.

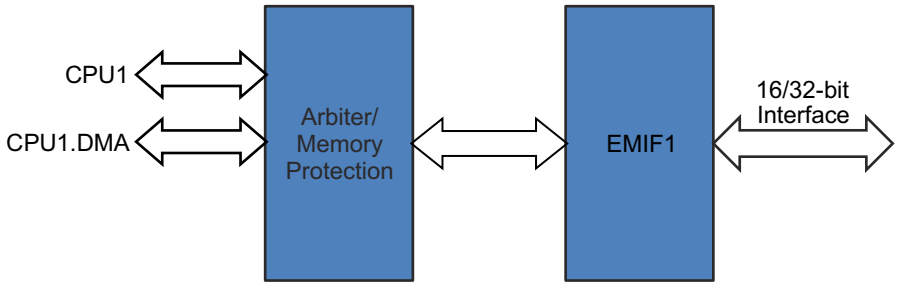

Figure 23-1. EMIF Module Overview

Table 23-1. Configuration for the EMIF1 Module

	EMIF1
Maximum Data Width	32
Maximum Address Width	22 (Some of EMIF1 pins are muxed with each other. Refer to Section 23.2.11 for usage)
SDRAM CSx Support	1 (CS0)
ASRAM CSx Support	3 (CS2/CS3/CS4)

Note

Subsequent sections in this chapter provide the details on the generic EMIF module. Unless otherwise specified, pin names are used from EMIF1 to define the functionality.

23.1.1 Purpose of the Peripheral

This EMIF memory controller is compliant with the JESD21-C SDR SDRAM memories utilizing a 32-bit/16-bit data bus. The purpose of this EMIF is to provide a means for the CPU to connect to a variety of external devices including:

- Single data rate (SDR) SDRAM
- Asynchronous devices including NOR Flash and SRAM

A common use for the EMIF is to interface with both a Flash device and an SDRAM device simultaneously. Section 23.3 contains an example of operating the EMIF in this configuration.

23.1.2 EMIF Related Collateral

Foundational Materials

- C2000 Academy - EMIF

Getting Started Materials

- *Design and Usage Guidelines for the C2000 External Memory Interface (EMIF) Application Report*

Expert Materials

- *Accessing External SDRAM on the TMS320F2837x/2807x Microcontrollers Using C/C++ Application Report*
  - In addition to the devices in the title, this material also applies to other devices with EMIF.

23.1.3 Features

The EMIF controller includes many features to enhance the ease and flexibility of connecting to the external SDR SDRAM and asynchronous devices.

23.1.3.1 Asynchronous Memory Support

The EMIF controller supports asynchronous:

- SRAM memories
- NOR Flash memories

There is an external wait input that allows slower asynchronous memories to extend the memory access. The EMIF module supports more than one chip select (enable). Each chip select has the following individually programmable attributes:

- Data bus width
- Read cycle timings: setup, hold, strobe
- Write cycle timings: setup, hold, strobe
- Bus turnaround time
- Extended wait option with programmable timeout
- Select strobe option

23.1.3.2 Synchronous DRAM Memory Support

The EMIF module supports 16-bit/32-bit SDRAM in addition to the asynchronous memories listed in Section 23.1.3.1. The EMIF module has a single SDRAM chip select. SDRAM configurations that are supported are:

- One, two and four bank SDRAM devices
- Devices with eight, nine, ten, and eleven column address
- CAS latency of two or three clock cycles
- 16-bit/32-bit data bus width
- 3.3V LVCMOS interface

Additionally, the EMIF supports placing the SDRAM in self-refresh and power-down modes. The self-refresh mode allows the SDRAM to be put in a low-power state while still retaining memory contents, since the SDRAM continues to refresh itself even without clocks from the microcontroller. The power-down mode achieves even lower power, except the microcontroller must periodically wake up and issue refreshes if data retention is required.

Note that the EMIF module does not support mobile SDRAM devices.

23.1.4 Functional Block Diagram

Figure 23-2 shows the connections between the EMIF and the internal requesters, along with the external EMIF pins. Section 23.2.2 contains a description of the entities internal to the MCU that can send requests to the EMIF, along with their prioritization. Section 23.2.3 describes the EMIF external pins and summarizes their purpose when interfacing with the SDRAM and asynchronous devices.

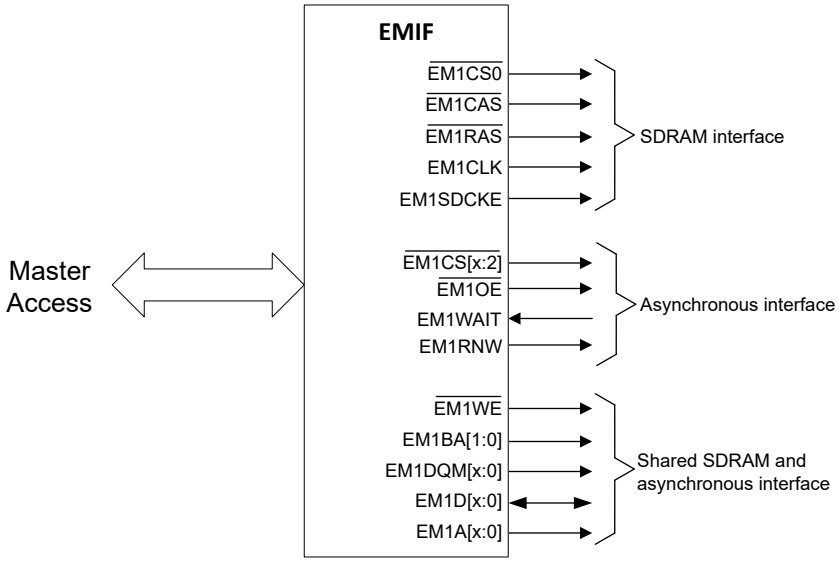

Figure 23-2. EMIF Functional Block Diagram

23.1.5 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

23.2 EMIF Module Architecture

This section provides details about the architecture and operation of the EMIF. Both the SDRAM and asynchronous interface are covered, along with other system-related configurations such as clock control.

23.2.1 EMIF Clock Control

The EMIF clock is output on the EM1CLK pin and must be used when interfacing to external SDRAM devices. The EMIF module gets the PLLSYSCLK clock domain as the input. The user can choose to run the EMIF at PLLSYSCLK/1 or PLLSYSCLK/2 clock frequency by configuring the EMIF1CLKDIV field in the PERCLKDIVSEL register in the *Clock Control* module.

23.2.2 EMIF Requests

Different sources within the MCU can make requests to the EMIF. These requests consist of accesses to the SDRAM memory, the asynchronous memory, and the EMIF registers. The EMIF can process only one request at a time. Therefore, a high performance master arbitration block exists within the MCU to provide prioritized requests from the different sources to the EMIF. The sources are:

- CPU1
- CPU1.DMA

If a request is submitted from two or more sources simultaneously, the crossbar switch forwards the highest priority request to the EMIF first. Upon completion of a request, the master arbitration block again evaluates the pending requests and forwards the highest priority pending request to the EMIF.

The master arbitration block always allows RD access from any of the masters. But for WR access (or execute access), the master arbitration block only allows access of masters from a CPU subsystem that takes master ownership of the EMIF module based on the configuration in the EMIF1MSEL register in the *Memory Controller* module.

When the EMIF receives a request, it is possible that the request is not immediately processed. In some cases, the EMIF performs one or more auto-refresh cycles before processing the request. For details on the EMIF internal arbitration between performing requests and performing auto-refresh cycles, see Section 23.2.13.

23.2.3 EMIF Signal Descriptions

This section describes the function of each of the EMIF signals.

Table 23-2. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories

Pins	I/O	Description
EM1D[x:0]	I/O	**EMIF data bus.**
EM1A[x:0]	O	**EMIF address bus.** When interfacing to an SDRAM device, these pins are primarily used to provide the row and column address to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in Table 23-14. EM1A[10] is also used during the PRE command to select which banks to deactivate. When interfacing to an asynchronous device, these pins are used in conjunction with the EM1BA pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in Section 23.2.6.1.
EM1BA[1:0]	O	**EMIF bank address.** When interfacing to an SDRAM device, these pins are used to provide the bank address inputs to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in Table 23-14. When interfacing to an asynchronous device, these pins are used in conjunction with the EM1A pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in Section 23.2.6.1.
EM1DQM[x:0]	O	**Active-low byte enables.** When interfacing to SDRAM, these pins are connected to the DQM pins of the SDRAM to individually enable/disable each of the bytes in a data access. When interfacing to an asynchronous device, these pins are connected to byte enables. See Section 23.2.6 for details.
$\overline{\text{EM1WE}}$	O	**Active-low write enable.** When interfacing to SDRAM, this pin is connected to the nWE pin of the SDRAM and is used to send commands to the device. When interfacing to an asynchronous device, this pin provides a signal which is active-low during the strobe period of an asynchronous write access cycle.

Table 23-3. EMIF Pins Specific to SDRAM

Pins	I/O	Description
$\overline{\text{EM1CS0}}$	O	**Active-low chip enable pin for SDRAM devices.** This pin is connected to the chip-select pin of the attached SDRAM device and is used for enabling/disabling commands. By default, EMIF keeps this SDRAM chip select active, even if EMIF is not interfaced with an SDRAM device. This pin is deactivated when accessing the asynchronous memory bank and is reactivated on completion of the asynchronous access.
EM1RAS	O	**Active-low row address strobe pin.** This pin is connected to the nRAS pin of the attached SDRAM device and is used for sending commands to the device.
EM1CAS	O	**Active-low column address strobe pin.** This pin is connected to the nCAS pin of the attached SDRAM device and is used for sending commands to the device.
EM1SDCKE	O	**Clock enable pin.** This pin is connected to the CKE pin of the attached SDRAM device and is used for issuing the SELF REFRESH command which places the device in self-refresh mode. See Section 23.2.5.7 for details.
EM1CLK	O	**SDRAM clock pin.** This pin is connected to the CLK pin of the attached SDRAM device. See Section 23.2.1 for details on the clock signal.

Table 23-4. EMIF Pins Specific to Asynchronous Memory

Pins	I/O	Description
$\overline{\text{EM1CS}}$[4:2]	O	**Active-low chip enable pins for asynchronous devices.** These pins are meant to be connected to the chip-select pins of the attached asynchronous device. These pins are active only during accesses to the asynchronous memory.
$\overline{\text{EM1OE}}$	O	**Active-low pin enable for asynchronous devices.** This pin provides a signal which is active-low during the strobe period of an asynchronous read access cycle.
EM1RNW	O	**EMIF asynchronous read/write control.** This pin stays high during reads and stays low during writes (same duration as CS).

23.2.4 EMIF Signal Multiplexing Control

Several EMIF signals are multiplexed with other functions on this microcontroller. Refer to the multiplexing section of the *General-Purpose Input/Output (GPIO)* chapter for more information on how to enable the output of these EMIF signals.

23.2.5 SDRAM Controller and Interface

The EMIF controller provides a glueless interface to most standard SDR SDRAM devices and supports features like self-refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The following sections include details on how to Interface and properly configure the EMIF to perform read and write operations to externally connected SDR SDRAM devices. Also, Section 23.3 provides a detailed example of interfacing the EMIF to a common SDRAM device.

23.2.5.1 SDRAM Commands

The EMIF controller supports the SDRAM commands described in Table 23-5. Table 23-6 shows the truth table for the SDRAM commands, and an example timing waveform of the PRE command is shown in Figure 23-3. EM1A[10] is pulled low in this example to deactivate only the bank specified by the EM1BA pins.

Table 23-5. EMIF SDRAM Commands

Command	Function
PRE	**Precharge.** Depending on the value of EM1A[10], the PRE command either deactivates the open row in all banks (EM1A[10] = 1) or only the bank specified by the EM1BA[1:0] pins (EM1A[10] = 0).
ACTV	**Activate**. The ACTV command activates the selected row in a particular bank for the current access.
READ	**Read.** The READ command outputs the starting column address and signals the SDRAM to begin the burst read operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.
WRT	**Write.** The WRT command outputs the starting column address and signals the SDRAM to begin the burst write operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.
BT	**Burst terminate**. The BT command is used to truncate the current read or write burst request. On this device, all the SDRAM accesses are single access except when EMIF controller splits a single access into multiple access (for example, a 32-bit access from CPU is split into two 16-bit accesses if external SDRAM device is 16 bit (NM =1).
LMR	**Load mode register**. The LMR command sets the mode register of the attached SDRAM devices and is only issued during the SDRAM initialization sequence described in Section 23.2.5.4.
REFR	**Auto refresh**. The REFR command signals the SDRAM to perform an auto refresh according to the internal address.
SLFR	**Self refresh**. The self-refresh command places the SDRAM into self-refresh mode, during which the SDRAM provides a clock signal and auto refresh cycles.
NOP	**No operation**. The NOP command is issued during all cycles in which one of the above commands is not issued.

Table 23-6. Truth Table for SDRAM Commands

SDRAM Pins:	CKE	nCS	nRAS	nCAS	nWE	BA[1:0]	A[12:11]	A[10]	A[9:0]
EMIF Pins:	EM1SDCKE	$\overline{\text{EM1CS}}$[0]	EM1RAS	EM1CAS	$\overline{\text{EM1WE}}$	EM1BA[1:0]	EM1A[12:11]	EM1A[10]	EM1A[9:0]

NOP	H	L	H	H	H	X	X	X	X

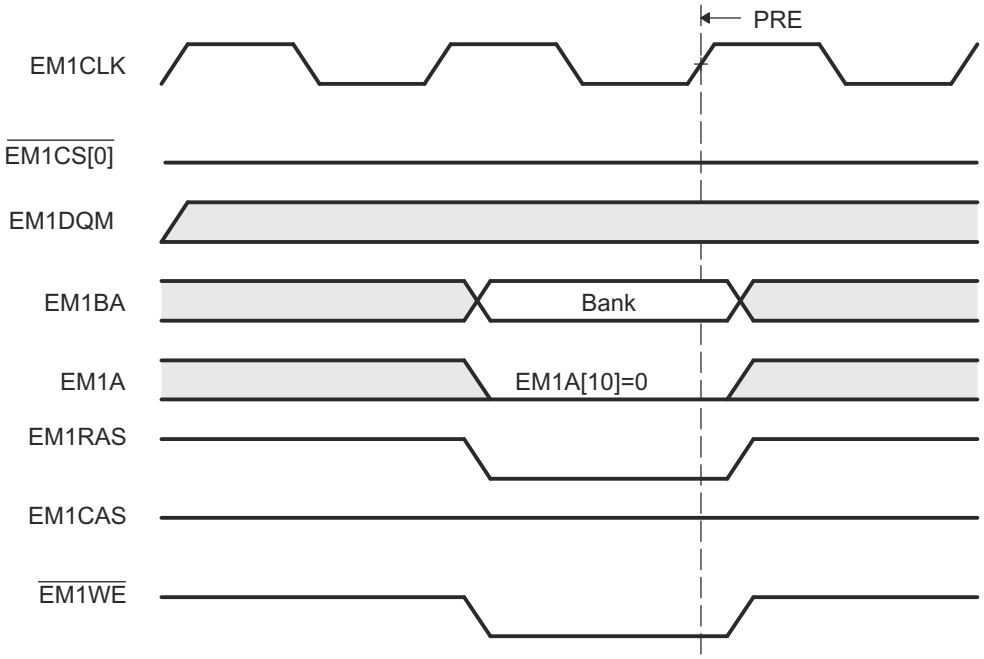

Figure 23-3. Timing Waveform of SDRAM PRE Command

23.2.5.2 Interfacing to SDRAM

The EMIF supports a glueless interface to SDRAM devices with the following characteristics:

- Pre-charge bit is A[10]
- The number of column address bits is 8, 9, 10, or 11.
- The number of row address bits is 13, 14, 15, or 16.
- The number of internal banks is 1, 2, or 4.

Figure 23-4 shows an interface between the EMIF and a 2M × 16 × 4 bank SDRAM device, and Figure 23-5 shows an interface between the EMIF and a 512K × 16 × 2 bank SDRAM device. For devices supporting 16-bit interface, refer to Table 23-7 for list of commonly-supported SDRAM devices and the required connections for the address pins.

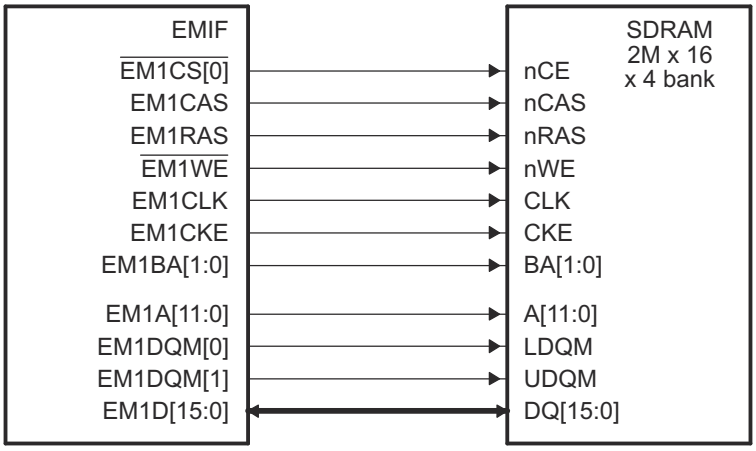

Figure 23-4. EMIF to 2M × 16 × 4 Bank SDRAM Interface

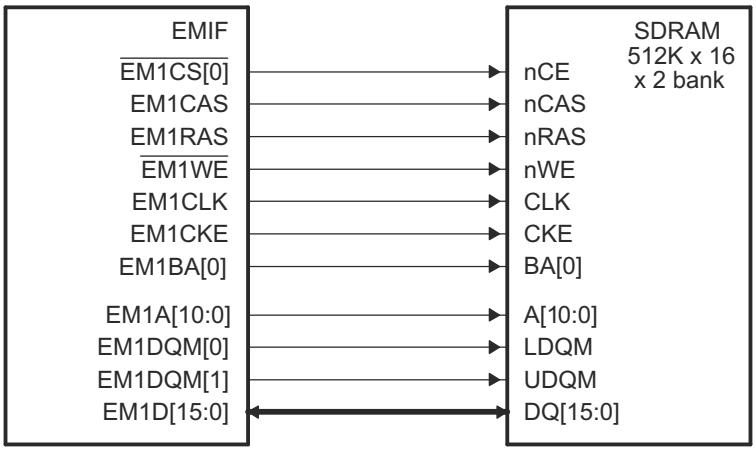

Figure 23-5. EMIF to 512K × 16 × 2 Bank SDRAM Interface

Table 23-7. 16-bit EMIF Address Pin Connections

SDRAM Size	Width	Banks	Device	Address Pins
16M bits	×16	2	SDRAM	A[10:0]
			EMIF	EM1A[10:0]
64M bits	×16	4	SDRAM	A[11:0]
			EMIF	EM1A[11:0]
128M bits	×16	4	SDRAM	A[11:0]
			EMIF	EM1A[11:0]
256M bits	x16	4	SDRAM	A[12:0]
			EMIF	EM1A[12:0]
512M bits	x16	4	SDRAM	A[12:0]
			EMIF	EM1A[12:0]

23.2.5.3 SDRAM Configuration Registers

The operation of the EMIF SDRAM interface is controlled by programming the appropriate configuration registers. This section describes the purpose and function of each configuration register, but Section 23.4 can be referred to for a more detailed description of each register, including the default registers values and bit-field positions. The following tables list the four such configuration registers, along with a description of each of their programmable fields.

Note

Writing to any of the fields: NM, CL, IBANK, and PAGESIZE in the SDRAM configuration register (SDRAM_CR) causes the EMIF to abandon whatever the EMIF is currently doing and trigger the SDRAM initialization procedure described in Section 23.2.5.4.

Table 23-8. Description of the SDRAM Configuration Register (SDRAM_CR)

Parameter	Description
SR	This bit controls entering and exiting of the self-refresh mode
PD	This bit controls entering and exiting of the power-down mode. If both SR and PD bits are set, the EMIF goes into self-refresh mode.
PDWR	Perform refreshes during power down. Writing a 1 to this bit causes the EMIF to exit the power-down state and issue an AUTO REFRESH command every time Refresh May level is set. This bit must be set along with PD when entering power-down mode.
NM	**Narrow Mode.** This bit defines the width of the data bus between the EMIF and the attached SDRAM device. When set to 1, the data bus is set to 16-bits. When set to 0, the data bus is set to 32-bits.
CL	**CAS latency.** This field defines the number of clock cycles between when an SDRAM issues a READ command and when the first piece of data appears on the bus. The value in this field is sent to the attached SDRAM device using the LOAD MODE REGISTER command during the SDRAM initialization procedure as described in Section 23.2.5.4. Only, values of 2h (CAS latency = 2) and 3h (CAS latency = 3) are supported and must be written to this field. While updating the CL field, BIT11_9LOCK bit field must be set to 1 simultaneously.
IBANK	**Number of Internal SDRAM Banks.** This field defines the number of banks inside the attached SDRAM devices in the following way: • When IBANK = 0, 1 internal bank is used • When IBANK = 1h, 2 internal banks are used • When IBANK = 2h, 4 internal banks are used This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See Section 23.2.5.11 for details.
PAGESIZE	**Page Size.** This field defines the internal page size of the attached SDRAM devices in the following way: • When PAGESIZE = 0, 256-word pages are used • When PAGESIZE = 1h, 512-word pages are used • When PAGESIZE = 2h, 1024-word pages are used • When PAGESIZE = 3h, 2048-word pages are used This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See Section 23.2.5.11 for details.

Table 23-9. Description of the SDRAM Refresh Control Register (SDRAM_RCR)

Parameter	Description
RR	**Refresh Rate**. This field controls the rate at which attached SDRAM devices are refreshed. The following equation can be used to determine the required value of RR for an SDRAM device: • RR = f_{EM1CLK} / (Required SDRAM Refresh Rate) More information about the operation of the SDRAM refresh controller is found in Section 23.2.5.6.

Table 23-10. Description of the SDRAM Timing Register (SDRAM_TR)

Parameter	Description
T_RFC T_RP T_RCD T_WR T_RAS T_RC T_RRD	**SDRAM Timing Parameters.** These fields configure the EMIF to comply with the AC timing requirements of the attached SDRAM devices. This allows the EMIF to avoid violating SDRAM timing constraints and to more efficiently schedule operations. More details about each of these parameters can be found in the SDRAM_TR register description. These parameters must be set to satisfy the corresponding timing requirements found in the SDRAM data sheet.

Table 23-11. Description of the SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG)

Parameter	Description
T_XS	**Self Refresh Exit Parameter.** The T_XS field of this register informs the EMIF about the minimum number of EM1CLK cycles required between exiting self-refresh and issuing any command. This parameter must be set to satisfy the t_{XSR} value for the attached SDRAM device.

23.2.5.4 SDRAM Auto-Initialization Sequence

The EMIF automatically performs an SDRAM initialization sequence, regardless of whether the EMIF is interfaced to an SDRAM device, when either of the following two events occur:

- The EMIF comes out of reset. No memory accesses to the SDRAM and asynchronous interfaces are performed until this auto-initialization is complete.
- A write is performed to any of the three least-significant bytes of the SDRAM configuration register (SDRAM_CR)

An SDRAM initialization sequence consists of the following steps:

1. If the initialization sequence is activated by a write to SDRAM_CR, and if any of the SDRAM banks are open, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks. This is done so that the maximum ACTV to PRE timing for an SDRAM is not violated.
2. The EMIF drives EM1SDCKE high and begins continuously issuing NOP commands until eight SDRAM refresh intervals have elapsed. An SDRAM refresh interval is equal to the value of the RR field of the SDRAM refresh control register (SDRAM_RCR), divided by the frequency of EM1CLK (RR/f_{EM1CLK}). This step is used to avoid violating the power-up constraint of most SDRAM devices that requires 200 µs (sometimes 100 µs) between receiving stable Vdd and CLK and the issuing of a PRE command. Depending on the frequency of EM1CLK, this step could be insufficient to avoid violating the SDRAM constraint. See Section 23.2.5.5 for more information.
3. After the refresh intervals have elapsed, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks.
4. The EMIF issues eight AUTO REFRESH commands.
5. The EMIF issues the LMR command with the EM1A[9:0] pins set as described in Table 23-12.
6. Finally, the EMIF performs a refresh cycle, which consists of the following steps:
   a. Issuing a PRE command with EM1A[10] held high if any banks are open
   b. Issuing an REF command

Table 23-12. SDRAM LOAD MODE REGISTER Command

EM1A[9:7]	EM1A[6:4]	EM1A[3]	EM1A[2:0]
0 (Write bursts are of the programmed burst length in EM1A[2:0])	These bits control the CAS latency of the SDRAM and are set according to CL field in the SDRAM configuration register (SDRAM_CR) as follows: • If CL = 2, EM1A[6:4] = 2h (CAS latency = 2) • If CL = 3, EM1A[6:4] = 3h (CAS latency = 3)	0 (Sequential Burst Type. Interleaved Burst Type not supported)	These bits control the burst length of the SDRAM and are set according to the NM field in the SDRAM configuration register (SDRAM_CR) as follows: • If NM = 0, EM1A[2:0] = 2h (Burst Length = 4) • If NM = 1, EM1A[2:0] = 3h (Burst Length = 8)

23.2.5.5 SDRAM Configuration Procedure

There are two different SDRAM configuration procedures. Although the EMIF automatically performs the SDRAM initialization sequence described in Section 23.2.5.4 when coming out of reset, follow one of the procedures before performing any EMIF memory requests.

Procedure A must be followed if the SDRAM power-up constraint was not violated during the SDRAM auto-initialization sequence detailed in Section 23.2.5.4 on coming out of Reset. The SDRAM power-up constraint specifies that 200µs (sometimes 100µs) must exist between receiving stable Vdd and CLK and the issuing of a PRE command.

Procedure B must be followed if the SDRAM power-up constraint was violated. The 200µs (100µs) SDRAM power-up constraint is violated, if the frequency of EM1CLK is greater than 50MHz (100MHz for 100µs SDRAM power-up constraint) during SDRAM Auto-Initialization Sequence. Procedure B must be followed if there is any doubt that the power-up constraint was not met.

Procedure A — Following is the procedure to be followed if the SDRAM power-up constraint was not violated:

1. Place the SDRAM into self-refresh mode by setting the SR bit of SDRAM_CR to 1. The SDRAM can be placed into self-refresh mode when changing the frequency of the EM1CLK to avoid incurring the 200µs power-up constraint again.
2. Configure the desired EMIF1 clock (EM1CLK) frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data sheet.
3. Remove the SDRAM from self-refresh mode by clearing the SR bit of the SDRAM_CR to 0.
4. Program SDRAM_TR and SDR_EXT_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
5. Program the RR field of SDRAM_RCR to match that of the attached device's refresh interval. See Section 23.2.5.6.1 details on determining the appropriate value.
6. Program the SDRAM_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in Section 23.2.5.4 to be re-run. This second initialization generally takes much less time due to the increased frequency of EM1CLK.

Procedure B — Following is the procedure to be followed if the SDRAM power-up constraint was violated:

1. Configure the desired EM1CLK clock frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data sheet.
2. Program SDRAM_TR and SDR_EXT_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
3. Program the RR field of the SDRAM_RCR such that the following equation is satisfied: $(RR \times 8)/(f_{EM1CLK}) > 200\mu s$ (sometimes 100µs). For example, an EM1CLK frequency of 100MHz requires setting RR to 2501 (9C5h) or higher to meet a 200µs constraint.
4. Program the SDRAM_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in Section 23.2.5.4 to be re-run with the new value of RR.
5. Perform a read from the SDRAM to make sure that step 5 of this procedure occurs after the initialization process has completed. Alternatively, wait for 200µs instead of performing a read.
6. Finally, program the RR field to match that of the attached device's refresh interval. See Section 23.2.5.6.1 details on determining the appropriate value.

After following the above procedure, the EMIF is ready to perform accesses to the attached SDRAM device.

23.2.5.6 EMIF Refresh Controller

An SDRAM device requires that each of the rows be refreshed at a minimum required rate. The EMIF can meet this constraint by performing auto refresh cycles at or above this required rate. An auto-refresh cycle consists of issuing a PRE command to all banks of the SDRAM device followed by issuing a REFR command. To inform the EMIF of the required rate for performing auto refresh cycles, the RR field of the SDRAM refresh control register (SDRAM_RCR) must be programmed. The EMIF uses this value along with two internal counters to automatically perform auto refresh cycles at the required rate. The auto-refresh cycles cannot be disabled, even if the EMIF is not interfaced with an SDRAM. The remainder of this section details the EMIF's refresh scheme and provides an example for determining the appropriate value to place in the RR field of the SDRAM_RCR.

The two counters used to perform auto-refresh cycles are a 13-bit refresh interval counter and a 4-bit refresh backlog counter. At reset and upon writing to the RR field, the refresh interval counter is loaded with the value from RR field and begins decrementing, by one, each EMIF clock cycle. When the refresh interval counter reaches zero, the following actions occur:

- The refresh interval counter is reloaded with the value from the RR field and restarts decrementing.
- The 4-bit refresh backlog counter increments unless the counter has already reached the maximum value.

The refresh backlog counter records the number of auto refresh cycles that the EMIF currently has outstanding. This counter is decremented by one each time an auto refresh cycle is performed and incremented by one each time the refresh interval counter expires. The refresh backlog counter saturates at the values of 0000b and 1111b. The EMIF uses the refresh backlog counter to determine the urgency with which an auto refresh cycle must be performed. The four levels of urgency are described in Table 23-13. This refresh scheme allows the required refreshes to be performed with minimal impact on access requests.

Table 23-13. Refresh Urgency Levels

Urgency Level	Refresh Backlog Counter Range	Action Taken
Refresh May	1-3	An auto-refresh cycle is performed only if the EMIF has no requests pending and none of the SDRAM banks are open.
Refresh Release	4-7	An auto-refresh cycle is performed if the EMIF has no requests pending, regardless of whether any SDRAM banks are open.
Refresh Need	8-11	An auto-refresh cycle is performed at the completion of the current access unless there are read requests pending.
Refresh Must	12-15	Multiple auto-refresh cycles are performed at the completion of the current access until the Refresh Release urgency level is reached. At that point, the EMIF can begin servicing any new read or write requests.

23.2.5.6.1 Determining the Appropriate Value for the RR Field

The value that must be programmed into the RR field of the SDRAM_RCR must can be calculated by using the frequency of the EM1CLK signal (f_{EM1CLK}) and the required refresh rate of the SDRAM ($f_{Refresh}$). The following formula can be used:

$RR = f_{EM1CLK} / f_{Refresh}$

The SDRAM data sheet often communicates the required SDRAM Refresh Rate in terms of the number of REFR commands required in a given time interval. The required SDRAM Refresh Rate in the formula above can therefore be calculated by dividing the number of required cycles per time interval (n_{cycles}) by the time interval given in the data sheet ($t_{Refresh\ Period}$) :

$f_{Refresh} = n_{cycles} / t_{Refresh\ Period}$

Combining these formulas, the value that must be programmed into the RR field can be computed as:

$RR = f_{EM1CLK} \times t_{Refresh\ Period} / n_{cycles}$

The following example illustrates calculating the value of RR. Given that:

- f_{EM1CLK} = 100MHz (frequency of EMIF clock)
- $t_{Refresh\ Period}$ = 64ms (required refresh interval of the SDRAM)
- n_{cycles} = 8192 (number of cycles in a refresh interval for the SDRAM)

RR can be calculated as:

RR = 100MHz × 64ms/8192

RR = 781.25

RR = 782 cycles = 30Eh cycles

23.2.5.7 Self-Refresh Mode

The EMIF can be programmed to enter the self-refresh state by setting the SR bit of SDRAM_CR to 1. This causes the EMIF to issue the SLFR command after completing any outstanding SDRAM access requests and clearing the refresh backlog counter by performing one or more auto refresh cycles. This places the attached SDRAM device into self-refresh mode in which the EMIF consumes a minimal amount of power while performing the refresh cycles.

While in the self-refresh state, the EMIF continues to service asynchronous bank requests and register accesses as normal, with one caveat. The EMIF does not park the data bus following a read to asynchronous memory while in the self-refresh state. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state to prevent floating inputs on the data bus. More information about data bus parking can be found in Section 23.2.7.

The EMIF exits from the self-refresh state, if either of the following events occur:

- The SR bit of SDRAM_CR is cleared to 0.
- An SDRAM accesses is requested.

The EMIF exits from the self-refresh state by driving EM1SDCKE high and performing an auto refresh cycle.

The attached SDRAM device must also be placed into self-refresh mode when changing the frequency of EM1CLK. If the frequency of EM1CLK changes while the SDRAM is not in self-refresh mode, Procedure B in Section 23.2.5.5 must be followed to reinitialize the device.

23.2.5.8 Power-Down Mode

To support low-power modes, the EMIF can be requested to issue a POWER DOWN command to the SDRAM by setting the PD bit in the SDRAM configuration register (SDRAM_CR). When this bit is set, the EMIF continues normal operation until all outstanding memory access requests have been serviced and the SDRAM refresh backlog (if there is one) has been cleared. At this point, the EMIF enters the power-down state. Upon entering this state, the EMIF issues a POWER DOWN command (same as a NOP command but driving the EM1SDCKE low on the same cycle). The EMIF then maintains the EM1SDCKE low until the EMIF exits the power-down state.

Since the EMIF services the refresh backlog before the EMIF enters the power-down state, all internal banks of the SDRAM are closed (precharged) prior to issuing the POWER DOWN command. Therefore, the EMIF only supports precharge power-down. The EMIF does not support active power-down, where internal banks of the SDRAM are open (active) before the POWER DOWN command is issued.

During the power-down state, the EMIF services the SDRAM, asynchronous memory, and register accesses as normal, returning to the power-down state upon completion.

The PDWR bit in the SDRAM_CR indicates whether the EMIF must perform refreshes in power-down state. If the PDWR bit is set, the EMIF exits the power-down state every time the Refresh Must level is set, performs AUTO REFRESH commands to the SDRAM, and returns back to the power-down state. This evenly distributes the refreshes to the SDRAM in power-down state. If the PDWR bit is not set, the EMIF does not perform any refreshes to the SDRAM. Therefore, the data integrity of the SDRAM is not maintained upon power-down exit, if the PDWR bit is not set.

If the PD bit is cleared while in the power-down state, the EMIF comes out of the power-down state. The EMIF:

- Drives EM1SDCKE high
- Enters the idle state

23.2.5.9 SDRAM Read Operation

When the EMIF receives a read request to the SDRAM from one of the requesters listed in Section 23.2.2, the EMIF performs one or more read access cycles. A read access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a READ command while specifying the desired bank and column address. EM1A[10] is held low during the READ command to avoid auto-precharging. The READ command signals the SDRAM device to output data from the specified address while EMIF issues NOP commands. Following a READ command, the CL field of the SDRAM configuration register (SDRAM_CR) defines how many delay cycles are present before the read data appears on the data bus. This is referred to as the CAS latency.

Figure 23-6 shows the signal waveforms for a basic SDRAM read operation in which multiple data is read from a single page. On this device, burst accesses are not supported; hence, the EMIF issues a READ command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM_CR) to 1 and CPU (or any other master) does a 32-bit READ access, a burst access is issued with a size of two.

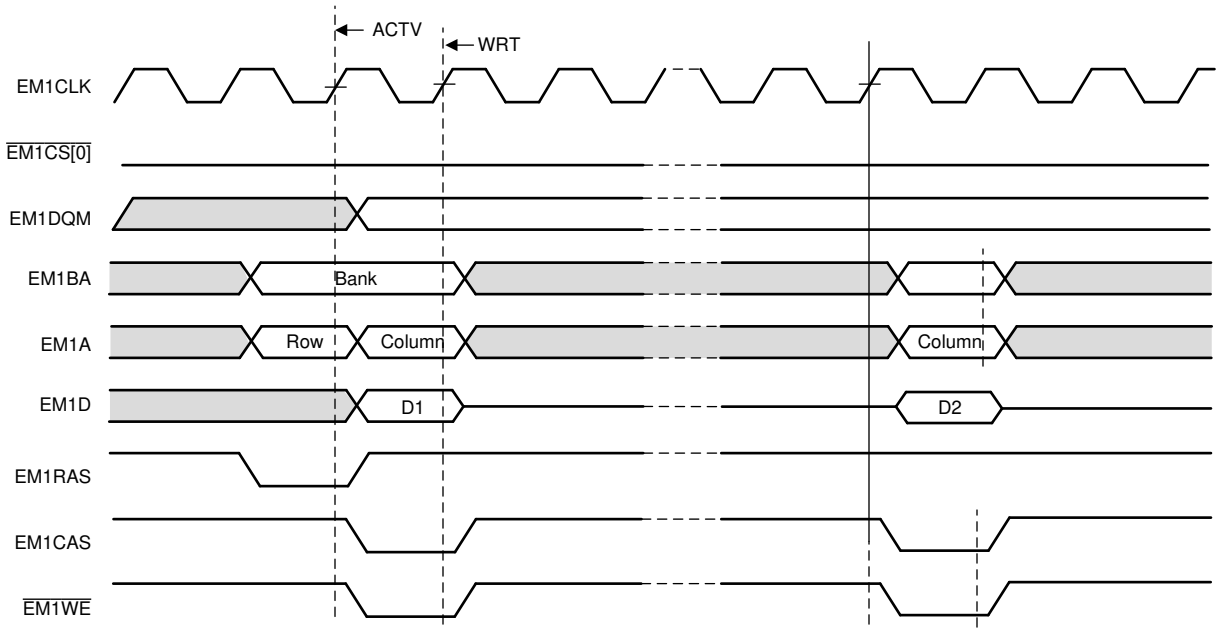

Figure 23-6. Timing Waveform for Basic SDRAM Read Operation

Several other pins are also active during a read access. The EM1DQM[x:0] pins are driven low during the READ commands and are kept low during the NOP commands that correspond to the burst request. The state of the other EMIF pins during each command can be found in Table 23-6.

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data manual. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands between various commands during an access. Refer to the register description of SDRAM_TR in the SDTIMER register for more details on the various timing parameters.

23.2.5.10 SDRAM Write Operations

When the EMIF receives a write request to SDRAM from one of the requesters listed in Section 23.2.2, the EMIF performs one or more write-access cycles. A write-access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a WRT command while specifying the desired bank and column address. EM1A[10] is held low during the WRT command to avoid auto-precharging. The WRT command signals the SDRAM device to start writing the given data to the specified address while the EMIF issues NOP commands. On this device, burst accesses are not supported; hence, the EMIF issues a WRITE command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM_CR) to 1 and CPU (or any other master) does a 32bit WRITE access, a burst access is issued with size of two.

Figure 23-7 shows the signal waveforms for a basic SDRAM write operation.

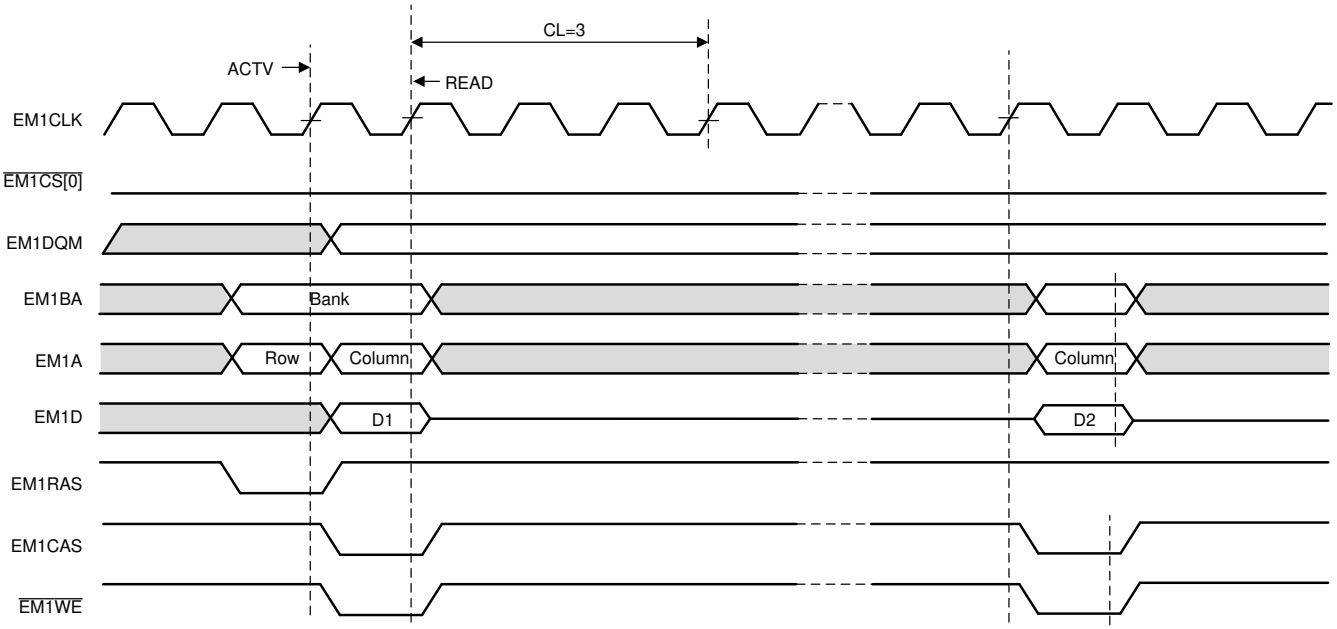

Figure 23-7. Timing Waveform for Basic SDRAM Write Operation

The EMIF truncates a series of bursting data if the remaining addresses of the burst are not part of the write request. The EMIF can truncate the burst in three ways:

- By issuing another WRT to the same page
- By issuing a PRE command to prepare for accessing a different page of the same bank
- By issuing a BT command to prepare for accessing a page in a different bank

Several other pins are also active during a write access. The EM1DQM[x:0] pins are driven to select which bytes of the data word are written to the SDRAM device. The pins are also used to mask out entire undesired data words during a burst access. The state of the other EMIF pins during each command can be found in Table 23-6.

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data sheet. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands during various cycles of an access. Refer to the register description of SDRAM_TR in the SDTIMR register for more details on the various timing parameters.

23.2.5.11 Mapping from Logical Address to EMIF Pins

When the EMIF receives an SDRAM access request, the EMIF must convert the address of the access into the appropriate signals to send to the SDRAM device. The details of this address mapping are shown in Table 23-14 for 32-bit operation and in Table 23-15 for 16-bit operation. Using the settings of the IBANK and PAGESIZE fields of the SDRAM configuration register (SDRAM_CR), the EMIF determines which bits of the logical address are mapped to the SDRAM row, column, and bank addresses.

As the logical address is incremented by one halfword (16-bit operation), the column address is likewise incremented by one until a page boundary is reached. When the logical address increments across a page boundary, the EMIF moves into the same page in the next bank of the attached device by incrementing the bank address EM1BA and resetting the column address. The page in the previous bank is left open until necessary to close the page. This method of traversal through the SDRAM banks helps maximize the number of open banks inside of the SDRAM and results in an efficient use of the device. There is no limitation on the number of banks that can be open at one time, but only one page within a bank can be open at a time.

The EMIF uses the EM1DQM[3:0] pins during a WRT command to mask out selected bytes or entire words. The EM1DQM[3:0] pins are always low during a READ command.

Table 23-14. Mapping from Logical Address to EMIF Pins for 32-bit SDRAM

IBANK	PAGESIZE	Logical Address													
		31:27	26	25	24	23	22	21:14	13	12	11	10	9	8:1	0
0	0	-						Row Address						Col Address	EM1DQM[2]/EM1DQM[3]
1	0	-						Row Address					EM1BA[0]	Col Address	EM1DQM[2]/EM1DQM[3]
2	0	-						Row Address				EM1BA[1:0]		Col Address	EM1DQM[2]/EM1DQM[3]
0	1	-						Row Address					Column Address		EM1DQM[2]/EM1DQM[3]
1	1	-						Row Address				EM1BA[0]	Column Address		EM1DQM[2]/EM1DQM[3]
2	1	-						Row Address			EM1BA[1:0]		Column Address		EM1DQM[2]/EM1DQM[3]
0	2	-						Row Address				Column Address			EM1DQM[2]/EM1DQM[3]
1	2	-						Row Address			EM1BA[0]	Column Address			EM1DQM[2]/EM1DQM[3]
2	2	-						Row Address		EM1BA[1:0]		Column Address			EM1DQM[2]/EM1DQM[3]
0	3	-						Row Address			Column Address				EM1DQM[2]/EM1DQM[3]
1	3	-						Row Address		EM1BA[0]	Column Address				EM1DQM[2]/EM1DQM[3]
2	3	-						Row Address		EM1BA[1:0]	Column Address				EM1DQM[2]/EM1DQM[3]

Table 23-15. Mapping from Logical Address to EMIF Pins for 16-bit SDRAM

IBANK	PAGESIZE	Logical Address												
		31:26	25	24	23	22	21	20:13	12	11	10	9	8	7:0
0	0	-						Row Address						Col Address
1	0	-						Row Address					EM1BA[0]	Col Address
2	0	-						Row Address				EM1BA[1:0]		Col Address
0	1	-						Row Address					Column Address	
1	1	-						Row Address				EM1BA[0]	Column Address	
2	1	-						Row Address			EM1BA[1:0]		Column Address	
0	2	-						Row Address				Column Address		
1	2	-						Row Address			EM1BA[0]	Column Address		
2	2	-						Row Address		EM1BA[1:0]		Column Address		
0	3	-						Row Address			Column Address			
1	3	-						Row Address		EM1BA[0]	Column Address			
2	3	-						Row Address		EM1BA[1:0]	Column Address			

Note

The upper bit of the row address is used only when addressing 256-Mbit and 512-Mbit SDRAM memories.

23.2.6 Asynchronous Controller and Interface

The EMIF easily interfaces to a variety of asynchronous devices including NOR Flash and SRAM. It can be operated in two major modes (see Table 23-16):

- Normal Mode
- Select Strobe Mode

Table 23-16. Normal Mode vs. Select Strobe Mode

Mode	Function of EM1DQM pins	Operation of $\overline{\text{EM1CS}}$[4:2]
Normal Mode	Byte enables	Active during the entire asynchronous access cycle
Select Strobe Mode	Byte enables	Active only during the strobe period of an access cycle

The first mode of operation is normal mode, in which the EM1DQM pins of the EMIF function as byte enables. In this mode, the $\overline{\text{EM1CS}}$[4:2] pins behave as typical chip select signals, remaining active for the duration of the asynchronous access. See Section 23.2.6.1 for an example interface with multiple 8-bit devices.

The second mode of operation is select strobe mode, in which the $\overline{\text{EM1CS}}$[4:2] pins act as a strobe, active only during the strobe period of an access. In this mode, the EM1DQM pins of the EMIF function as standard byte enables for reads and writes. A summary of the differences between the two modes of operation are shown in Table 23-16. Refer to Section 23.2.6.4 for the details of asynchronous operations in normal mode, and to Section 23.2.6.5 for the details of asynchronous operations in select strobe mode. The EMIF hardware defaults to normal mode, but can be manually switched to select strobe mode by setting the SS bit in the asynchronous *m* (m = 1, 2, 3, or 4) configuration register (CE*n*CFG) (*n* = 2, 3, or 4). Throughout the chapter, *m* can hold the values 1, 2, 3 or 4; and *n* can hold the values 2, 3, or 4.

The EMIF also provides configurable cycle timing parameters and an extended wait mode that allows the connected device to extend the strobe period of an access cycle. The following sections describe the features related to interfacing with external asynchronous devices.

23.2.6.1 Interfacing to Asynchronous Memory

Figure 23-8 shows the EMIF's external pins used in interfacing with an asynchronous device. In $\overline{\text{EM1CS}}$[n], n = 2, 3, or 4.

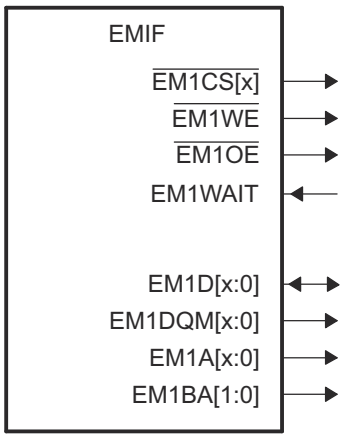

Figure 23-8. EMIF Asynchronous Interface

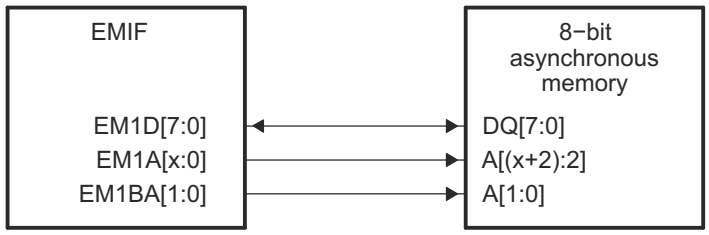
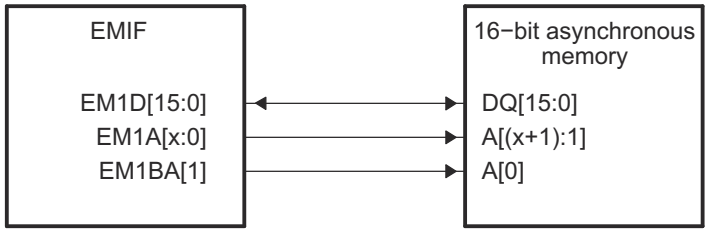
Of special note is the connection between the EMIF and the external device's address bus. The EMIF address pin EM1A[0] always provides the least-significant bit of a 32-bit word address. Therefore, when interfacing to a 16-bit or 8-bit asynchronous device, the EM1BA[1] and EM1BA[0] pins provide the least-significant bits of the halfword or byte address, respectively. Figure 23-9 and Figure 23-10 show the mapping between the EMIF and the connected device's data and address pins for various programmed data bus widths. The data bus width can be configured in the asynchronous *n* configuration register (ASYNC_CS*n*_CR).

Figure 23-10 shows an interface between the EMIF and an external memory with byte enables. The EMIF must be operated in either normal mode or select strobe mode when using this interface, so that the EM1DQM signals operate as byte enables.



a) EMIF to 8-bit memory interface



b) EMIF to 16-bit memory interface

Figure 23-9. EMIF to 8-bit/16-bit Memory Interface

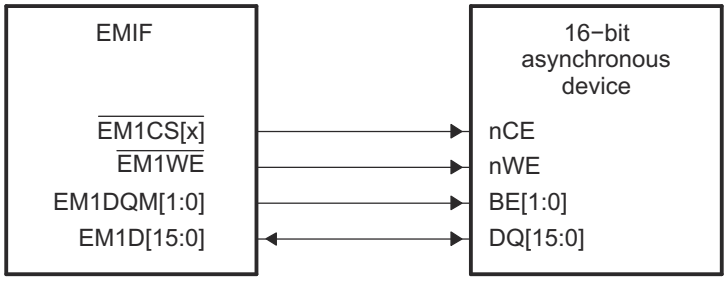


Figure 23-10. Common Asynchronous Interface

23.2.6.2 Accessing Larger Asynchronous Memories

If a device such as a large asynchronous Flash needs to be attached to the EMIF, then GPIO pins can be used to control the Flash device upper address lines.

23.2.6.3 Configuring EMIF for Asynchronous Accesses

The operation of the EMIF's asynchronous interface can be configured by programming the appropriate register fields. The reset value and bit position for each register field can be found in Section 23.4. The following tables list the register fields that can be programmed and describe the purpose of each field. These registers can be programmed prior to accessing the external memory, and the transfer following a write to these registers uses the new configuration.

Table 23-17. Description of the Asynchronous *m* Configuration Register (ASYNC_CSn_CR)

Parameter	Description
SS	**Select Strobe mode.** This bit selects the EMIF's mode of operation in the following way: • SS = 0 selects Normal Mode – EM1DQM pins function as byte enables – $\overline{\text{EM1CS}}$[4:2] active for duration of access • SS = 1 selects Select Strobe Mode – EM1DQM pins function as byte enables – $\overline{\text{EM1CS}}$[4:2] acts as a strobe.
EW	**Extended Wait Mode enable.** • EW = 0 disables extended wait mode • EW = 1 enables extended wait mode When set to 1, the EMIF enables the extended wait mode in which the strobe width of an access cycle can be extended in response to the assertion of the EM1WAIT pin. The WP*n* bit in the asynchronous wait cycle configuration register (ASYNC_WCCR) controls the polarity of the EM1WAIT pin. See Section 23.2.6.6 for more details on this mode of operation.
W_SETUP/R_SETUP	**Read/Write setup widths.** These fields define the number of EMIF clock cycles of setup time for the address pins (EM1A), byte enables (EM1DQM), and asynchronous chip enable ($\overline{\text{EM1CS}}$[4:2]) before the read strobe pin (EM103) or write strobe pin ($\overline{\text{EM1WE}}$) falls, minus one cycle. For writes, the W_SETUP field also defines the setup time for the data pins (EM1D). Refer to the asynchronous device 's data sheet to determine the appropriate setting for this field.
W_STROBE/R_STROBE	**Read/Write strobe widths.** These fields define the number of EMIF clock cycles between the falling and rising of the read strobe pin (EM103) or write strobe pin (EM1WEn), minus one cycle. If Extended Wait Mode is enabled by setting the EW field in the asynchronous *n* configuration register (ASYNC_CS*n*_CR), these fields must be set to a value greater than zero. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.
W_HOLD/R_HOLD	**Read/Write hold widths.** These fields define the number of EMIF clock cycles of hold time for the address pins (EM1A and EM1BA), byte enables (EM1DQM), and asynchronous chip enable ($\overline{\text{EM1CS}}$[4:2]) after the read strobe pin (EM103) or write strobe pin ($\overline{\text{EM1WE}}$) rises, minus one cycle. For writes, the W_HOLD field also defines the hold time for the data pins (EM1D). Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.
TA	**Minimum turnaround time.** This field defines the minimum number of EMIF clock cycles between asynchronous reads and writes, minus one cycle. The purpose of this feature is to avoid contention on the bus. The value written to this field also determines the number of cycles that are inserted between asynchronous accesses and SDRAM accesses. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.

Table 23-17. Description of the Asynchronous *m* Configuration Register (ASYNC_CSn_CR) (continued)

Parameter	Description
ASIZE	**Asynchronous Device Bus Width.** This field determines the data bus width of the asynchronous interface in the following way: • ASIZE = 0 selects an 8-bit bus • ASIZE = 1 selects a 16-bit bus • ASIZE = 2 selects a 32-bit bus The configuration of ASIZE determines the function of the EM1A and EM1BA pins as described in Section 23.2.6.1. This field also determines the number of external accesses required to fulfill a request generated by one of the sources mentioned in Section 23.2.2. For example, a request for a 32-bit word requires four external access when ASIZE = 0. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.

Table 23-18. Description of the Asynchronous Wait Cycle Configuration Register (ASYNC_WCCR)

Parameter	Description
WP*n*	**EM_WAIT Polarity.** • WP*n* = 0 selects active-low polarity • WP*n* = 1 selects active-high polarity When set to 1, the EMIF waits if the EM1WAIT pin is high. When cleared to 0, the EMIF waits if the EM1WAIT pin is low. The EMIF must have the Extended Wait Mode enabled for the EM1WAIT pin to affect the width of the strobe period.
MAX_EXT_WAIT	**Maximum Extended Wait Cycles.** This field configures the number of EMIF clock cycles the EMIF waits for the EM1WAIT pin to be deactivated during the strobe period of an access cycle. The maximum number of EMIF clock cycles the EMIF waits is determined by the following formula: Maximum Extended Wait Cycles = (MAX_EXT_WAIT + 1) × 16 If the EM1WAIT pin is not deactivated within the time specified by this field, the EMIF resumes the access cycle, registering whatever data is on the bus and proceeding to the hold period of the access cycle. This situation is referred to as an Asynchronous Timeout. An Asynchronous Timeout generates an interrupt, if the interrupt has been enabled in the EMIF interrupt mask set register (INT_MSK_SET). Refer to Section 23.2.9.1 for more information about EMIF interrupts.

Table 23-19. Description of EMIF Interrupt Mask Set Register (INT_MSK_SET)

Parameter	Description
WR_MASK_SET	**Wait Rise Mask Set.** Writing a 1 enables an interrupt to be generated when a rising edge on EM1WAIT occurs.
AT_MASK_SET	**Asynchronous Timeout Mask Set.** Writing a 1 to this bit enables an interrupt to be generated when an Asynchronous Timeout occurs.

Table 23-20. Description of EMIF Interrupt Mast Clear Register (INT_MSK_CLR)

Parameter	Description
WR_MASK_CLR	**Wait Rise Mask Clear.** Writing a 1 to this bit disables the interrupt, clearing the WR_MASK_SET bit in EMIF interrupt mask set register (INT_MSK_SET).
AT_MASK_CLR	**Asynchronous Timeout Mask Clear.** Writing a 1 to this bit prevents an interrupt from being generated when an Asynchronous Timeout occurs.

Note

The EMIF performs SDRAM refreshes even if the SDRAM interface is not used. If using only the ASRAM interface, then SDRAM refreshes impact the ASRAM performance. To avoid this, set PD=1 in the SDRAM_CR register (Emif1Regs.SDRAM_CR.bit.PD=1). This bit can be updated only if there are no pending EMIF accesses.

23.2.6.4 Read and Write Operations in Normal Mode

Normal mode is the asynchronous interface's default mode of operation. It is selected when the SS bit in the asynchronous *n* configuration register (ASYNC_CS*n*_CR) is cleared to 0. In this mode, the EM1DQM pins operate as byte enables. Section 23.2.6.4.1 and Section 23.2.6.4.2 explain the details of read and write operations while in normal mode.

23.2.6.4.1 Asynchronous Read Operations (Normal Mode)

Note

During an entire asynchronous read operation, the $\overline{\text{EM1WE}}$ pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in Section 23.2.2 request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 23.2.13. In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by EMIF until the entire request is fulfilled. The details of an asynchronous read operation in normal mode are described in Table 23-21. Also, Figure 23-11 shows an example timing diagram of a basic read operation.

Table 23-21. Asynchronous Read Operation in Normal Mode

Time Interval	Pin Activity in Normal Mode
Turnaround period	Once the read operation becomes the highest priority task for EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CS*n*_CR). Between each access (write or read), the EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS*n*_CR. • The address pins EM1A and EM1BA become valid and carry the values described in Section 23.2.6.1. • $\overline{\text{EM1CS}}$[4:2] falls to enable the external device (if not already low from a previous operation)

Table 23-21. Asynchronous Read Operation in Normal Mode (continued)

Time Interval	Pin Activity in Normal Mode
Strobe period	The following actions occur during the strobe period of a read operation: 1. $\overline{\text{EM1OE}}$ falls at the start of the strobe period 2. On the rising edge of the clock that is concurrent with the end of the strobe period: • $\overline{\text{EM1OE}}$ rises • The data on the EM1Dx bus is sampled by EMIF. In Figure 23-11, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. Section 23.2.6.6 contains more details on using the EM1WAIT pin.
End of the hold period	At the end of the hold period: • The address pins EM1A and EM1BA become invalid • $\overline{\text{EM1CS}}$[4:2] rises (if no more operations are required to complete the current request) The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turn-round cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, EMIF instead enters directly into the turnaround period for the pending read or write operation.

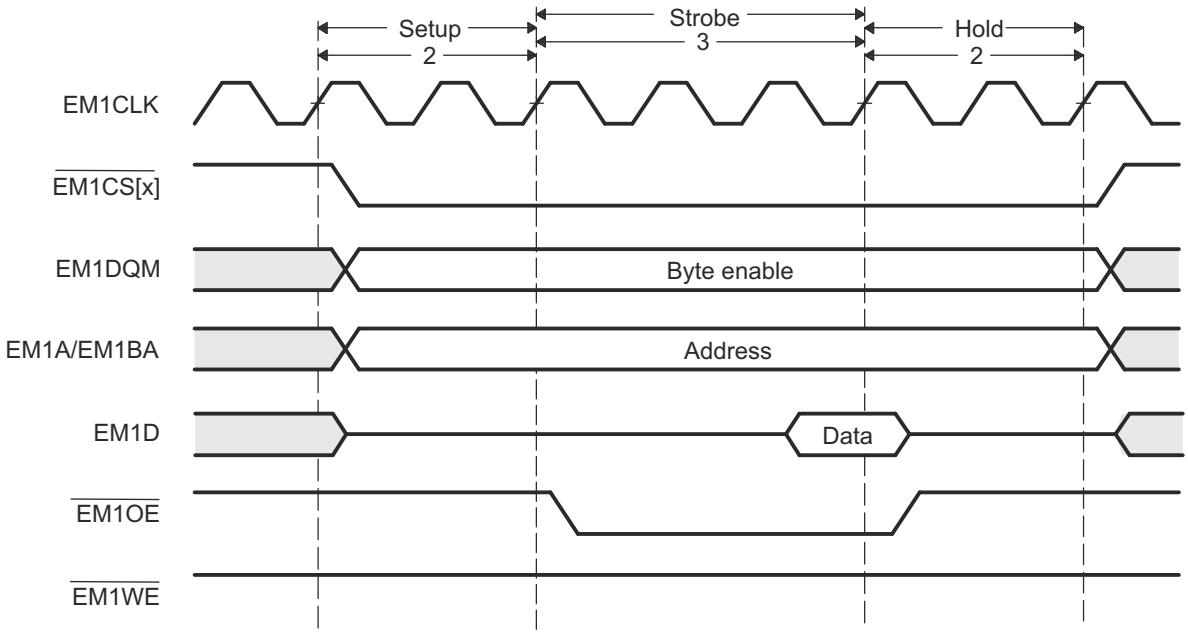

Figure 23-11. Timing Waveform of an Asynchronous Read Cycle in Normal Mode

23.2.6.4.2 Asynchronous Write Operations (Normal Mode)

Note

During an entire asynchronous write operation, the $\overline{\text{EM1OE}}$ pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in Section 23.2.2 request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 23.2.13. In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in normal mode are described in Table 23-22. Also, Figure 23-12 shows an example timing diagram of a basic write operation.

Table 23-22. Asynchronous Write Operation in Normal Mode

Time Interval	Pin Activity in Normal Mode
Turnaround period	Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CS*n*_CR). Between each access (write or read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CS*n*_CR. • The address pins EM1A and EM1BA and the data pins EM1Dx become valid. The EM1A and EM1BA pins carry the values described in Section 23.2.6.1. • $\overline{\text{EM1CS}}$[4:2] falls to enable the external device (if not already low from a previous operation).
Strobe period	The following actions occur at the start of the strobe period of a write operation: 1. $\overline{\text{EM1WE}}$ falls 2. The EM1DQM pins become valid as byte enables. The following actions occur on the rising edge of the clock that is concurrent with the end of the strobe period: 1. $\overline{\text{EM1WE}}$ rises 2. The EM1DQM pins deactivate In Figure 23-12, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to accept the data. Section 23.2.6.6 contains more details on using the EM1WAIT pin.
End of the hold period	At the end of the hold period: • The address pins EM1Ax and EM1BAx become invalid • The data pins become invalid • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) rises (if no more operations are required to complete the current request) The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.

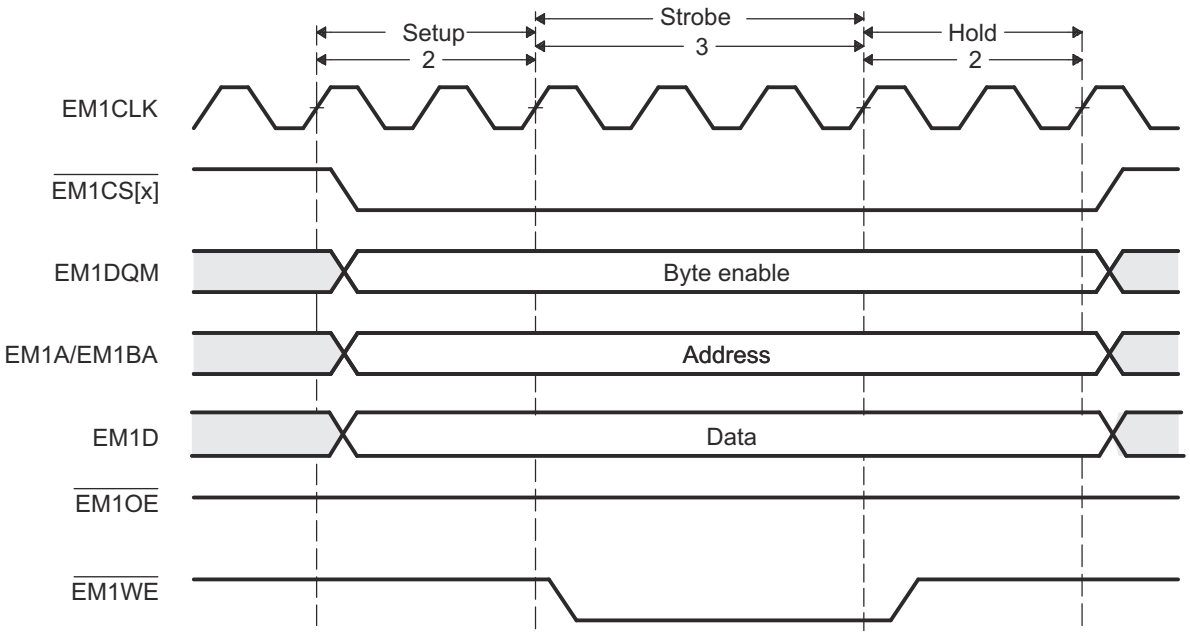

Figure 23-12. Timing Waveform of an Asynchronous Write Cycle in Normal Mode

23.2.6.5 Read and Write Operation in Select Strobe Mode

Select Strobe Mode is the EMIF's second mode of operation. It is selected when the SS bit of the asynchronous *n* configuration register (ASYNC_CSn_CR) is set to 1. In this mode, the EM1DQM pins operate as byte enables and the $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) pin is only active during the strobe period of an access cycle. Section 23.2.6.4.1 and Section 23.2.6.4.2 explain the details of read and write operations while in select strobe mode.

23.2.6.5.1 Asynchronous Read Operations (Select Strobe Mode)

Note

During the entirety of an asynchronous read operation, the EM1WEn pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in Section 23.2.2 request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 23.2.13. In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous read operation in select strobe mode are described in Table 23-23. Also, Figure 23-13 shows an example timing diagram of a basic read operation.

Table 23-23. Asynchronous Read Operation in Select Strobe Mode

Time Interval	Pin Activity in Select Strobe Mode
Turnaround period	Once the read operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CSn_CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS*n*_CR. • The address pins EM1A and EM1BA become valid and carry the values described in Section 23.2.6.1. • The EM1DQM pins become valid as byte enables.

Strobe period	The following actions occur during the strobe period of a read operation:
	1. $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1OE}}$ fall at the start of the strobe period
	2. On the rising edge of the clock that is concurrent with the end of the strobe period:
	  • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM10E}}$ rise
	  • The data on the EM1D bus is sampled by EMIF.
	In Figure 23-13, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give more time to provide the data. Section 23.2.6.6 contains more details on using the EM1WAIT pin.

End of the hold period	At the end of the hold period: • The address pins EM1A and EM1BA become invalid • The EM1DQM pins become invalid The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.

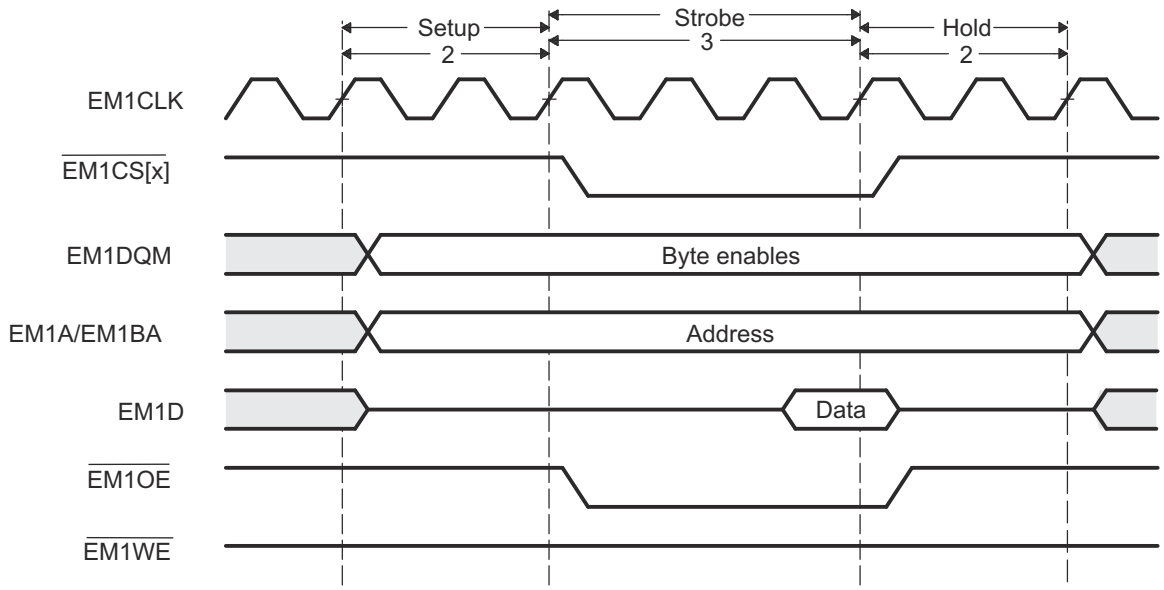

Figure 23-13. Timing Waveform of an Asynchronous Read Cycle in Select Strobe Mode

23.2.6.5.2 Asynchronous Write Operations (Select Strobe Mode)

Note

During the entirety of an asynchronous write operation, the $\overline{\text{EM1OE}}$ pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in Section 23.2.2 request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 23.2.13. In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in select strobe mode are described in Table 23-24. Also, Figure 23-14 shows an example timing diagram of a basic write operation.

Table 23-24. Asynchronous Write Operation in Select Strobe Mode

Time Interval	Pin Activity in Select Strobe Mode
Turnaround period	Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CSn_CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CSn_CR. • The address pins EM1A and EM1BA and the data pins EM1D become valid. The EM1A and EM1BA pins carry the values described in Section 23.2.6.1. • The EM1DQM pins become active as byte enables.
Strobe period	The following actions occur at the start of the strobe period of a write operation: • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1WE}}$ fall The following actions occur on the rising edge of the clock which is concurrent with the end of the strobe period: • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1WE}}$ rise In Figure 23-14, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give more time to accept the data. Section 23.2.6.6 contains more details on using the EM1WAIT pin.
End of the hold period	At the end of the hold period: • The address pins EM1A and EM1BA become invalid • The data pins become invalid • The EM1DQM pins become invalid The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.

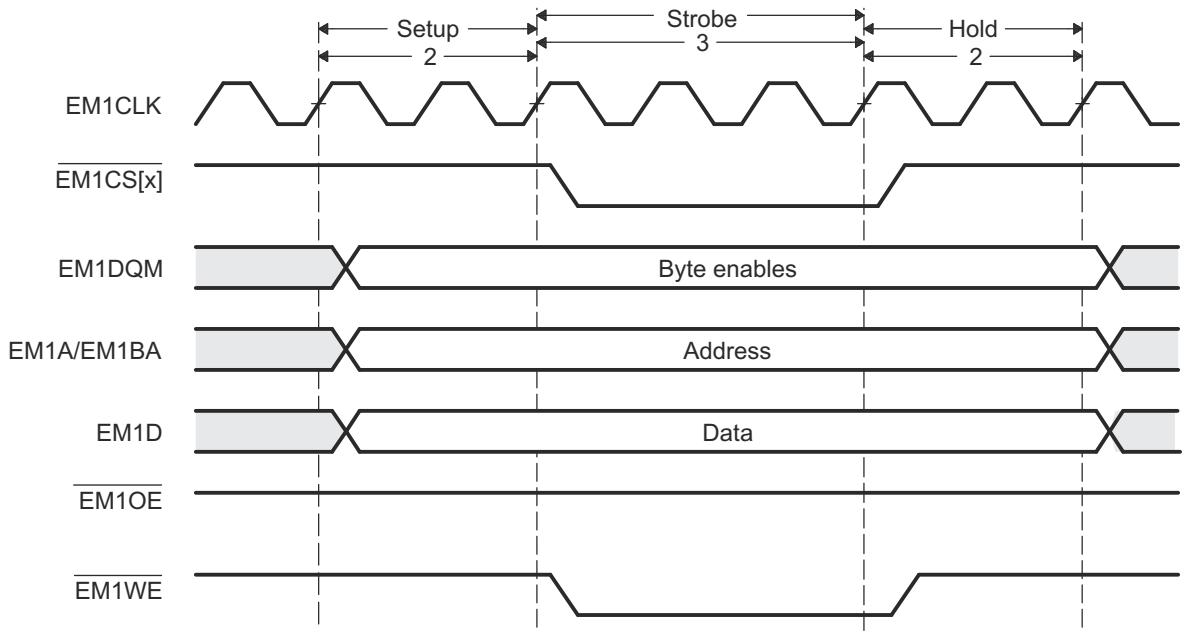

Figure 23-14. Timing Waveform of an Asynchronous Write Cycle in Select Strobe Mode

23.2.6.6 Extended Wait Mode and the EM1WAIT Pin

The EMIF supports the extended wait mode. This is a mode that the external asynchronous device can assert control over the length of the strobe period. The extended wait mode can be entered by setting the EW bit in the asynchronous *n* configuration register (ASYNC_CS*n*_CR (*n* = 2, 3, or 4). When this bit is set, the EMIF monitors the EM1WAIT pin to determine if the attached device wishes to extend the strobe period of the current access cycle beyond the programmed number of clock cycles.

When the EMIF detects that the EM1WAIT pin has been asserted, the EMIF begins inserting extra strobe cycles into the operation until the EM1WAIT pin is deactivated by the external device. The EMIF then returns to the last cycle of the programmed strobe period and the operation proceeds as usual from this point. Refer to the device data sheet for details on the timing requirements of the EM1WAIT signal.

The EM1WAIT pin cannot be used to extend the strobe period indefinitely. The programmable MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC) determines the maximum number of EM1CLK cycles the strobe period can be extended beyond the programmed length. When the counter expires, the EMIF proceeds to the hold period of the operation regardless of the state of the EM1WAIT pin. The EMIF can also generate an interrupt upon expiration of this counter. See Section 23.2.9.1 for details on enabling this interrupt.

For the EMIF to function properly in the extended wait mode, the WP*n* bit of AWCC must be programmed to match the polarity of the EM1WAIT pin. In the reset state of 1, the EMIF inserts wait cycles when the EM1WAIT pin is sampled high. When set to 0, the EMIF inserts wait cycles only when EM1WAIT is sampled low. This programmability allows for a glueless connection to larger variety of asynchronous devices.

Finally, a restriction is placed on the strobe period timing parameters when operating in extended wait mode. Specifically, the sum of the W_SETUP and W_STROBE fields must be greater than four, and the sum of the R_SETUP and R_STROBE fields must be greater than four for the EMIF to recognize the EM1WAIT pin has been asserted. The W_SETUP, W_STROBE, R_SETUP, and R_STROBE fields are in ASYNC_CS*n*_CR.

23.2.7 Data Bus Parking

The EMIF always drives the data bus to the previous write data value when the EMIF is idle. This feature is called data bus parking. Only when the EMIF issues a read command to the external memory does the EMIF stop driving the data bus. After the EMIF latches the last read data, the EMIF immediately parks the data bus again.

The one exception to this behavior occurs after performing an asynchronous read operation while the EMIF is in the self-refresh state. In this situation, the read operation is not followed by the EMIF parking the data bus. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state, to prevent floating inputs on the data bus. External pull-ups, such as 10-kohm resistors, must be placed on the 16 EMIF data bus pins (that do not have internal pull-ups) if required to perform reads in this situation. The precise resistor value must be chosen so that the worst case combined off-state leakage currents do not cause the voltage levels on the associated pins to drop below the high-level input voltage requirement.

For information about the self-refresh state, see Section 23.2.5.7.

23.2.8 Reset and Initialization Considerations

The EMIF memory controller has two active-low reset signals, CHIP_RST_n and MOD_G_RST_n. Both these reset signals are driven by the device system reset signal. This device does not offer the flexibility to reset just the EMIF state machine without also resetting the EMIF controller's memory-mapped registers. As soon as the device system reset is released (driven high), the EMIF memory controller immediately begins its initialization sequence. Command and data stored in the EMIF memory controller FIFOs are lost. Refer to Section 23.2 for more information on conditions that can cause a device system reset to be asserted.

When system reset is released, the EMIF automatically begins running the SDRAM initialization sequence described in Section 23.2.5.4. Even though the initialization procedure is automatic, a special procedure, found in Section 23.2.5.5 must still be followed.

23.2.9 Interrupt Support

The EMIF supports a single interrupt to the CPU. Section 23.2.9.1 details the generation and internal masking of EMIF interrupts.

23.2.9.1 Interrupt Events

There are three conditions that can cause the EMIF to generate an interrupt to the CPU. These conditions are:

- A rising edge on the EM1WAIT signal (wait rise interrupt)
- An asynchronous time out
- Usage of unsupported addressing mode (line trap interrupt)

The wait rise interrupt occurs when a rising edge is detected on EM1WAIT signal. This interrupt generation is not affected by the WP*n* bit in the asynchronous wait cycle configuration register (ASYNC_WCCR). The asynchronous time out interrupt condition occurs when the attached asynchronous device fails to deassert the EM1WAIT pin within the number of cycles defined by the MAX_EXT_WAIT bit in AWCC (this happens only in extended wait mode). The EMIF supports only linear incrementing and cache line wrap addressing modes . If an access request for an unsupported addressing mode is received, the EMIF sets the LT bit in the EMIF interrupt raw register (INT_RAW) and treats the request as a linear incrementing request.

Only when the interrupt is enabled by setting the appropriate bit (WR_MASK_SET/AT_MASK_SET/ LT_MASK_SET) in the EMIF interrupt mask set register (INT_MSK_SET) to 1, is the interrupt sent to the CPU. Once enabled, the interrupt can be disabled by writing a 1 to the corresponding bit in the EMIF interrupt mask clear register (INT_MSK_CLR). The bit fields in both the INT_MSK_SET and INT_MSK_CLR can be used to indicate whether the interrupt is enabled. When the interrupt is enabled, the corresponding bit field in both the INT_MSK_SET and INT_MSK_CLR have a value of 1; when the interrupt is disabled, the corresponding bit field has a value of 0.

The EMIF interrupt raw register (INT_RAW) and the IF interrupt mask register (INT_MSK) indicate the status of each interrupt. The appropriate bit (WR/AT/LT) in INT_RAW is set when the interrupt condition occurs, whether or not the interrupt has been enabled. However, the appropriate bit (WR_MASKED/AT_MASKED/LT_MASKED) in INT_MSK is set only when the interrupt condition occurs and the interrupt is enabled. Writing a 1 to the bit in INT_RAW clears the INT_RAW bit as well as the corresponding bit in INT_MSK. Table 23-25 contains a brief summary of the interrupt status and control bit fields. See for complete details on the register fields.

Table 23-25. Interrupt Monitor and Control Bit Fields

Register Name	Bit Name	Description
EMIF interrupt raw register (INT_RAW)	WR	This bit is set when an rising edge on the EM1WAIT signal occurs. Writing a 1 clears the WR bit as well as the WR_MASKED bit in INT_MSK.
	AT	This bit is set when an asynchronous timeout occurs. Writing a 1 clears the AT bit as well as the AT_MASKED bit in INT_MSK.
	LT	This bit is set when an unsupported addressing mode is used. Writing a 1 clears LT bit as well as the LT_MASKED bit in INT_MSK.
EMIF interrupt mask register (INT_MSK)	WR_MASKED	This bit is set only when a rising edge on the EM1WAIT signal occurs and the interrupt has been enabled by writing a 1 to the WR_MASK_SET bit in INT_MSK_SET.
	AT_MASKED	This bit is set only when an asynchronous timeout occurs and the interrupt has been enabled by writing a 1 to the AT_MASK_SET bit in INT_MSK_SET.
	LT_MASKED	This bit is set only when line trap interrupt occurs and the interrupt has been enabled by writing a 1 to the LT_MASK_SET bit in INT_MSK_SET.
EMIF interrupt mask set register (INT_MSK_SET)	WR_MASK_SET	Writing a 1 to this bit enables the wait rise interrupt.
	AT_MASK_SET	Writing a 1 to this bit enables the asynchronous timeout interrupt.
	LT_MASK_SET	Writing a 1 to this bit enables the line trap interrupt.
EMIF interrupt mask clear register (INT_MSK_CLR)	WR_MASK_CLR	Writing a 1 to this bit disables the wait rise interrupt.
	AT_MASK_CLR	Writing a 1 to this bit disables the asynchronous timeout interrupt.
	LT_MASK_CLR	Writing a 1 to this bit disables the line trap interrupt.

23.2.10 DMA Event Support

The EMIF memory controller is a DMA slave peripheral and therefore does not generate DMA events. Data read and write requests can be made directly, by masters and the DMA.

23.2.11 EMIF Signal Multiplexing

For details on the EMIF signal multiplexing, see the *GPIO* chapter, I/O Multiplexing Module section, of this technical reference manual.

23.2.12 Memory Map

For information describing the device memory-map, see the data sheet.

23.2.13 Priority and Arbitration

Section 23.2.2 describes the external prioritization and arbitration among requests from different sources within the microcontroller. The result of this external arbitration is that only one request is presented to the EMIF at a time. Once the EMIF completes a request, the external arbiter then provides the EMIF with the next pending request.

Internally, the EMIF undertakes memory device transactions according to a strict priority scheme. The highest priority events are:

- A device reset.
- A write to any of the three least significant bytes of the SDRAM configuration register (SDRAM_CR).

Either of these events causes the EMIF to immediately commence the initialization sequence as described in Section 23.2.5.4.

Once the EMIF has completed its initialization sequence, the EMIF performs memory transactions according to the following priority scheme (highest priority listed first):

1. If the EMIF's backlog refresh counter is at the Refresh Must urgency level, the EMIF performs multiple SDRAM auto-refresh cycles until the Refresh Release urgency level is reached.
2. If an SDRAM or asynchronous read has been requested, the EMIF performs a read operation.
3. If the EMIF's backlog refresh counter is at the Refresh Need urgency level, the EMIF performs an SDRAM auto-refresh cycle.
4. If an SDRAM or asynchronous write has been requested, the EMIF performs a write operation.
5. If the EMIF's backlog refresh counter is at the Refresh May or Refresh Release urgency level, the EMIF performs an SDRAM auto-refresh cycle.
6. If the value of the SR bit in SDRAM_CR has been set to 1, the EMIF enters the self-refresh state as described in Section 23.2.5.7.

After taking one of the actions listed above, the EMIF then returns to the top of the priority list to determine the next action.

Because the EMIF does not issue auto-refresh cycles when in the self-refresh state, the above priority scheme does not apply when in this state. See Section 23.2.5.7 for details on the operation of the EMIF when in the self-refresh state.

23.2.14 System Considerations

This section describes various system considerations to keep in mind when operating the EMIF.

23.2.14.1 Asynchronous Request Times

In a system that interfaces to both SDRAM and asynchronous memory, the asynchronous requests must not take longer than the smaller of the following two values:

- t_{RAS} (typically 120 µs) - to avoid violating the maximum time allowed between issuing an ACTV and PRE command to the SDRAM.
- $t_{Refresh\ Rate}$ × 11 (typically 15.7 µs × 11 = 172.7 µs) - to avoid refresh violations on the SDRAM.

The length of an asynchronous request is controlled by multiple factors, the primary factor being the number of access cycles required to complete the request. For example, an asynchronous request for 4 bytes requires four access cycles using an 8-bit data bus and only two access cycle using a 16-bit data bus. The maximum request size that the EMIF can be sent is 16 words; therefore, the maximum number of access cycles per memory request is 64 when the EMIF is configured with an 8-bit data bus. The length of the individual access cycles that make up the asynchronous request is determined by the programmed setup, strobe, hold, and turnaround values, but can also be extended with the assertion of the EM1WAIT input signal up to a programmed maximum limit. The user must make sure that an entire asynchronous request does not exceed the timing values listed above when also interfacing to an SDRAM device. This can be done by limiting the asynchronous timing parameters.

23.2.15 Power Management

Power dissipation from the EMIF memory controller can be managed by following methods:

- Self-refresh mode
- Power-down mode
- Gating input clocks to the module off

Gating input clocks off to the EMIF memory controller achieves higher power savings when compared to the power savings of self-refresh or power down mode. The input clock to EMIF can be turned off through the use of the Global Clock Module (GCM). Before gating clocks off, the EMIF memory controller must place the SDR SDRAM memory in self-refresh mode. If the external memory requires a continuous clock, the VCLK3 clock domain must not be turned off because this can result in data corruption. See the following subsections for the proper procedures to follow when stopping EMIF memory controller clocks.

23.2.15.1 Power Management Using Self-Refresh Mode

The EMIF memory controller can be placed into a self-refresh state in order to place the attached SDRAM devices into self-refresh mode, which consumes less power for most SDRAM devices. In this state, the attached SDRAM device uses an internal clock to perform its own auto refresh cycles. This maintains the validity of the data in the SDRAM without the need for any external commands. Refer to Section 23.2.5.7 for more details on placing the EMIF into the self-refresh state.

23.2.15.2 Power Management Using Power Down Mode

In the power down mode, the EMIF drives EM1SDCKE low to lower the power consumption. EM1SDCKE goes high when there is a need to send refresh (REFR) commands, after which EM1SDCKE is again driven low. EM1SDCKE remains low until any request arrives. Refer to Section 23.2.5.8 for more details on placing the EMIF in power-down mode.

23.2.16 Emulation Considerations

The EMIF remains fully functional during emulation halts in order to allow emulation access to external memory.

23.3 Example Configuration

This section presents an example of interfacing the EMIF1 to both an SDR SDRAM device and an asynchronous Flash device.

23.3.1 Hardware Interface

Figure 23-15 shows the hardware interface between the EMIF, a Samsung K4S641632H-TC(L)70 64Mb SDRAM device, and a SHARP LH28F800BJE-PTTL90 8Mb Flash memory. The connection between EMIF and the SDRAM is straightforward, but the connection between the EMIF and the Flash deserves a detailed look.

The address inputs for the Flash are provided by three sources. The A[18:0] address inputs are provided by a combination of the EM1A and EM1BA pins according to Section 23.2.6.1, and a set of GPIO pins. The RD/nBY signal from Flash is connected to EM1WAIT pin of the EMIF.

Finally, this example configuration connects the $\overline{\text{EM1WE}}$ pin to the nWE input of the Flash and operates the EMIF in select strobe mode.

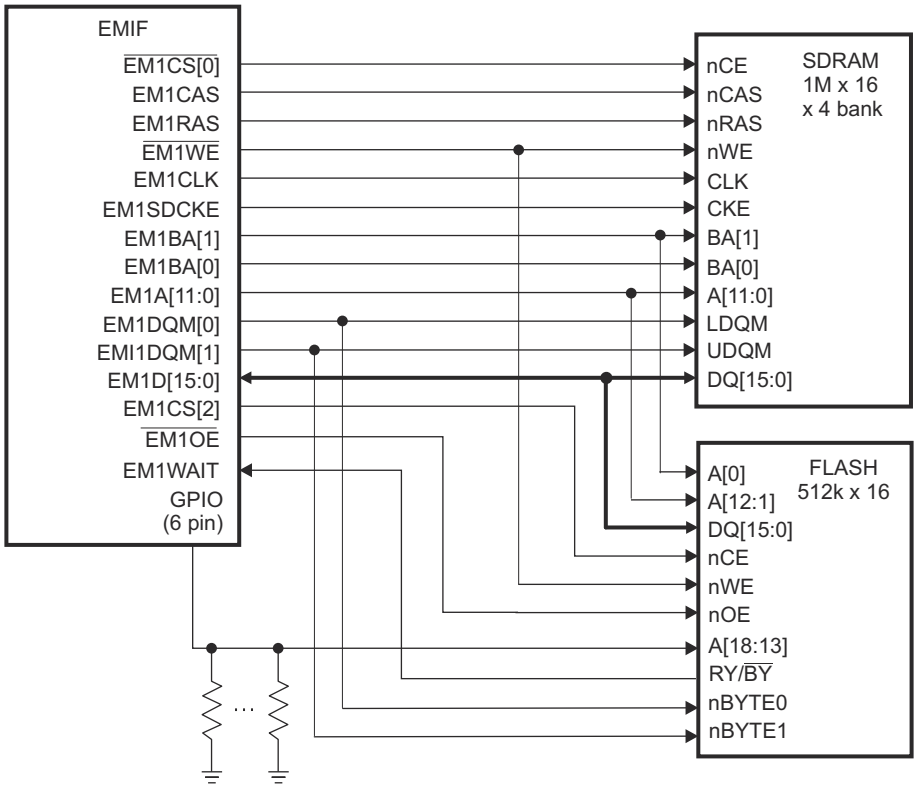

Figure 23-15. Example Configuration Interface

23.3.2 Software Configuration

The following sections describe how to configure the EMIF registers and bit fields to interface the EMIF with the Samsung K4S641632H-TC(L)70 SDRAM and the SHARP LH28F800BJE-PTTL90 8Mb Flash memory.

23.3.2.1 Configuring the SDRAM Interface

This section describes how to configure the EMIF to interface with the Samsung K4S641632H-TC(L)70 SDRAM with a clock frequency of f_{EM1CLK} = 100MHz. Procedure A described in Section 23.2.5.5 is followed that assumes that the SDRAM power-up timing constraints were met during the SDRAM auto-initialization sequence after reset.

23.3.2.1.1 PLL Programming for EMIF to K4S641632H-TC(L)70 Interface

If the system PLL is programmed to provide a SYSCLK frequency > 100MHz, then configure the EMIF1CLKDIV field in the PERSYSCLKDIVSEL register to make EM1CLK = SYSCLK/2 (default configuration). Before doing this, the SDRAM must be placed in self-refresh mode by setting the SR bit in the SDRAM configuration register. Once the EM1CLK frequency has been configured, remove the SDRAM from self-refresh by clearing the SR bit in SDRAM_CR.

Table 23-26. SR Field Value For EMIF to K4S641632H-TC(L)70 Interface

Field	Value	Purpose
SR	1 then 0	To place the EMIF into the self-refresh state

23.3.2.1.2 SDRAM Timing Register (SDRAM_TR) Settings for EMIF to K4S641632H-TC(L)70 Interface

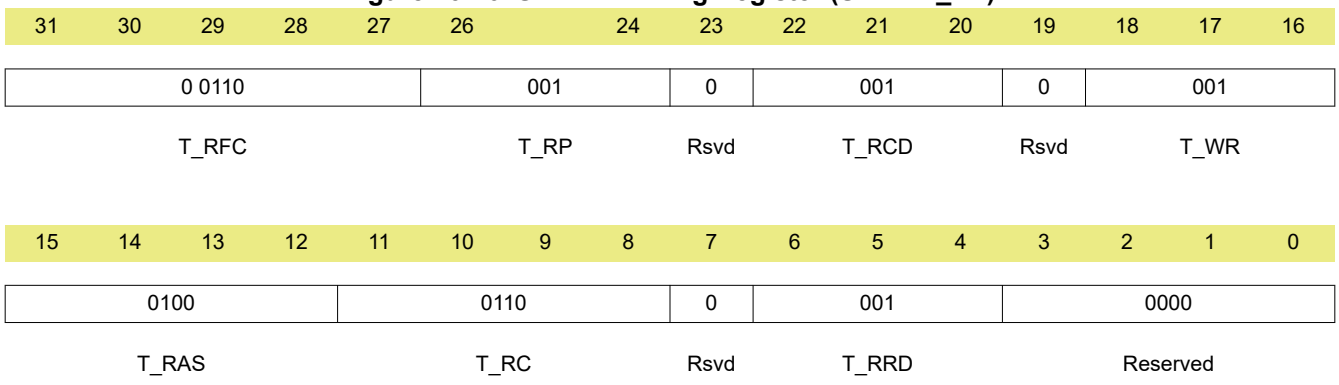
The fields of the SDRAM timing register (SDRAM_TR) must be programmed first as described in Table 23-27 to satisfy the required timing parameters for the K4S641632H-TC(L)70. Based on these calculations, a value of 6111 4610h must be written to the SDRAM_TR. Figure 23-16 shows a graphical description of how the SDRAM_TR must be programmed.

Table 23-27. SDRAM_TR Field Calculations for EMIF to K4S641632H-TC(L)70 Interface

Field Name	Formula	Value from K4S641632H-TC(L)70 Data Sheet	Value Calculated for Field
T_RFC	T_RFC >= (t_{RFC} × f_{EM1CLK}) - 1	t_{RC} = 68 ns (min)(1)	6
T_RP	T_RP >= (t_{RP} × f_{EM1CLK}) - 1	t_{RP} = 20 ns (min)	1
T_RCD	T_RCD >= (t_{RCD} × f_{EM1CLK}) - 1	t_{RCD} = 20 ns (min)	1
T_WR	T_WR >= (t_{WR} × f_{EM1CLK}) - 1	t_{RDL} = 2 CLK = 20 ns (min)(2)	1
T_RAS	T_RAS >= (t_{RAS} × f_{EM1CLK}) - 1	t_{RAS} = 49 ns (min)	4
T_RC	T_RC >= (t_{RC} × f_{EM1CLK}) - 1	t_{RC} = 68 ns (min)	6
T_RRD	T_RRD >= (t_{RRD} × f_{EM1CLK}) - 1	t_{RRD} = 14 ns (min)	1

(1) The Samsung data sheet does not specify a t_{RFC} value. Instead, Samsung specifies t_{RC} as the minimum auto refresh period.
(2) The Samsung data sheet does not specify a t_{WR} value. Instead, Samsung specifies t_{RDL} as last data in to row precharge minimum delay.

Figure 23-16. SDRAM Timing Register (SDRAM_TR)



23.3.2.1.3 SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM self-refresh exit timing register (SDSRETR) must be programmed second to satisfy the t_{XSR} timing requirement from the K4S641632H-TC(L)70 data sheet. Table 23-28 shows the calculation of the proper value to program into the T_XS field of this register. Based on this calculation, a value of 6h must be written to the SDSRETR. Figure 23-17 shows how the SDSRETR must be programmed.

Table 23-28. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface

Field Name	Formula	Value from K4S641632H-TC(L)70 Data Sheet	Value Calculated for Field
T_XS	T_XS >= (t_{XSR} × f_{EM1CLK}) - 1	t_{RC} = 68 ns (min)(1)	6

(1) The Samsung data sheet does not specify a t_{XSR} value. Instead, Samsung specifies t_{RC} as the minimum required time after CKE going high to complete self-refresh exit.

23.3.2.1.4 SDRAM Refresh Control Register (SDRAM_RCR) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM refresh control register (SDRAM_RCR) can next be programmed to satisfy the required refresh rate of the K4S641632H-TC(L)70. Table 23-29 shows the calculation of the proper value to program into the RR field of this register. Based on this calculation, a value of 61Ah must be written to the SDRAM_RCR. Figure 23-18 shows how the SDRAM_RCR must be programmed.

Table 23-29. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface

Field Name	Formula	Values	Value Calculated for Field
RR	RR ≤ f_{EM1CLK} × $t_{Refresh\ Period}$ / n_{cycles}	From SDRAM data sheet: $t_{Refresh\ Period}$ = 64ms; n_{cycles} = 4096 EMIF clock rate: f_{EM1CLK} = 100MHz	RR = 1562 cycles = 61Ah cycles

Figure 23-18. SDRAM Refresh Control Register (SDRAM_RCR)

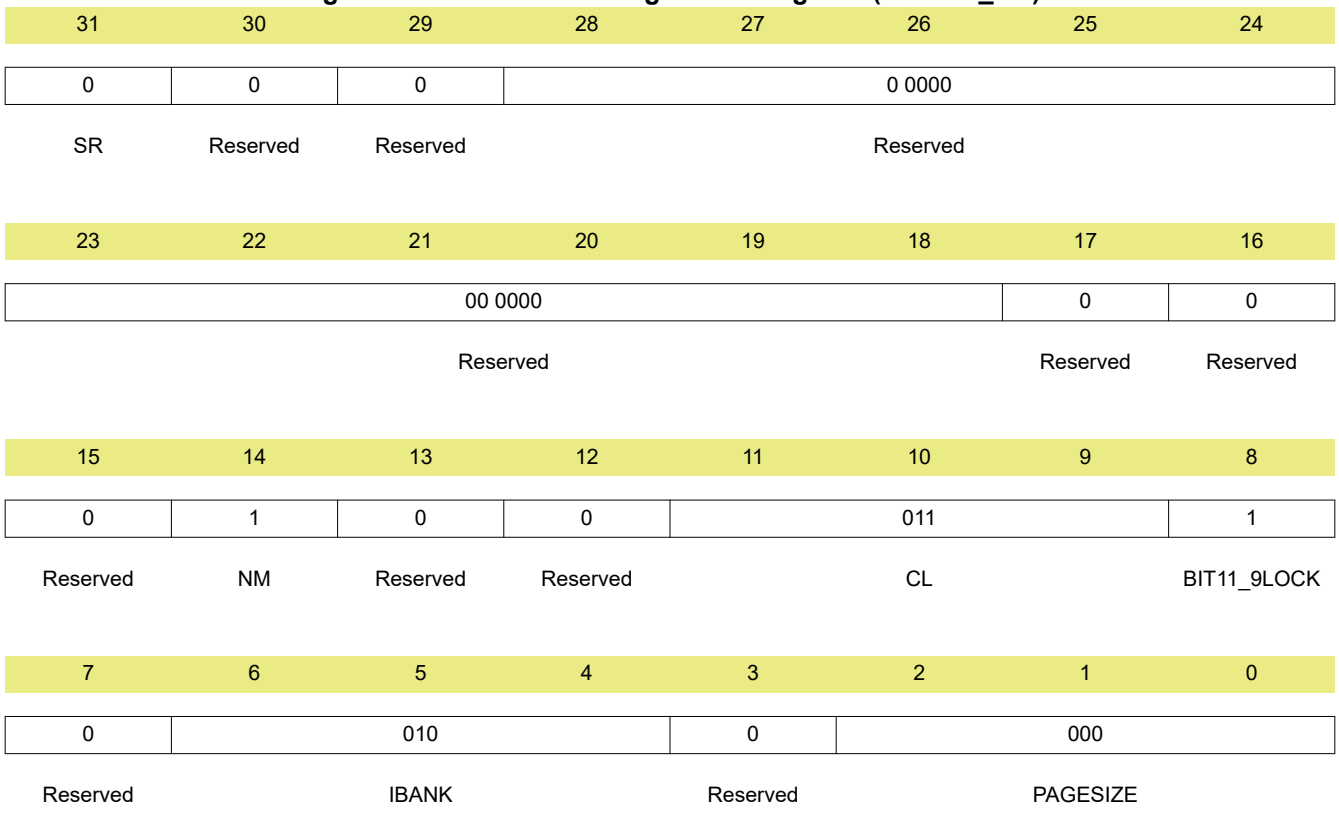
23.3.2.1.5 SDRAM Configuration Register (SDRAM_CR) Settings for EMIF to K4S641632H-TC(L)70 Interface

Finally, the fields of the SDRAM configuration register (SDRAM_CR) must be programmed as described in Table 23-30 to properly interface with the K4S641632H-TC(L)70 device. Based on these settings, a value of 4720h must be written to the SDRAM_CR. Figure 23-19 shows how the SDRAM_CR must be programmed. The EMIF is now ready to perform read and write accesses to the SDRAM.

Table 23-30. SDRAM_CR Field Values For EMIF to K4S641632H-TC(L)70 Interface

Field	Value	Purpose
SR	0	To avoid placing the EMIF into the self-refresh state
NM	1	To configure the EMIF for a 16-bit data bus
CL	011b	To select a CAS latency of 3
BIT11_9LOCK	1	To allow the CL field to be written
IBANK	010b	To select 4 internal SDRAM banks
PAGESIZE	0	To select a page size of 256 words

Figure 23-19. SDRAM Configuration Register (SDRAM_CR)



23.3.2.2 Configuring the Flash Interface

This section describes how to configure the EMIF to interface with the SHARP LH28F800BJE-PTTL90 8Mb Flash memory with a clock frequency of f_{EM1CLK} = 100MHz.

23.3.2.2.1 Asynchronous 1 Configuration Register (ASYNC_CS2_CFG) Settings for EMIF to LH28F800BJE-PTTL90 Interface

The asynchronous 1 configuration register (ASYNC_CS2_CFG) is the only register that is necessary to program for this asynchronous interface. The SS bit must be set to 1 to enable select strobe command and the ASIZE field can be set to 1 to select a 16-bit interface. The other fields in this register control the shaping of the EMIF signals, and the proper values can be determined by referring to the AC Characteristics in the Flash data sheet and the device data sheet. Table 23-31 and Table 23-32 show the pertinent AC Characteristics for reads and writes to the Flash device, and Figure 23-20 and Figure 23-21 show the associated timing waveforms. Finally, Figure 23-22 shows programming the ASYNC_CS2_CFG with the calculated values.

Table 23-31. AC Characteristics for a Read Access

AC Characteristic	Device	Definition	Minimum	Maximum	Unit
t_{SU}	EMIF	Setup time, read EM1D before EM1OE high	15		ns
t_H	EMIF	Data hold time, read EM1D after EM1OE high	0		ns
t_{ELQV}	Flash	nCE to Output Delay		90	ns
t_{EHQZ}	Flash	nCE High to Output in High Impedance		55	ns

Table 23-32. AC Characteristics for a Write Access

AC Characteristic	Device	Definition	Minimum	Maximum	Unit
t_{AVAV}	Flash	Write Cycle Time	90		ns
t_{ELEH}	Flash	nCE Pulse Width Low	50		ns
t_{EHEL}	Flash	nCE Pulse Width High (not shown in Figure 23-21)	30		ns

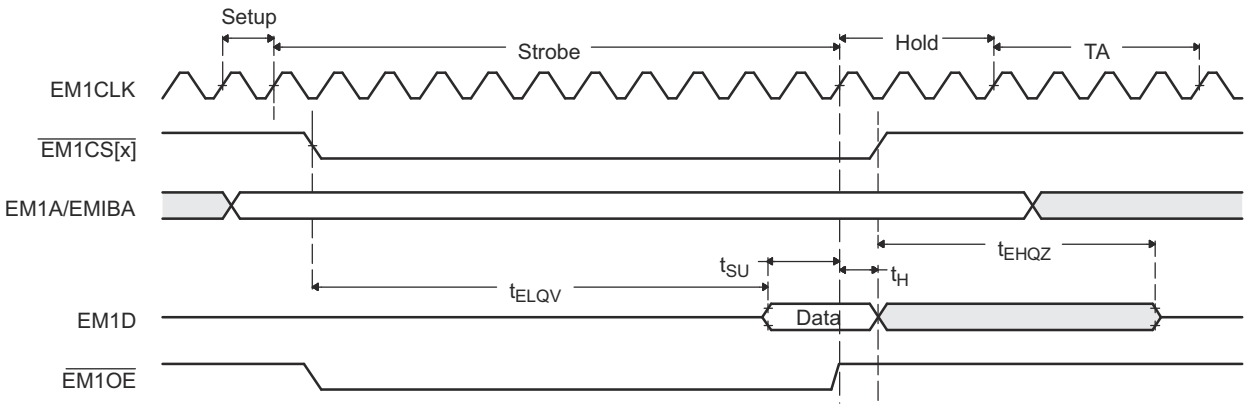


Figure 23-20. LH28F800BJE-PTTL90 to EMIF Read Timing Waveforms

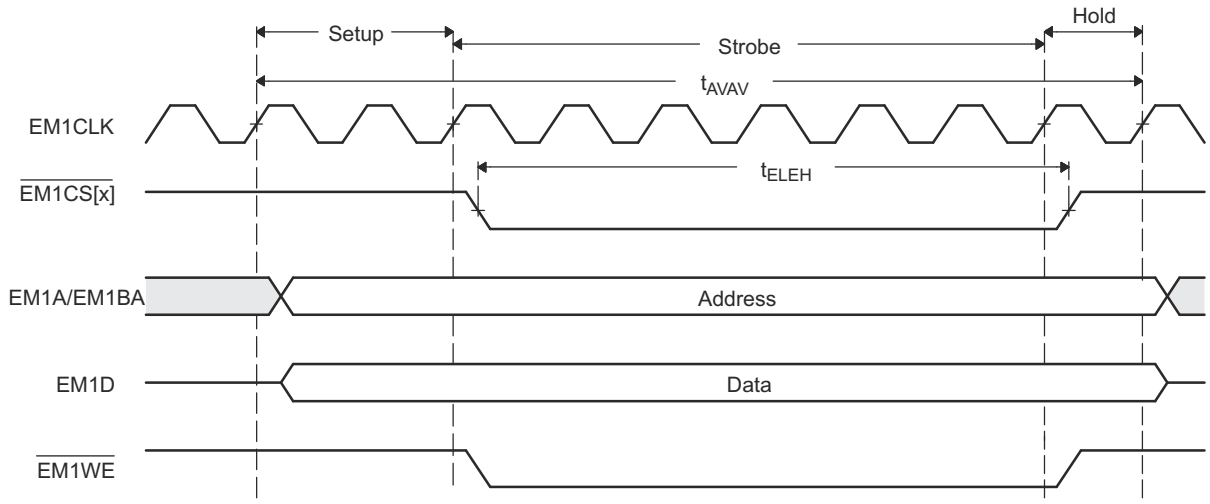

Figure 23-21. LH28F800BJE-PTTL90 to EMIF Write Timing Waveforms

The R_STROBE field must be set to meet the following equation:

$R\_STROBE >= (t_{ELQV} + t_{SU}) \times f_{EM1CLK} - 1$

$R\_STROBE >= (90ns + 15ns) \times 200MHz - 1$

$R\_STROBE >= 20$

$R\_STROBE = 20$

The R_HOLD field must be large enough to satisfy EMIF Data hold time, t_H:

$R\_HOLD > = t_H \times f_{EM1CLK} - 1$

$R\_HOLD >= 0ns \times 200MHz - 1$

$R\_HOLD >= -1$

The R_HOLD field must also combine with the TA field to satisfy the Flash nCE High to Output in High Impedance time, t_{EHQZ}:

$R\_HOLD + TA >= t_{EHQZ} \times f_{EM1CLK} - 2$

$R\_HOLD + TA >= 55ns \times 200MHz - 2$

$R\_HOLD + TA >= 9$

The largest value that can be programmed into the TA field is 3h, therefore the following values must be used:

R_HOLD = 6

TA = 3

For Writes, the W_STROBE field must be set to satisfy the Flash nCE Pulse Width constraint, t_{ELEH}:

$W\_STROBE >= t_{ELEH} \times f_{EM1CLK} - 1$

$W\_STROBE >= 50ns \times 200MHz - 1$

$W\_STROBE >= 9$

The W_SETUP and W_HOLD fields must combine to satisfy the Flash nCE Pulse Width High constraint, t_{EHEL}:

W_SETUP + W_HOLD > = t_{EHEL} × f_{EM1CLK} - 2

W_SETUP + W_HOLD > = 30ns × 200MHz - 2

W_SETUP + W_HOLD > = 4

In addition, the entire Write access length must satisfy the Flash minimum Write Cycle Time, t_{AVAV}:

W_SETUP + W_STROBE + W_HOLD >= t_{AVAV} × f_{EM1CLK} - 3

W_SETUP + W_STROBE + W_HOLD >= 90ns × 200MHz - 3

W_SETUP + W_STROBE + W_HOLD >= 15

Solving the above equations for the Write fields results in the following:

W_SETUP = 4

W_STROBE = 10

W_HOLD = 1

Adding a 5ns (1 cycle) margin to each of the periods (excluding TA that is already at the maximum) in this example produces the following recommended values:

W_SETUP = 5h

W_STROBE = Bh

W_HOLD = 2h

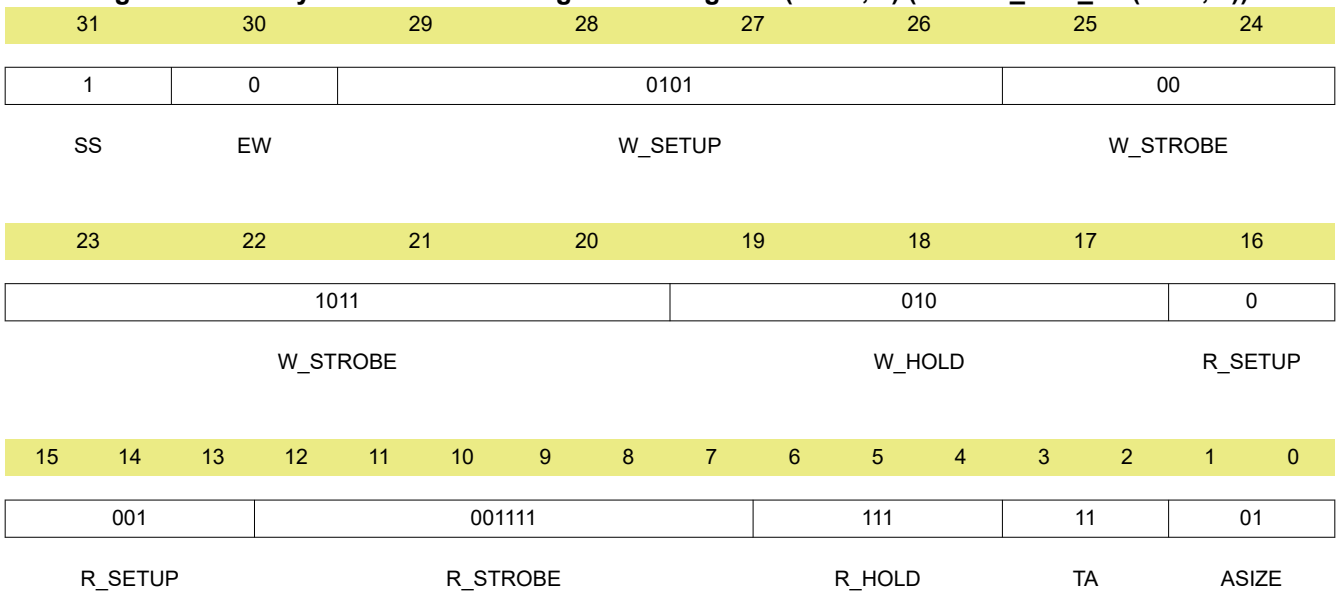
R_SETUP = 1h

R_STROBE = 15h

R_HOLD = 7h

TA = 3h

Figure 23-22. Asynchronous *m* Configuration Register (*m* = 1, 2) (ASYNC_CS*n*_CR(*n* = 2, 3))



23.4 EMIF Registers

This section describes the External Memory Interface Registers.

23.4.1 EMIF Base Addresses

Table 23-33. EMIF Base Address Table

Device Registers	Register Name	Start Address	End Address
Emif1Regs	EMIF_REGS	0x0004_7000	0x0004_77FF
Emif2Regs(1)	EMIF_REGS	0x0004_7800	0x0004_7FFF
Emif1ConfigRegs	EMIF1_CONFIG_REGS	0x0005_F480	0x0005_F49F
Emif2ConfigRegs	EMIF2_CONFIG_REGS	0x0005_F4A0	0x0005_F4BF

(1) Only available on CPU1.

23.4.2 EMIF_REGS Registers

Table 23-34 lists the memory-mapped registers for the EMIF_REGS registers. All register offset addresses not listed in Table 23-34 should be considered as reserved locations and the register contents should not be modified.

Table 23-34. EMIF_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	RCSR	Revision Code and Status Register		Go
2h	ASYNC_WCCR	Async Wait Cycle Config Register		Go
4h	SDRAM_CR	SDRAM (EMxCS0n) Config Register		Go
6h	SDRAM_RCR	SDRAM Refresh Control Register		Go
8h	ASYNC_CS2_CR	Async 1 (EMxCS2n) Config Register		Go
Ah	ASYNC_CS3_CR	Async 2 (EMxCS3n) Config Register		Go
Ch	ASYNC_CS4_CR	Async 3 (EMxCS4n) Config Register		Go
10h	SDRAM_TR	SDRAM Timing Register		Go
18h	TOTAL_SDRAM_AR	Total SDRAM Accesses Register		Go
1Ah	TOTAL_SDRAM_ACTR	Total SDRAM Activate Register		Go
1Eh	SDR_EXT_TMNG	SDRAM SR/PD Exit Timing Register		Go
20h	INT_RAW	Interrupt Raw Register		Go
22h	INT_MSK	Interrupt Masked Register		Go
24h	INT_MSK_SET	Interrupt Mask Set Register		Go
26h	INT_MSK_CLR	Interrupt Mask Clear Register		Go

Complex bit access types are encoded to fit into small table cells. Table 23-35 shows the codes that are used for access types in this section.

Table 23-35. EMIF_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

23.4.2.1 RCSR Register (Offset = 0h) [Reset = 40000205h]

RCSR is shown in Figure 23-23 and described in Table 23-36.

Return to the Summary Table.

Table 23-41. ASYNC_CS3_CR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SS	R/W	0h	Select Strobe mode. Set to 1 if chip selects need to have write or read strobe timing. Reset type: SYSRSn
30	EW	R/W	0h	Extend Wait mode. Set to 1 if extended asynchronous cycles are required based on EMxWAIT. Reset type: SYSRSn
29-26	W_SETUP	R/W	Fh	Write Strobe Setup cycles. Number of EMxCLK cycles from EMxAy, EMxBAy, EMxDQMy, and EMxCS3n being set to EMxWEn asserted, minus one cycle. The reset value is 16 cycles. Reset type: SYSRSn
25-20	W_STROBE	R/W	3Fh	Write Strobe Duration cycles. Number of EMxCLK cycles for which EMxWEn is held active, minus one cycle. The reset value is 64 cycles. This field cannot be zero when ew = 1. Reset type: SYSRSn
19-17	W_HOLD	R/W	7h	Write Strobe Hold cycles. Number of EMxCLK cycles for which EMxAy, EMxBAy, EMxDQMy, and EMxCS3n are held after EMxWEn has been deasserted, minus one cycle. The reset value is 8 cycles. Reset type: SYSRSn
16-13	R_SETUP	R/W	Fh	Read Strobe Setup cycles. Number of EMxCLK cycles from EMxAy, EMxBAy, EMxDQMy, and EMxCS3n being set to EMxOEn asserted, minus one cycle. The reset value is 16 cycles. Reset type: SYSRSn
12-7	R_STROBE	R/W	3Fh	Read Strobe Duration cycles. Number of EMxCLK cycles for which EMxOEn is held active, minus one cycle. The reset value is 64 cycles. This field cannot be zero when ew = 1. Reset type: SYSRSn
6-4	R_HOLD	R/W	7h	Read Strobe Hold cycles. Number of EMxCLK cycles for which EMxAy, EMxBAy, EMxDQMy, and EMxCS3n are held after EMxOEn has been deasserted, minus one cycle. The reset value is 8 cycles. Reset type: SYSRSn
3-2	TA	R/W	3h	Turn Around cycles. Number of EMxCLK cycles between the end of one asynchronous memory access and the start of another asynchronous memory access, minus one cycle. This delay is not incurred between a read followed by a read, or a write followed by a write to the same chip select. The reset value is 4 cycles. Reset type: SYSRSn

Table 23-41. ASYNC_CS3_CR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	ASIZE	R/W	1h	Asynchronous Memory Size. Defines the width of the asynchronous device's data bus : 00: 8 Bit data bus. 01: 16 Bit data bus. 10: 32 Bit data bus. 11: Reserved. Reset type: SYSRSn

23.4.2.7 ASYNC_CS4_CR Register (Offset = Ch) [Reset = 3FFFFFDh]

ASYNC_CS4_CR is shown in Figure 23-29 and described in Table 23-42.

Return to the Summary Table.

23.4.3 EMIF1_CONFIG_REGS Registers

Table 23-51 lists the memory-mapped registers for the EMIF1_CONFIG_REGS registers. All register offset addresses not listed in Table 23-51 should be considered as reserved locations and the register contents should not be modified.

Table 23-51. EMIF1_CONFIG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	EMIF1LOCK	EMIF1 Config Lock Register	EALLOW	Go
2h	EMIF1COMMIT	EMIF1 Config Lock Commit Register	EALLOW	Go
8h	EMIF1ACCPROT0	EMIF1 Config Register 0	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 23-52 shows the codes that are used for access types in this section.

Table 23-52. EMIF1_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

23.4.3.1 EMIF1LOCK Register (Offset = 0h) [Reset = 00000000h]

EMIF1LOCK is shown in Figure 23-38 and described in Table 23-53.

-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

23.4.4.1 EMIF2LOCK Register (Offset = 0h) [Reset = 00000000h]

EMIF2LOCK is shown in Figure 23-41 and described in Table 23-58.

Chapter 24

Configurable Logic Block (CLB)

This chapter describes the features and operation of the configurable logic block (CLB) that is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions.

24.1 Introduction

The configurable logic block (CLB) is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions. The CLB is able to enhance existing peripherals through a set of crossbar interconnections, which provide a high level of connectivity to existing control peripherals such as enhanced pulse width modulators (ePWM), enhanced capture modules (eCAP), and enhanced quadrature encoder pulse modules (eQEP). The crossbars also allow the CLB to be connected to external GPIO pins. In this way, the CLB can be configured to interact with device peripherals to perform small logical functions such as simple PWM generators, or to implement custom serial data exchange protocols.

The CLB peripheral is configured through the CLB tool. For more information on the CLB tool, available examples, application reports, and user's guide, refer to the following location in your C2000WARE package (C2000Ware_2_00_00_03 and higher): C2000WARE_INSTALL_LOCATION\utilities\clb_tool\clb_syscfg\doc

24.2 Description

The CLB subsystem contains a number of identical tiles. There are four such tiles in the CLB subsystem; other devices can contain more or fewer tiles. Tiles are numbered 1 to N, where N is the total tile count on the device. Each tile contains combinational and sequential logic blocks, as well as other dedicated hardware to be described later in this document. Figure 24-1 shows the structure of the CLB subsystem in the device.

The tile contains the core logic, providing the logic reconfiguration capability. Each CLB tile is associated with a separate CPU interface, which contains the registers needed to control and configure the logic in the tile. The CPU interface also contains data transfer buffers that can be used as part of the configurable logic to exchange data with the rest of the device. Figure 24-2 shows the connections between the tile, the CPU interface, and the device.

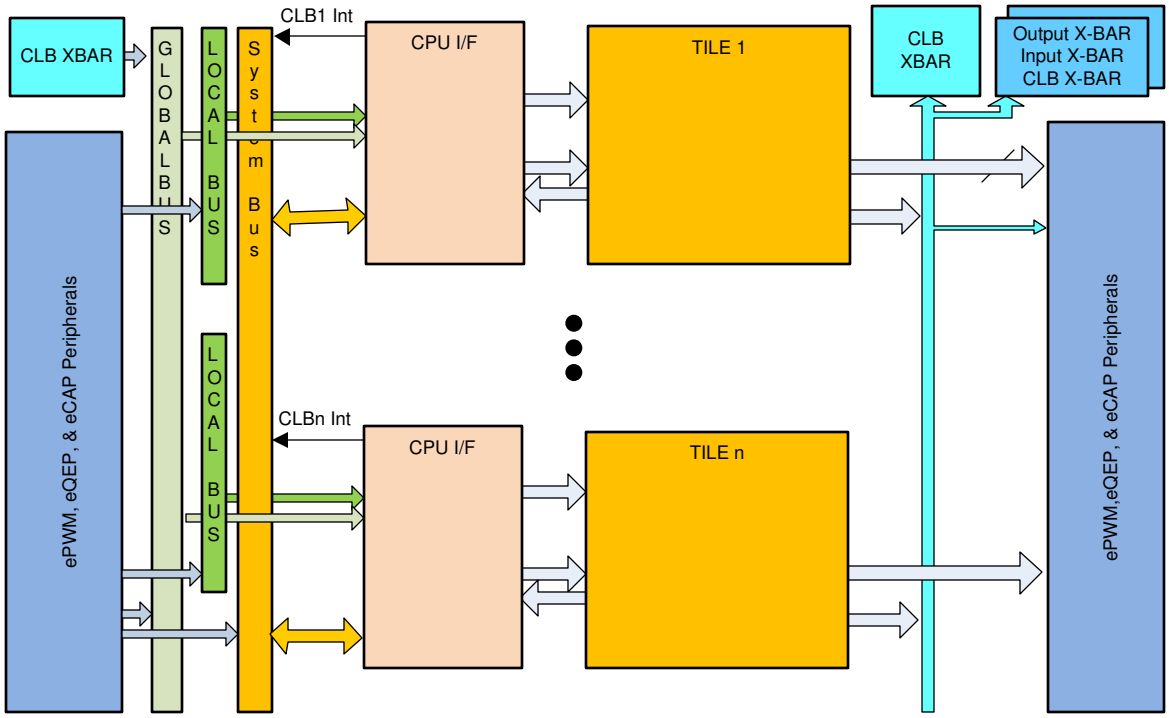

Figure 24-1. Block Diagram of the CLB Subsystem in the Device

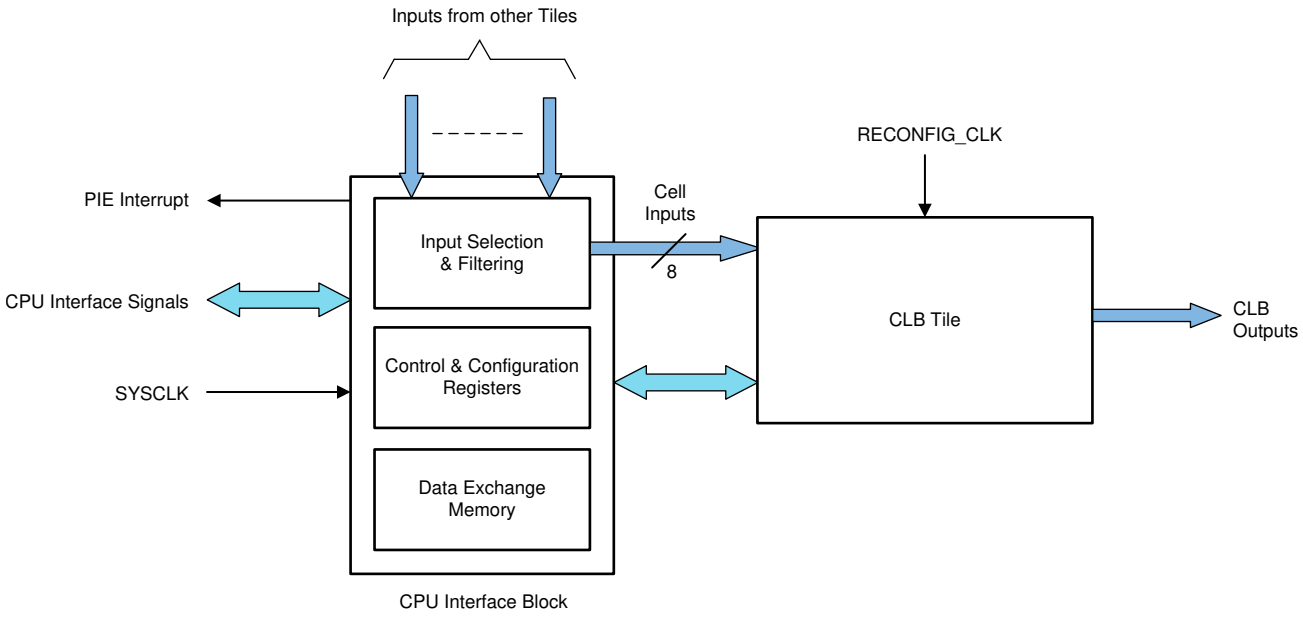

Figure 24-2. Block Diagram of a CLB Tile and CPU Interface

24.2.1 CLB Clock

In this device, the CLB clock is the same as the ePWM1 clock, and the maximum frequency is 100MHz. When using CLBx, the corresponding EPWMx module clock bit must be enabled. For example, when CLB1 is being used on the device, EPWM1 clock must be enabled. Likewise, EPWM2 clock must be enabled when making use of CLB2. The other CLBs on the device follow similar requirements.

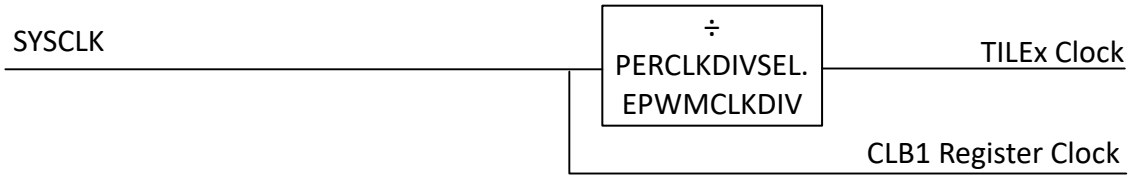

Figure 24-3. CLB Clocking

24.3 CLB Input/Output Connection

24.3.1 Overview

There are four instances of the CLB module in the device. Each CLB instance has a common set of input signals referred to as global input signals. Additionally, each CLB instance has a specific set of input signals that are unique to each instance, and are referred to as local input signals. Each of the eight inputs of a CLB can be chosen from any of the global input signals or the local input signals.

Note

Signals routed into the CLB using the XBAR must be synchronized within the CLB.

24.3.2 CLB Input Selection

Each CLB module has eight inputs that are applied to the reconfigurable logic cell. Each of these inputs can be selectively driven by a predefined set of signals. A two-level mux structure allows each input of each CLB instance to select a signal.

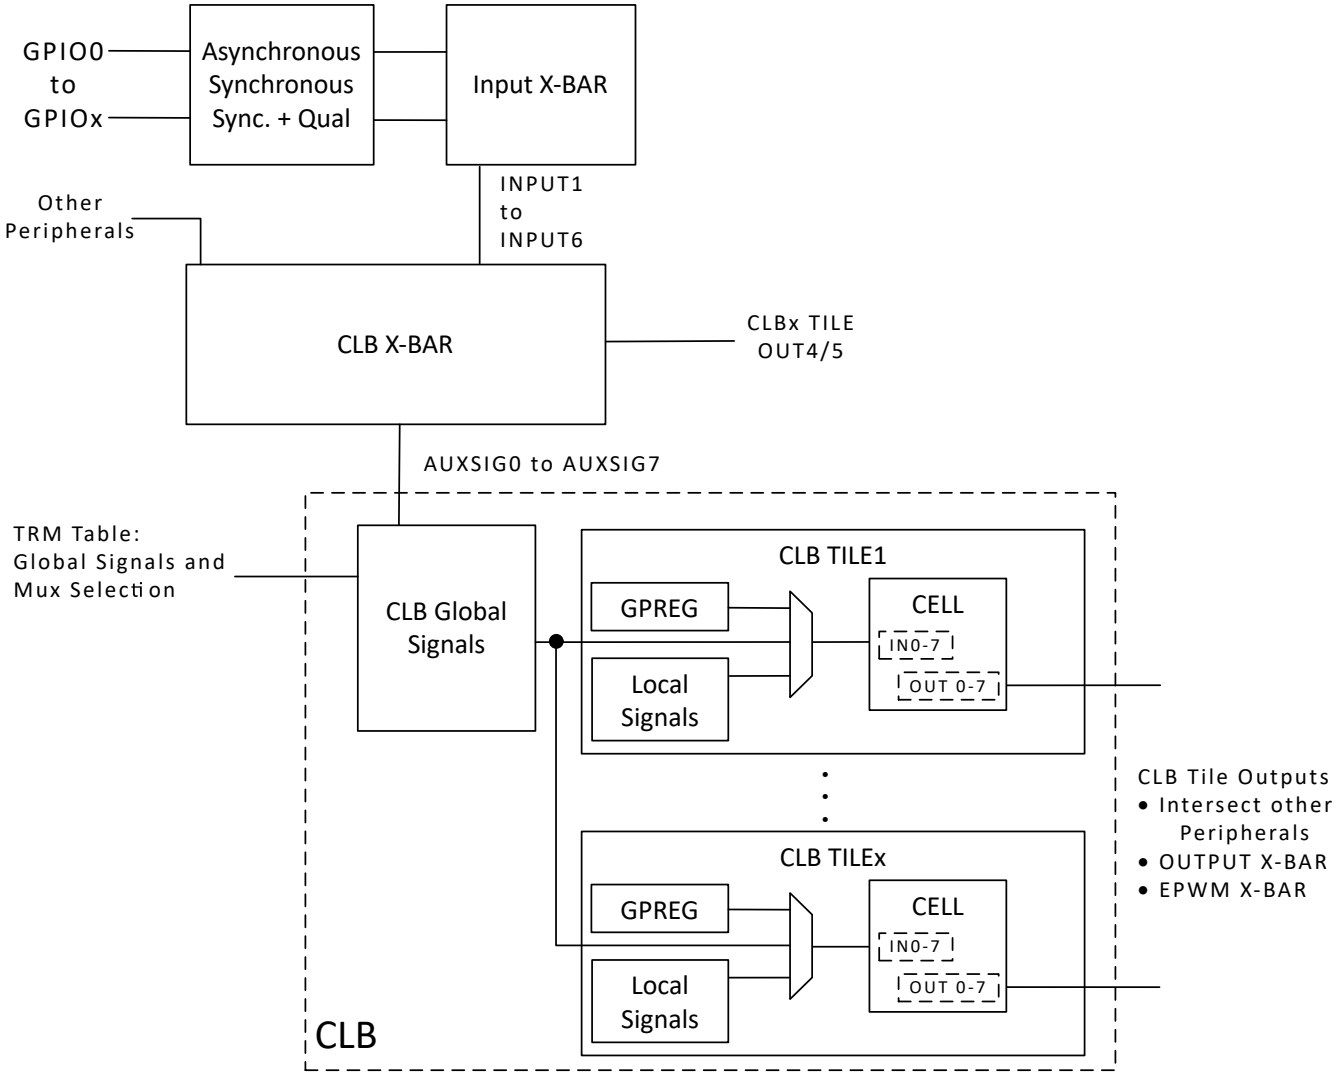

Figure 24-4. GPIO to CLB Tile Connections

A set of signals is common to all the CLB instances. These are referred to as global inputs in Figure 24-5. A separate set of signals is unique to each instance of the CLB. These are referred to as local inputs in Figure 24-5.

Registers CLB_LCL_MUX_SEL_1 and CLB_LCL_MUX_SEL_2 control the local mux selection for each of the eight inputs. The mux control registers CLB_GLBL_MUX_SEL_1 and CLB_GLBL_MUX_SEL_2 control the global mux selection for each of the eight inputs.

The local mux select value of 0 causes the selected global mux input signal to be connected to the corresponding CLB Input. For example, setting CLB_LCL_MUX_SEL_IN_0 = 0 and CLB_GLBL_MUX_SEL_IN_0 = 8 causes the global mux input number 8 to be connected to CLB Input 0. The input filter feature can be used to enable edge detection on the CLB inputs. The input filter feature can also synchronize the input with the CLB clock.

The global mux settings are shown in Table 24-1. The local input mux settings are shown in Table 24-2.

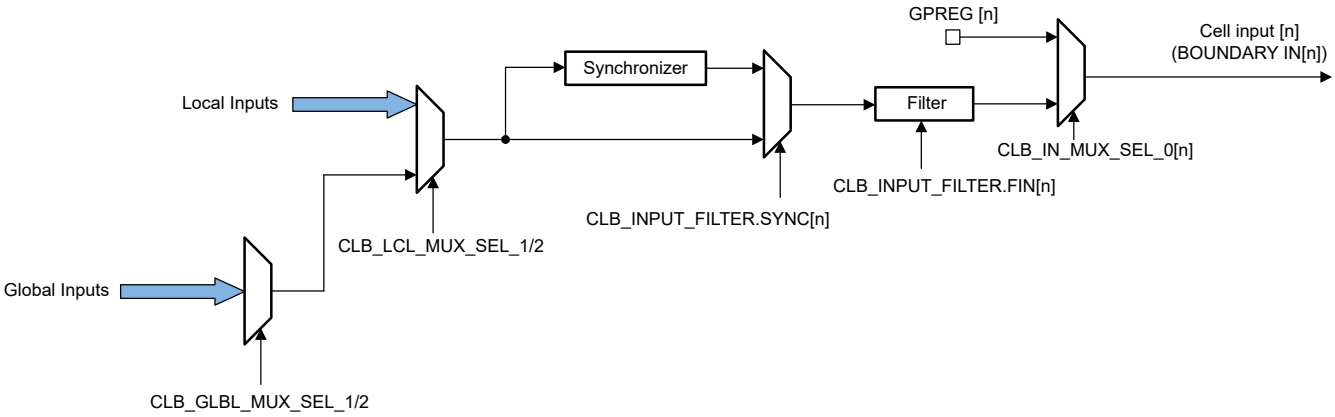

Figure 24-5. CLB Input Mux and Filter

Figure 24-6 shows an example of how to use synchronization for an asynchronous signal, in this case the ePWM signal.

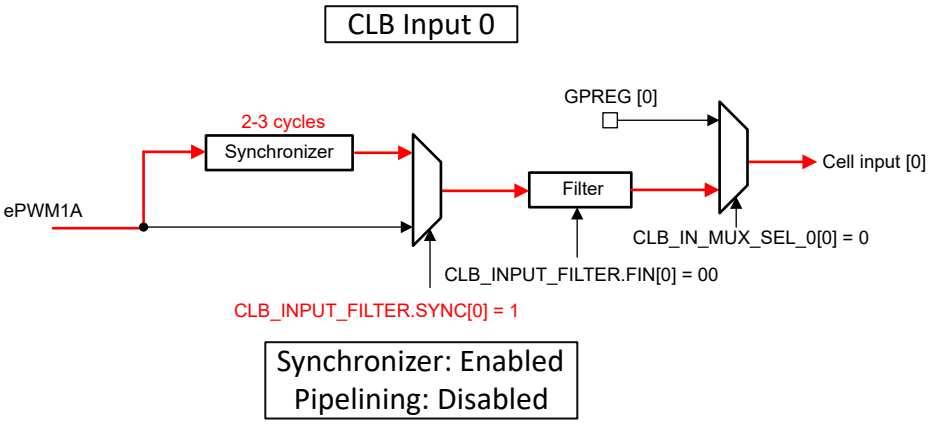

Figure 24-6. CLB Input Synchronization Example

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

Table 24-1. Global Signals and Mux Selection

Select Value	CLB1 Input	CLB2 Input	CLB3 Input	CLB4 Input	Synchronization Requirement

The GPREG is accessible by the CPU and the bits of this register can be used as BOUNDARY INPUTs for the CLB Tiles. For example, CLB1s GPREG[0] can be used as BOUNDARY IN0 (Cell Input 0) for the corresponding CLB Tile.

To connect multiple tiles to each other, you can use the CLBx OUT4/5 and connect to CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

Another option is to connect the CLBx OUT0-7 to a GPIO and then use the INPUT X-BAR to bring the signal back in to the device and connect to the CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

To use GPIOs as inputs to the CLB, you must utilize the Input X-BAR and the CLB X-BAR. Figure 24-4 shows how GPIOs can be used as inputs to the CLB tiles.

24.3.3 CLB Output Selection

The eight outputs of the CLB are replicated to create 16 output signals. Each of these 16 outputs has a separate enable bit defined in the CLB output enable register, CLB_OUT_EN. The CLB outputs go to the ePWM, eCAP, eQEP and the crossbar module in the device. This allows the user to enhance the functionality of these modules with the CLB. Figure 24-7 shows the CLB outputs.

Note

The output from OUTLUT0 is connected to OUT0 and OUT8. While the signal is the same, each OUTy has access to a different peripheral as shown in Section 24.3.4. Likewise, OUTLUT1 is connected to OUT1 and OUT9, and are the same signal.

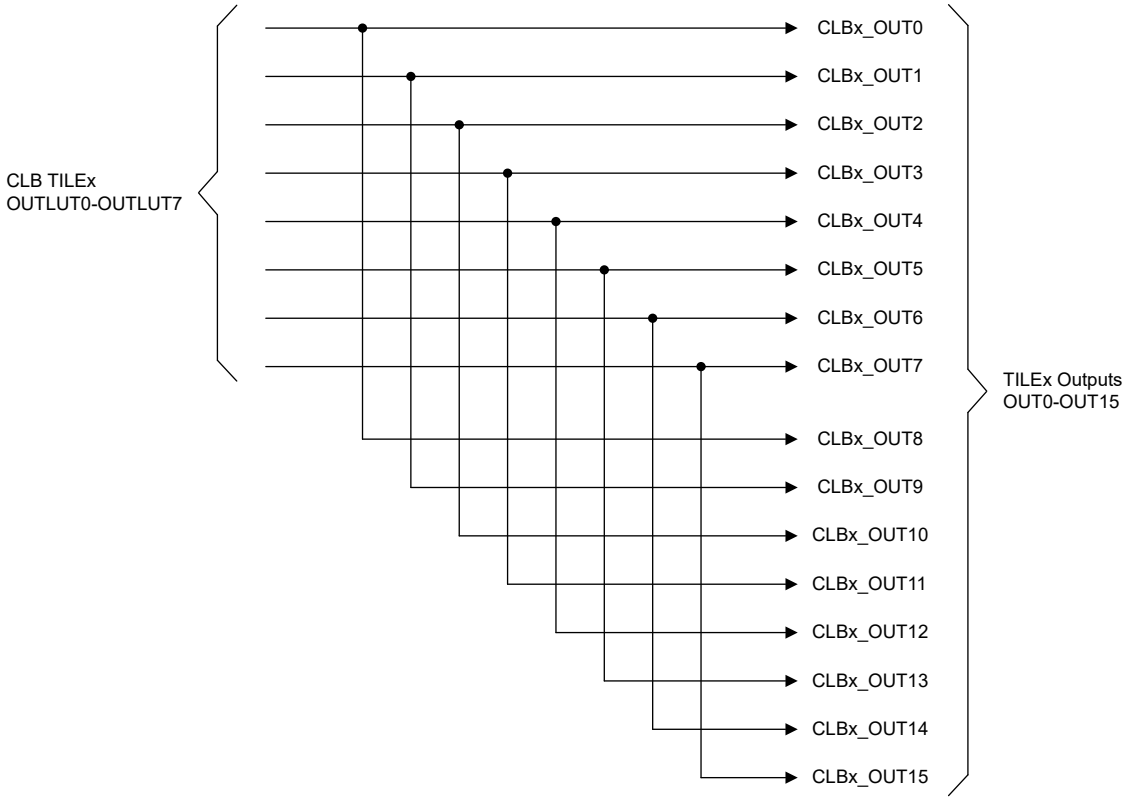

Figure 24-7. CLB Outputs

24.3.4 CLB Output Signal Multiplexer

Each CLB output signal passes through an external multiplexer that intersects a specific peripheral signal, see Figure 24-8. The output of the multiplexer is connected to the destination of the original peripheral signal and the default multiplexer setting is that the peripheral signal is passed through. The multiplexer is controlled by bit[n] in the CLB output enable register CLB_OUT_EN.

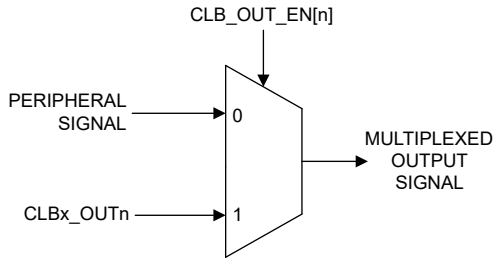

Figure 24-8. CLB Output Signal Multiplexer

For example, if the CLB1 OUT0 must override the EPWM1A signal, the OUPTUT ENABLE bit for OUT0 must be set to 1.

Table 24-3 shows the allocation of peripheral signals and the CLB outputs.

Table 24-3. CLB Output Signal Multiplexer Table

CLB Output	CLB OUTLUT	CLB1 Destination	CLB2 Destination	CLB3 Destination	CLB4 Destination
0	OUTLUT0	EPWM1A	EPWM2A	EPWM3A	EPWM4A
1	OUTLUT1	EPWM1A_OE	EPWM2A_OE	EPWM3A_OE	EPWM4A_OE

Note

When not explicitly specified in the table above, refer to corresponding IP chapters for exact CLB Output destinations (that is, FSI, ECAP, XBAR connections).

24.4 CLB Tile

The purpose of the CLB tile is to provide the logic reconfiguration capability of the CLB. The CLB tile contains the following submodules:

- **Counter:** The counter submodule can be configured as an adder, a counter, or a shifter. When functioning as an adder, the counter submodule can either add or subtract. When functioning as a counter, the counter submodule can count up or count down. When functioning as a shifter, the counter submodule can shift left or shift right. The counter event inputs, as well as the reset input, can be freely connected to any of the other submodules in the same tile. There are three counters in each tile.
- **LUT4:** The LUT4 submodule has a 4-input look-up table functionality and is capable of realizing any combinatorial Boolean equation of up to four inputs. There are three LUT4 submodules in each CLB tile.
- **FSM:** The Finite State Machine (FSM) submodule can be configured either as a single four-state finite state machine, or as two independent two-state finite state machines. The FSM accepts two external inputs, and generates two state outputs and one combination output. When not used as a state machine, the FSM submodule can accept two external inputs and function as a 4-input LUT. There are three FSM submodules in each CLB tile.
- **Output LUT:** The output LUT is a 3-input lookup table submodule capable of realizing any combinatorial Boolean equation of up to three inputs. There are eight such blocks in a CLB tile, each associated with one of the tile outputs.
- **High Level Controller:** The High Level Controller (HLC) submodule is an event-driven block that can handle up to four concurrent events. The event can be an activity on any of the other block outputs. A predefined set of operations is executed when each event occurs. The HLC also provides a data exchange and interrupt mechanism to the CPU subsystem. There are four working registers (R0, R1, R2, and R3) that can be used for basic operations, and to modify or set up values for the three counter blocks. Unlike the other submodules, there is only one HLC in each CLB tile.
- **Static Switch Block:** The static switch block provides dynamic connectivity between all of the blocks listed above. Submodules can be connected by the user, with the only restriction that the submodules must not form a combinational loop within the tile.

A CLB tile consists of three sets each of the counter block, FSM, and LUT4, one high-level controller, and eight output LUT blocks. The submodule numbering is shown in Figure 24-9.

The functionality of the LUT submodules is configured using a register field containing the binary pattern of the output of the desired look-up table. For example, a 4-input LUT has 16 possible input permutations, each of which corresponds to a desired binary 0 or 1 at the output. The register field can, therefore, be 16-bits in length, with each bit representing the desired result of a binary pattern. Input pattern sequences start at 0000 and continue sequentially to 1111. A similar method is used to encode the 16-bit state equations in the FSM submodule.

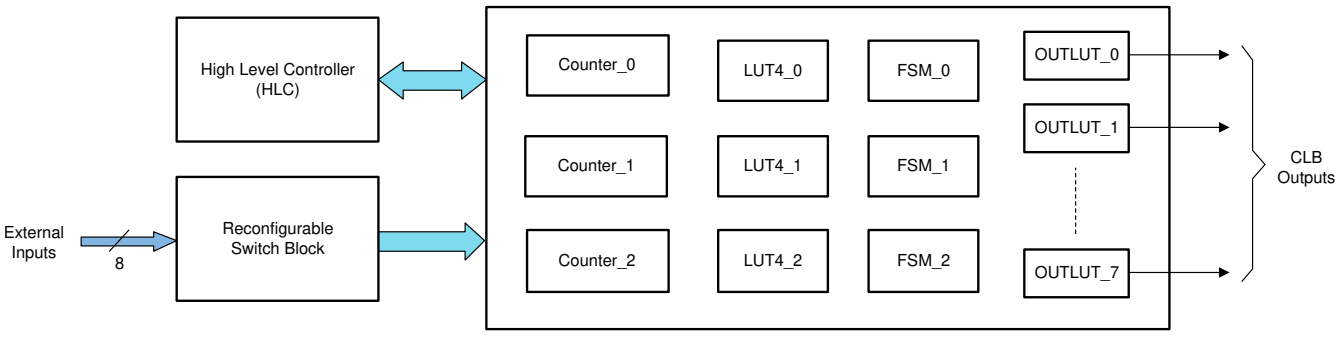

Figure 24-9. CLB Tile Submodules

24.4.1 Static Switch Block

The Static Switch Block provides the configurable connectivity between the submodules in the CLB tile. The outputs of all the submodules and the eight external inputs are connected to a common internal bus inside the tile. Every input port has a 32-to-1 multiplexer and an associated 5-bit selection value that allows the user to select one of the inputs on the bus. The only restrictions are certain signals (described below) that are tied off in the design to prevent creation of accidental combinatorial loops.

Table 24-4. Output Table

Bit Position	Signal Connection	Comment
0	Always 0	This select value is used to tie an input to 0.
1	COUNTER_0 MATCH2	
2	COUNTER_0 ZERO	
3	COUNTER_0 MATCH1	
4	FSM_0 STATE_BIT_0	
5	FSM_0 STATE_BIT_1	
6	FSM_0 LUT output	
7	LUT4_0 output	
8	Always 1	This select value is used to tie an input to 1.
9	COUNTER_1 MATCH2	
10	COUNTER_1 ZERO	
11	COUNTER_1 MATCH1	
12	FSM_1 STATE_BIT_0	
13	FSM_1 STATE_BIT_1	
14	FSM_1 LUT output	
15	LUT4_1 output	
16	Always ‘0’	
17	COUNTER_2 MATCH2	
18	COUNTER_2 ZERO	
19	COUNTER_2 MATCH1	
20	FSM_2 STATE_BIT_0	
21	FSM_2 STATE_BIT_1	
22	FSM_2 LUT output	
23	LUT4_2 output	
24	External Input 0	
25	External Input 1	
26	External Input 2	
27	External Input 3	
28	External Input 4	
29	External Input 5	
30	External Input 6	
31	External Input 7	

Table 24-5. Input Table

Module Name	Port Name	Description
Counter Block	RESET	Acts as an active high reset when used as a counter
	MODE_0	Acts as an enable when used as a counter. The counter counts only when this input is 1.
	MODE_1	Acts as a direction control when used as a counter. If this input is 1, then the counter counts up; else, the counter counts down.
LUT	IN0	Input 0 of the 4-input LUT.
	IN1	Input 1 of the 4-input LUT.
	IN2	Input 2 of the 4-input LUT.
	IN3	Input 3 of the 4-input LUT.
FSM	EXT_IN0	Input 0 of the FSM block.
	EXT_IN1	Input 1 of the FSM block.
	EXTRA_EXT_IN0	Extra external input 0 of the FSM block. This input matters only if configured in the LUT mode.
	EXTRA_EXT_IN1	Extra external input 1 of the FSM block. This input matters only if configured in the LUT mode.

The static switch block allows the user to define the input connection of any submodule to come from any of the outputs in Table 24-4. It is therefore easy to create a combinatorial loop. To prevent this, certain paths are broken in the input path of each submodule. These port positions are tied to 0, as shown in Table 24-6.

Table 24-6. Ports Tied Off to Prevent Combinatorial Loops

Module Name	Ports of Input MUX Tied Off to 0 to Prevent Combinational Loops
LUT_0	LUT_0 , LUT_1, and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
FSM_0	LUT_1 and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
LUT_1	LUT_1 and LUT_2 output, FSM_1 and FSM_2 output.
FSM_1	LUT_2 output, FSM_1 and FSM_2 output.
LUT_2	LUT_2 output, FSM_2 output.
FSM_2	FSM_2 output.

24.4.2 Counter Block

24.4.2.1 Counter Description

The counter block is a complex functional submodule that can be configured either as a counter, an adder, or a shifter. Apart from the normal operational control, this block has a dedicated EVENT input, which can trigger an addition, subtraction or shift operation, or load data into the counter register. The inputs to the counter submodule are shown in Figure 24-10.

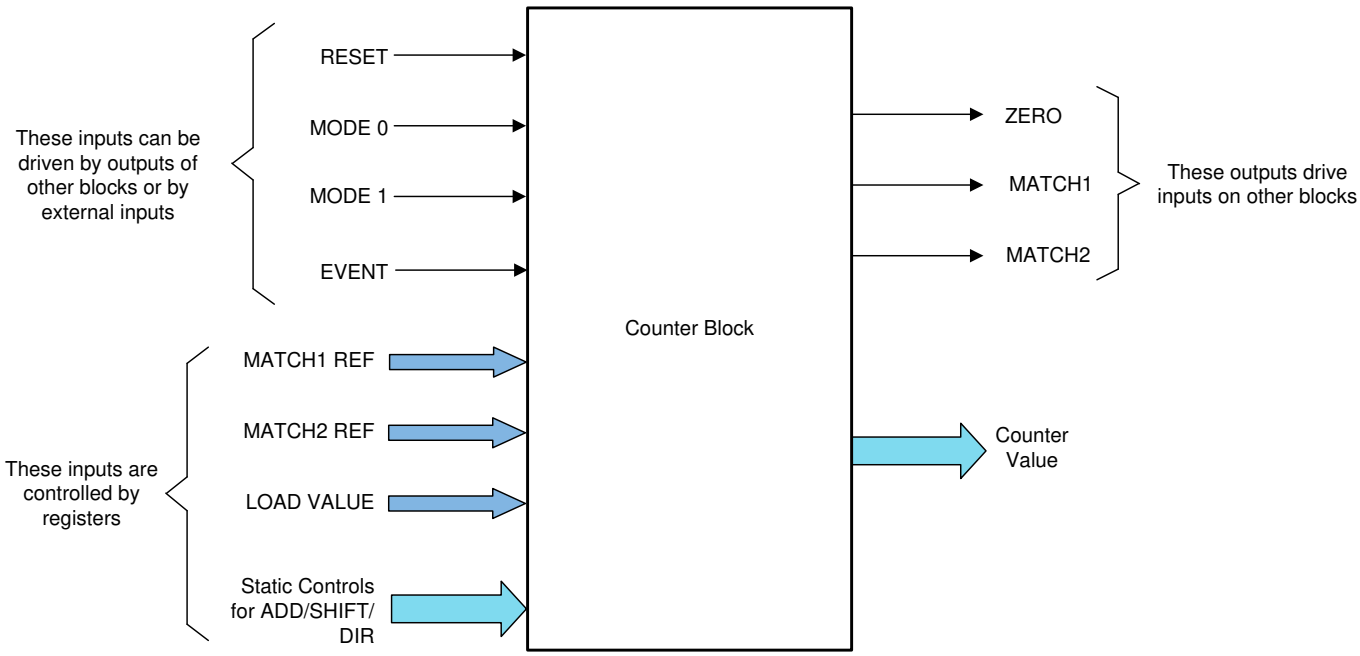

Figure 24-10. Counter Block

24.4.2.2 Counter Operation

At the heart of the counter block is a 32-bit count register. This register can either be loaded statically before counting commences, or dynamically at run time. The operation of the counter submodule is determined by the inputs described below. Note that each of the inputs can be connected to the outputs of any of the other blocks in the CLB tile. These connections are made by configuring the static switch block.

The counter inputs are:

- **RESET:** This is the highest priority input and takes precedence over all other inputs. The input is level sensitive and as long as the input remains high, the counter resets to 0 on the next clock cycle.
- **MODE_0:** This input is an enable for the counter. The counter begins counting (up or down depending on the MODE_1 setting) only when this input is high. If this input is low, then no counting takes place.
- **MODE_1:** This input is the direction control for the counter. If this input is high, then the counter increments on every clock cycle where MODE_0 is high. If this input is low, then the counter decrements on every clock cycle where MODE_0 is high. The counter wraps around to 0x0000 0000 after 0xFFFF FFFF when counting up. The counter wraps around to 0xFFFF FFFF after 0x0000 0000 when counting down. The only exception to this is when an EVENT occurs at exactly the same time, causing a different value to be loaded into the counter.
- **EVENT:** This input is defined for the purpose of triggering actions in the counter based on certain events. The event can be any of the outputs of the other blocks or an external input to the tile. The counter's static control inputs define the behavior of the counter on an active event. An active event is defined as a rising edge on the EVENT input. The counter can be configured to perform one of the following actions:
  - Load a predefined 32-bit value from the LOAD VALUE register into the count register
  - Shift the contents of the counter register left or right by a predefined amount between 0 and 31
  - Add or subtract a predefined 32-bit value. Addition and subtraction are treated as 32-bit unsigned operations and there is no saturation.

  Note that the effect of a rising edge on the EVENT input only lasts for one cycle. On the next cycle, the counter operation continues based on the MODE_0, MODE_1, and RESET inputs.

MATCH1 REF and MATCH2 REF are 32-bit reference values that are used to generate the MATCH1 and MATCH2 outputs. The MATCH1 output becomes active high whenever the counter register value matches the 32-bit MATCH1 REF value. MATCH2 behaves in a similar manner in relation to the MATCH2 REF register. The reference values for MATCH1 and MATCH2 can either be setup once before the start of operation, or can be modified dynamically. The High Level Controller can load desired values into the MATCH1 REF and MATCH2 REF registers.

Note that the counter load and match registers are not memory-mapped. For more information, see Section 24.5.2.

The three logic outputs of the counter block are:

- **ZERO:** This output goes high whenever the counter register is 0.
- **MATCH1:** This output goes high whenever the counter register is equal to the MATCH1 REF input register.
- **MATCH2:** This output goes high whenever the counter register is equal to the MATCH2 REF input register.

The operation of the counter block is controlled by the CFG_MISC_CTRL register. The following three bits of this register are relevant for each counter. The "x" below refers to the counter instance; 0, 1, or 2. For more information, see the CLB_MISC_CONTROL register description located in Section 24.8.

- COUNT_EVENT_CTRL_x: This bit defines whether the counter performs an addition or a shift on an event. A value of 0 means that on an event, the counter loads the static value; 1 means an add/shift operation is performed. This bit must be 0 for indirect loads and HLC loads of the counter to take effect.
- COUNT_ADD_SHIFT_x. 1 means add, 0 means shift.
- COUNT_DIR_x. 1 means left shift or add. 0 means right shift or subtract.

Table 24-7 shows the logical operation of the counter block in terms of the inputs and control register bits. Count up and down modes are the normal operation with EVENT = 0. The operations on the CNTVAL register are:

Load: CNTVAL = EVENT_LOAD_VAL

Shift right: CNTVAL = CNTVAL >> EVENT_LOAD_VAL

Shift left: CNTVAL = CNTVAL << EVENT_LOAD_VAL

Subtract: CNTVAL = CNTVAL - EVENT_LOAD_VAL

Add: CNTVAL = CNTVAL + EVENT_LOAD_VAL

Table 24-7. Counter Block Operating Modes

EVENT	MODE_0	MODE_1	COUNT_EVENT_CTRL_x	COUNT_ADD_SHIFT_x	COUNT_DIR_x	Action on CNTVAL
0	0	0	X	X	X	None
0	0	1	X	X	X	None
0	1	0	X	X	X	Count down
0	1	1	X	X	X	Count up
1	X	X	0	X	X	Load
1	X	X	1	0	0	Shift right
1	X	X	1	0	1	Shift left
1	X	X	1	1	0	Subtract
1	X	X	1	1	1	Add

24.4.3 FSM Block

The Finite State Machine (FSM) block provides the ability to build programmable finite state machines with up to four states. The FSM block has two register bits and two external inputs, and can be programmed either as two 2-state machines or as a single 4-state machine. For additional flexibility, there are two auxiliary inputs (EXTRA_EXT_IN0 and EXTRA_EXT_IN1) that can be used to create larger combinational functions by giving up a state functionality. The structure of the FSM is shown in Figure 24-11.

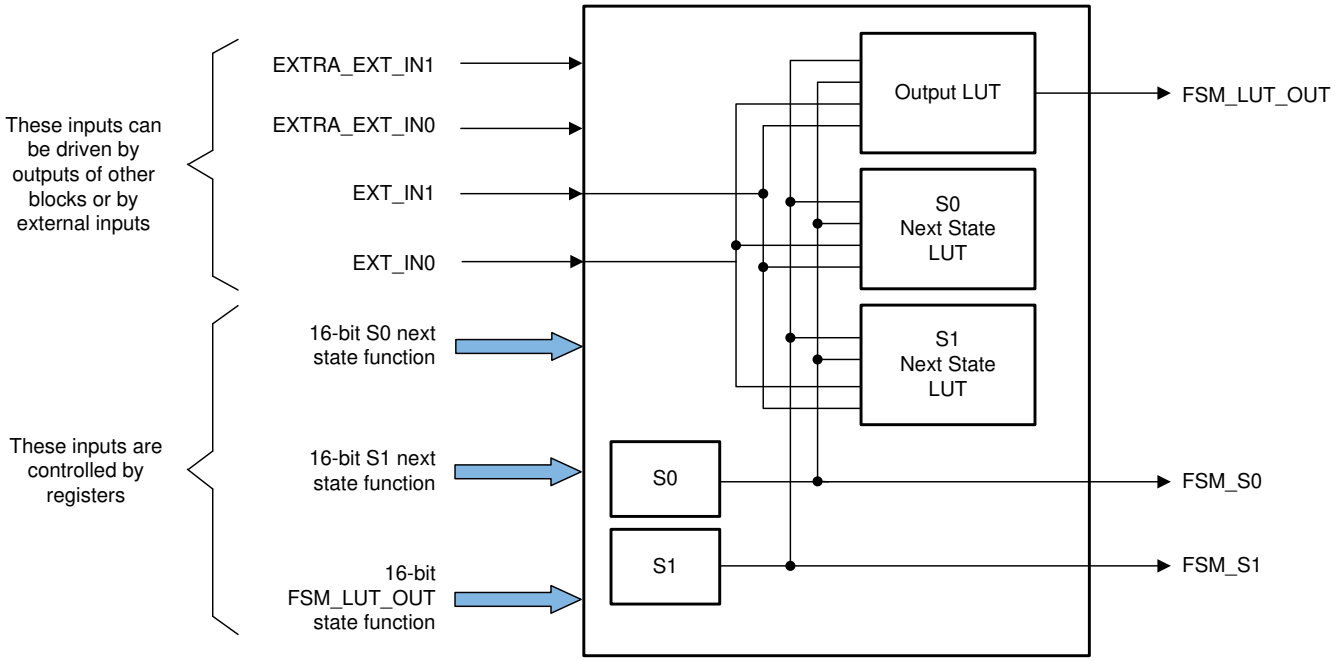

Figure 24-11. FSM Block

The signals and functionality of the FSM block are:

- **EXT_IN0 and EXT_IN1:** These are the two external inputs that can be used to control the output FSM_LUT_OUT or either of the states S0 and S1.
- **S0** and **S1** are two state bits that have independent state control equations.
- **16-bit S0 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S0.
- **16-bit S1 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S1.
- **16-bit output equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the output value of FSM_LUT_OUT. An additional level of configurability is provided such that FSM_LUT_OUT can use extra inputs in case the states S0 and S1 are unused.

  One extra bit is used to select EXTRA_EXT_IN0 instead of S0. One extra bit is used to select EXTRA_EXT_IN1 instead of S1. Using these, one can effectively build 3-input or a 4-input LUT for the FSM_LUT_OUT by giving up one or two state bits, respectively.

The CFG_MISC_CTRL register controls the operation of the FSM block. Two bits in this register are used for each FSM Block to determine whether the FSM output LUT function uses the state variable S0/S1, or the corresponding extra external input signal FSM_EXTRA_EXT_INx. A 0 means use the state bit, and a 1 means use the FSM_EXTRA_EXT_IN0 / FSM_EXTRA_EXT_IN1 signal.

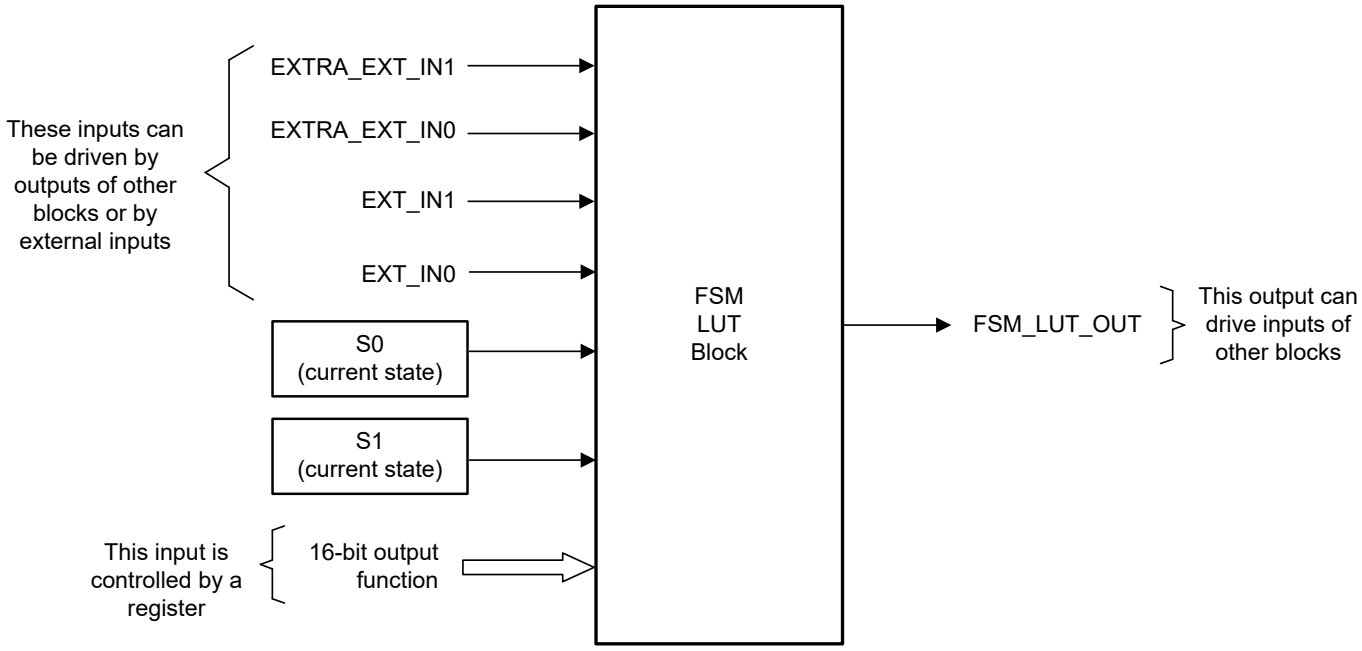

Figure 24-12. FSM LUT Block

24.4.4 LUT4 Block

This is a simple four input Look-Up table (LUT) block with inputs IN0, IN1, IN2, and IN3 (see Figure 24-13). Any combinatorial Boolean equation using the four inputs can be realized by programming the 16-bit control register associated with each LUT4 block. For more information, see the LUT4 register descriptions located in Section 24.8.

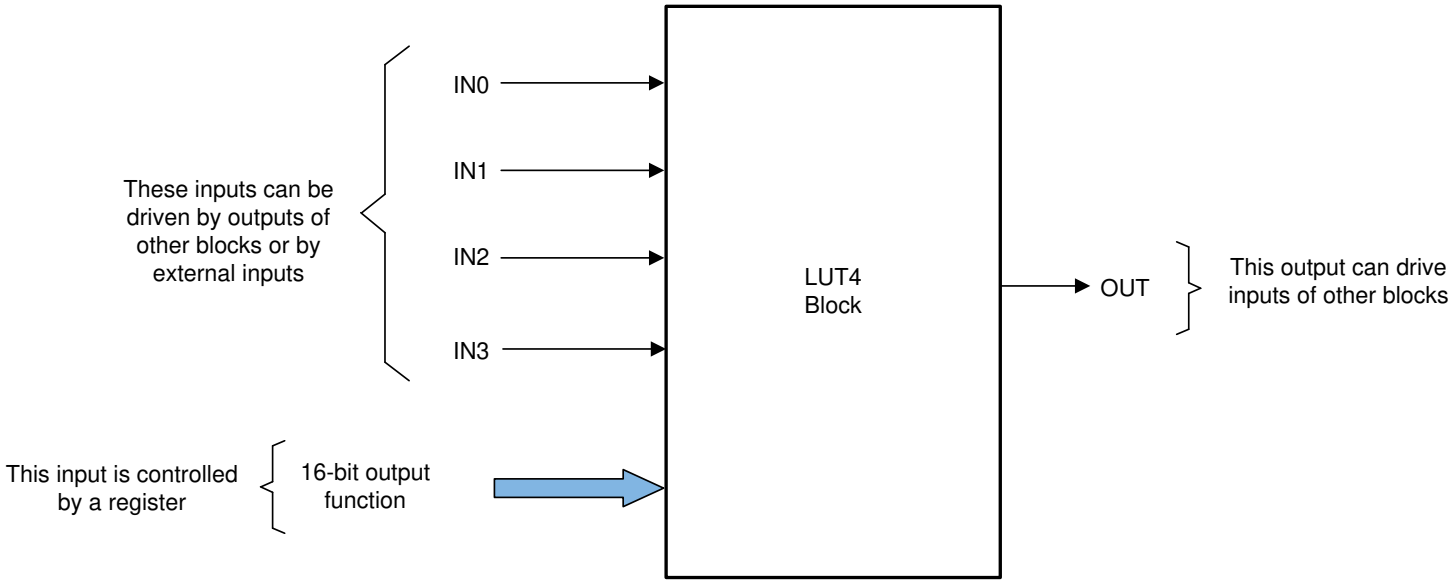

Figure 24-13. LUT4 Block

24.4.5 Output LUT Block

The output LUT block (Figure 24-14) is very similar in functionality to the LUT4 block, except that the output LUT block has three inputs. Unlike the other sub blocks, the outputs of these blocks are meant to go out of the tile and hence cannot be used by any other block within the tile. Any combinatorial function of the three inputs can be realized by the output LUT block. For more information, see the output LUT register descriptions located in Section 24.8.

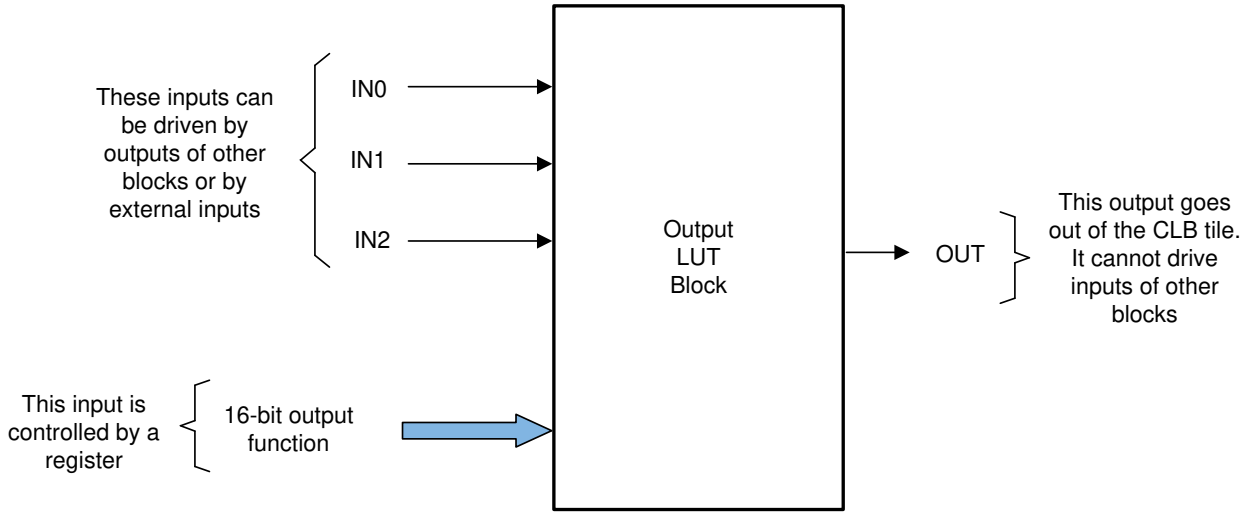

Figure 24-14. Output LUT Block

24.4.6 High Level Controller (HLC)

The High Level Controller (HLC) is significantly more complex than the other blocks in the CLB tile. The HLC performs two main functions:

- Provides a means of communication and data exchange with the rest of the device. This is done through two methods: a global access path to four general purpose HLC registers (R0 through R3) and PUSH and PULL FIFOs between the CPU and the HLC. The general-purpose HLC registers are designed to only be written to during device configuration time. To avoid unexpected behavior, the HLC registers must not be written to during run-time operation. The PUSH and PULL FIFOs are the primary avenues of data exchange during run-time, refer to Section 24.4.6.4 for more information.
- Provides a programmable, event-based action system, which performs computation, manipulation of logic functionality, and data movement. In other words, events can be configured to trigger a predefined set of actions in the CLB tile, or to initiate data exchange with the rest of the device.

The architecture of the HLC is shown in Figure 24-15. The HLC is an event-based system capable of handling up to four simultaneous events that can be selected from any outputs of the other blocks within the tile or from an external input.

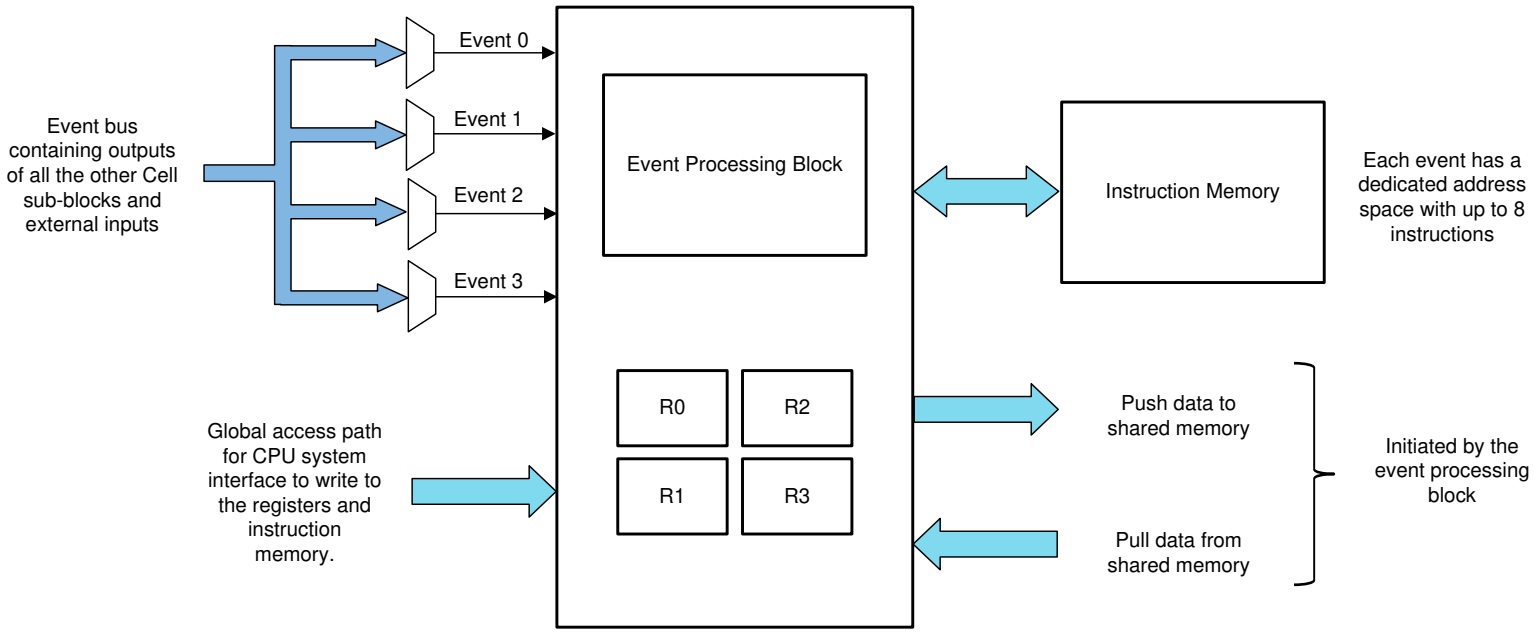

Figure 24-15. High Level Controller Block

24.4.6.1 High Level Controller Events

Each of the four HLC events has a dedicated address from which instructions are executed. Events are selected from the set of signals listed in Table 24-8. The lowest numbered event (Event 0) has the highest priority, and the highest numbered event (Event 3) has the lowest priority.

Table 24-8. HLC Event List

Index	HLC Event Mux
0	Always 0
1	COUNTER_0 MATCH2
2	COUNTER_0 ZERO
3	COUNTER_0 MATCH1
4	FSM_0 STATE_BIT_0
5	FSM_0 STATE_BIT_1
6	FSM_0 LUT output
7	LUT4_0 output
8	Always 1
9	COUNTER_1 MATCH2
10	COUNTER_1 ZERO
11	COUNTER_1 MATCH1
12	FSM_1 STATE_BIT_0
13	FSM_1 STATE_BIT_1
14	FSM_1 LUT output
15	LUT4_1 output
16	Always ‘0’
17	COUNTER_2 MATCH2
18	COUNTER_2 ZERO
19	COUNTER_2 MATCH1
20	FSM_2 STATE_BIT_0
21	FSM_2 STATE_BIT_1
22	FSM_2 LUT output
23	LUT4_2 output
24	External Input 0
25	External Input 1
26	External Input 2
27	External Input 3
28	External Input 4
29	External Input 5
30	External Input 6
31	External Input 7

24.4.6.2 High Level Controller Instructions

The instruction memory supports up to eight instructions per event. Each instruction sequence gets triggered on the rising edge of the corresponding event.

The HLC memory supports up to eight instructions per event, starting at the beginning of the fixed address range shown in Table 24-9. An instruction sequence is triggered on the rising edge of the corresponding event. If two or more events occur simultaneously, the associated instruction sequences each are executed sequentially in priority order.

Table 24-9. HLC Instruction Address Ranges

Address	Instructions for
00000 to 00111	Event 0
01000 to 01111	Event 1
10000 to 10111	Event 2
11000 to 11111	Event 3

The HLC instruction format is shown in Table 24-10.

Table 24-10. HLC Instruction Format

Last Instruction Bit	5-Bit Opcode	3-Bit Source	3-Bit Destination
This bit when set to 1 stops execution after the current instruction.	MOV 00000 MOV_T1 00001 MOV_T2 00010 PUSH 00011 PULL 00100 ADD 00101 SUB 00110 INTR 00111	Source can be R0, R1, R2, R3, C0, C1, C2.	Destination can be R0, R1, R2, R3, C0, C1, C2. Note that for ADD/SUB instructions, only R0, R1, R2, or R3 can be the destination.

R0, R1, R2, and R3 are four 32-bit general-purpose registers in the HLC. C0, C1, and C2 are three counter registers present in the CLB tile. <Src> is used to indicate the source and <Dest> is used to indicate the destination. Table 24-11 describes the HLC instructions.

Table 24-11. HLC Instruction Description

Instruction	Description
ADD <Src>, <Dest>	This instruction performs an unsigned 32-bit addition. <Dest> = <Dest> + <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3.
INTR <6-bit constant>	This instruction flags an interrupt through the CPU interface. The 6-bit constant is stored in the interrupt flag register CLB_INTR_TAG_REG. If multiple INTR instructions are called consecutively, only the first one has an effect. When multiple INTR calls are needed, each can be separated by other HLC instructions to make sure the interrupt calls take effect.
MOV <Src>, <Dest>	This instruction moves <Src> to <Dest>. Both <Src> and <Dest> can be any of R0, R1, R2, R3, C0, C1, or C2. The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and HLC loads of the counter to take effect.
MOV_T1 <Src>, <Dest>	This instruction moves <Src> to the Match1 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match1 register of any of the counters C0, C1, or C2. Examples are: • This instruction moves the count value in C1 into register R0: MOV_T1 C1 R0 • This instruction moves the value in R2 into the Match1 register of counter C0: MOV_T1 R2 C0
MOV_T2 <Src>, <Dest>	This instruction is similar to MOV_T1. The instruction moves <Src> to the Match2 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match2 register of any of the counters C0, C1, or C2.

Table 24-11. HLC Instruction Description (continued)

Instruction	Description
PULL <Dest>	This instruction transfers data from the data exchange pull memory buffer in the CPU interface to the <Dest> register. <Dest> can be any of R0, R1, R2, or R3. The PULL instruction is used as seen from the High Level Controller and a PULL operation reads (pulls) data from an internal 4-word FIFO. **Note** Back-to-back PUSH/PULL instructions cannot be used, if using more than one HLC EVENT channel.
PUSH <Src>	This instruction transfers data from <Src> to the data exchange push memory buffer in the CPU interface. <Src> can be any of R0, R1, R2, R3, C0, C1, or C2. The PUSH instruction is used as seen from the High Level Controller and pushes data into an internal 4 word FIFO.
SUB <Src>, <Dest>	This instruction performs an unsigned 32-bit subtraction. <Dest> = <Dest> - <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3.

MOV, MOV_T1, MOV_T2, ADD, SUB, and INTR instructions take one cycle to execute. PUSH and PULL require two cycles to execute. Note that the PUSH and PULL instructions are pipeline protected, meaning that a register can be used immediately after a PUSH/PULL to that register.

For multiple events triggered simultaneously, if the last instruction in the higher priority event is a PUSH or a PULL, there is an additional cycle delay between the end of the higher priority event and the start of the next event. If the last instruction is not a PUSH or PULL, then there is no cycle delay between the events.

If there is the possibility of more than one event coming into the HLC, then PUSH/PULL instructions must not be placed back-to-back. It is necessary to re-order the HLC instructions such that every PUSH and PULL is followed by a non-PUSH/PULL instruction. If only one event can enter the HLC at any time, then back-to-back PUSH/PULL is not an issue.

24.4.6.3 <Src> and <Dest>

Three bits are used to encode the <Src> and <Dest> registers as shown in Table 24-12.

Table 24-12. HLC Register Encoding

Bits	Register
000	R0
001	R1
010	R2
011	R3
100	C0
101	C1
110	C2

24.4.6.4 Operation of the PUSH and PULL Instructions (Overflow and Underflow Detection)

The PUSH and PULL operations of the HLC are intended for data exchange with the host system. There are separate FIFO buffers for PUSH and PULL operations. For example, a series of PUSH operations write to successive locations in a linearly mapped-memory buffer. The PUSH buffer and the PULL buffer are mapped at address offsets shown in the *Registers* section.

The CPU can read from and write to the PUSH and PULL buffers, respectively, to exchange data with the HLC. Data pushed by the HLC is read by the CPU from the PUSH buffers. Data sent from the CPU to the HLC is written by the CPU to the PULL buffer and is read by the HLC using the PULL instruction.

Refer to *clb_ex13_push_pull* for guidance on properly using the PUSH and PULL buffers. To make use of one of the CLB inputs as a GPREG, have this input indicate when data is written to the FIFO by the CPU.

There are separate PUSH and PULL address pointers that increment each time the HLC performs a PUSH or PULL operation. These address pointers are also memory-mapped so that the CPU can determine the value. These address pointers are also writable and can be reset by the CPU at any time.

Overflow and underflow detection is done by simply reading the values of the PUSH and PULL address pointers.

In the CLB module of the device, the depth of the PUSH and PULL FIFOs is four 32-bit words each. If the CPU starts a fresh data transfer to the PULL buffers and sees the address pointer greater than four, then an underflow has occurred since the HLC has pulled more data than the number of words written by the CPU into the buffer.

Note

Back-to-back PUSH and PULL instructions (in either order) do not work, if you have more than one HLC event enabled.

24.5 CPU Interface

24.5.1 Register Description

There are three classes of registers that are used to control and configure the CLB tile. This specification only describes the offset addresses of the registers. The absolute register addresses are different for each CLB tile. The three instances of the various blocks (LUT4, FSM, and Counter Block) are numbered 0, 1, and 2.

- **Logic configuration registers (0x000 – 0x0FF):** These registers control the core reconfiguration logic for the tile. All registers in this group are EALLOW protected and also protected by the LOCK register.
- **Top level control registers (0x100 – 0x1FF):** These registers are used for top level and device related control of the CLB. These registers typically control mux selects for inputs, global enables, and so forth, and are accessible by normal memory mapped access. Some of these registers have EALLOW and LOCK protection.
- **Data exchange registers (0x200 – 0x3FF):** These registers are used to exchange data between the CLB and the rest of the device. The registers are accessible by normal memory-mapped access and no EALLOW or LOCK protection exists.

Note

EALLOW protection means that the write access to the register is enabled only when the EALLOW instruction has been executed prior to the write access. The complementary EDIS instruction disables access to all registers protected in this way. For more information, see Section 24.8.

24.5.2 Non-Memory Mapped Registers

The memory-mapped CLB registers are described later in this chapter; however, many of the CLB resources including counters, the instruction memory of the High Level Controller, and the HLC general-purpose registers (R0 through R3) are only indirectly accessible through a local interface bus and are not memory-mapped. These registers are accessible through the two memory-mapped registers CLB_LOAD_DATA and CLB_LOAD_ADDR. Note that the general-purpose registers R0 through R3 must only be written to during configuration-time and are not intended to be written to during run-time. Writes during run-time can lead to unexpected behavior. If run-time data exchange is desired, refer to Section 24.4.6.4.

Load the data to be written into the CLB_LOAD_DATA register, then load the appropriate address into CLB_LOAD_ADDR to determine where this data is written. Writing a 1 to bit position 0 in the CLB_LOAD_EN register then causes an internal write operation to be triggered. The address allocation for the CLB_LOAD_ADDR register is shown in Table 24-13.

Note

The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and for HLC loads of the counter to take effect.

Table 24-13. Non-Memory Mapped Register Addresses

Address (Binary)	Resource
000000 to 000010	Counter 0 to 2 Load value
000100 to 000110	Counter 0 to 2 Match1 value
001000 to 001010	Counter 0 to 2 Match2 value
001100 to 001111	R0 to R3 of High Level Controller
100000 to 100111	Instructions for Event 0
101000 to 101111	Instructions for Event 1
110000 to 110111	Instructions for Event 2
111000 to 111111	Instructions for Event 3

Use the following steps to load the value 0x11223344 into the general purpose R0 register:

1. Write 0x11223344 to CLB_LOAD_DATA.
2. Write 0xc to CLB_LOAD_ADDR.
3. Write 0x1 to CLB_LOAD_EN.

Note

Even though HLC registers are accessible by the CPU, your application code needs to make sure that no other CLB internal logics are updating the same HLC register at the same time, causing a race condition.

24.6 DMA Access

The DMA does not have access to the CLB memory-mapped registers, including the PUSH and PULL FIFO registers. For more information, refer to Section 24.8.

24.7 Software

24.7.1 CLB Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/clb

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

24.7.1.1 CLB Empty Project

FILE: empty.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

24.7.1.2 CLB Combinational Logic

FILE: clb_ex1_combinatorial_logic.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

The objective of this example is to prevent simultaneous high or low outputs on a PWM pair. PWM modules 1 and 2 are configured to generate identical waveforms based on a fixed frequency up-count mode.

24.7.1.3 CLB GPIO Input Filter

FILE: clb_ex2_gpio_input_filter.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example demonstrates use of finite state machines (FSMs) and counters to implement a simple ‘glitch’ filter which might, for example, be applied to an incoming GPIO signal to remove unwanted short duration pulses.

24.7.1.4 CLB Auxilary PWM

FILE: clb_ex3_auxiliary_pwm.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example configures a CLB tile as an auxiliary PWM generator. The example uses combinatorial logic (LUTs), state machines (FSMs), counters, and the high level controller (HLC) to demonstrate the PWM output generation capabilities using CLB.

24.7.1.5 CLB PWM Protection

FILE: clb_ex4_pwm_protection.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example extends the features of example 1 to ensure an active high complementary pair PWM configuration always operates with a minimum value of dead-band irrespective of how the generating PWM module is configured. The example illustrates the configuration of four separate PWM tiles to implement PWM protection on four PWM modules. The outputs of PWM modules 1 to 4 are operated on by CLB tiles 1 to 4, respectively.

24.7.1.6 CLB Event Window

FILE: clb_ex5_event_window.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example uses the counter, FSM, and HLC sub-modules of the CLB to implement an event timing feature which detects whether an interrupt service routine takes too long to respond to an interrupt. The example configures four PWM modules to operate in up-count mode and generate a low-to-high edge on a timer zero match event. The zero match event also triggers a PWM ISR which, for the purposes of this example, contains a dummy payload of variable length. At the end of the ISR, a write operation takes place to a CLB GP register to indicate the ISR has ended.

24.7.1.7 CLB Signal Generator

FILE: clb_ex6_siggen.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

This example uses CLB1 to generate a rectangular wave and CLB2 to check the rectangular wave generated by CLB1 doesn't exceed the defined duty cycle and period limits.

24.7.1.8 CLB State Machine

FILE: clb_ex7_state_machine.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\Designing With the C2000 CLB.pdf This application report describes the process of creating this CLB example and can be used as guidance on desiging custom logic with the CLB. This example uses all submodules inside a CLB TILE in order to implement a complete system.

24.7.1.9 CLB External Signal AND Gate

FILE: clb_ex8_external_signal_AND_gate.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, two external signals from two GPIOs are passed through the Input X-BAR and the CLB X-BAR to the CLB TILE. Inside the CLB module these two signals are ANDED. The output of the AND gate is then exported to a GPIO, using Output X-BAR.

24.7.1.10 CLB Timer

FILE: clb_ex9_timer.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a COUNTER module is used to create timed events. The use of the GP Register is shown. Through setting/clearing the bits in the GP register, the timer is started, stopped or changes direction. The output of the timer event (1-clock cycle) is exported to a GPIO. Interrupts are generated from the timer event using the HLC module. A GPIO is also toggled inside the CLB ISR. The indirect CLB register access is used to update the timer's event match value and the active counter register to modify the frequency of the timer.

24.7.1.11 CLB Timer Two States

FILE: clb_ex10_timer_two_states.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the timer is setup the same as the previous example. The difference is the use of the FSM submodule to toggle the output of the CLB which is then exported to a GPIO. The FSM module acts as a single bit memory block. Interrupts are setup in the same format as the previous example. The interrupt delay of the CLB can be seen by comparing the output of the CLB and the GPIO toggled in the ISR.

24.7.1.12 CLB Interrupt Tag

FILE: clb_ex11_interrupt_tag.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a timer is setup with two different match values. These two events are used by the HLC submodule to generate interrupts. The interrupt TAG is used to differentiate between the interrupt generated due to the match1 event of the CLB counter and the match2 event of the CLB counter.

24.7.1.13 CLB Output Intersect

FILE: clb_ex12_output_intersect.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the CLB module is set up the same as the external_AND_gate example. However, instead of the output being exported to the GPIO using Output X-BAR, the output is exported to the GPIO by replacing the output of ePWM1. This is done by configuring the GPIO for EPWM1A output, followed by enabling output intersection.

24.7.1.14 CLB PUSH PULL

FILE: clb_ex13_push_pull.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the use of the PUSH-PULL interface is shown. Multiple COUNTER submodules, HLC submodule, FSM submodules, and OUTLUT submodules are used. The PUSH-PULL interface is used alongside the GP register to update the COUNTER submodules' event frequencies.

24.7.1.15 CLB Multi Tile

FILE: clb_ex14_multi_tile.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a CLB TILE is passed to the input of another CLB TILE. The output of the second CLB TILE is then exported to a GPIO, showcasing how two CLB TILEs can be used in series.

24.7.1.16 CLB Tile to Tile Delay

FILE: clb_ex15_tile_to_tile_delay.c

For the detailed description of this example, please refer to:
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a GPIO is taken into the CLB TILE through INPUT XBAR and the CLB XBAR. The signal is forwarded by the TILE to the next TILE. This time the signal only goes through the CLB XBAR and NOT the Input XBAR. This is done to show that delays are added when the signals are passed from TILE to TILE and the delay is NOT characterized. The user should always avoid passing signals with timing requirements between tiles. The COUNTER modules inside the CLBs will count the amount of delay in cycles.

24.7.1.17 CLB based One-shot PWM

FILE: clb_ex17_one_shot_pwm.c

For the detailed description of this example, please refer to :
C2000Ware_PATH\utilities\clb_tool\clb_syscfg\doc\CLB Tool Users Guide.pdf

24.7.1.18 CLB Trip Zone Timestamp

FILE: clb_ex29_timestamp.c

This example displays how to timestamp interrupts generated by the CLB. An interrupt is generated when ePWM1 is tripped.

ePWM1 is configured to be interrupted by TZ1 and TZ2, both one shot trip sources.

The CLB is configured as follows:

- COUNTER0 and COUNTER1 continually count when the program begins.
- COUNTER0 timestamps TZ1 and COUNTER1 timestamps TZ2.
- COUNTER2 increments once when COUNTER0/COUNTER1 overflows using LUT2.
- FSM0/1 are configured to sync counters and stop COUNTER0/1 when an interrupt is received.
- TZ1 (GPIO12) and TZ2 (GPIO13) are routed as inputs through CLBXBAR.
- BOUNDARY.boundaryInput0 denotes TZ1. On rising edge, HLC issues an interrupt with tag 12.
- BOUDNARY.in1 denotes TZ2. On rising edge, HLC issues an interrupt with tag 13.
- BOUNDARY.boundaryInput7 serves as a simultaneous enable for COUNTER0/1 to begin counting.

TZ1 is tripped when GPIO12 is connected to GND. TZ2 is tripped when GPIO13 is connected to GND. When an interrupt occurs, the interrupt handler determines the initial trip source and stores this value in a variable 'initialTripZone'.

View these variables in Debug Expressions tab:

initialTripZone: stores the first TZ to have been tripped tz1Counter64bit: stores the counter value at the instant that TZ1 is tripped. tz2Counter64bit: stores the counter value at the instant that TZ2 is tripped.

24.8 CLB Registers

This section describes the Configurable Logic Block Registers.

24.8.1 CLB Base Addresses

Table 24-14. CLB Base Address Table (C28)

Bit Field Name		DriverLib Name	Base Address
Instance	Structure		
Clb1LogicCfgRegs	CLB_LOGIC_CONFIG_REGS	CLB1_LOGICCFG_BASE	0x0000_3000
Clb1LogicCtrlRegs	CLB_LOGIC_CONTROL_REGS	CLB1_LOGICCTRL_BASE	0x0000_3100
Clb1DataExchRegs	CLB_DATA_EXCHANGE_REGS	CLB1_DATAEXCH_BASE	0x0000_3200

Complex bit access types are encoded to fit into small table cells. Table 24-16 shows the codes that are used for access types in this section.

Table 24-16. CLB_LOGIC_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write

Table 24-16. CLB_LOGIC_CONFIG_REGS Access Type Codes (continued)

Access Type	Code	Description
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

24.8.2.1 CLB_COUNT_RESET Register (Offset = 2h) [Reset = 00000000h]

CLB_COUNT_RESET is shown in Figure 24-16 and described in Table 24-17.

Return to the Summary Table.

24.8.3 CLB_LOGIC_CONTROL_REGS Registers

Table 24-46 lists the memory-mapped registers for the CLB_LOGIC_CONTROL_REGS registers. All register offset addresses not listed in Table 24-46 should be considered as reserved locations and the register contents should not be modified.

Table 24-46. CLB_LOGIC_CONTROL_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CLB_LOAD_EN	Global enable & indirect load enable control, only Global Enable Bit is LOCK protected	LOCK	Go
2h	CLB_LOAD_ADDR	Indirect address		Go
4h	CLB_LOAD_DATA	Data for indirect loads		Go
6h	CLB_INPUT_FILTER	Input filter selection for both edge detection and synchronizers	LOCK	Go
8h	CLB_IN_MUX_SEL_0	Input selection to decide between Signals and GP register	LOCK	Go
Ah	CLB_LCL_MUX_SEL_1	Input Mux selection for local mux	LOCK	Go
Ch	CLB_LCL_MUX_SEL_2	Input Mux selection for local mux	LOCK	Go
Eh	CLB_BUF_PTR	PUSH and PULL pointers		Go
10h	CLB_GP_REG	General purpose register for CELL inputs		Go
12h	CLB_OUT_EN	CELL output enable register		Go
14h	CLB_GLBL_MUX_SEL_1	Global Mux select for CELL inputs	LOCK	Go
16h	CLB_GLBL_MUX_SEL_2	Global Mux select for CELL inputs	LOCK	Go
20h	CLB_INTR_TAG_REG	Interrupt Tag register		Go
22h	CLB_LOCK	Lock control register	EALLOW	Go
30h	CLB_DBG_R0	R0 of High level Controller		Go
32h	CLB_DBG_R1	R1 of High level Controller		Go
34h	CLB_DBG_R2	R2 of High level Controller		Go
36h	CLB_DBG_R3	R3 of High level Controller		Go
38h	CLB_DBG_C0	Count of Unit 0		Go
3Ah	CLB_DBG_C1	Count of Unit 1		Go
3Ch	CLB_DBG_C2	Count of Unit 2		Go
3Eh	CLB_DBG_OUT	Outputs of various units in the Cell		Go

Complex bit access types are encoded to fit into small table cells. Table 24-47 shows the codes that are used for access types in this section.

Table 24-47. CLB_LOGIC_CONTROL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

Table 24-47. CLB_LOGIC_CONTROL_REGS Access Type Codes (continued)

Access Type	Code	Description
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

24.8.3.1 CLB_LOAD_EN Register (Offset = 0h) [Reset = 0000h]

CLB_LOAD_EN is shown in Figure 24-45 and described in Table 24-48.

Return to the Summary Table.

Global enable & indirect load enable control, only Global Enable Bit is LOCK protected

RESERVED					STOP	GLOBAL_EN	LOAD_EN
R-0-0h					R/W-0h	R/W-0h	R/W-0h

Table 24-48. CLB_LOAD_EN Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R-0	0h	Reserved
2	STOP	R/W	0h	This bit defines the behaviour of the sequential elements in the CELL during debug HALTs of the CPU. If this bit is set to 0, the debug HALT condition is ignored. Reset type: SYSRSn
1	GLOBAL_EN	R/W	0h	This bit is a global enable signal for the logic in the CELL. This also acts as a soft reset for the CELL logic. CLB outputs (including LUTs and OUTLUTs) will be gated when this bit is cleared from 1 to 0, i.e., the CLB outputs will be low when GLOBAL_EN is low. Additionally, the FSM and AOC blocks will also be reset. Note that when this bit goes low, the COUNTER blocks and HLC are simply halted, but they will NOT be reset internally. This allows the ability to preload these submodules when GLOBAL_EN is 0. This bit is normally set after all the other configuration settings are completed. This bit is LOCK protected. Reset type: SYSRSn
0	LOAD_EN	R/W	0h	A write with this bit set to 1 will pulse the Load Enable signal for the indirect register loads in the CELL. Reset type: SYSRSn

24.8.3.2 CLB_LOAD_ADDR Register (Offset = 2h) [Reset = 00000000h]

CLB_LOAD_ADDR is shown in Figure 24-46 and described in Table 24-49.

Return to the Summary Table.

24.8.4 CLB_DATA_EXCHANGE_REGS Registers

Table 24-70 lists the memory-mapped registers for the CLB_DATA_EXCHANGE_REGS registers. All register offset addresses not listed in Table 24-70 should be considered as reserved locations and the register contents should not be modified.

Table 24-70. CLB_DATA_EXCHANGE_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h + formula	CLB_PUSH_y	CLB_PUSH FIFO Registers (from HLC)		Go
100h + formula	CLB_PULL_y	CLB_PULL FIFO Registers (TO HLC)		Go

Complex bit access types are encoded to fit into small table cells. Table 24-71 shows the codes that are used for access types in this section.

Table 24-71. CLB_DATA_EXCHANGE_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

24.8.4.1 CLB_PUSH_y Register (Offset = 0h + formula) [Reset = 00000000h]

CLB_PUSH_y is shown in Figure 24-67 and described in Table 24-72.

Return to the Summary Table.

CLB_PUSH FIFO Registers (from HLC)

• Moved Figure 23-15 to Section 23.3.1	2629

IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATA SHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES “AS IS” AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI’s products are provided subject to TI’s Terms of Sale or other applicable terms available either on ti.com or provided in conjunction with such TI products. TI’s provision of these resources does not expand or otherwise alter TI’s applicable warranties or warranty disclaimers for TI products.

TI objects to and rejects any additional or different terms you may have proposed.
