The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user mut ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol

requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Note

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

15.4.4.9.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19:16] WEONTIME bit field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.9.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device data manual.
- The GPMC_CLK clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When the cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

Note

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

15.4.4.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of the control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by a half-GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

15.4.4.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC_CONFIG5_i[20:16] RDACCESSTIME and GPMC_CONFIG6_i[28:24] WRACCESSTIME bit fields (where i = 0 to 7). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

15.4.4.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

15.4.4.9.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC_CLK edge for a synchronous write access. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

15.4.4.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field (where i = 0 to 7) can be set with a granularity of 1 or 2 through theGPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

15.4.4.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

15.4.4.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC_CLK edge in synchronous write mode. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

15.4.4.9.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

15.4.4.10 NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (where i = 0 to 7). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit where (i = 0 to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

Note

The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

15.4.4.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

15.4.4.10.1.1 Access on Address/Data Multiplexed Devices

15.4.4.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 15-65 shows an asynchronous single read operation on an address/data-multiplexed device.

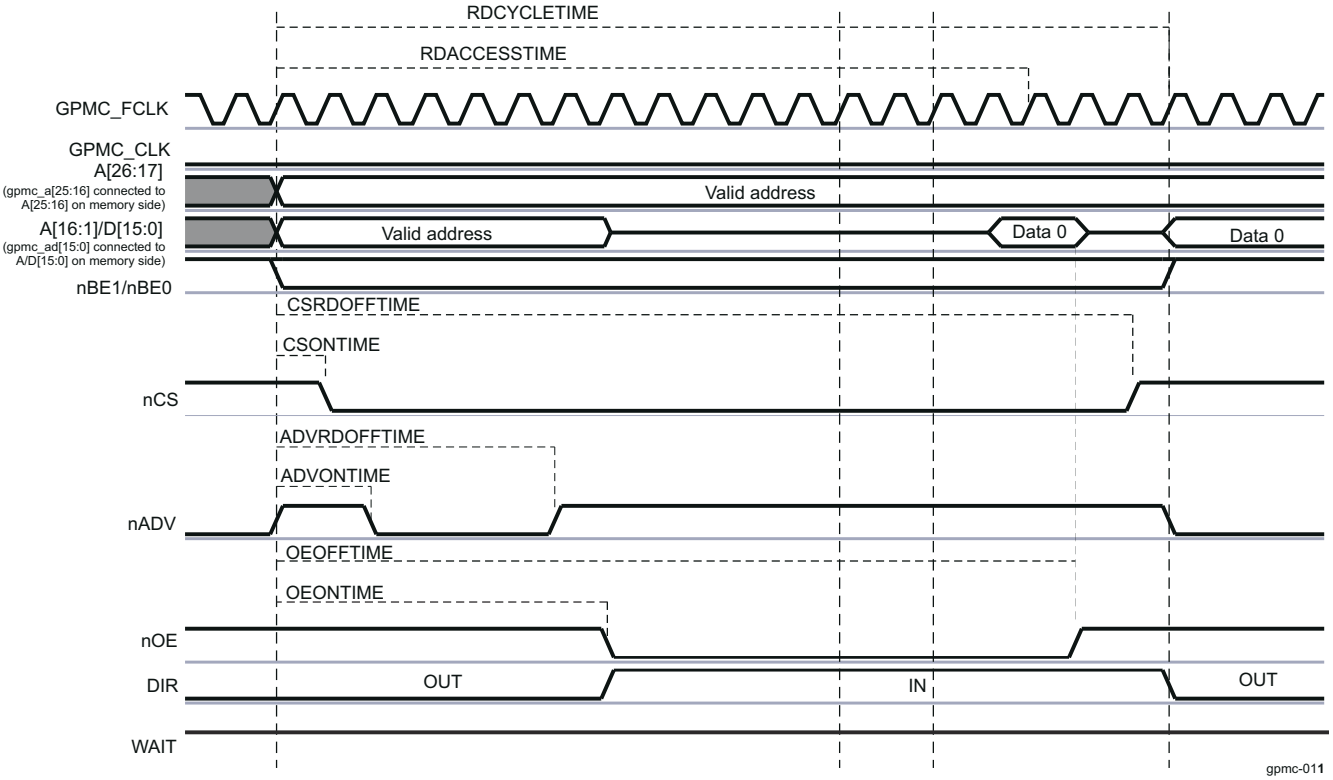

Figure 15-65. Asynchronous Single Read on an Address/Data-Multiplexed Device

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-294 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.8.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc_a[27:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field.

- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 15.4.4.10.5, *System Burst Versus External Device Burst Support*.

Between two successive accesses, if an nCS pulse is needed:

- The GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

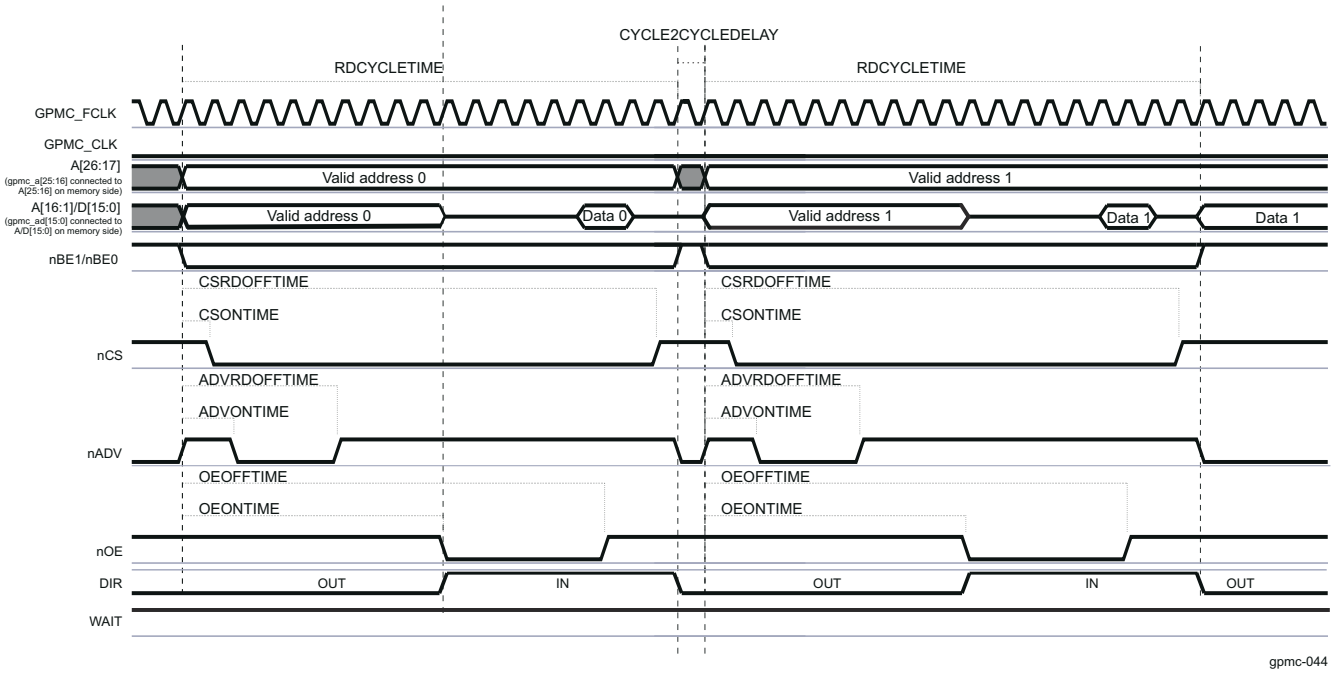

Figure 15-66. Two Asynchronous Single-Read Accesses on an Address/Data-Multiplexed Device (32-Bit Read Split Into 2 x 16-Bit Read)

15.4.4.10.1.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

Figure 15-67 shows an asynchronous single-write operation on an address/data-multiplexed device.

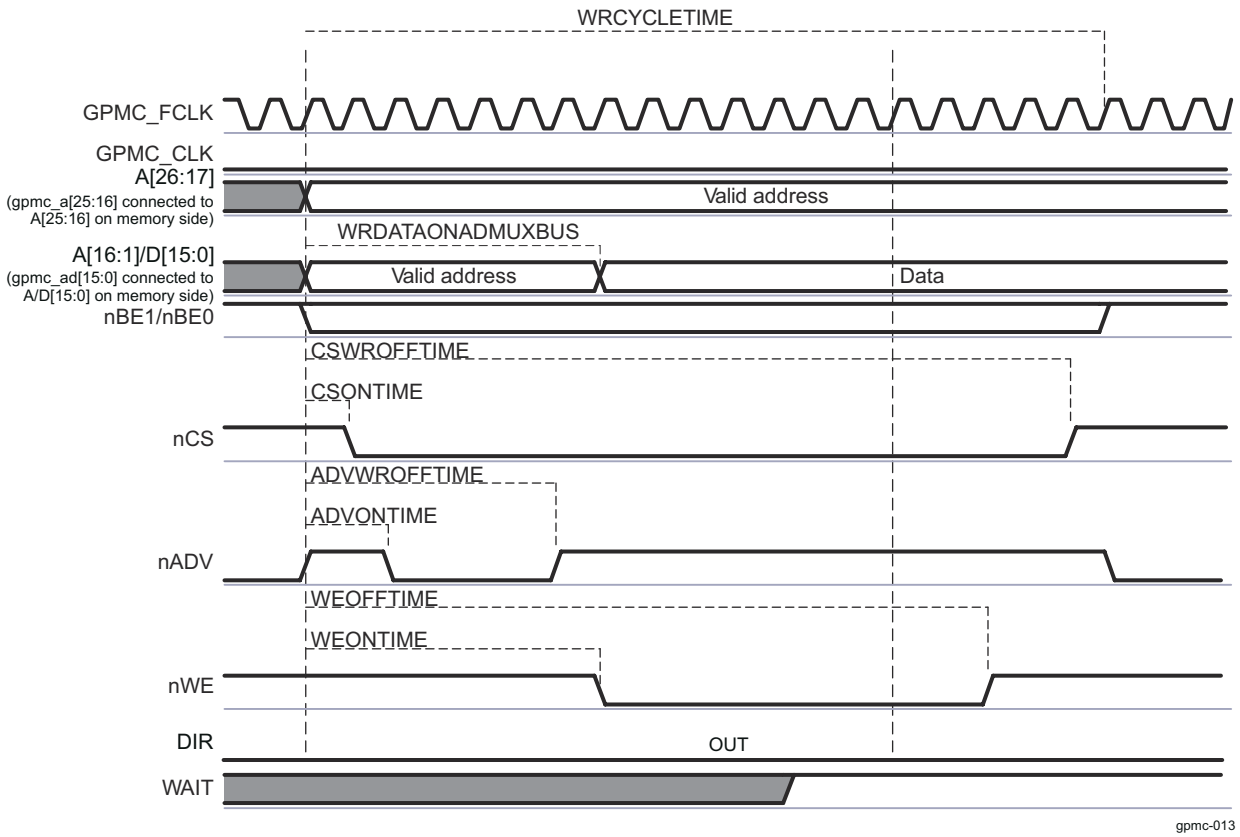

Figure 15-67. Asynchronous Single-Write on an Address/Data-Multiplexed Device

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-294 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see Section 15.4.4.8.2.3, *Address/Data-Multiplexing Interface*.

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12:8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS time.

Note

Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 15.4.4.9.10, *Bus Keeping Support*.

15.4.4.10.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see Section 15.4.4.10.3, *Asynchronous and Synchronous Accesses in Nonmultiplexed Mode*.

15.4.4.10.1.2 Access on Address/Address/Data-Multiplexed Devices

15.4.4.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 15-68 shows an asynchronous single-read operation on an AAD-multiplexed device.

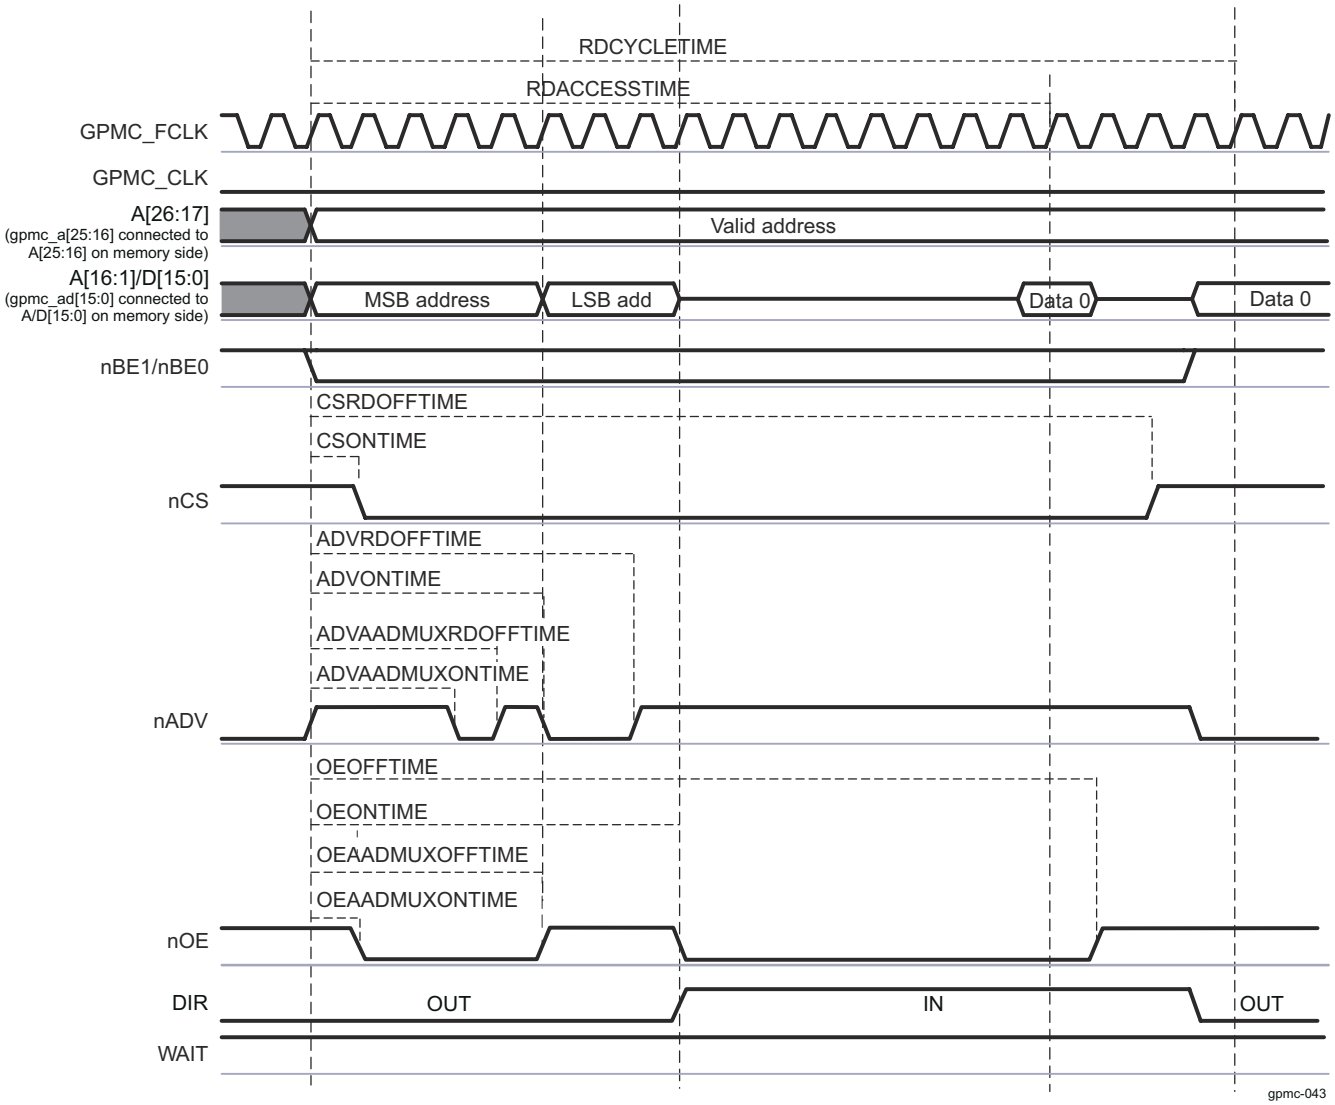

Figure 15-68. Asynchronous Single Read on an AAD-Multiplexed Device

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-294 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.

  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

15.4.4.10.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

Figure 15-69 shows an asynchronous single-write operation on an AAD-multiplexed device.

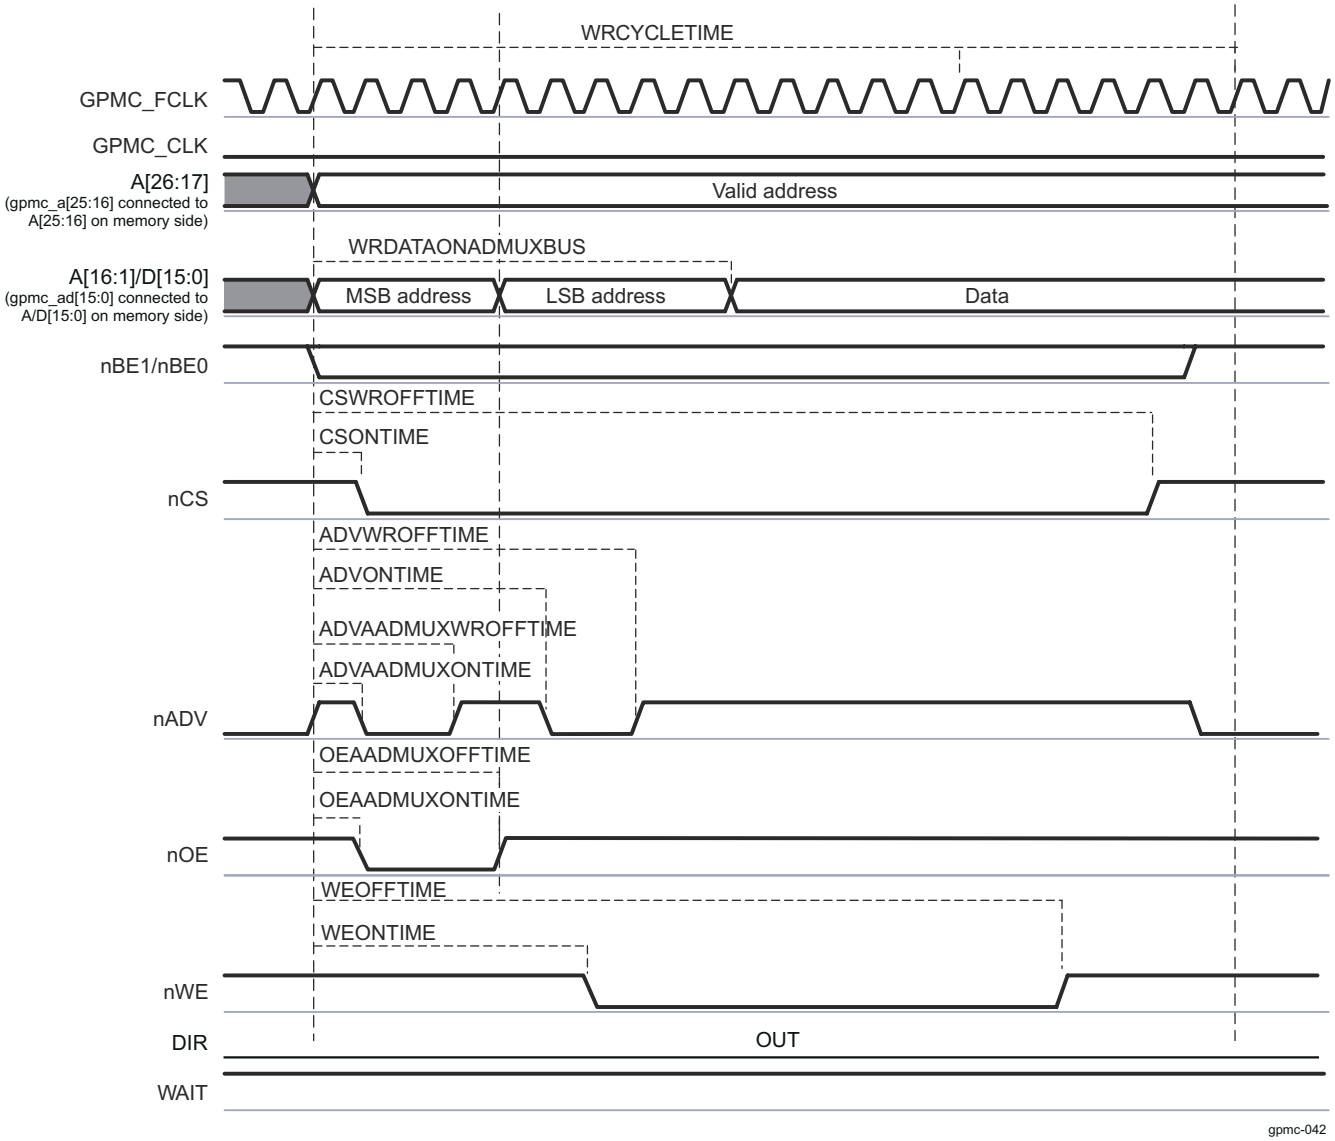

Figure 15-69. Asynchronous Single Write on an AAD-Multiplexed Device

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-294 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See Table 15-285.

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS parameter.

15.4.4.10.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see Section 15.4.4.10.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

15.4.4.10.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (nonmultiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on nonmultiplexed devices, see Section 15.4.4.10.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field. In the following section i stands for the chip-select number, i = 0 to 7.
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field specifies that the GPMC_CLK is provided outside the GPMC for 0 to 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

15.4.4.10.2.1 Synchronous Single Read

Figure 15-70 and Figure 15-71 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

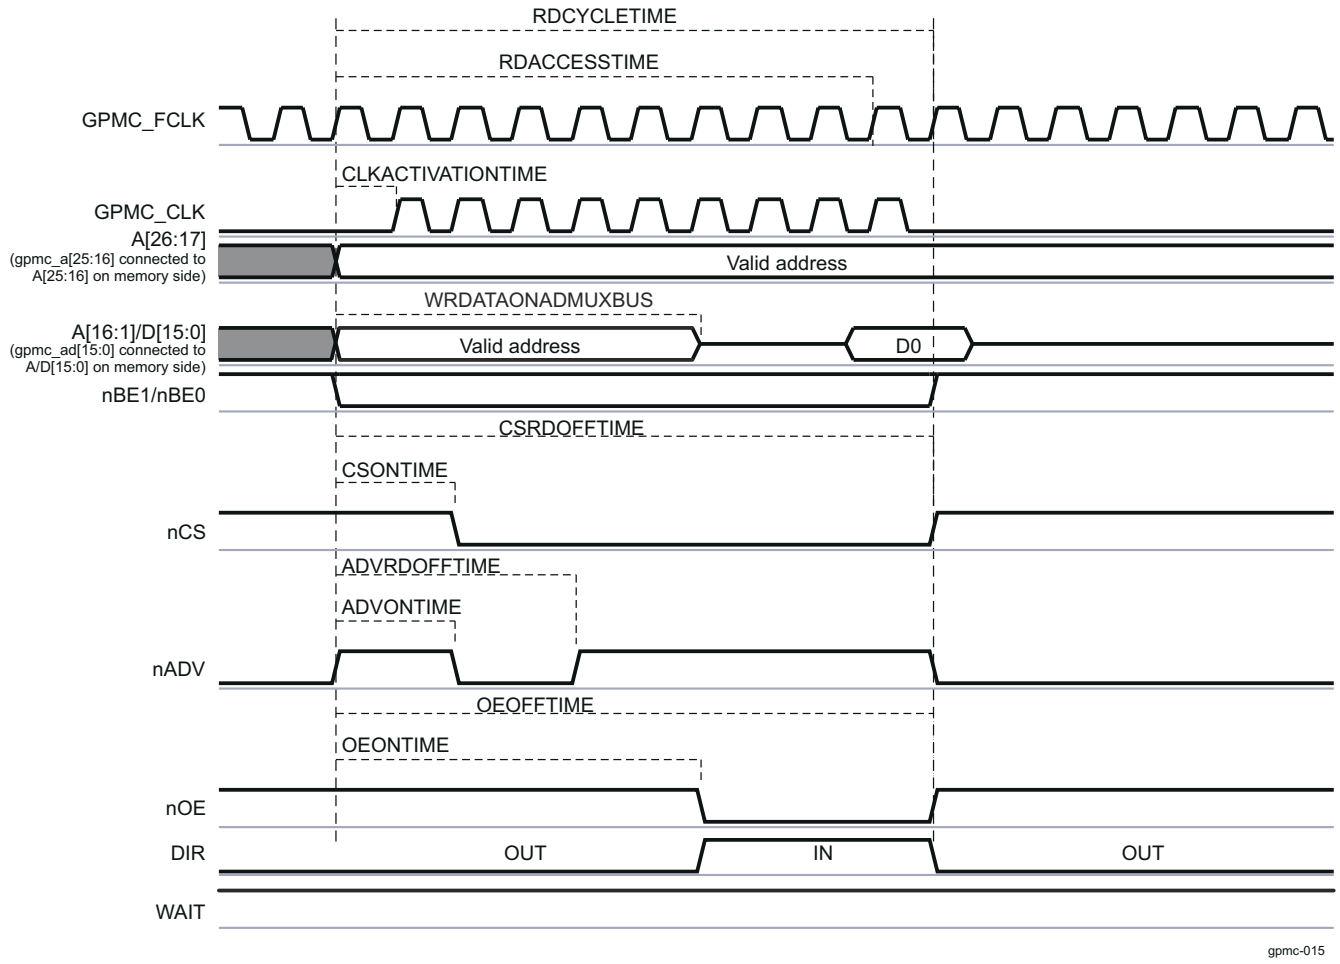

Figure 15-70. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

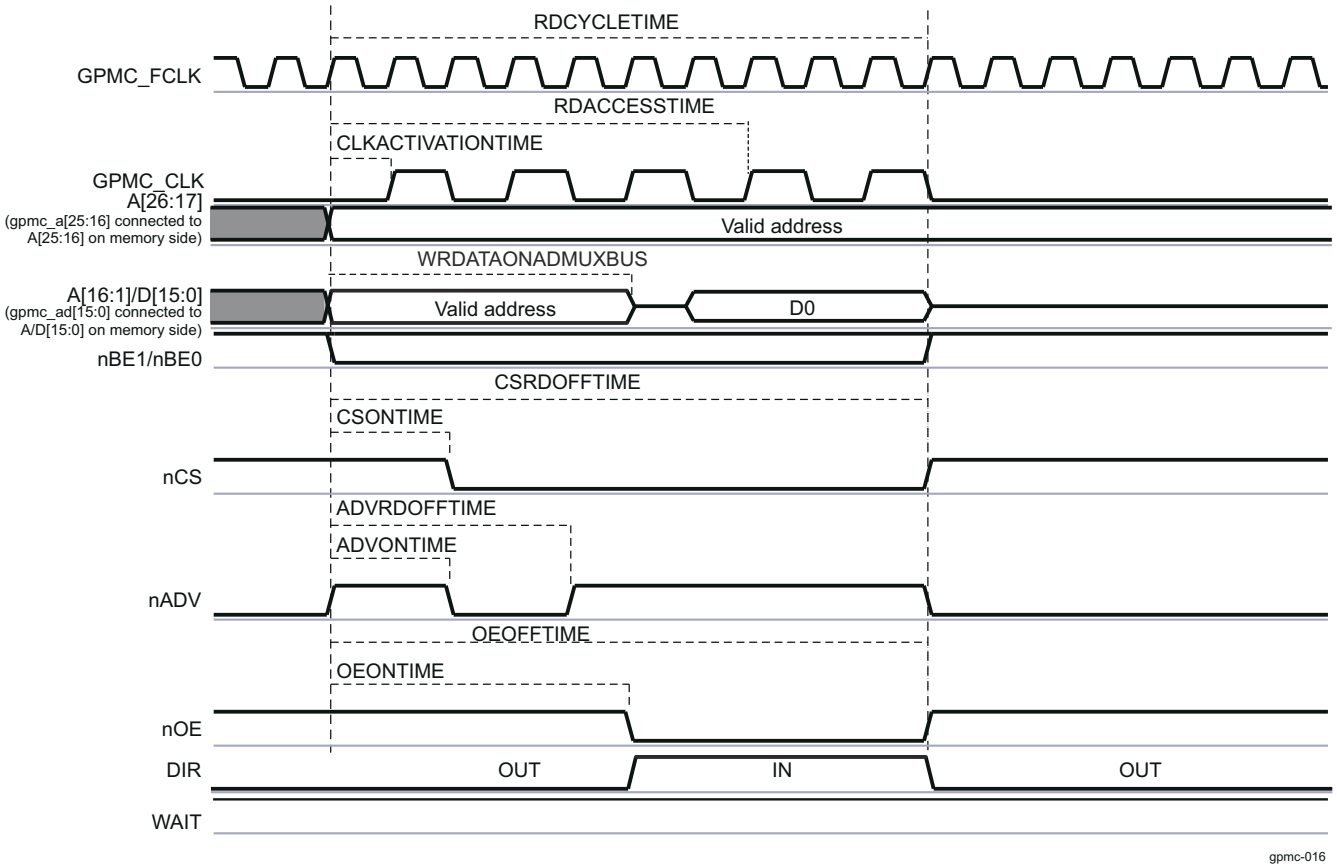

Figure 15-71. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-294 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.8.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.9.10, *Bus Keeping Support*.

15.4.4.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 15-72 and Figure 15-73 show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

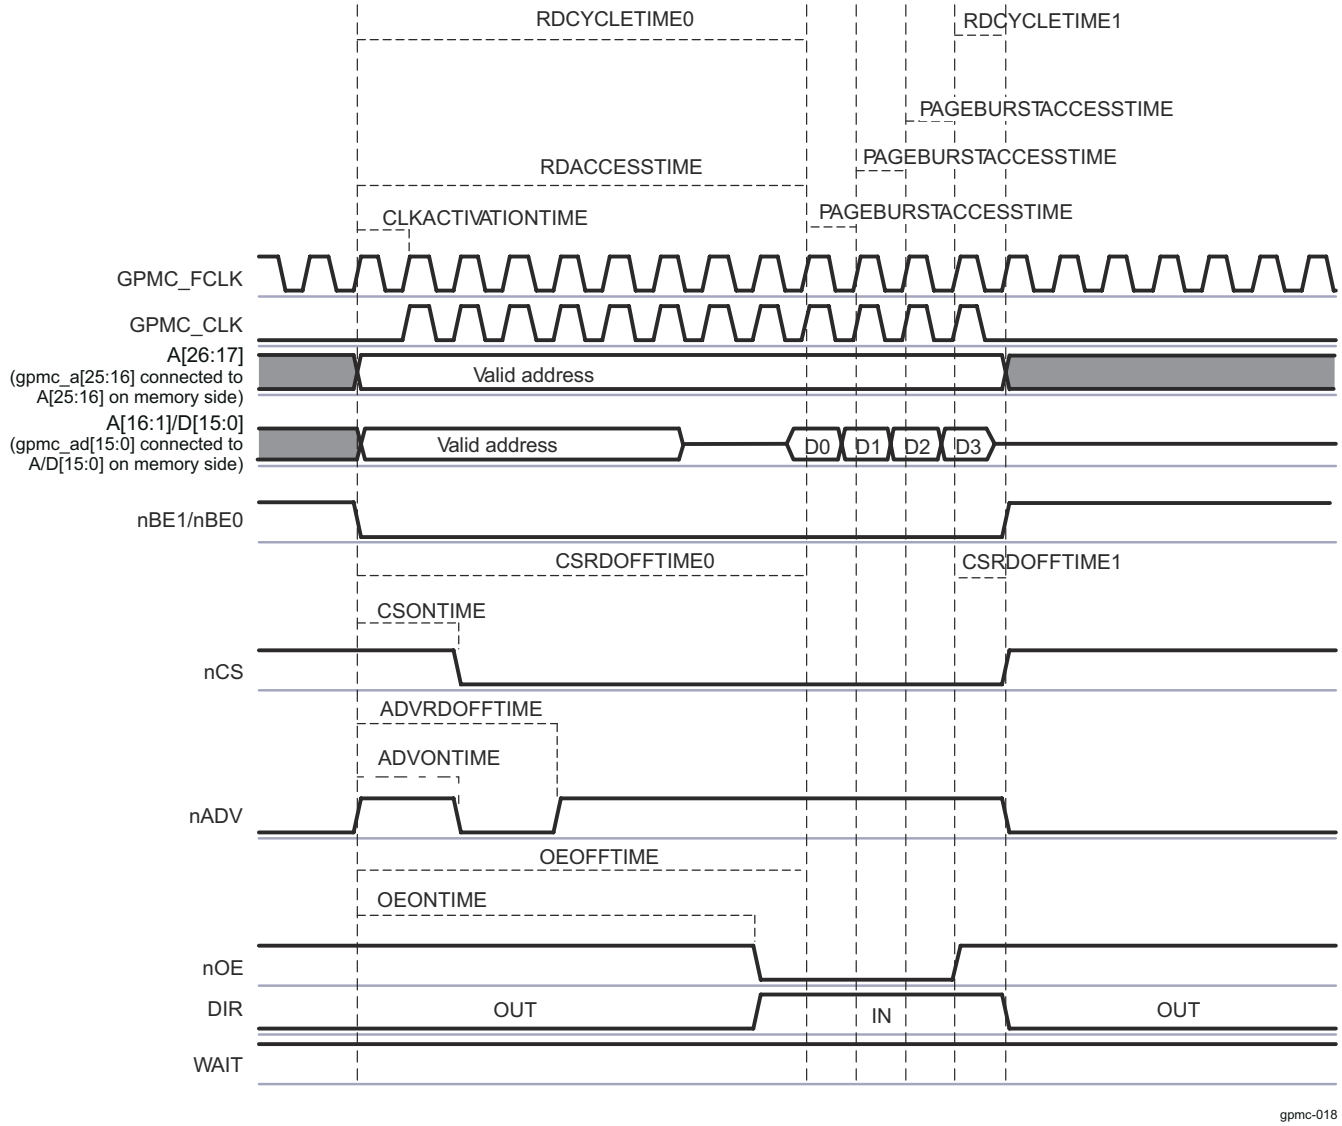

Figure 15-72. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

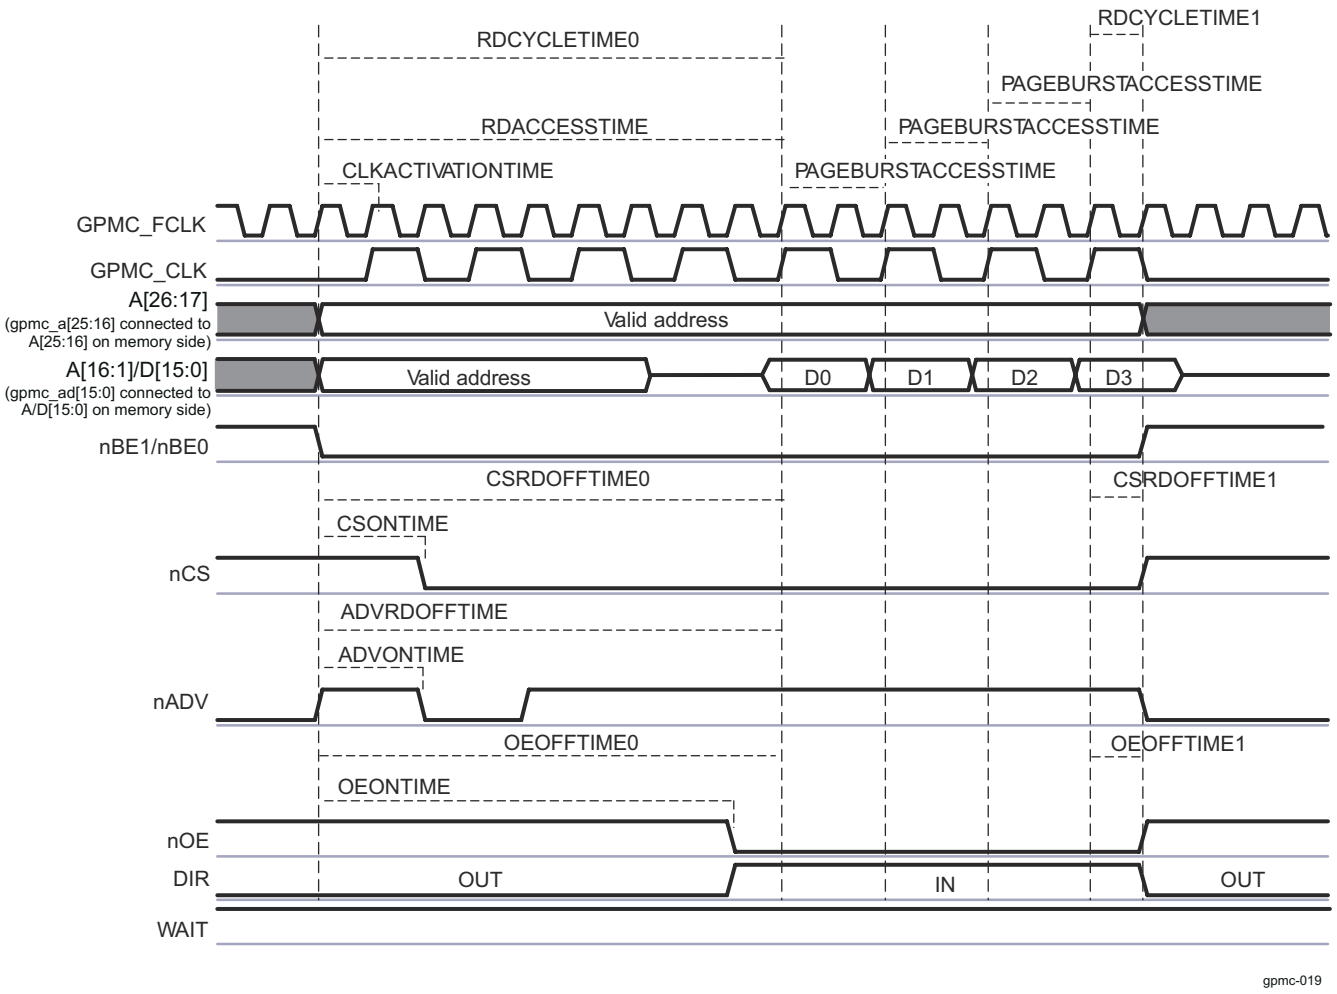

Figure 15-73. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

When the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See Table 15-280.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4:0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-73, the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.9.10, *Bus Keeping Support*.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field.

15.4.4.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

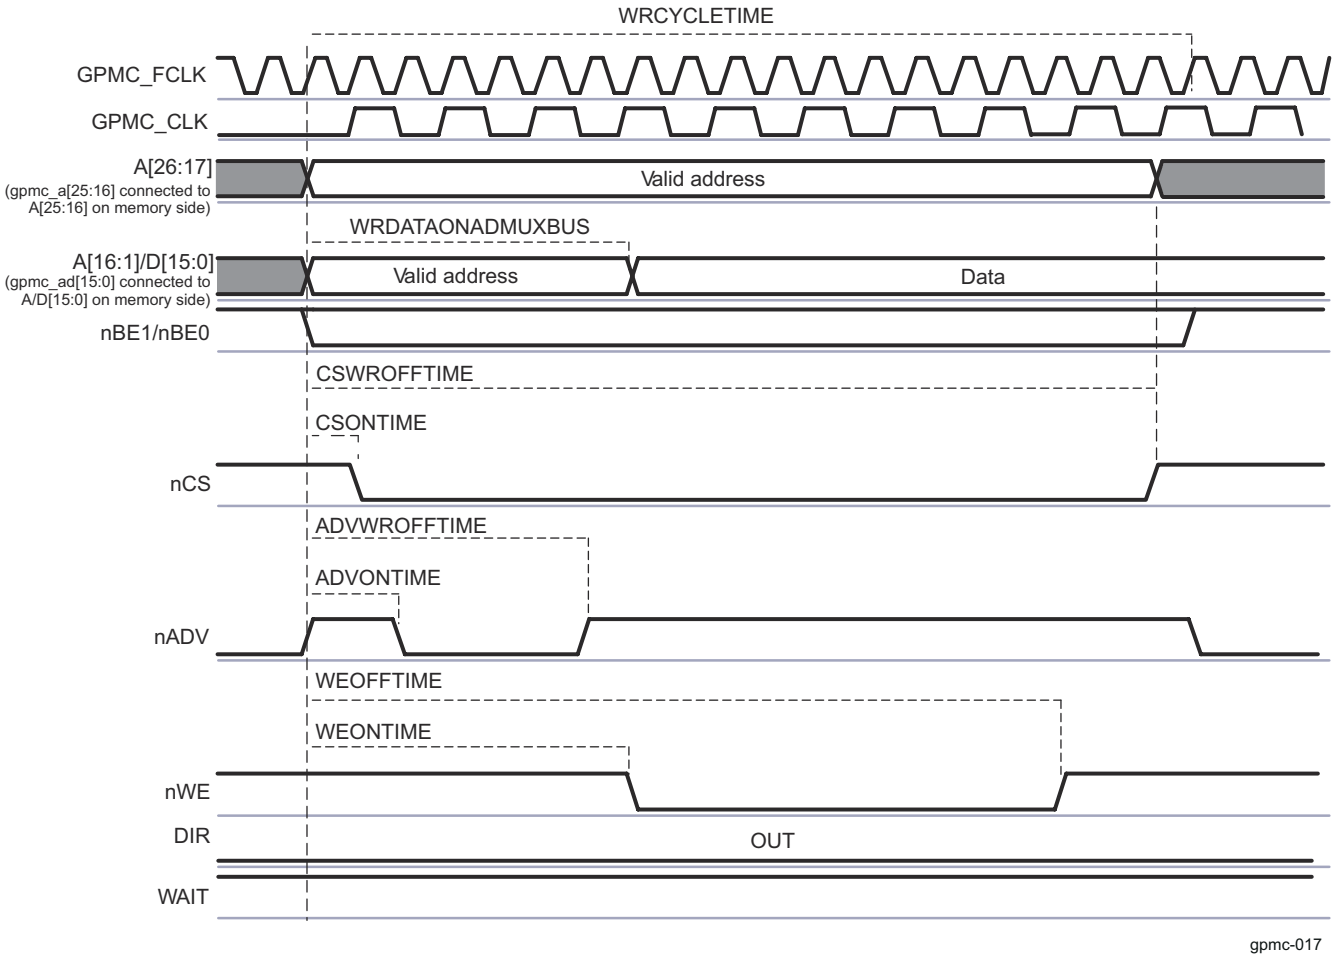

Figure 15-74. Synchronous Single Write on an Address/Data-Multiplexed Device

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

15.4.4.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 15-75 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

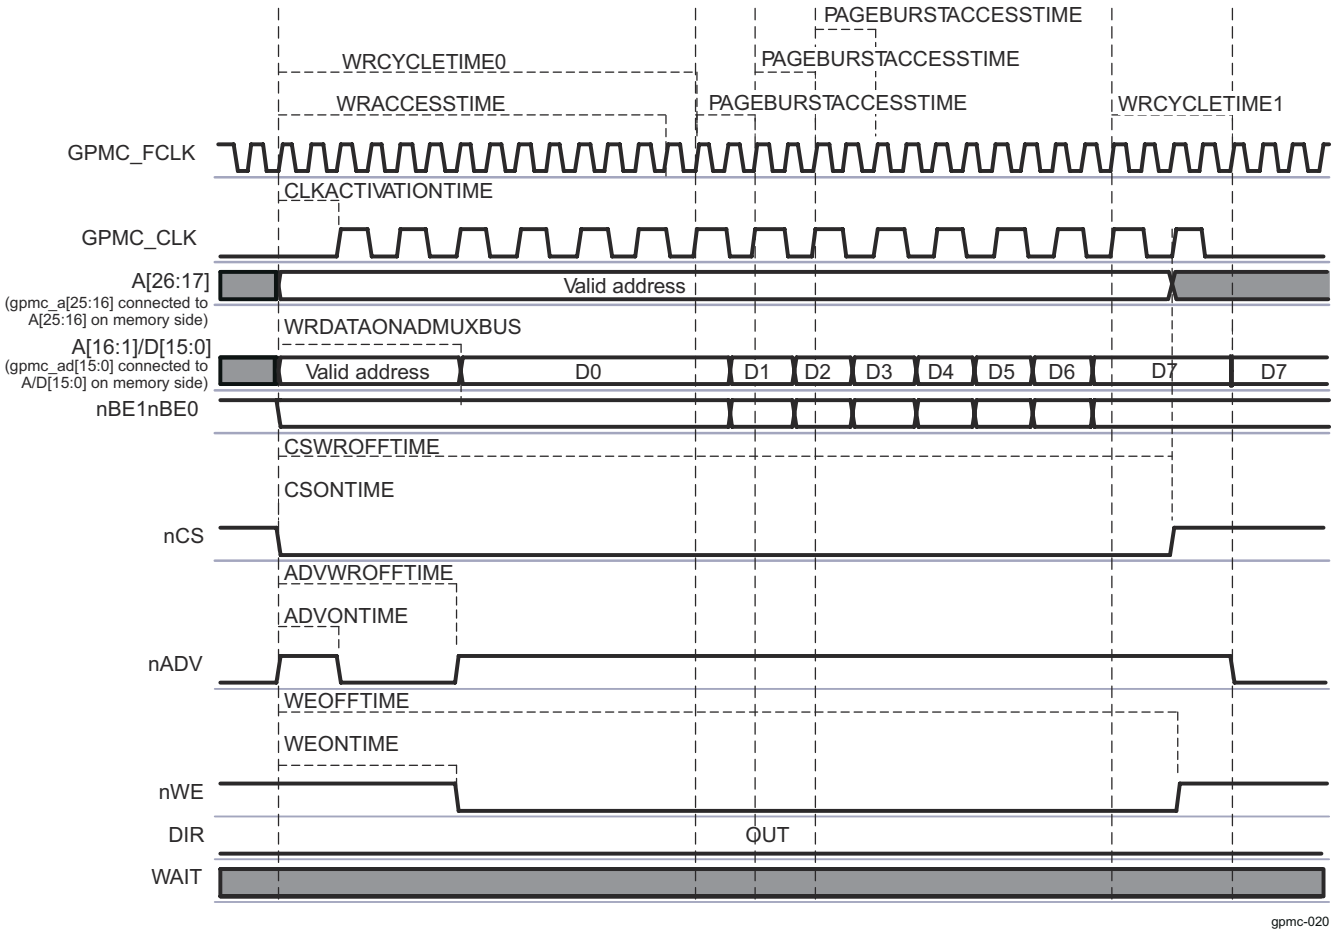

Figure 15-75. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

Figure 15-76 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

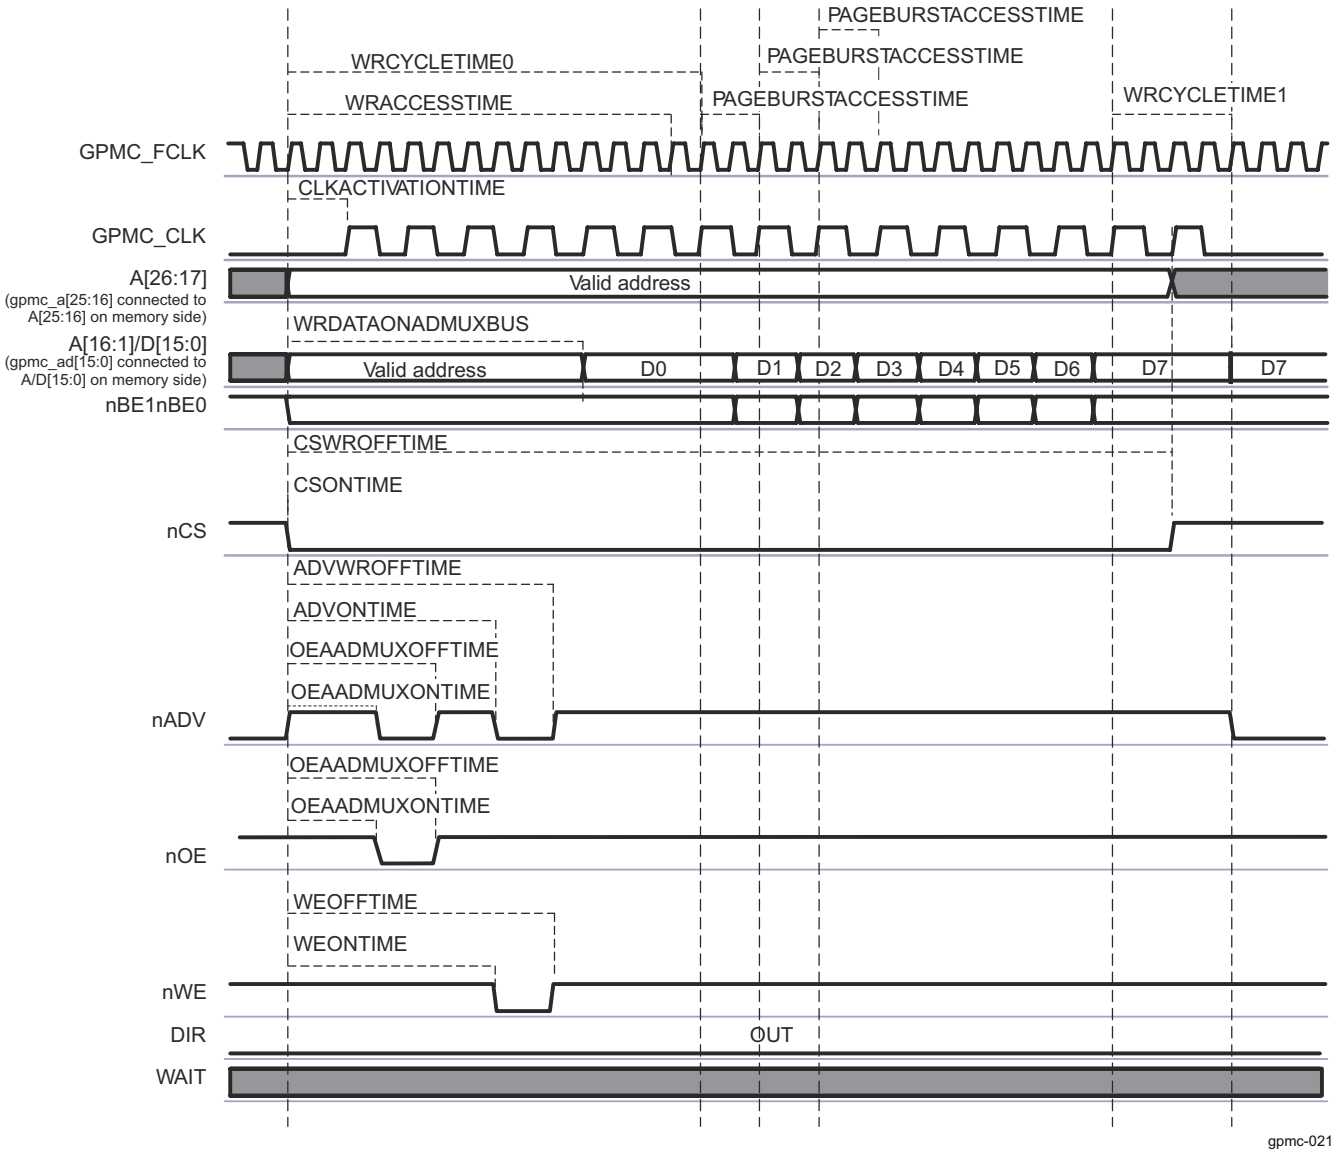

Figure 15-76. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

The first data of the burst is driven on the A/D bus at the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.8.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field (where i = 0 to 7) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC_CONFIG2_i[20:16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.

  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.

Note

The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described..

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG4_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12:8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28:24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12:8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-75, the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 15.4.4.9.10, *Bus Keeping Support*.

15.4.4.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is available only in nonmultiplexed mode.

- Asynchronous single-read operation on a nonmultiplexed device
- Asynchronous single-write operation on a nonmultiplexed device
- Asynchronous multiple- (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

15.4.4.10.3.1 Asynchronous Single-Read Operation on Nonmultiplexed Device

Figure 15-77 shows an asynchronous single-read operation on a nonmultiplexed device.

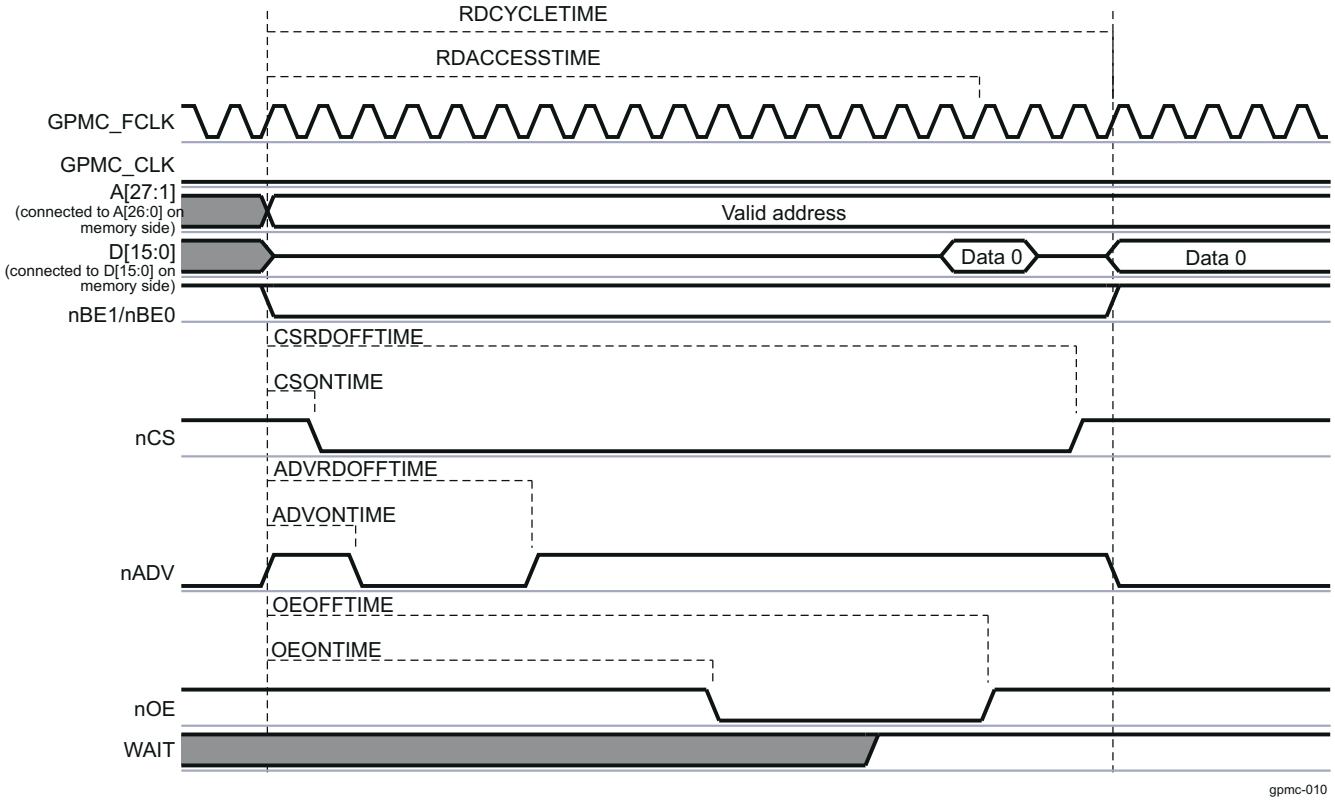

Figure 15-77. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

The 27-bit address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at GPMC_CONFIG1_5[20:16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4:0] RDCYCLETIME parameter.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-285).

15.4.4.10.3.2 Asynchronous Single-Write Operation on Nonmultiplexed Device

Figure 15-78 shows an asynchronous single-write operation on a nonmultiplexed device.

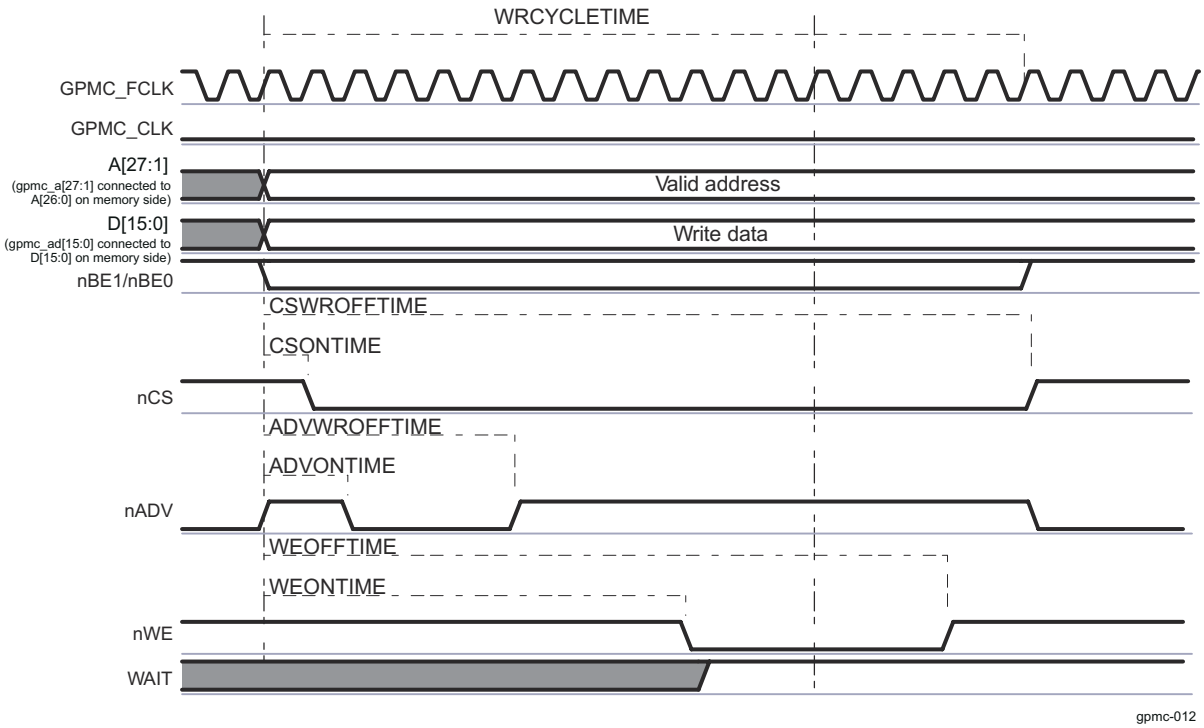

Figure 15-78. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-285).

15.4.4.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on Nonmultiplexed Device

Figure 15-79 shows an asynchronous multiple-read operation on a nonmultiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

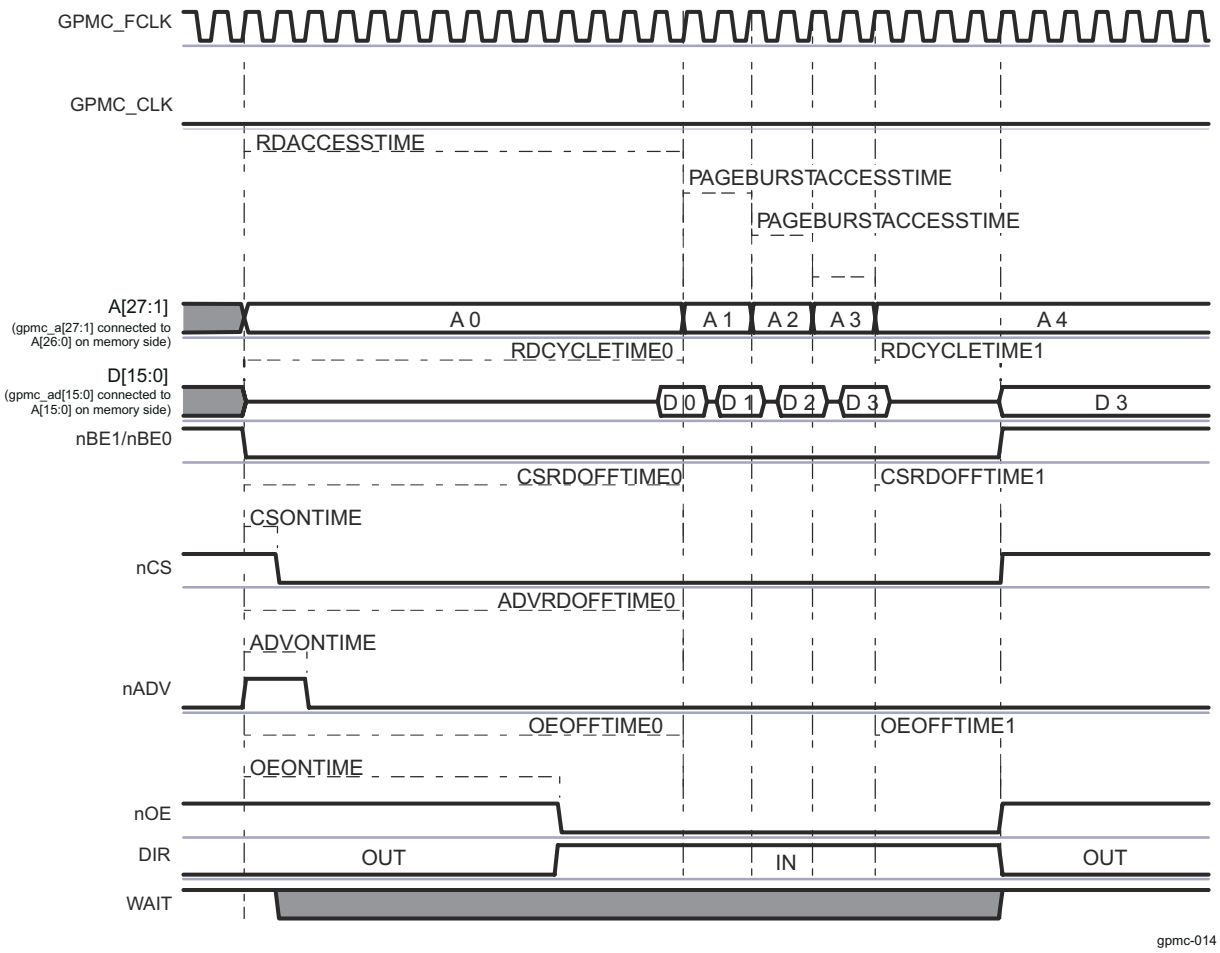

Figure 15-79. Asynchronous Multiple (Page Mode) Read

Note

The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-285).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20:16] RDACCESSTIME completion time (where i = 0 to 7). The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field.

- In Figure 15-79, the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

15.4.4.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 15.4.5.3, *GPMC Configuration in NOR Mode*.

15.4.4.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (where i = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

Note

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing

15.4.4.10.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 7). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (where i = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only

fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), wait pin monitoring must be enabled to dynamically control data access completion within the burst.

Note

When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

15.4.4.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[11:10] DEVICETYPE bit field (where i = 0 to 7) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

15.4.4.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

15.4.4.12.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

15.4.4.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MiB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in Table 15-263. Failure to comply with these settings corrupts the NAND interface protocol.

Table 15-263. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] (1)	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface

Table 15-263. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9:8]	0b00	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

(1) i = 0 to 7

The GPMC_CONFIG1_i to GPMC_CONFIG4_i registers (where i = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

15.4.4.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (where i = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations must be posted for faster operations (where i = 0 to 7). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers (where i = 0 to 7) are 32-bit word locations, which means any 32-or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC_NAND_COMMAND_i and a GPMC_NAND_ADDRESS_i (where i = 0 to 7) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

15.4.4.12.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i location (where i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.

- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 15-80 shows the NAND command latch cycle.

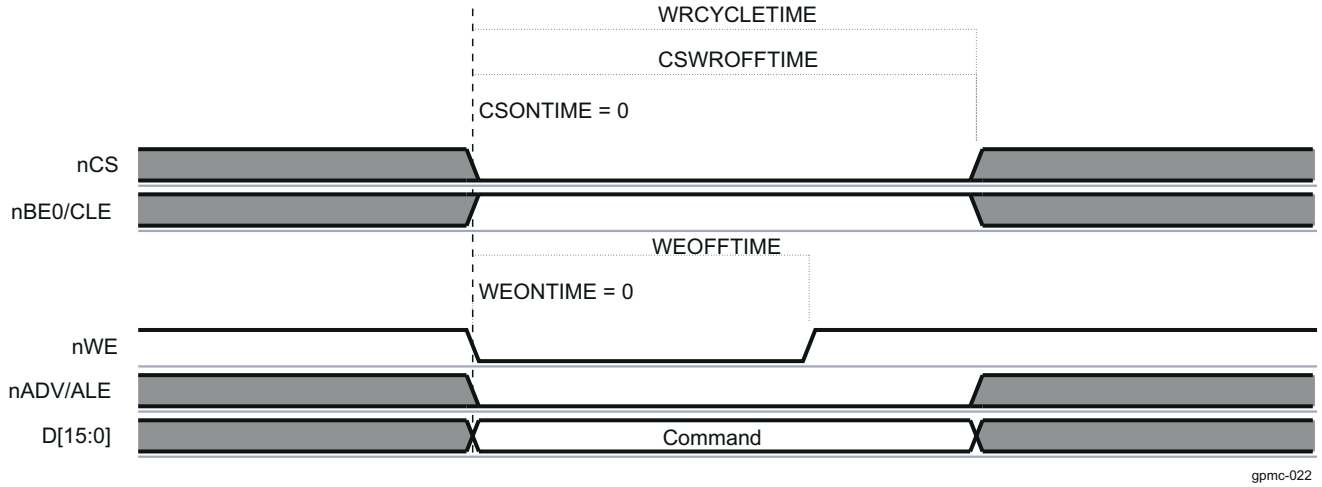

Figure 15-80. NAND Command Latch Cycle

Note

CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

15.4.4.12.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (where i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 15-81 shows the NAND address latch cycle.

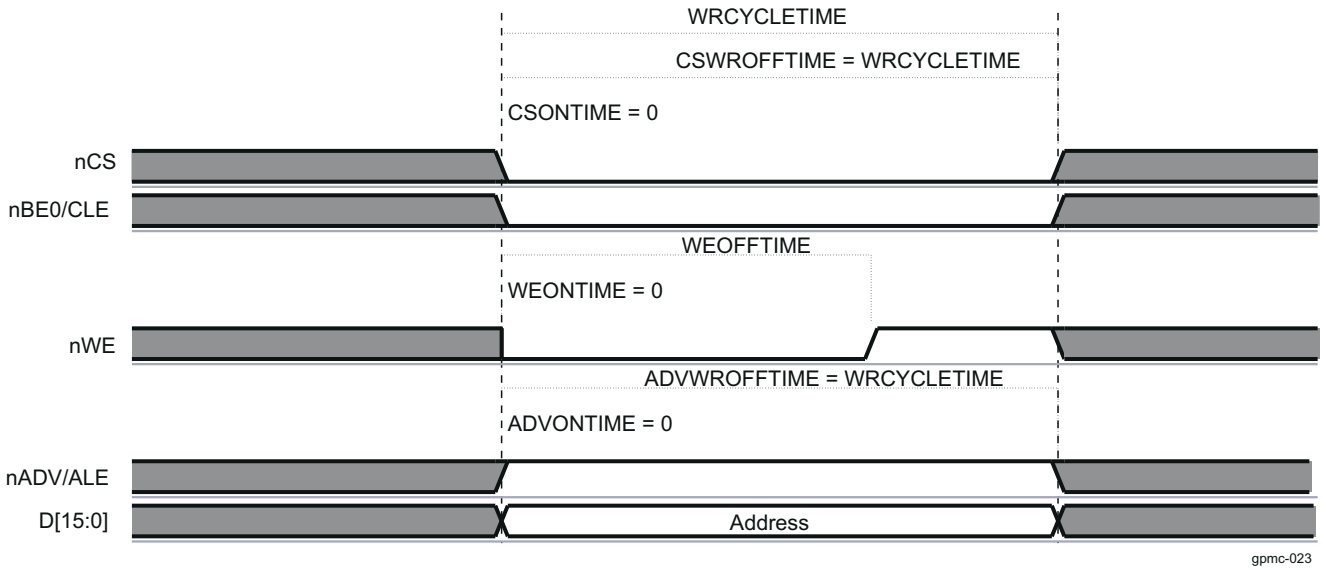

Figure 15-81. NAND Address Latch Cycle

Note

ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

15.4.4.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (where i = 0 to 7) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 15-82 shows the NAND data read cycle.

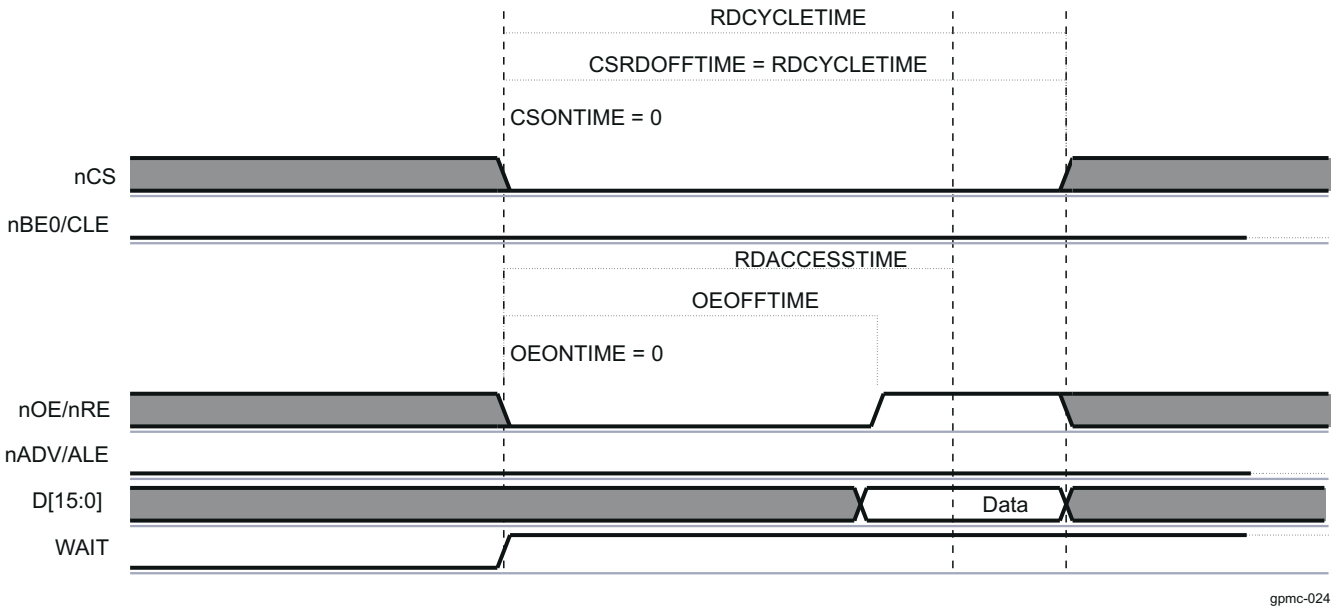

Figure 15-82. NAND Data Read Cycle

Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 15-83 shows the NAND data write cycle.

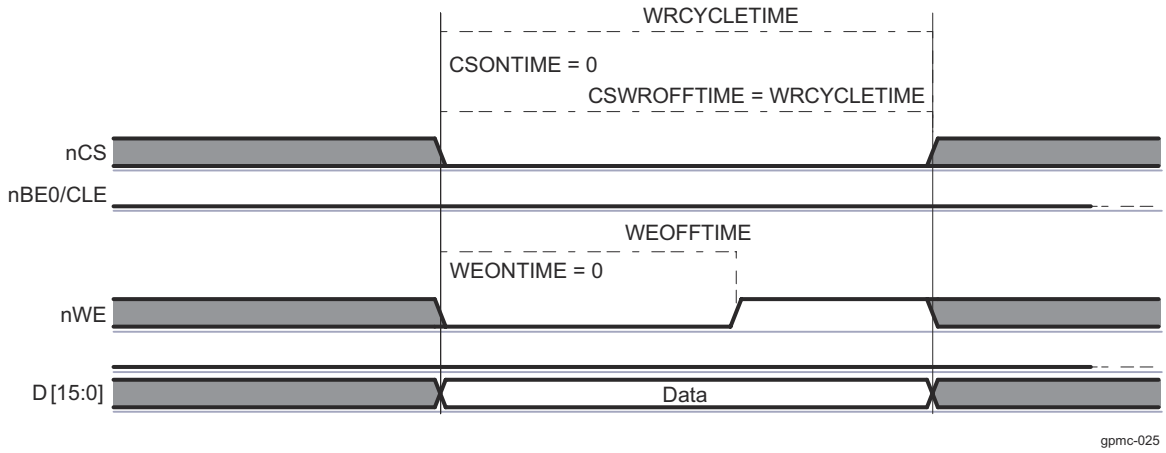

Figure 15-83. NAND Data Write Cycle

15.4.4.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see Section 15.4.4.12.4, *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

15.4.4.12.1.7 Read and Write Access Size Adaptation

15.4.4.12.1.7.1 8-Bit-Wide NAND Device

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

15.4.4.12.1.7.2 16-Bit-Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

15.4.4.12.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

Note

If a read access to a NAND flash is done using wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where i = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 2) of the GPMC_STATUS .
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

15.4.4.12.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (where x = 0 to 2). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

15.4.4.12.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (where x = 0 to 2) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 2) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for NAND device ready signal monitoring.

15.4.4.12.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhurl-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3:1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

15.4.4.12.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

15.4.4.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3:0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC_ECCj_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (where j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KiB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8] RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

15.4.4.12.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3:1] ECCCS bit field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZE (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 15-264 describes the ECC enable settings.

Table 15-264. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.

Table 15-264. ECC Enable Settings (continued)

Bit Field	Register	Value	Comments
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

15.4.4.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 15-84 and Figure 15-85. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream
P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

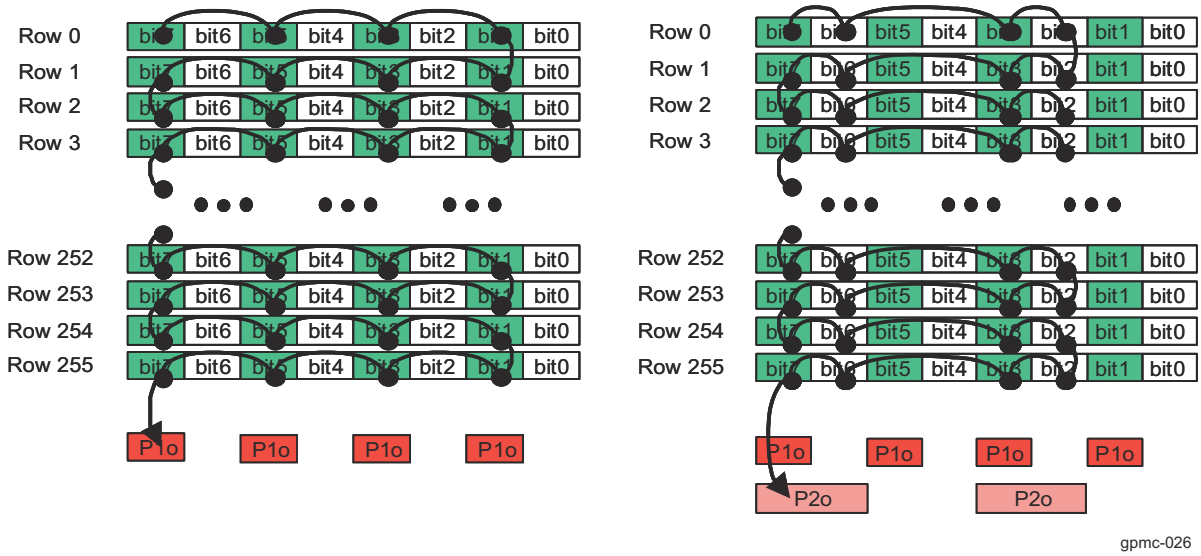

Figure 15-84. Hamming Code Accumulation Algorithm (1/2)

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254
P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253
P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

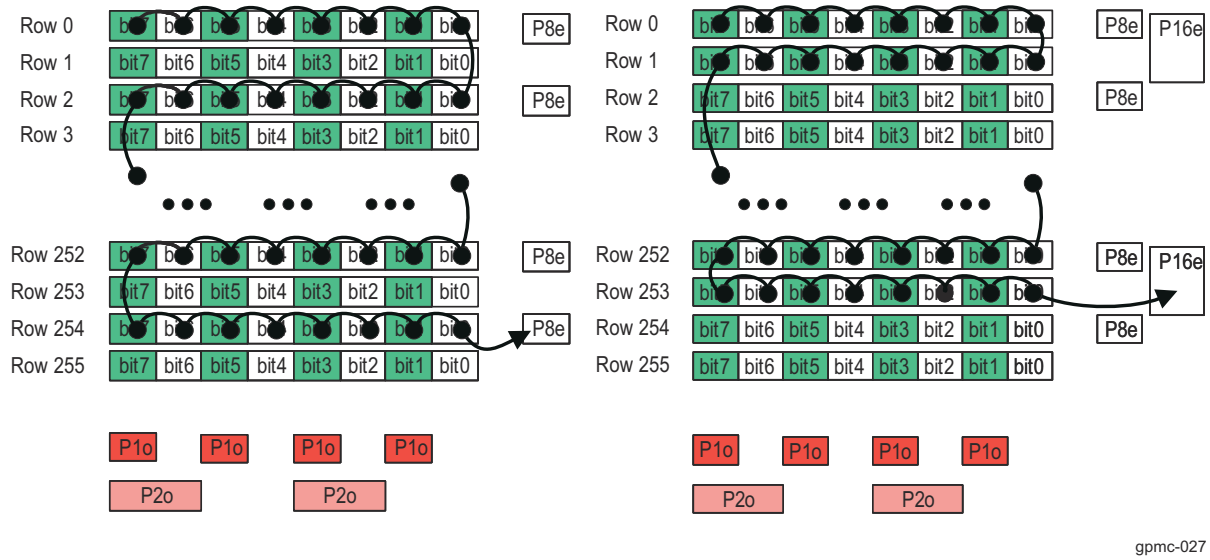

Figure 15-85. Hamming Code Accumulation Algorithm (2/2)

Unused parity bits in the result registers are set to 0.

Figure 15-86 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

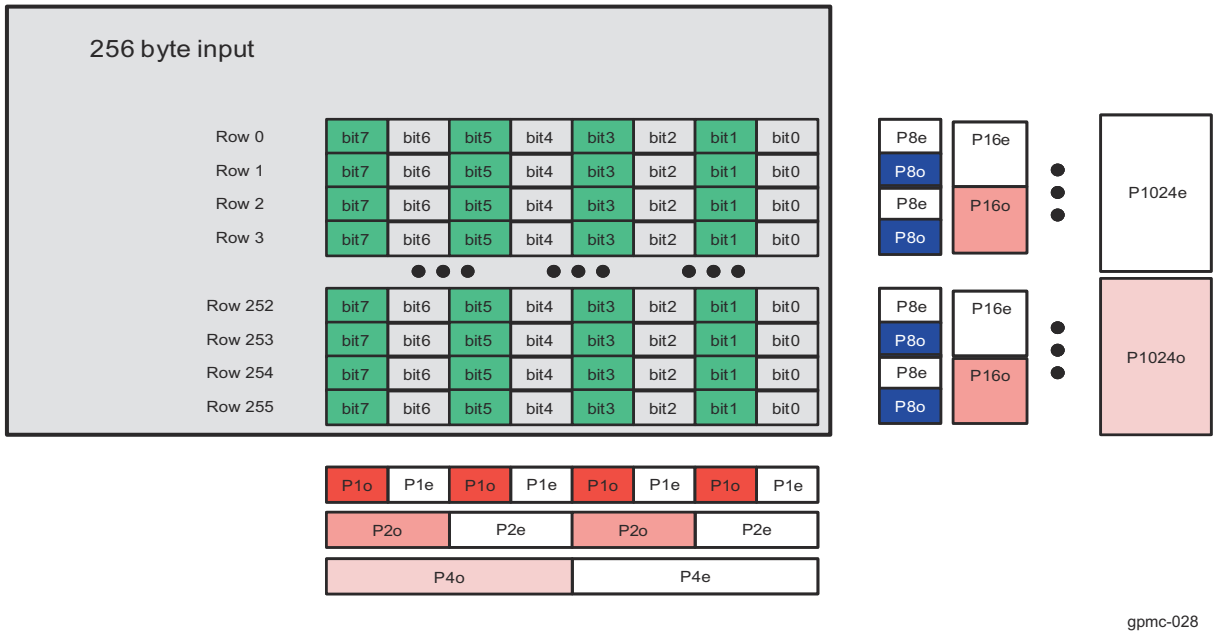

Figure 15-86. ECC Computation for a 256-Byte Data Stream (Read or Write)

Figure 15-87 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

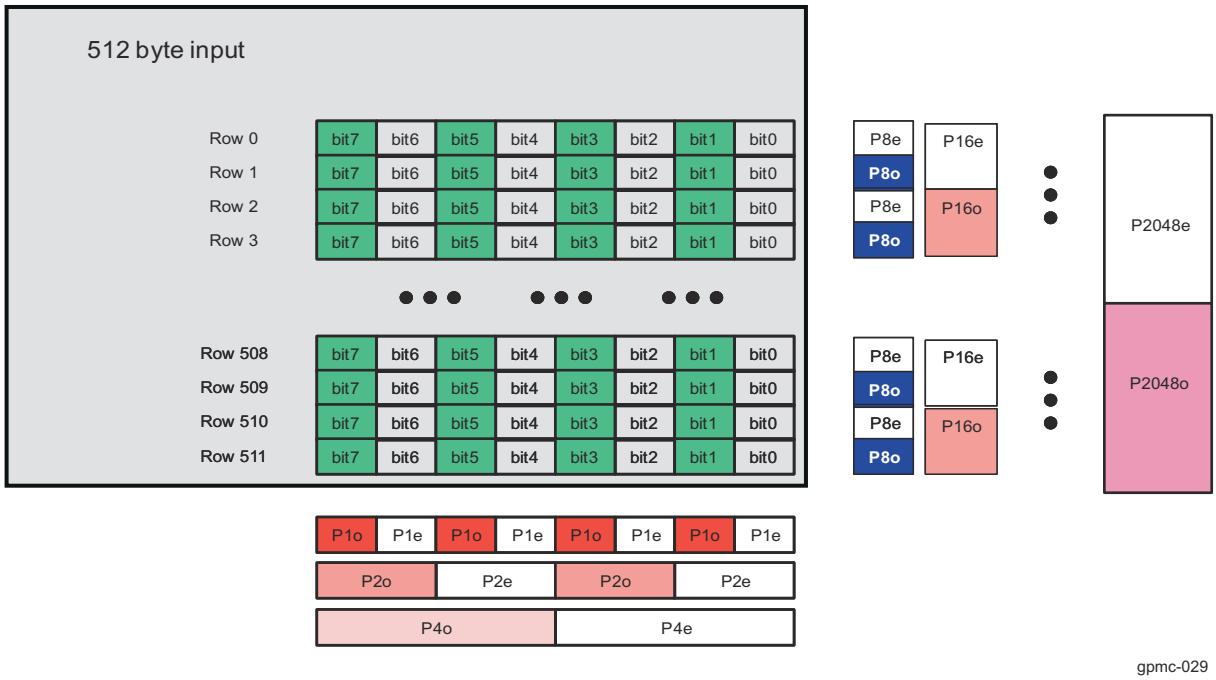

Figure 15-87. ECC Computation for a 512-Byte Data Stream (Read or Write)

For a 2-KiB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (where j = 1 to 9).

15.4.4.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

15.4.4.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

15.4.4.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. Figure 15-88 and Figure 15-89 show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

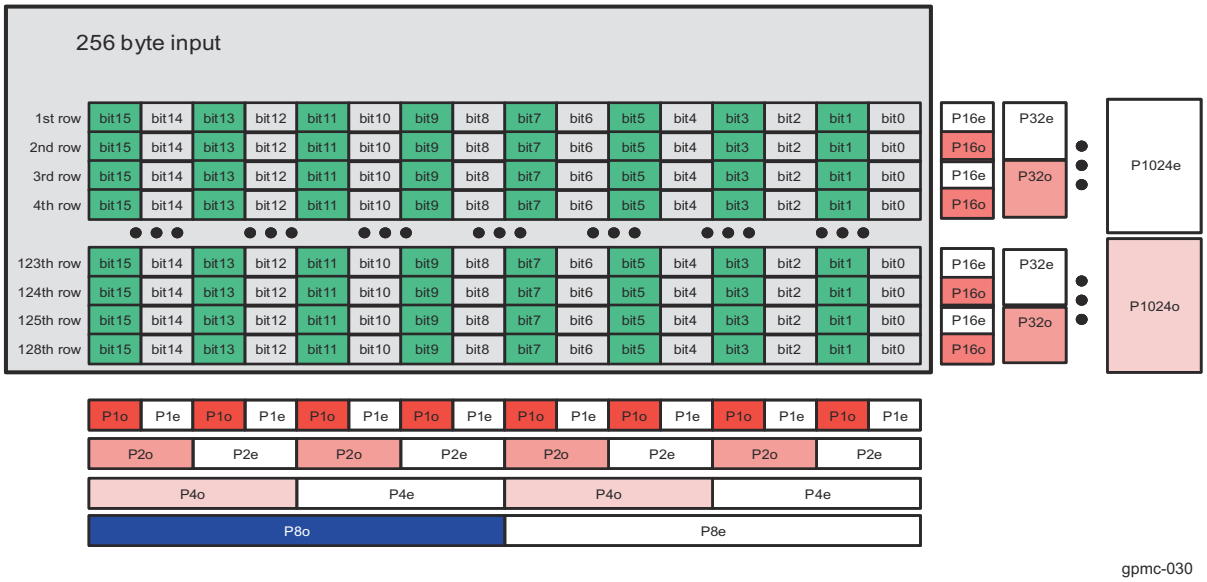

Figure 15-88. 128 Word16 ECC Computation

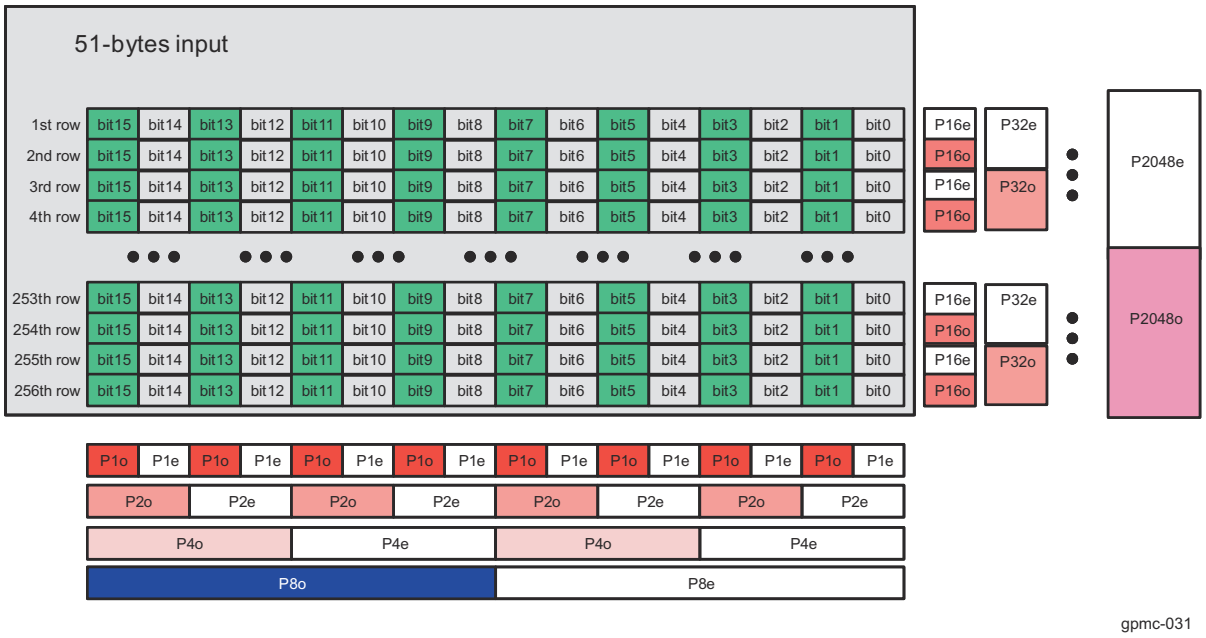

Figure 15-89. 256 Word16 ECC Computation

15.4.4.12.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

15.4.4.12.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
   - Typical page write sequence:
     - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy accesses.

  - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
  - NAND writes its cache line (page) to the array.
- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.

2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
3. Each page can hold up to 4KiB of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

   The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

15.4.4.12.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In a standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} – 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x), as described in Table 15-265.

Table 15-265. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)			ECC R(x)		
Bit Number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) – 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where i = 0 to 7):

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

15.4.4.12.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LSB) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + ... + b0 * x^{i}$

- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

Note

The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 15-266 and Table 15-267 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset modulo 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2^{12}–1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

Table 15-266. Aligned Message Byte Mapping in 8-Bit NAND

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

Table 15-267. Aligned Message Byte Mapping in 16-Bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 15-268 through Table 15-273 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

Table 15-268. Aligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 – 2	Nibble 3	Nibble 2
S/2 – 1	Nibble 1	Nibble 0 (LSB)

(S + 3) / 2 – 2			Nibble 0 (LSB)	

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

15.4.4.12.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword

(concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

15.4.4.12.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see Section 15.4.4.12.3.2.3, *Supported NAND Page Mappings and ECC Schemes*.

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

15.4.4.12.3.2.2.3.1 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 In the same example, 5 nibbles to process + 3 to discard = 8 nibbles = 2 × 16-bit accesses. Software must set:

- GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 = 0x5
- GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 = 0x3

Note

In the following figures, size and size0 are the same parameter.

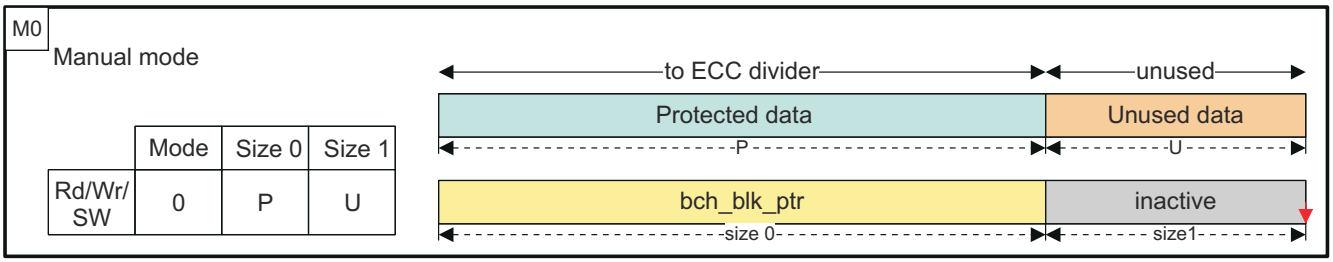

Figure 15-90. Manual Mode Sequence and Mapping

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

15.4.4.12.3.2.2.3.2 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.12.3.2.2.3.3 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

15.4.4.12.3.2.2.3.4 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.12.3.2.2.3.5 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

15.4.4.12.3.2.2.3.6 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S – size1)

15.4.4.12.3.2.2.3.7 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

15.4.4.12.3.2.2.3.8 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

15.4.4.12.3.2.2.3.9 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

15.4.4.12.3.2.2.3.10 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.12.3.2.2.3.11 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

15.4.4.12.3.2.2.3.12 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.12.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 15.4.4.12.3.2.2.1, *Memory Mapping of Data Message*.

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 15-91 through Figure 15-93, the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KiB + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits; that codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword: (512) + P + E
  - Other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords (512) + E

15.4.4.12.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

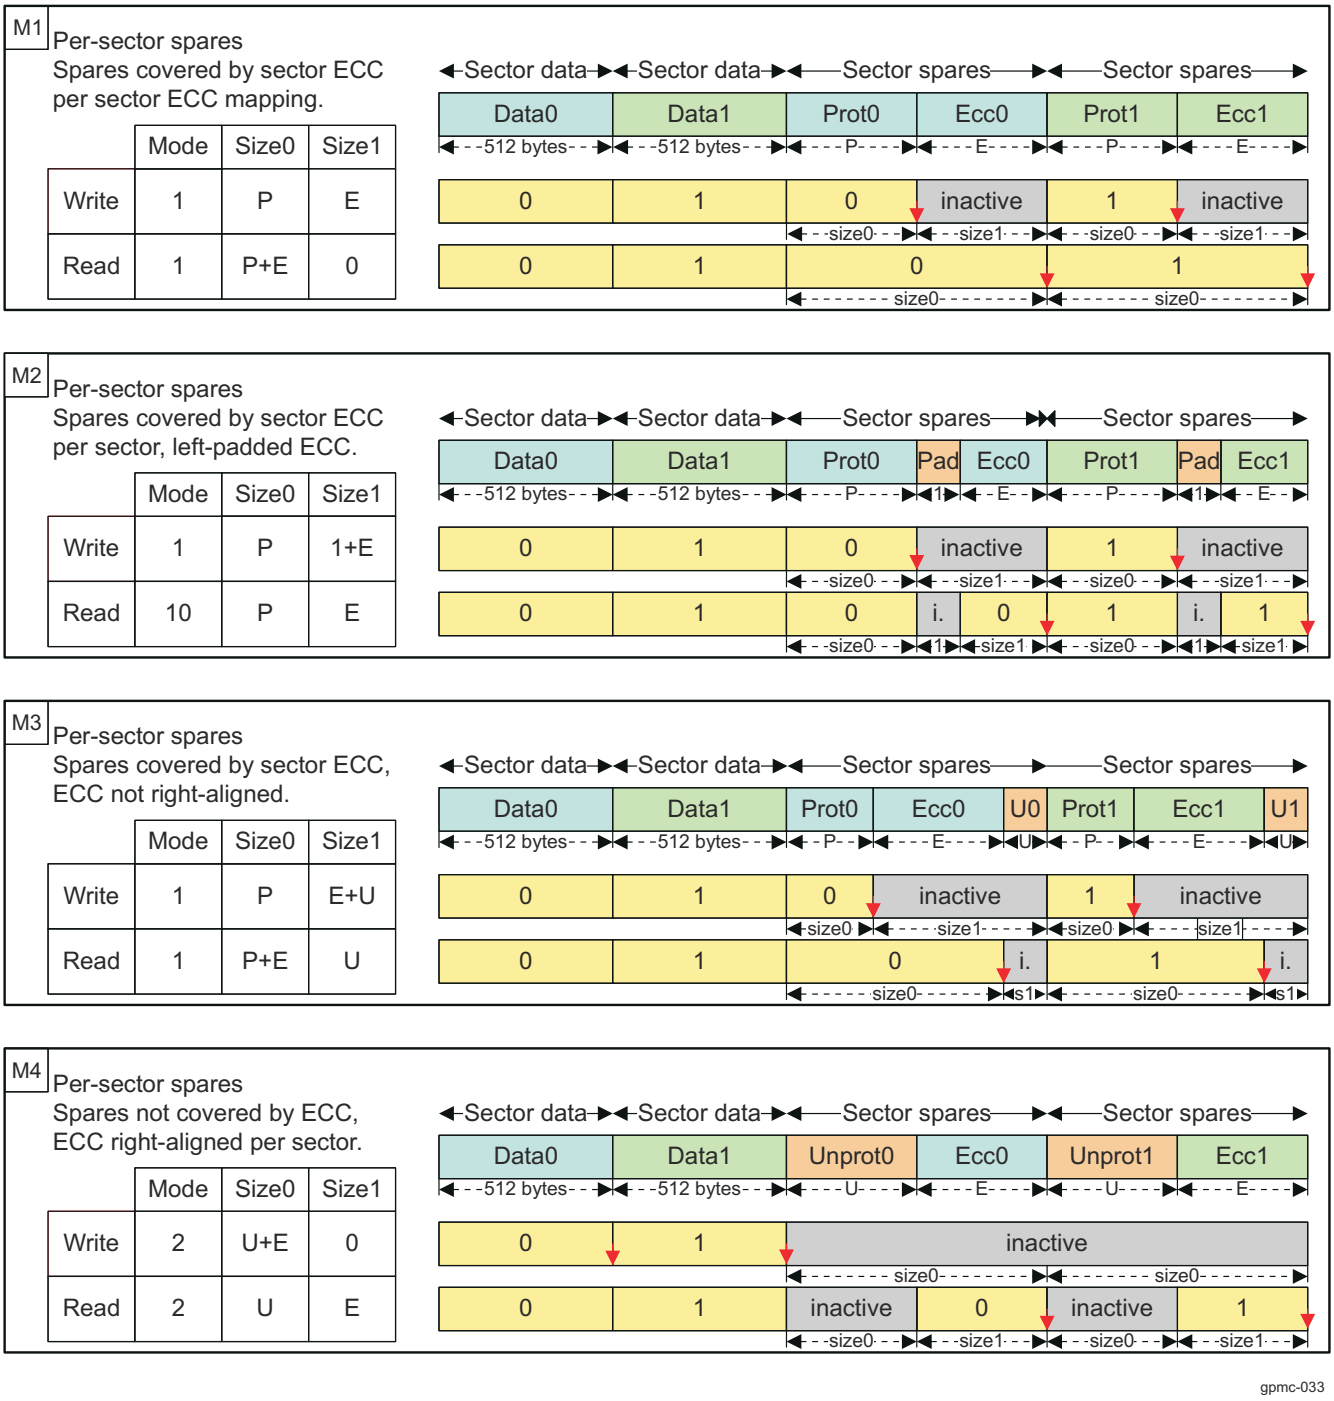

Figure 15-91. NAND Page Mapping and ECC: Per-Sector Schemes

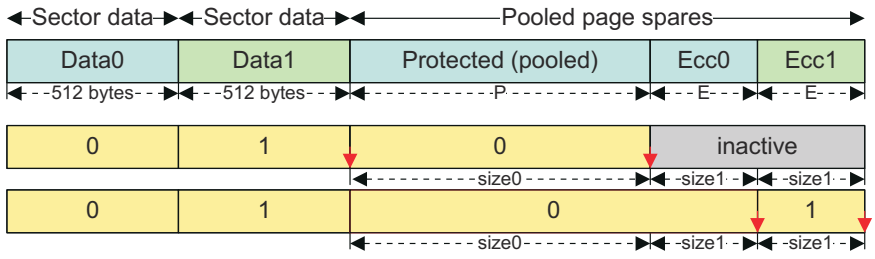
15.4.4.12.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

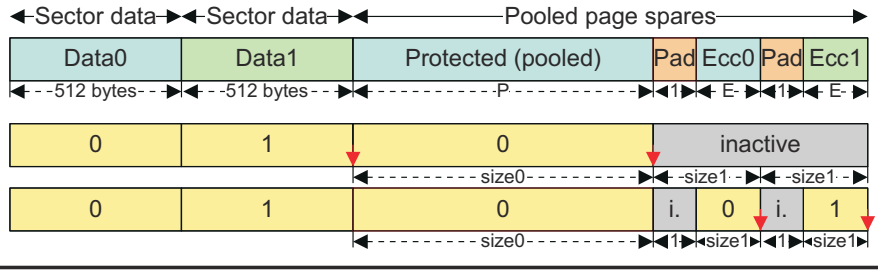
M5
Pooled spares
Spares covered by ECC0.
All ECC at the end (of page).

	Mode	Size0	Size1
Write	7	P	E
Read	3	P	E



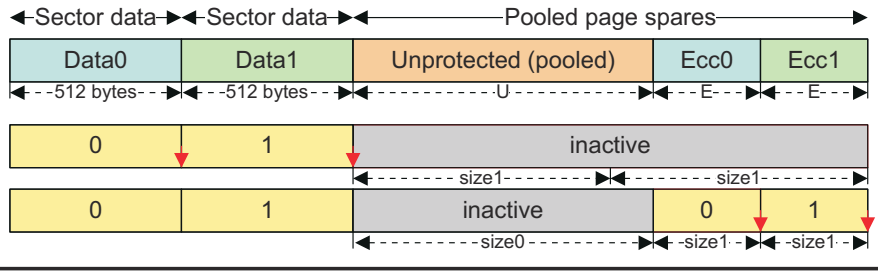
M6
Pooled spares
Spares covered by ECC0.
All ECC at the end, left-padded.

	Mode	Size0	Size1
Write	7	P	1+E
Read	8	P	E



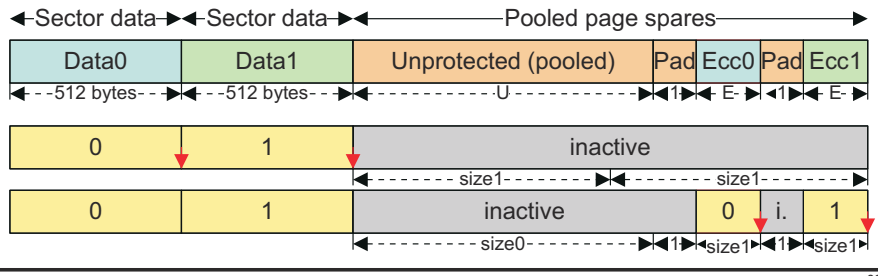
M7
Pooled spares
Spares not covered by ECC.
All ECC at the end.

	Mode	Size0	Size1
Write	6	0	U/S +E
Read	4	U	E



M8
Pooled spares
Spares not covered by ECC.
All ECC at the end, left-padded.

	Mode	Size0	Size1
Write	6	0	U/S +1+E
Read	9	U	E



gpmc-034

Figure 15-92. NAND Page Mapping and ECC: Pooled Spare Schemes

15.4.4.12.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

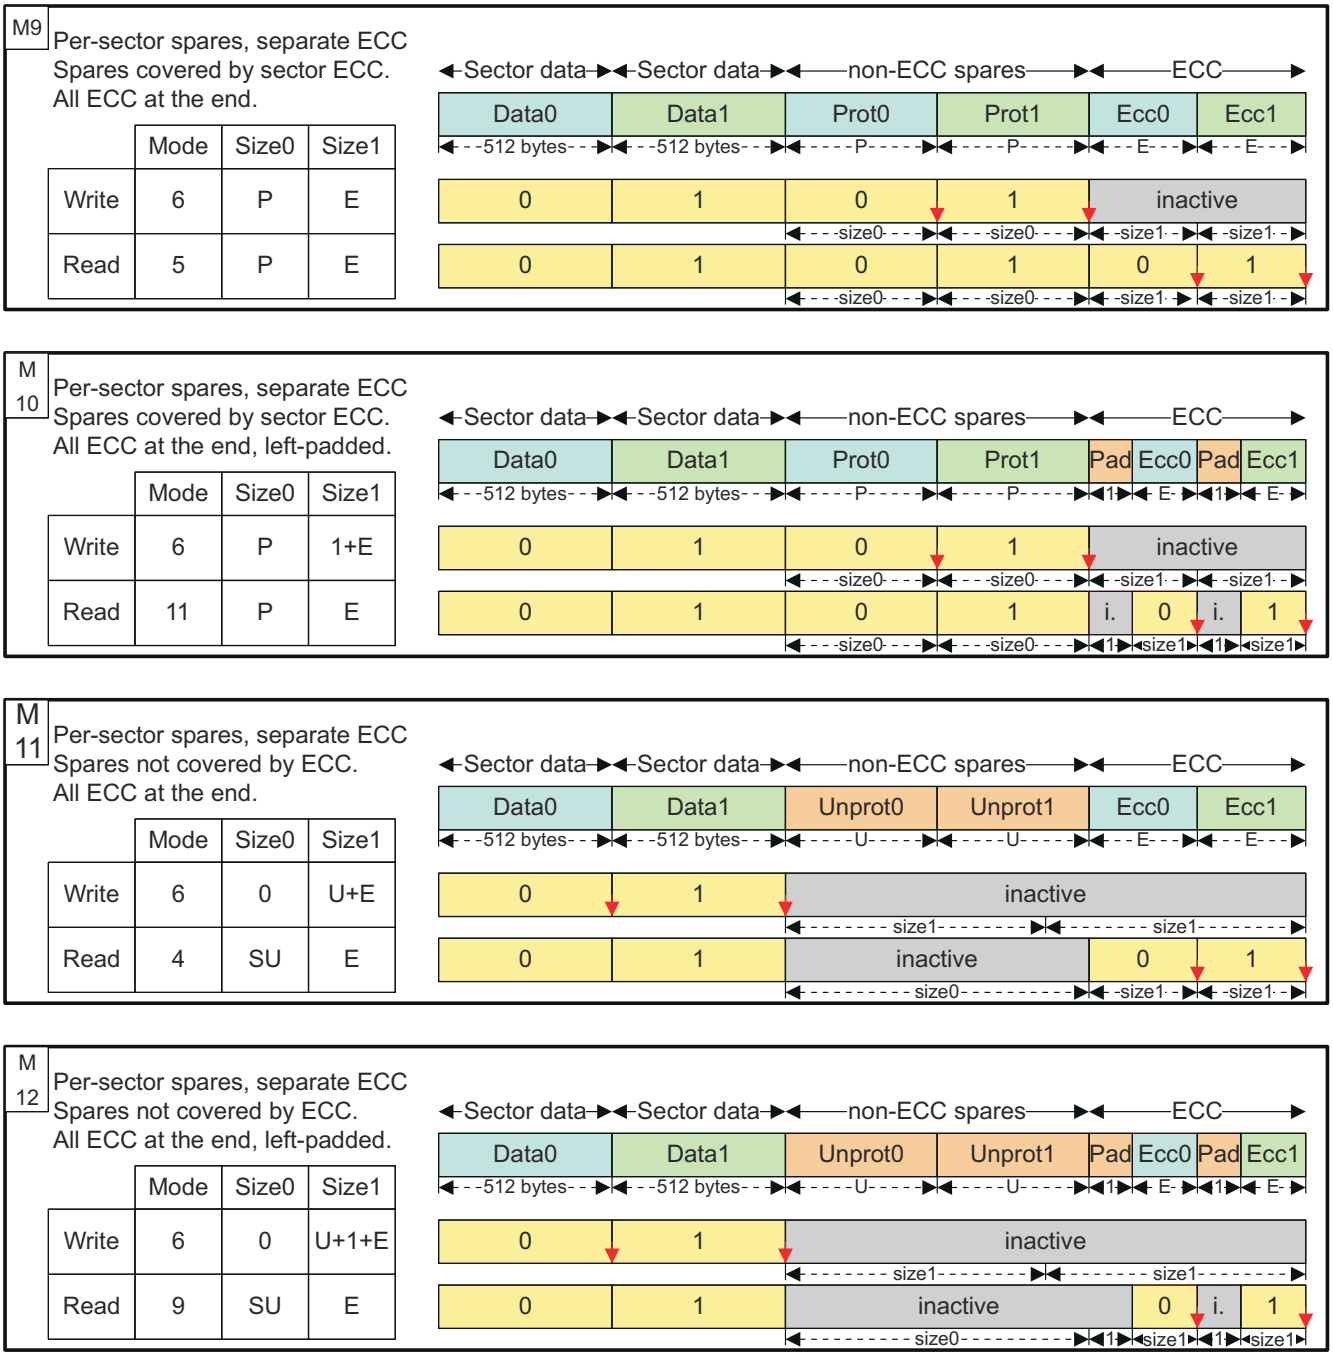


Figure 15-93. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC

15.4.4.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

Note

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

15.4.4.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 7):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

15.4.4.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see Section 15.4.4.12.2.2, *Ready Pin Monitored by Hardware Interrupt*). The GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR bit field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT bit field.

Table 15-274 describes the prefetch mode configuration.

Table 15-274. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17:16]	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.12.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by a device host processor or a DMA module channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes , or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit . The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

Note

The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and

transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

15.4.4.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 15-275 describes the write-posting configuration.

Table 15-275. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.

Table 15-275. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.12.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by a device host processor or a DMA module channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit . The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

Note

The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA

access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or MPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

15.4.4.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i location, where i = 0 to 7) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field defines the number of GPMC_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 15-94 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field.

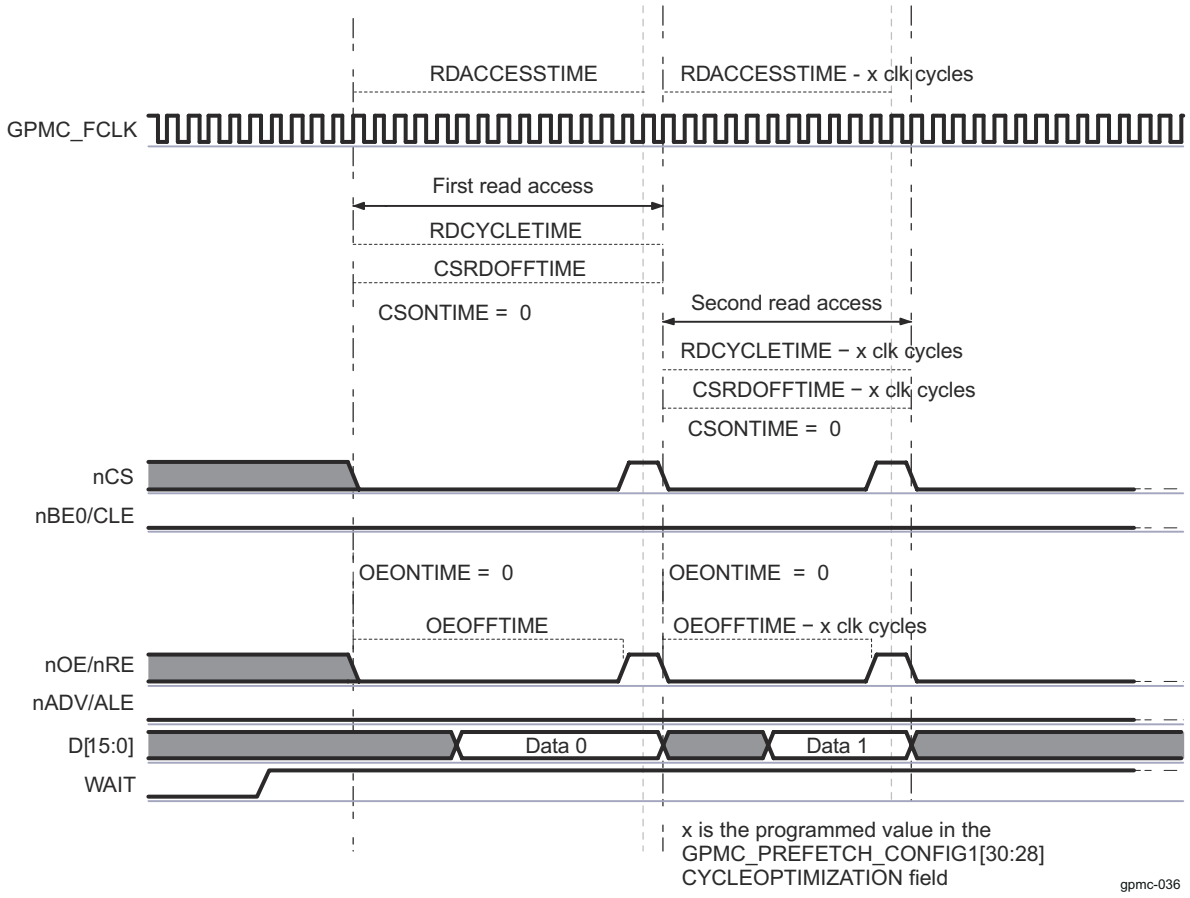

Figure 15-94. NAND Read Cycle Optimization Timing Description

15.4.4.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

15.4.5 GPMC Basic Programming Model

15.4.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

Figure 15-95 and Table 15-276 through Table 15-278 show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

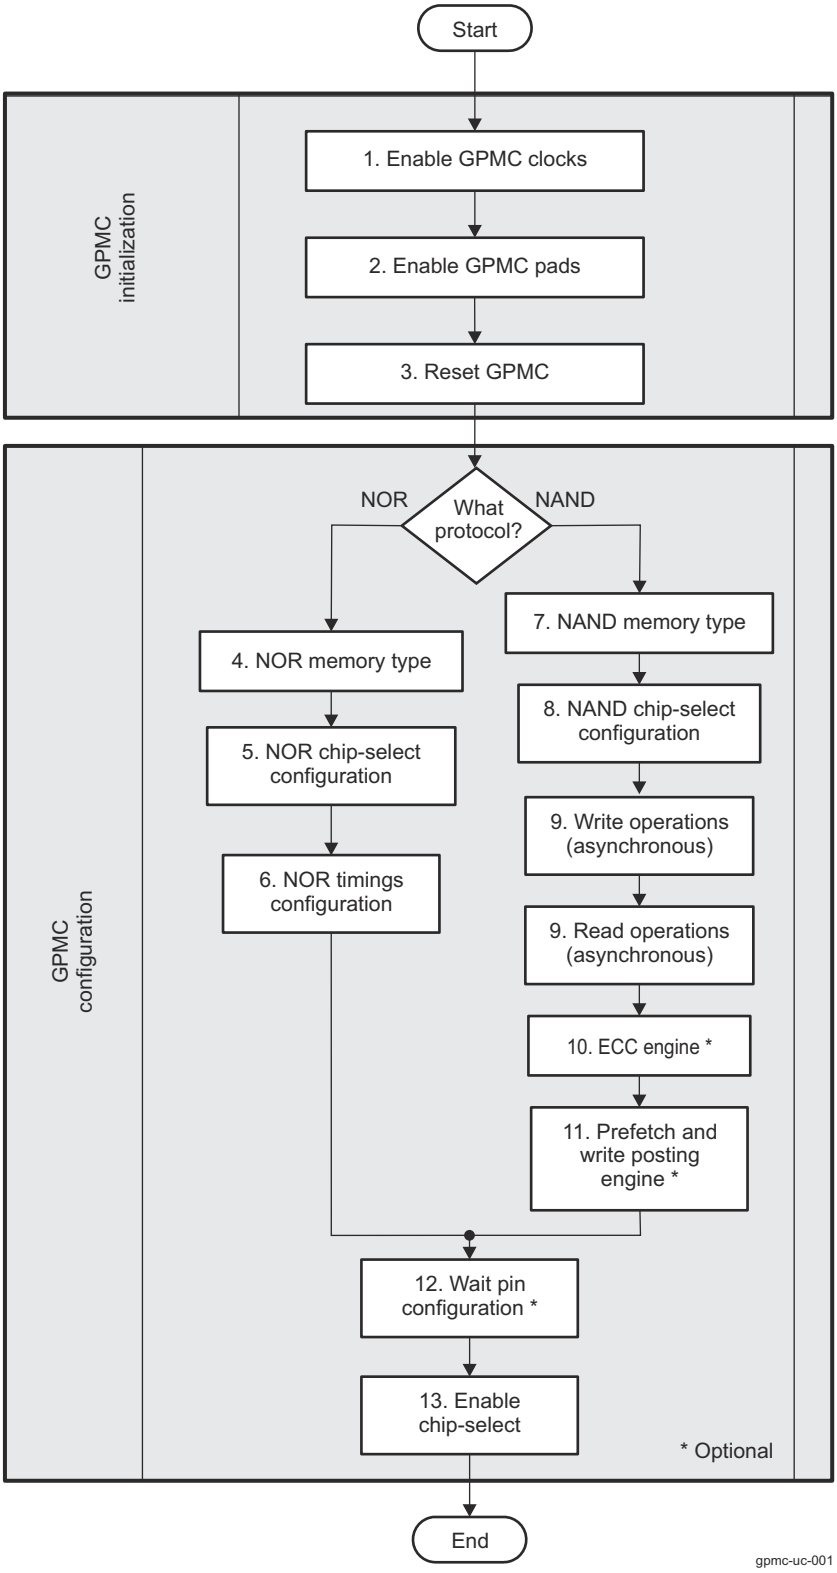

Figure 15-95. Programming Model Top-Level Diagram

Table 15-276. GPMC Initialization

Step	Description
Enable GPMC clocks.	Module interface and functional clocks must be enabled. See *Power, Reset, and Clock Management*.
Enable GPMC pads.	Module-specific pad multiplexing and configuration must be set in the control module. See *Pad Configuration Registers* in *Control Module*.
Reset GPMC.	See Table 15-279.

Table 15-277. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 15-280.
NOR Chip-Select Configuration	See Table 15-281.
NOR Timings Configuration	See Table 15-282.
Wait Pin Configuration	See Table 15-290.
Enable Chip-Select	See Table 15-291.

Table 15-278. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 15-285.
NAND Chip-Select Configuration	See Table 15-286.
Write Operations (Asynchronous)	See Table 15-287.
Read Operations (Asynchronous)	See Table 15-287.
ECC Engine	See Table 15-288.
Prefetch and Write-Posting Engine	See Table 15-289.
Wait Pin Configuration	See Table 15-290.
Enable Chip-Select	See Table 15-291.

15.4.5.2 GPMC Initialization

Table 15-307 describes the settings required to prepare the GPMC; that is enabling its clock and pads, and proceeding to a GPMC reset.

Table 15-279. Reset GPMC

Subprocess Name	Register/Bit Field	Value
Start a software reset.	GPMC_SYSCONFIG[1] SOFTRESET	0x1
Wait until	GPMC_SYSSTATUS[0] RESETDONE =	0x1

15.4.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 15-280. NOR Memory Type

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency (1).	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	x
Choose an output clock activation time (1).	GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations (1).	GPMC_CONFIG1_i[30] READMULTIPLE	x

Table 15-280. NOR Memory Type (continued)

Subprocess Name	Register / Bit Field	Value
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

(1) Applies only to synchronous configurations (or nonmultiplexed asynchronous for multiple access one)

Table 15-281. NOR Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-282. NOR Timings Configuration

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See Section 15.4.5.6, *GPMC Timing Parameters*	

Table 15-283. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Enable or disable wait pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time.	GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select.	GPMC_CONFIG1_i[17:16] WAITPINSELECT	x

Table 15-284. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

15.4.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Table 15-285. NAND Memory Type

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See Section 15.4.5.5, *Set Memory Access*.	x

Table 15-286. NAND Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select minimum granularity (16MiB).	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-287. Asynchronous Read and Write Operations

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 15.4.5.6, *GPMC Timing Parameters*.	

Table 15-288. ECC Engine

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3:0] ECCPOINTER	x (2)
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 and [29:22] ECCSIZE1	x (1)
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9	x
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3:1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13:12] ECCBCHTSEL and GPMC_ECC_CONFIG[6:4] ECCTOPSECTOR	x
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

(1) Depends on the size of each sector in the NAND page
(2) This parameter depends on the numbers of sectors in a page.

Table 15-289. Prefetch and Write-Posting Engine

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request.	GPMC_PREFETCH_CONFIG1[14:8] FIFOTHRESHOLD	x
Select DMA synchronized mode or software manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

Table 15-290. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

Table 15-291. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

15.4.5.5 Set Memory Access

This section describes the bit field to configure to set the GPMC in various memory modes. Table 15-292 and Table 15-293 provide check lists for mode parameters and access type parameters, respectively.

Table 15-292. Mode Parameters Check List

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	–	0x1 (1)	N/S	0x0	–	0x1	–
GPMC_CONFIG1_i	29	READTYPE	0x0	–	0x0 (1)	N/S	0x1	–	0x1	–
GPMC_CONFIG1_i	28	WRITEMULTIPLE	–	0x0	- (1)	N/S	–	0x0	–	0x1
GPMC_CONFIG1_i	27	WRITETYPE	–	0x0	- (1)	N/S	–	0x1	–	0x1

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in nonmultiplexed mode.

Table 15-293. Access Type Parameters Check List

Register	Bit	Name	Access Type		
			Nonmultiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9:8	MUXADDDATA	0x0	0x2	0x1

15.4.5.6 GPMC Timing Parameters

Figure 15-96 shows a programming model diagram for the NOR interfacing timing parameters.

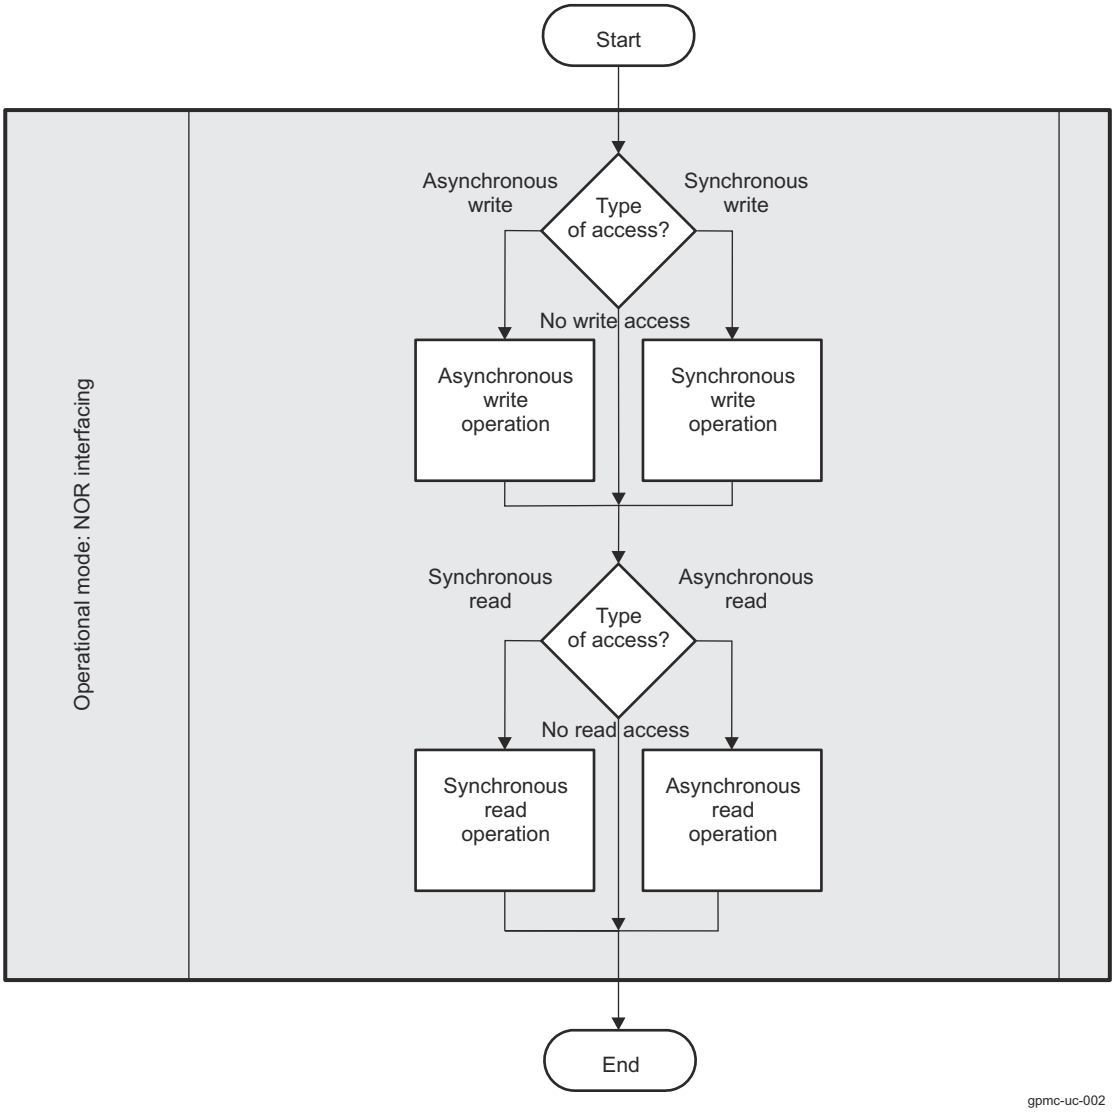

Figure 15-96. NOR Interfacing Timing Parameters Diagram

Table 15-294 lists the bit fields to configure adequate timing parameters in various memory modes.

Table 15-294. Timing Parameters

			Asynchronous			Synchronous				Access Type		
Register	Bit	Name	Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiplexed	Address/ Data-Multiplexed	AAD Multiplexed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	29	READTYPE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	30	READMULTIPLE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	27	WRITETYPE		y			y		y	y	y	y
GPMC_CONFIG1_i	28	WRITEMULTIPLE		y			y		y	y	y	y
GPMC_CONFIG1_i	31	WRAPBURST						y	y	y	y	y

Table 15-294. Timing Parameters (continued)

			Asynchronous			Synchronous			Access Type		
GPMC_CONFIG1_i	26:25	CLKACTIVATIONTIME				y	y	y	y	y	y	y

15.4.5.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device data manual.

15.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x2. Table 15-295 describes the NAND timing parameters.

Table 15-295. NAND Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_wen valid time
B	ns	Delay time – gpmc_cs valid to gpmc_wen valid
C	ns	Delay time – gpmc_ben0/gpmc_advn_ale high to gpmc_wen valid
D	ns	Delay time – gpmc_ad[15:0] valid to gpmc_wen valid
E	ns	Delay time – gpmc_wen invalid to gpmc_ad[15:0] invalid
F	ns	Delay time – gpmc_wen invalid to gpmc_ben0/gpmc_advn_ale invalid
G	ns	Delay time – gpmc_wen invalid to gpmc_cs invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – gpmc_cs valid to gpmc_oen_ren valid
J	ns	Setup time – gpmc_ad[15:0] valid to gpmc_oen_ren invalid
K	ns	Pulse duration – gpmc_oen_ren valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – gpmc_oen_ren invalid to gpmc_cs invalid

The configuration parameters are calculated through the following formulas. For more information, see the device data manual.

A = (WEOffTime – WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime – ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime – WEOffTime * (TimeParaGranularity + 1) – 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay – WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay – WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

I = ((OEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

J = ((RdAccessTime – OEOffTime) * (TimeParaGranularity + 1) – 0.5 * OEExtraDelay)) * GPMC_FCLK period

K = (OEOffTime – OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

M = (CSRdOffTime – OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 15-97 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

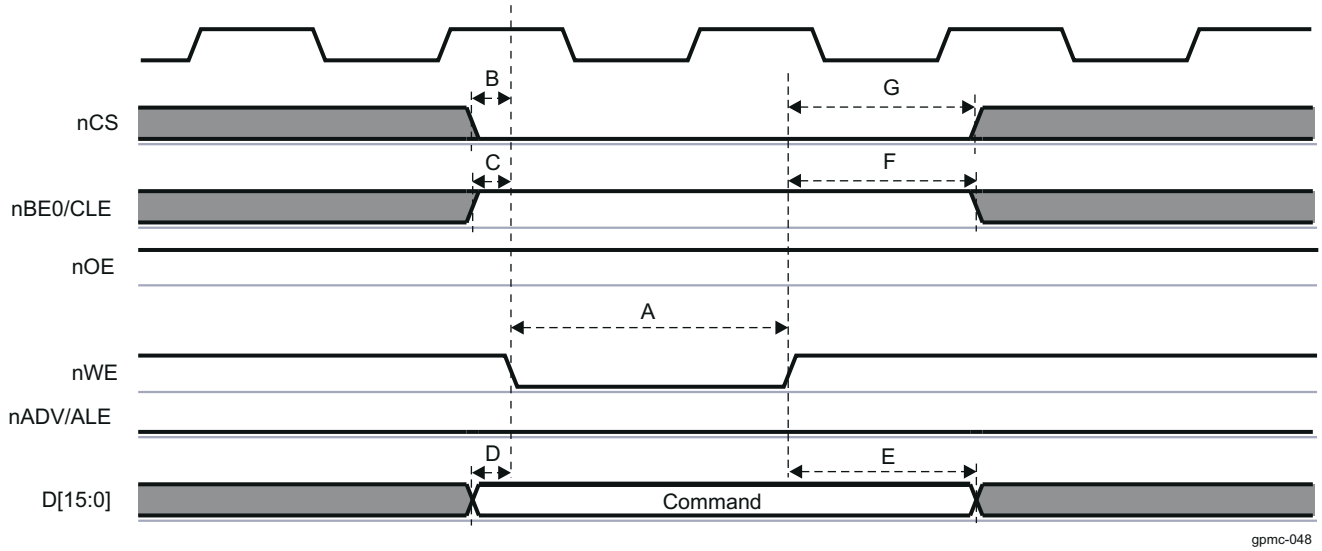

Figure 15-97. NAND Command Latch Cycle Timing Simplified Example

15.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode. Table 15-296 describes the synchronous NOR formulas.

Table 15-296. Synchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_cs low
B	ns	Delay time – address bus valid to gpmc_clk first edge
		Delay time – gpmc_ben0/gpmc_ben1 valid to gpmc_clk first edge
C	ns	Pulse duration – gpmc_ben0/gpmc_ben1 low
D	ns	Delay time – gpmc_clk rising edge to gpmc_ben0/gpmc_ben1 invalid
		Delay time – gpmc_clk rising edge to gpmc_advn_ale invalid
E	ns	Delay time – gpmc_clk rising edge to gpmc_cs invalid
		Delay time – gpmc_clk rising edge to gpmc_oen_ren invalid
F	ns	Delay time – gpmc_clk rising edge to gpmc_cs transition
G	ns	Delay time – gpmc_clk rising edge to gpmc_advn_ale transition
H	ns	Delay time – gpmc_clk rising edge to gpmc_oen_ren transition
I	ns	Delay time – gpmc_clk rising edge to gpmc_wen transition
J	ns	Delay time – gpmc_clk rising edge to gpmc_ad data bus transition
		Delay time – gpmc_clk rising edge to gpmc_ben0/gpmc_ben1 transition
K	ns	Pulse duration – gpmc_advn_ale low
L	ns	Delay time – gpmc_wait invalid to first data latching gpmc_clk edge

The configuration parameters are calculated through the following formulas. For more information, see the device data manual.

1. For single read accesses:
   A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – RDACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME – RDACCESSTIME) * GPMC_FCLK period

2. For burst read accesses (where n is the page burst access number):
   A = (CSRDOFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (RDCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSRDOFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
3. For burst write accesses (where n is the page burst access number):
   A = (CSWROFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (WRCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (WRCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSWROFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
4. For all accesses:
   For nCS falling edge (chip-select activated):
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
   - Case where GPMCFCLKDIVIDER = 0x3:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 4
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
     F = (3 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

   For nCS rising edge (chip-select deactivated) in reading mode:
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
   - Case where GPMCFCLKDIVIDER = 0x3:

F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
F = (3 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nCS rising edge (chip-select deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  F = (3 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nADV falling edge (nADV activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 4
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4

G = (3 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  G = (3 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  G = (3 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nOE falling edge (nOE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:

H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)
H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 4
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  H = (3 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nOE rising edge (nOE deactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  H = (3 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nWE falling edge (nWE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 3

I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

- Case where GPMCFCLKDIVIDER = 0x3:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 4
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  I = (3 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nWE rising edge (nWE deactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  I = (3 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For gpmc_nadv low pulse duration:

- Read operation:
  K = (ADVRDOFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation:
  K = (ADVWROFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For gpmc_wait invalid to first data latching gpmc_clk edge:

- L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC_CLK period

Figure 15-98 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

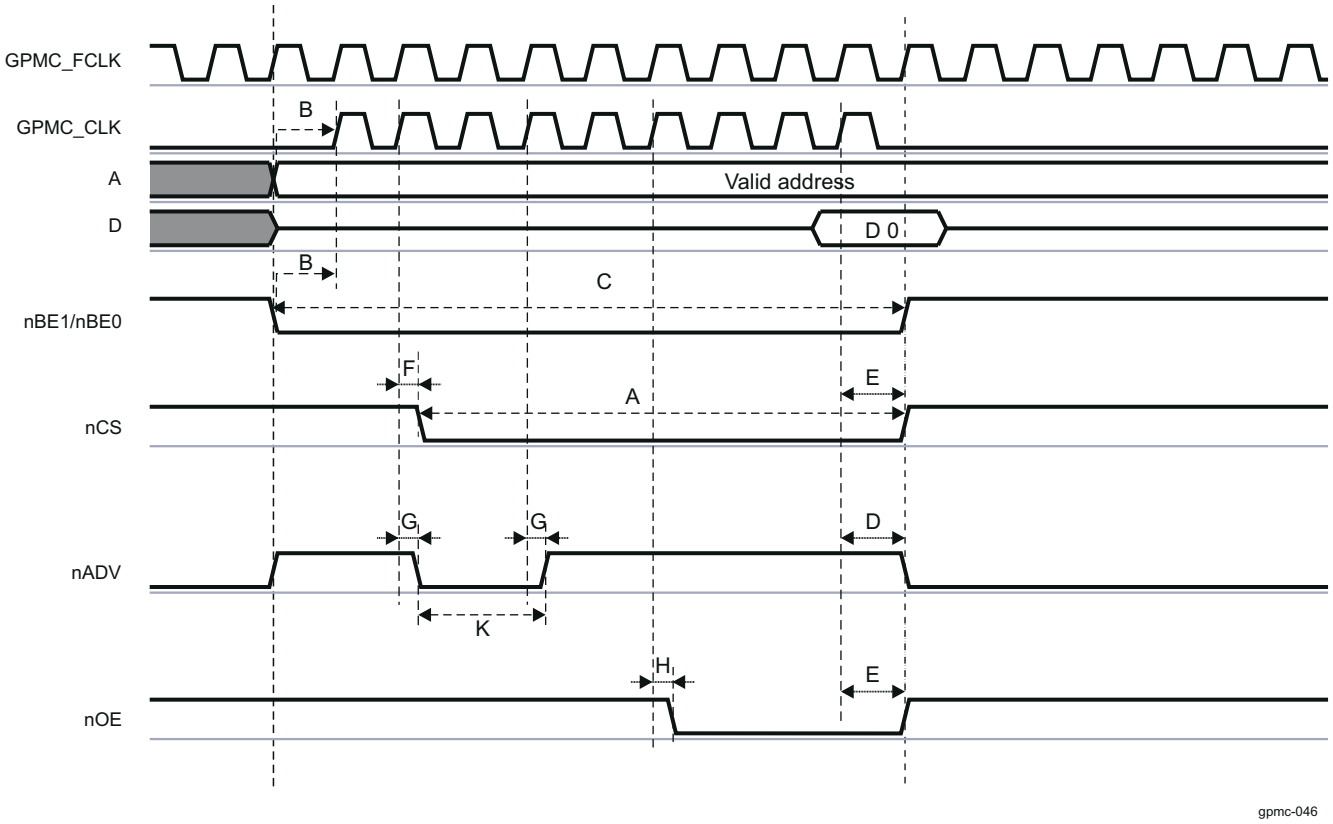

Figure 15-98. Synchronous NOR Single Read Simplified Example

15.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 15-297 describes the asynchronous NOR formulas.

Table 15-297. Asynchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_cs low
B	ns	Delay time – gpmc_cs valid to gpmc_advn_ale invalid
C	ns	Delay time – gpmc_cs valid to gpmc_oen_ren invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – gpmc_cs valid to gpmc_wen valid
F	ns	Delay time – gpmc_cs valid to gpmc_wen invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before gpmc_oen_ren high
I	ns	Delay time – gpmc_cs valid to gpmc_oen_ren invalid (burst read)
J	ns	Delay time – address bus valid to gpmc_cs valid
		Delay time – data bus valid to gpmc_cs valid
		Delay time – gpmc_ben0/gpmc_ben1 valid to gpmc_cs valid
K	ns	Delay time – gpmc_cs valid to gpmc_advn_ale valid
L	ns	Delay time – gpmc_cs valid to gpmc_oen_ren valid
M	ns	Delay time – gpmc_cs valid to first data latching edge
N	ns	Pulse duration – gpmc_ben0/gpmc_ben1 valid time

Table 15-297. Asynchronous NOR Formulas Description (continued)

Configuration Parameter	Unit	Description
O	ns	Delay time – gpmc_cs valid to gpmc_advn_ale valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device data manual.

- gpmc_cs low pulse:
  For single read: A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: A = (CSRDOFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For single write: A = (CSWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst write: A = (CSWROFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- gpmc_cs valid to gpmc_advn_ale invalid delay:
  For reading: B = ((ADVRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
  For writing: B = ((ADVWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- C = ((OEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- E = ((WEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- F = ((WEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- G = CYCLE2CYCLEDELAY * GPMC_FCLK period
- H = ((OEOFFTIME – RDACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period
- I = ((OEOFFTIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number
- J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- K = ((ADVONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- L = ((OEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- M = ((RDACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) – 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- gpmc_ben0/gpmc_ben1 pulse:
  For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: N = (RDCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For burst write: N = (WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- O = ((WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period

Figure 15-99 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

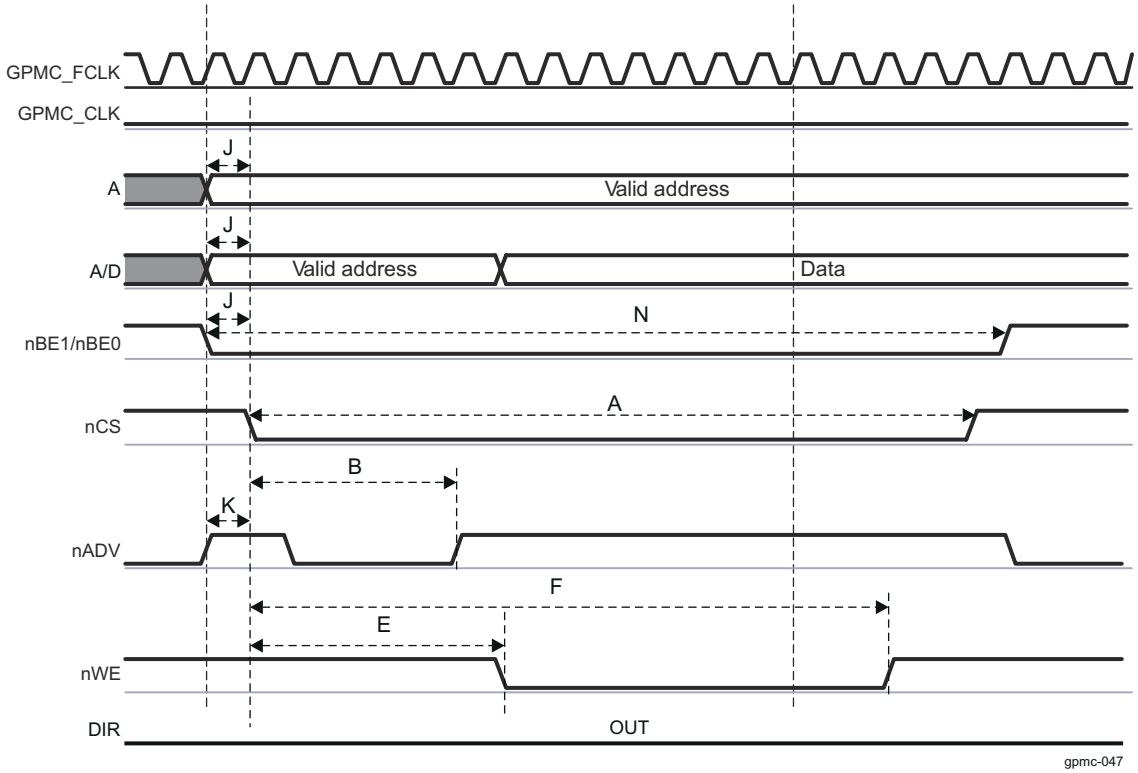

Figure 15-99. Asynchronous NOR Single Write Simplified Example

Note

Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

15.4.6 GPMC Use Cases and Tips

15.4.6.1 How to Set GPMC Timing Parameters for Typical Accesses

15.4.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

15.4.6.1.2 Typical GPMC Setup

Table 15-298 lists some of the I/Os of the GPMC module.

Table 15-298. GPMC Signals

Signal Name	I/0	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	O	External clock provided to the external device for synchronous operations
gpmc_a[26:16]	O	Address
gpmc_ad[15:0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_csx	O	Chip-select (where x = 0, or 1)
gpmc_advn_ale	O	Address valid enable
gpmc_oen_ren	O	Output enable (read access only)
gpmc_wen	O	Write enable (write access only)
gpmc_wait[1:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 15-100 shows the typical connection between the GPMC module and an attached NOR Flash memory.

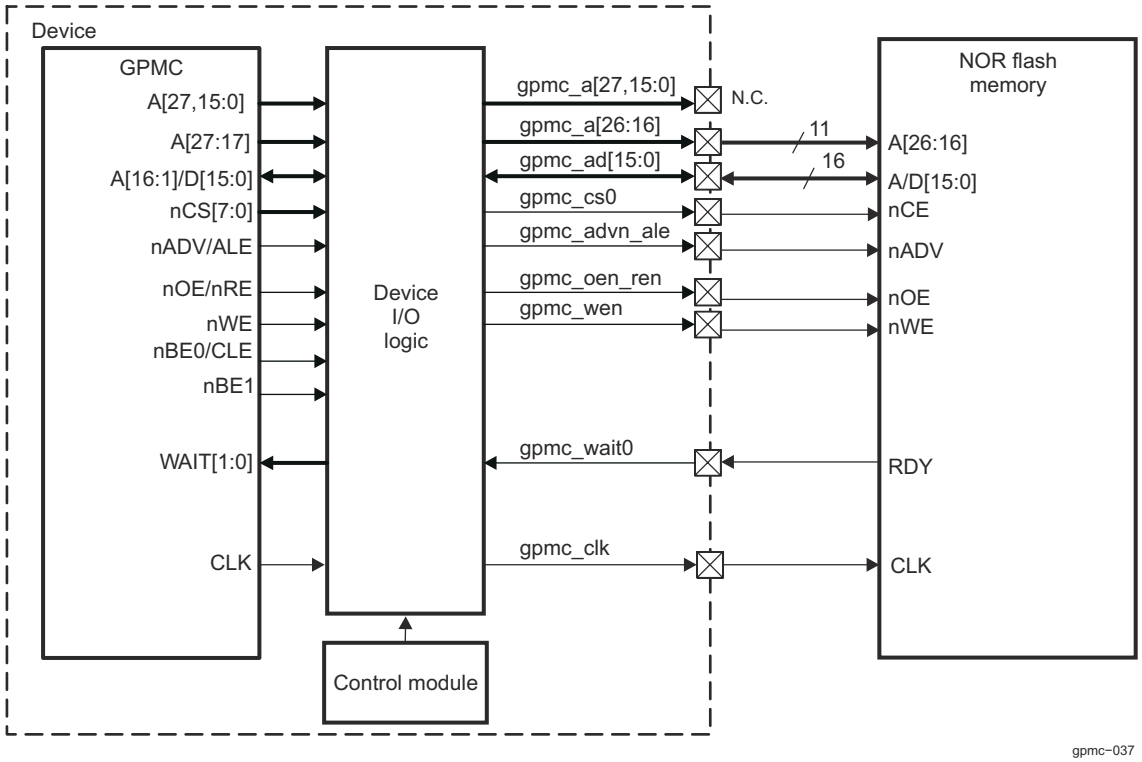

Figure 15-100. GPMC Connection to an External NOR Flash Memory

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

15.4.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

Note

The examples in Section 15.4.6.1.2.1 through Section 15.4.6.1.2.3 are based on a clock rate of 104 MHz. Refer to the device Data Manual for the maximum frequency appropriate for this device and to the memory datasheet for the maximum frequency for the particular memory device.

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-299 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-300 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-101 shows the synchronous burst read access.

Table 15-299. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7

Table 15-299. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9,615 ns). The read access time between two bursts of data is tBACC = 5.2 ns. Therefore, data setup time is a clock period – tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 15-300. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94.03: (9,615 + 80 + 4,415)	10: roundmax (94.03 / 9,615)	RDACCESSTIME = 0x0A
PageBurst RdAccessTime	roundmax (tBACC)	roundmax (5.2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	RdAccess time + max (tCEZ, tOEZ)	101.03: (94.03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC (1)	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC (2)	12	2	ADVRDOFFTIME = 0x02
OeOnTime (3)	(ClkActivationTime + tACH) < OeOnTime (ClkActivationTime + tIACC)	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0x0B

(1) The external clock provided to the NOR flash is not yet available.
(2) AdvRdOffTime – AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.
(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

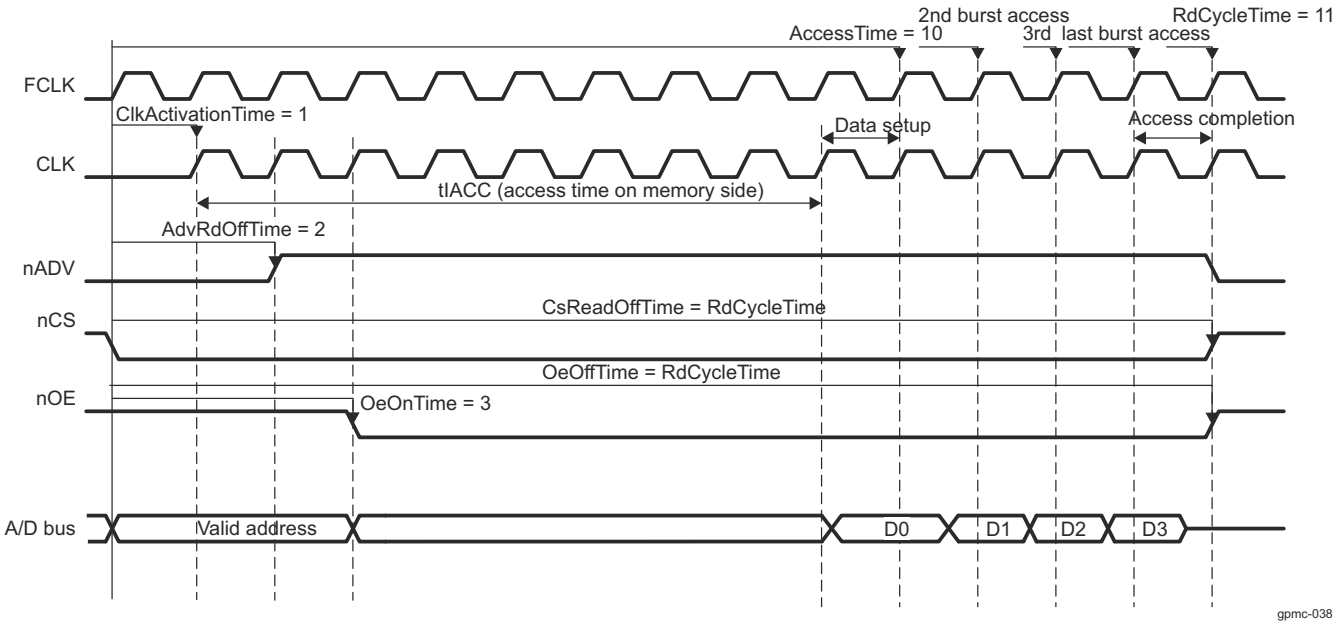

Figure 15-101. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

15.4.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-301 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-302 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-102 shows the asynchronous read access.

Table 15-301. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ:

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 15-301: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

   The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).

4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.
5. Addresses can now be relatched and a new read cycle begun.

Table 15-302. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = 0x0A
PageBurstAccessTime	N/A (single access)			
RdCycleTime	RdAccessTime + 1cycle + tOEZ	96, 615	12	RDCYCLETIME = 0x0C
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	RdAccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0X1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	RdAccessTime + 1cycle	89, 615	11	OEOFFTIME = 0x0B

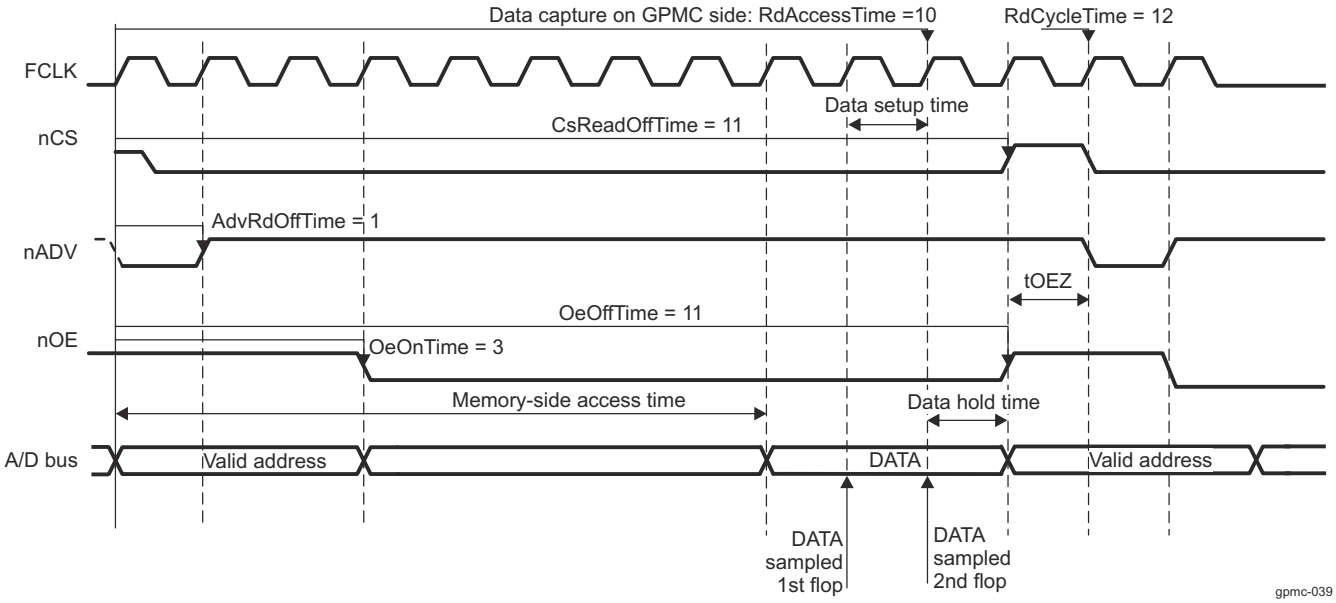

Figure 15-102. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

15.4.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 15-304 shows how to calculate timings for the GPMC using the memory parameters.

Table 15-303 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 15-103 shows the synchronous burst write access.

Table 15-303. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60

Table 15-303. AC Characteristics for Asynchronous Single Write (Memory Side) (continued)

AC Characteristics on the Memory Side	Description	Duration (ns)
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device data manual.

Table 15-304. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime	N/A (asynchronous mode)			
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	N/A (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

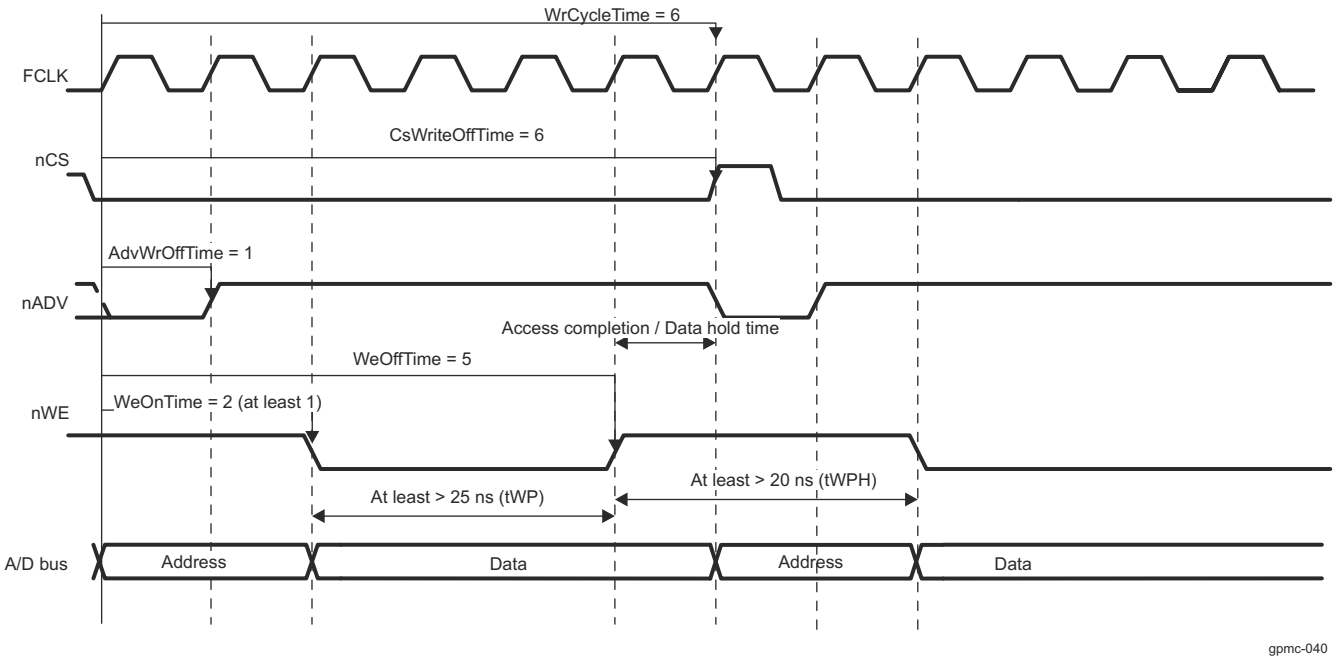

Figure 15-103. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)

15.4.6.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

15.4.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, OneNAND™, etc.)
- 8- and 16-bit NAND flash devices

15.4.6.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

Table 15-305. Supported Memories Interfaces

(1) Addresses seen from the device side. When interfacing to the external device, A1 is connected to the memory A0, A2 to the memory A1, and so on.

15.4.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 15-306 summarizes the NAND interface signals level applied to external device or memories.

Table 15-306. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	nCE	nWE (1)	nRE (1)
Read (cmd input)	H	L	L	RE	H
Read (add input)	L	H	L	RE	H

Table 15-306. NAND Interface Bus Operations Summary (continued)

Bus Operation	CLE	ALE	nCE	nWE (1)	nRE (1)
Write (cmd input)	H	L	L	RE	H
Write (add input)	L	H	L	RE	H
Data input	L	L	L	RE	H
Data output	L	L	L	H	FE
Busy (during read)	x	x	H (2)	H (2)	H (2)
Busy (during program)	x	x	x	x	x
Busy (during erase)	x	x	x	x	x
Standby	x	x	H	x	x

(1) RE stands for rising edge; FE stands for falling edge
(2) Can be nCE high, or WE and nRE high.

15.4.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

Table 15-307 summarizes the level of the NOR interface signals applied to external devices or memories.

Table 15-307. NOR Interface Bus Operations Summary

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

15.4.6.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

OneNAND is a high-density, low-power memory device. OneNAND is based on single- or multilevel-cell NAND core with SRAM and logic. It interfaces as a synchronous NOR flash and has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for mass storage and code storage.

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It also has synchronous write capability.

15.4.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read burst access with wrap capability (4, 8, 16 Word16)

15.4.6.2.2 GPMC Features and Settings

The features and settings of the GPMC are:

- Supported device type: Up to four NAND or NOR protocol external memories or devices
- Operating voltage: 1.8 V, 3.3 V
- Maximum operating frequency provided externally: See the device data manual for precise information.
- Maximum GPMC addressing capability: 512MiB divided into eight chip-selects
- Maximum supported memory size: 256MiB (must be a power-of-two)
- Minimum supported memory size: 16MiB (must be a power-of-two). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8, 16 bits wide
- Burst and page access: burst of 4, 8, 16 Word16
- Supports bus keeping
- Supports bus turnaround

15.4.7 GPMC Register Manual

This section provides information about the GPMC instance in this product. Table 15-309 provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

15.4.7.1 GPMC Register Summary

Table 15-308. GPMC Instance Summary

Module Name	Base Address	Size
GPMC	0x5000 0000	16 MiB

Table 15-309. GPMC Registers Mapping Summary

15.4.7.2 GPMC Register Descriptions

Note

All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register location is accessed, the endianness is access-dependent.

In this section i corresponds to the chip-select number, where i = 0 to 7.

7:1	RESERVED	Read returns 0 (reserved for interconnect-socket status information).	R	0x00
0	RESETDONE	Internal reset monitoring 0x0: Internal module reset is ongoing. 0x1: Reset is complete.	R	0x-

Table 15-313. GPMC_IRQSTATUS

Address Offset	0x0000 0018		
Physical Address	0x5000 0018	**Instance**	GPMC
Description	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						WAIT1EDGEDETECTIONSTATUS	WAIT0EDGEDETECTIONSTATUS	RESERVED						TERMINALCOUNTSTATUS	FIFOEVENTSTATUS

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1EDGEDETECTIONSTATUS	Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected. Write 0x0: WAIT1EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT1 input pin has been detected. Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset.	RW	0x0
8	WAIT0EDGEDETECTIONSTATUS	Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected. Write 0x0: WAIT0EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT0 input pin has been detected. Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset.	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00

Bits	Field Name	Description	Type	Reset
1	TERMINALCOUNTSTATUS	Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit is unchanged. Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset.	RW	0x0
0	FIFOEVENTSTATUS	Status of the FIFOEvent interrupt Read 0x0: Indicates that less than GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and less than FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x0: FIFOEVENTSTATUS bit is unchanged. Read 0x1: Indicates that at least GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and at least FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x1: FIFOEVENTSTATUS bit is reset.	RW	0x0

Table 15-314. GPMC_IRQENABLE

Address Offset	0x0000 001C		
Physical Address	0x5000 001C	**Instance**	GPMC
Description	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						WAIT1EDGEDETECTIONENABLE	WAIT0EDGEDETECTIONENABLE	RESERVED						TERMINALCOUNTEVENTENABLE	FIFOEVENTENABLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1EDGEDETECTIONENABLE	Enables the Wait1 Edge Detection interrupt 0x0: Wait1EdgeDetection interrupt is masked. 0x1: Wait1EdgeDetection event generates an interrupt if occurs.	RW	0x0
8	WAIT0EDGEDETECTIONENABLE	Enables the Wait0 Edge Detection interrupt 0x0: Wait0EdgeDetection interrupt is masked. 0x1: Wait0EdgeDetection event generates an interrupt if occurs.	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTEVENTENABLE	Enables TerminalCountEvent interrupt issuing in prefetch or write-posting mode 0x0: TerminalCountEvent interrupt is masked. 0x1: TerminalCountEvent interrupt is not masked.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	FIFOEVENTENABLE	Enables the FIFOEvent interrupt 0x0: FIFOEvent interrupt is masked. 0x1: FIFOEvent interrupt is not masked.	RW	0x0

Table 15-315. GPMC_TIMEOUT_CONTROL

Address Offset	0x0000 0040		
Physical Address	0x5000 0040	**Instance**	GPMC
Description	The GPMC_TIMEOUT_CONTROL register allows the user to set the start value of the timeout counter.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																TIMEOUTSTARTVALUE								RESERVED							TIMEOUTENABLE

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
12:4	TIMEOUTSTARTVALUE	Start value of the time-out counter 0x000: Zero GPMC_FCLK cycle 0x001: One GPMC_FCLK cycle ... 0x1FF: 511 GPMC_FCLK cycles	RW	0x1FF
3:1	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
0	TIMEOUTENABLE	Enable bit of the TimeOut feature 0x0: TimeOut feature is disabled. 0x1: TimeOut feature is enabled.	RW	0x0

Table 15-316. GPMC_ERR_ADDRESS

Address Offset	0x0000 0044		
Physical Address	0x5000 0044	**Instance**	GPMC
Description	The GPMC_ERR_ADDRESS register stores the address of the illegal access when an error occurs.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	ILLEGALADD																														

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
30:0	ILLEGALADD	Address of illegal access A30: 0 for memory region, 1 for GPMC register region A29-A0: 1 GiB maximum	R	0x00000000

Table 15-317. GPMC_ERR_TYPE

Address Offset	0x0000 0048		
Physical Address	0x5000 0048	**Instance**	GPMC
Description	The GPMC_ERR_TYPE register stores the type of error when an error occurs.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					ILLEGALMCMD			RESERVED			ERORNOTSUPPADD	ERORNOTSUPPMCMD	ERORTIMEOUT	RESERVED	ERORVALID

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
10:8	ILLEGALMCMD	System command of the transaction that caused the error	R	0x0
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	ERRORNOTSUPPADD	Not supported address error 0x0: No error occurs. 0x1: The error is due to a nonsupported address.	R	0x0
3	ERRORNOTSUPPMCMD	Not supported command error 0x0: No error occurs. 0x1: The error is due to a nonsupported command	R	0x0
2	ERRORTIMEOUT	Time-out error 0x0: No error occurs. 0x1: The error is due to a timeout.	R	0x0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
0	ERRORVALID	Error validity status - Must be explicitly cleared with a write 1 transaction 0x0: All error fields no longer valid 0x1: Error detected and logged in the other error fields	RW	0x0

Table 15-318. GPMC_CONFIG

Address Offset	0x0000 0050		
Physical Address	0x5000 0050	**Instance**	GPMC
Description	The configuration register allows global configuration of the GPMC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						WAIT1PINPOLARITY	WAIT0PINPOLARITY	RESERVED						RESERVED	NANDFORCEPOSTEDWRITE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000

Bits	Field Name	Description	Type	Reset
9	WAIT1PINPOLARITY	Selects the polarity of input pin WAIT1 0x0: WAIT1 active low 0x1: WAIT1 active high	RW	0x1
8	WAIT0PINPOLARITY	Selects the polarity of input pin WAIT0 0x0: WAIT0 active low 0x1: WAIT0 active high	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	RESERVED	Write 0 for future compatibility. Read returns 0.	RW	0x0
0	NANDFORCEPOSTEDWRITE	Enables the Force Posted Write feature to NAND Cmd/Add/Data location 0x0: Disables Force Posted Write 0x1: Enables Force Posted Write	RW	0x0

Table 15-319. GPMC_STATUS

Address Offset	0x0000 0054		
Physical Address	0x5000 0054	**Instance**	GPMC
Description	The status register provides global status bits of the GPMC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						WAIT1STATUS	WAIT0STATUS	RESERVED							EMPTYWRITEBUFFERSTATUS

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1STATUS	Is a copy of input pin WAIT1. (Reset value is WAIT1 input pin sampled at device reset.) 0x0: WAIT1 asserted (inactive state) 0x1: WAIT1 deasserted	R	0x-
8	WAIT0STATUS	Is a copy of input pin WAIT0. (Reset value is WAIT0 input pin sampled at device reset.) 0x0: WAIT0 asserted (inactive state) 0x1: WAIT0 deasserted	R	0x-
7:1	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x00
0	EMPTYWRITEBUFFERSTATUS	Stores the empty status of the write buffer 0x0: Write buffer is not empty. 0x1: Write buffer is empty.	R	0x1

Table 15-320. GPMC_CONFIG1_i

Address Offset	0x0000 0060 + (0x0000 0030 * i)	**Index**	i = 0 to 7
Physical Address	0x5000 0060 + (0x0000 0030 * i)	**Instance**	GPMC
Description	The configuration register 1 sets signal control parameters per chip-select.		

Table 15-320. GPMC_CONFIG1_i (continued)

Type RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31	RESERVED	TI Internal use - Do not modify.	RW	1
30:29	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
28:24	WRACCESSTIME	Delay from start access time to the GPMC_FCLK rising edge corresponding the GPMC_CLK rising edge used by the attached memory for the first data capture 0x00: 0 GPMC_FCLK cycle 0x01: 1 GPMC_FCLK cycle ... 0x1F: 31 GPMC_FCLK cycles	RW	0x0F
23:20	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0

Bits	Field Name	Description	Type	Reset
19:16	WRDATAONADMUXBUS	Specifies on which GPMC_FCLK rising edge the first data of the write is driven in the add/data mux bus	RW	0x7
15:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
11:8	CYCLE2CYCLEDELAY	Chip-select high pulse delay between successive accesses 0x0: 0 GPMC_FCLK cycle 0x1: 1 GPMC_FCLK cycle ... 0xF: 15 GPMC_FCLK cycles	RW	0x0
7	CYCLE2CYCLESAMECSEN	Add CYCLE2CYCLEDELAY between successive accesses to the same chip-select (any access type) 0x0: No delay between the two accesses 0x1: Add CYCLE2CYCLEDELAY	RW	0
6	CYCLE2CYCLEDIFFCSEN	Add CYCLE2CYCLEDELAY between successive accesses to a different chip-select (any access type) 0x0: No delay between the two accesses 0x1: Add CYCLE2CYCLEDELAY	RW	0x0
5:4	RESERVED	Write 0s for future compatibility. Reads return 0.	RW	0x0
3:0	BUSTURNAROUND	Bus turnaround latency between successive accesses to the same chip-select (read to write) or to a different chip-select (read to read and read to write) 0x0: 0 GPMC_FCLK cycle 0x1: 1 GPMC_FCLK cycle ... 0xF: 15 GPMC_FCLK cycles	RW	0x0

Table 15-326. GPMC_CONFIG7_i

Address Offset	0x0000 0078 + (0x0000 0030 * i)	**Index**	i = 0 to 7
Physical Address	0x5000 0078 + (0x0000 0030 * i)	**Instance**	GPMC
Description	CS address mapping configuration		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																				MASKADDRESS				RESERVED				CSVALID			
BASEADDRESS																															

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11:8	MASKADDRESS	CS mask address. 0x0000: Chip-select size of 256 MiB 0x1000: Chip-select size of 128 MiB 0x1100: Chip-select size of 64 MiB 0x1110: Chip-select size of 32 MiB 0x1111: Chip-select size of 16 MiB Other values must be avoided as they create holes in the chip-select address space.	RW	0xF
7	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
6	CSVALID	CS enable 0x0: CS disabled 0x1: CS enabled	RW	See (1)
5:0	BASEADDRESS	CSi base address where i = 0 to 7 (16-MiB minimum granularity) bits [5:0] corresponds to A29, A28, A27, A26, A25, and A24. See Figure 15-59	RW	0x00

(1) Reset value is 0x1 for CS0 and 0x0 for CS1 to CS7

Table 15-327. GPMC_NAND_COMMAND_i

Address Offset	0x0000 007C + (0x0000 0030 * i)	**Index**	i = 0 to 7
Physical Address	0x5000 007C + (0x0000 0030 * i)	**Instance**	GPMC
Description	This register is not a true register, only an address location.		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPMC_NAND_COMMAND																															

Bits	Field Name	Description	Type	Reset
31:0	GPMC_NAND_COMMAND	This register is not a true register, only an address location. Writing data at the GPMC_NAND_COMMAND_i location places the data as the NAND command value on the bus, using a regular asynchronous write access.	W	0x-

Table 15-328. GPMC_NAND_ADDRESS_i

Address Offset	0x0000 0080 + (0x0000 0030 * i)	**Index**	i = 0 to 7
Physical Address	0x5000 0080 + (0x0000 0030 * i)	**Instance**	GPMC
Description	This register is not a true register, only an address location.		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPMC_NAND_ADDRESS																															

Bits	Field Name	Description	Type	Reset
31:0	GPMC_NAND_ADDRESS	This register is not a true register, only an address location. Writing data at the GPMC_NAND_ADDRESS_i location places the data as the NAND partial address value on the bus, using a regular asynchronous write access.	W	0x-

Table 15-329. GPMC_NAND_DATA_i

Address Offset	0x0000 0084 + (0x0000 0030 * i)	**Index**	i = 0 to 7
Physical Address	0x5000 0084 + (0x0000 0030 * i)	**Instance**	GPMC
Description	This register is not a true register,only an address location.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPMC_NAND_DATA																															

Bits	Field Name	Description	Type	Reset
31:0	GPMC_NAND_DATA	This register is not a true register, only an address location. Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.	W	0x-

Table 15-330. GPMC_PREFETCH_CONFIG1

15.5 Error Location Module

15.5.1 Error Location Module Overview

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

The ELM has the following features:

- 4, 8 and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

Figure 15-104 shows the ELM overview.

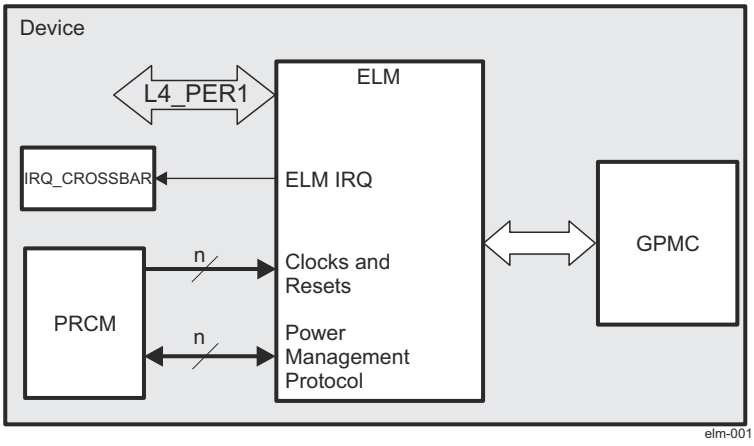

Figure 15-104. ELM Overview

15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-105 shows the integration of the ELM subsystem in the device.

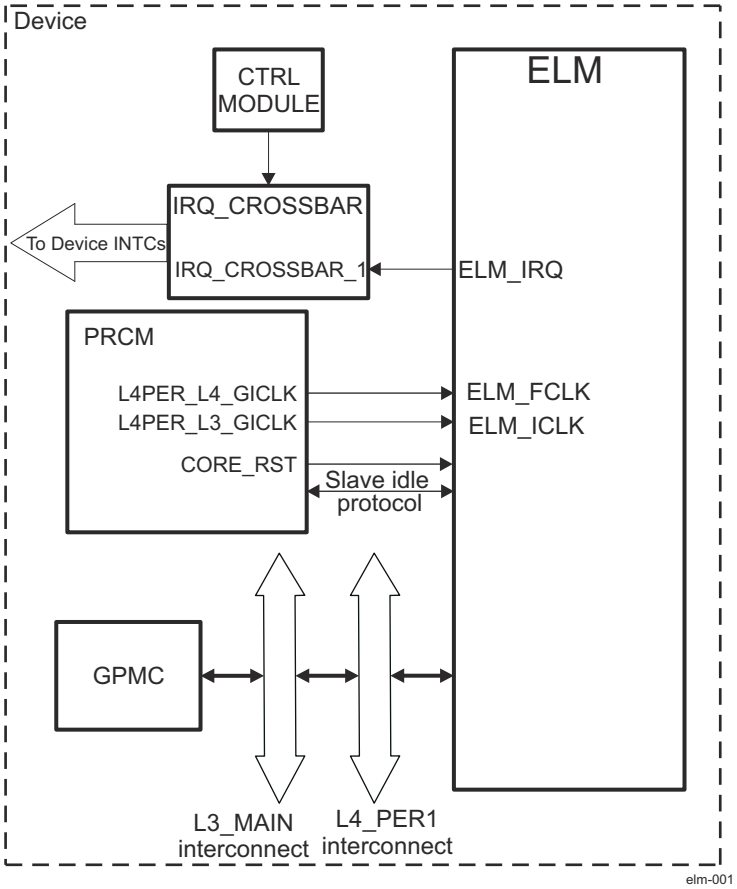

Figure 15-105. ELM Integration

Table 15-346 through Table 15-348 summarize the integration of the module in the device.

Table 15-346. ELM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ELM	PD_COREAON	No	L4_PER1

Interrupt Requests				
Module Instance	**Source Signal Name**	**IRQ_CROSSBAR**	**Default Mapping**	**Description**
ELM	ELM_IRQ	IRQ_CROSSBAR_1	MPU_IRQ_4	BCH error-location module interrupt
			DSP1_IRQ_32	BCH error-location module interrupt
			PRUSS1_IRQ_32	BCH error-location module interrupt
			PRUSS2_IRQ_32	BCH error-location module interrupt

Note

The "**Default Mapping**" column in Table 15-348 *ELM Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

15.5.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

15.5.3.1 ELM Software Reset

To perform a software reset, set the ELM_SYSCONFIG[1] SOFTRESET bit to 1. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

15.5.3.2 ELM Power Management

Table 15-349 describes the power-management features available to the ELM.

Note

- For information about source clock gating and a description of the sleep/wake-up transitions, see the *CD_L4_PER1 Clock Domain*, in *Power, Reset, and Clock Management*.
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see *Clock Management Functional Description*, in *Power, Reset, and Clock Management*

Table 15-349. Local Power-Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained during the wake-up period.
Master standby modes	N/A	
Global wake-up enable	N/A	
Wake-up sources enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see *Power, Reset, and Clock Management*.

15.5.3.3 ELM Interrupt Requests

Table 15-350 lists the event flags, and their masks, that can cause module interrupts.

Table 15-350. Events

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

15.5.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit field defines the error-correction level used (4-,8-, or 16-bit error correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.

- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second is logged in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 15-351 describes the ELM_LOCATION_STATUS_i value decoding.

Table 15-351. ELM_LOCATION_STATUS_i Value Decoding

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. Software must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, software must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bits. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

Note

Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM_IRQSTATUS bits to check for their status.

15.5.4 ELM Basic Programming Model

15.5.4.1 ELM Low-Level Programming Model

15.5.4.1.1 Processing Initialization

Table 15-352. ELM Processing Initialization

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value.
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value.
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value.
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value.
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
else (page mode is used)	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value.
endif		Set value.

Table 15-352. ELM Processing Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value.
	ELM_SYNDROME_FRAGMENT_1_i	Set value.
	ELM_SYNDROME_FRAGMENT_5_i	Set value.
	ELM_SYNDROME_FRAGMENT_6_i	Set value.
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

15.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 15-353 and Table 15-354 describe the processing completion for continuous and page modes, respectively.

Table 15-353. ELM Processing Completion for Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 15-354. ELM Processing Completion for Page Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependent.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	

Table 15-354. ELM Processing Completion for Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

15.5.4.1.3

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see Table 15-355). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 15-355. Use Case: Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2 × 528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C

Table 15-355. Use Case: Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 15-356 are given in decimal format.

Table 15-356. 16-Bit NAND Sector Buffer Address Map

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

15.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode (see Table 15-357). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

Table 15-357. Use Case: Page Mode

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1

Table 15-357. Use Case: Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x2
Defines the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in page mode (four blocks in a page)	ELM_PAGE_CTRL[0] SECTOR_0	0x1
	ELM_PAGE_CTRL[1] SECTOR_1	0x1
	ELM_PAGE_CTRL[2] SECTOR_2	0x1
	ELM_PAGE_CTRL[3] SECTOR_3	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	ELM_IRQENABLE	0x100
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xE0B718EF
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xA329AA05

	ELM_SYNDROME_FRAGMENT_4_i (where i = 1)	0xC22E6669
	ELM_SYNDROME_FRAGMENT_5_i (where i = 1)	0x49A0D932
	ELM_SYNDROME_FRAGMENT_6_i (where i = 1)	0xBAD0
Set the input syndrome polynomial 2.	ELM_SYNDROME_FRAGMENT_0_i (where i = 2)	0x60BA3189
	ELM_SYNDROME_FRAGMENT_1_i (where i = 2)	0x1579EF7D
	ELM_SYNDROME_FRAGMENT_2_i (where i = 2)	0x54556EA0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 2)	0xA6498FEE
	ELM_SYNDROME_FRAGMENT_4_i (where i = 2)	0xEC3697FA
	ELM_SYNDROME_FRAGMENT_5_i (where i = 2)	0xB86ABCD5
	ELM_SYNDROME_FRAGMENT_6_i (where i = 2)	0x69D9
Set the input syndrome polynomial 3.	ELM_SYNDROME_FRAGMENT_0_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_1_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_2_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_3_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_4_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_5_i (where i = 3)	0x0
	ELM_SYNDROME_FRAGMENT_6_i (where i = 3)	0x0
Initiates the computation process for syndrome polynomial 0	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Initiates the computation process for syndrome polynomial 1	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 1)	0x1
Initiates the computation process for syndrome polynomial 2	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 2)	0x1
Initiates the computation process for syndrome polynomial 3	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 3)	0x1

Table 15-357. Use Case: Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial 0, 1, 2, and 3: Wait until the ELM_IRQ interrupt is generated or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Read the process exit status for syndrome polynomial 0: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the process exit status for syndrome polynomial 1: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 1)	0x1
Read the process exit status for syndrome polynomial 2: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 2)	0x1
Read the process exit status for syndrome polynomial 3: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 3)	0x1
Read the number of errors for syndrome polynomial 0: four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4
Read the number of errors for syndrome polynomial 1: two errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 1)	0x2
Read the number of errors for syndrome polynomial 2: one error detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 2)	0x1
Read the number of errors for syndrome polynomial 3: no errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 3)	0x0
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers:	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1FE
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x617
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x650
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the first two registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x4
	ELM_ERROR_LOCATION_1_i (where i = 1)	0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x3E8
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

15.5.5.2.2 ELM Register Description

Table 15-360 through Table 15-390 describe the individual ELM registers.

Table 15-360. ELM_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4807 8000	**Instance**	ELM
Description	This register contains the IP revision code. (A write or reset of to this register has no effect.)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision (TI internal data)	R	0x-

Table 15-361. ELM_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4807 8010	**Instance**	ELM
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLOCKACTIVITYOCP	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOGATING

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000
8	CLOCKACTIVITYOCP	OCP clock activity when module is in IDLE mode (during wake-up mode period) 0x0: OCP clock can be switched off. 0x1: OCP clock is maintained during wake-up period.	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: Force-idle. IDLE request is acknowledged unconditionally and immediately (Default *Dumb* mode for safety) 0x1: No-idle. IDLE request is never acknowledged. 0x2: Smart-idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2
2	RESERVED	Reserved	R	0

Bits	Field Name	Description	Type	Reset
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (during reads, it always returns 0). It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible effect other than saving power) 0x0: OCP clock is free-running. 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

Table 15-362. ELM_SYSSTATUS

Address Offset	0x0000 0014		
Physical Address	0x4807 8014	**Instance**	ELM

15.6 On-Chip Memory (OCM) Subsystem

15.6.1 OCM Subsystem Overview

The OCM subsystem consists of one OCM Controller (OCMC) that is associated with the on-chip RAM. This is the OCMC_RAM1 with 512 KiB of dedicated memory space. The OCM controller is also introduced in Section 15.1.6, *OCM Overview* of Section 15.1, *Memory Subsystem Overview*.

Figure 15-106 shows the OCMC_RAM controller.

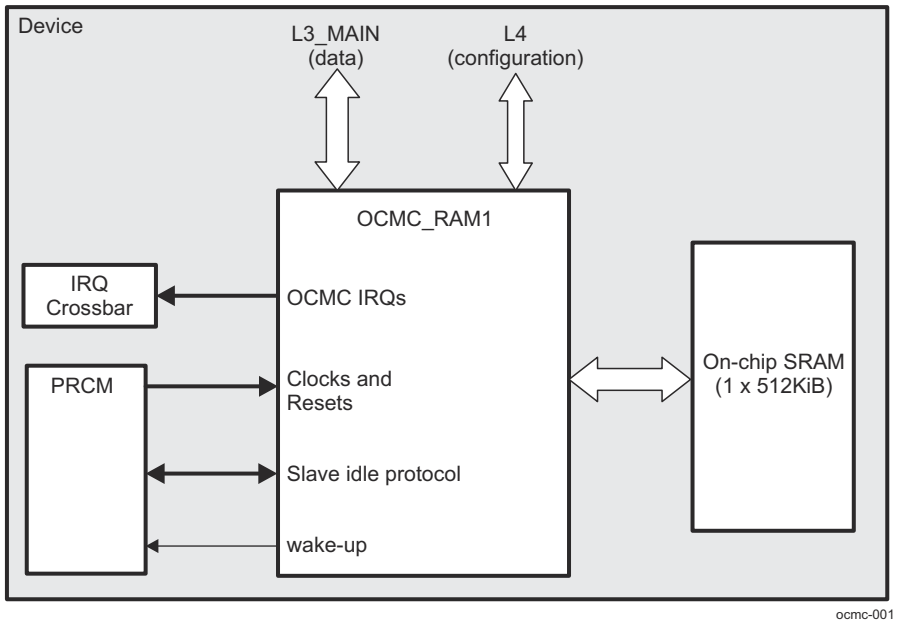

Figure 15-106. OCMC_RAM1 Overview

15.6.2 OCM Subsystem Integration

Figure 15-107 shows the integration of the OCMC_RAM1 in the device.

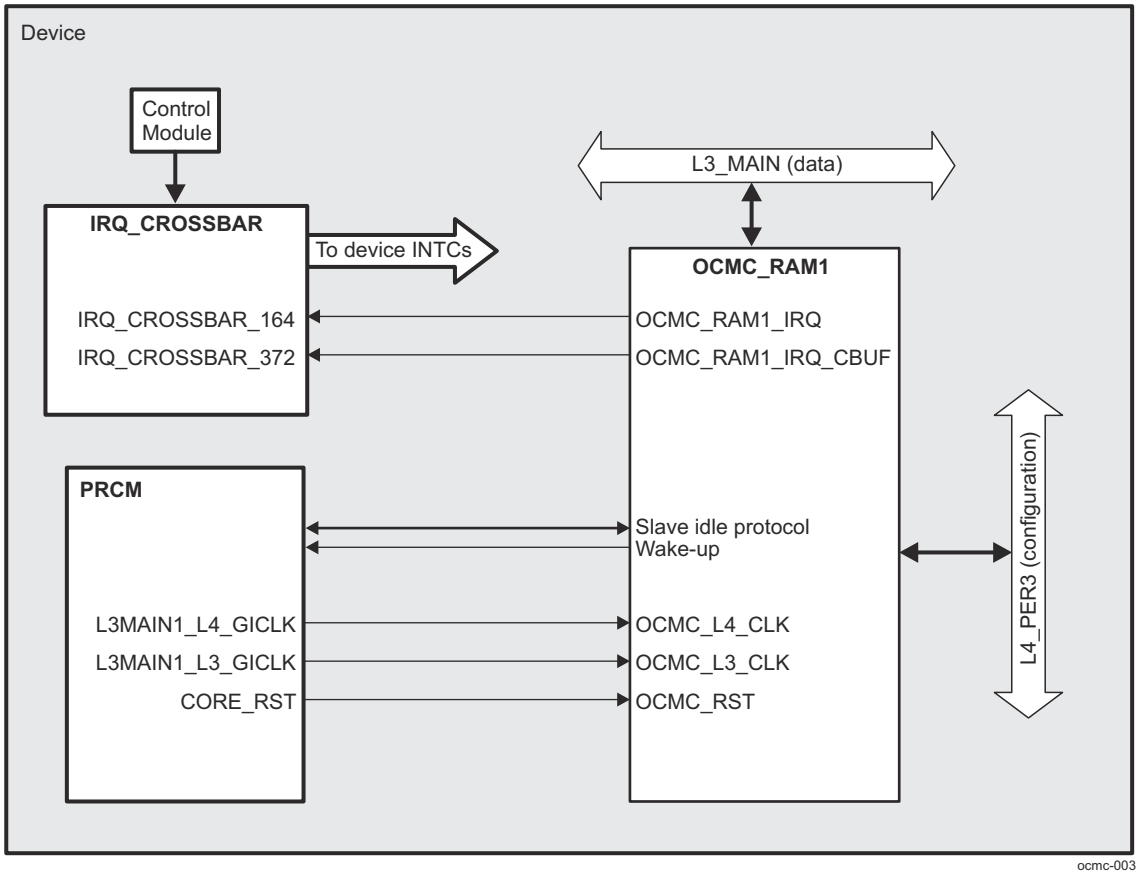

Figure 15-107. OCMC_RAM1 Integration

Table 15-391 through Table 15-393 summarize the integration of the OCMC_RAM1 in the device.

Table 15-391. OCMC_RAM1 Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
OCMC_RAM1	PD_COREAON	Yes	L3_MAIN
			L4_PER3

Table 15-392. OCMC_RAM1 Clocks and Resets

Clocks

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
OCMC_RAM1	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.

Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
OCMC_RAM1	OCMC_RST	CORE_RST	PRCM	Reset signal for the OCMC_RAM1

Table 15-393. OCMC_RAM1 Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
OCMC_RAM1	OCMC_RAM1_IRQ	IRQ_CROSSBAR_164	-	First OCMC_RAM1 interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM1_IRQ_CBUF	IRQ_CROSSBAR_372	-	Second OCMC_RAM1 interrupt request. This IRQ source signal is not mapped by default to any device INTC.

Note

The "**Default Mapping**" column in Table 15-393 *OCMC_RAM1 Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For description of the interrupt sources, see Section 15.6.3.4, *Interrupt Requests*.

15.6.3 OCM Subsystem Functional Desctiption

15.6.3.1 Block Diagram

Figure 15-108 shows the OCMC block diagram.

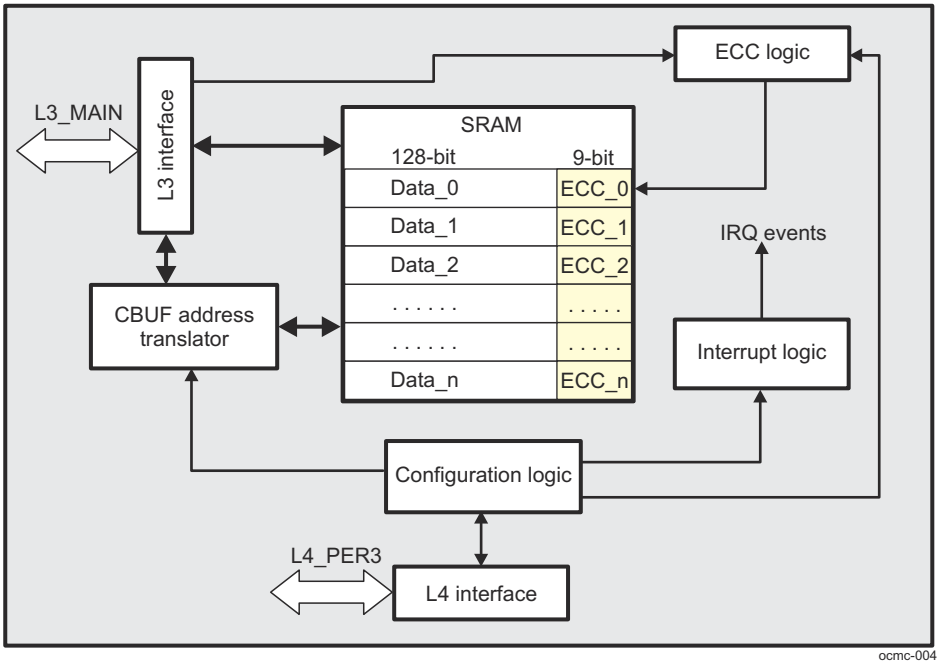

Figure 15-108. OCMC Block Diagram

The module is composed by the following main blocks:

- L3 interface used for data transactions
- L4 interface used for configuration
- CBUF address translator which converts the L3_MAIN VBUF addresses into SRAM addresses
- ECC logic to support single error correction and double error detection
- SRAM used for storring data and the corresponding for each 128-bit word ECC
- Interrupt logic used for generating interrupt requests
- Configuration logic in which reside the registers used for configuring the OCM controller operation modes

15.6.3.2 Resets

The OCMC_RST is the reset signal for the OCM controller which asynchronously resets the whole internal logic of the controller, including all configuration registers. It does not reset the SRAM. In addition, the OCMC_SYSCONFIG_RST[0] SW_RST bit provides a software way to reset the OCM controller. In this case all of its internal logic is reset except the configuration registers accessible through the L4_PER3.

15.6.3.3 Clock Management

The OCM controller complies with the PRCM slave idle protocol. The OCMC_L3_CLK and OCMC_L4_CLK clocks are gated based on the values loaded in the OCMC_SYSCONFIG_PM[3:2] IDLEMODE bit field.

15.6.3.4 Interrupt Requests

The OCM controller generates two interrupt requests, OCMC_RAM1_IRQ and OCMC_RAM1_IRQ_CBUF.

The OCMC_RAM1_IRQ line is associated with the following registers:

- INTR0_STATUS_RAW_SET - interrupt raw status register
- INTR0_STATUS_ENABLED_CLEAR - interrupt status register
- INTR0_ENABLE_SET - interrupt enable register
- INTR0_ENABLE_CLEAR - interrupt disable register

The OCMC_RAM1_IRQ_CBUF line is associated with the following registers:

- INTR1_STATUS_RAW_SET - interrupt raw status register
- INTR1_STATUS_ENABLED_CLEAR - interrupt status register
- INTR1_ENABLE_SET - interrupt enable (event unmask) register
- INTR1_ENABLE_CLEAR - interrupt disable (event mask) register

Both the register groups previously described have identical bits. When for example, only one event occurs one or the two IRQ lines will be asserted depending on the masks applied to the INTR0_ENABLE_SET and INTR1_ENABLE_SET registers. When for example, a short frame detection event occurs and if both the INTR0_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND and INTR1_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND bits are set to 0x1, then both the OCMC_RAM1_IRQ and OCMC_RAM1_IRQ_CBUF lines are asserted. If only the INTR0_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND bit is set to 0x1, then only the OCMC_RAM1_IRQ line is asserted and the OCMC_RAM1_IRQ_CBUF line remains inactive (deasserted). Thus depending on the mask applied one IRQ line of the OCM controller can be associated only with CBUF events for example, and the other one IRQ line can be associated with ECC events. In other words, two unique interrupts can be provided.

Table 15-394 lists the interrupt events which can assert the two interrupt lines of the OCM controller.

The OCM controller asserts each of its interrupt lines only if the interrupts are enabled by setting to 0x1 the corresponding bits in the INTR0_ENABLE_SET/INTR1_ENABLE_SET register. These interrupts can be disabled by setting to 0x1 the corresponding bits in the INTR0_ENABLE_CLEAR/ INTR1_ENABLE_CLEAR register. After the interrupt has been serviced the corresponding status flag must be cleared by software. This is done by setting to 0x1 the corresponding bit in the INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR register which also clears the corresponding bit in the INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET register. The status flags in the INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET register are set even if the corresponding interrupt is disabled as opposed to those in the INTR0_STATUS_ENABLED_CLEAR/

INTR1_STATUS_ENABLED_CLEAR register, which are set only if the corresponding interrupt is enabled. An interrupt is also generated by the OCM controller, if certain bit in the INTR0_STATUS_RAW_SET/ INTR1_STATUS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the INTR0_ENABLE_SET/INTR1_ENABLE_SET register. This is useful when user software debugging is performed. Additionally, even if interrupts are not enabled, certain status bit in the INTR0_STATUS_RAW_SET/ INTR1_STATUS_RAW_SET register can be cleared by setting to 0x1 the corresponding bit in the INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR register.

For additional details regarding the CBUF related events, see Section 15.6.3.11, *CBUF Mode Error Handling*.

Table 15-394. OCMC_RAM1 Events

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND and INTR0_STATUS_ENABLED_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_ENABLED_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND	INTR0_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND and INTR0_ENABLE_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_ENABLE_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND	This bit indicates a short frame detection. It is set if at least one of the bits in the STATUS_CBUF_SHORT_FRAME_DETECT register is set to 0x1.
INTR0_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND	INTR0_ENABLE_SET[13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_ENABLE_SET[13] CBUF_UNDERFLOW_ERR_FOUND and INTR0_ENABLE_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_ENABLE_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND	Indicates CBUF underflow detction. This bit is set if at least one of the bits in the STATUS_CBUF_UNDERFLOW register is set to 0x1.
INTR0_STATUS_RAW_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_STATUS_RAW_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND	INTR0_ENABLE_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_ENABLE_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND and INTR0_ENABLE_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_ENABLE_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND	Indicates Cbuf_Overflow_Wrap event
INTR0_STATUS_RAW_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_STATUS_RAW_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND	INTR0_ENABLE_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_ENABLE_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND and INTR0_ENABLE_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_ENABLE_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND	Indicates Cbuf_Overflow_Mid event

Table 15-394. OCMC_RAM1 Events (continued)

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND	INTR0_ENABLE_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND and INTR0_ENABLE_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND	This flag indicates that at least one CBUF read address is not incrementing in raster scan order(1).
INTR0_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND	INTR0_ENABLE_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_ENABLE_SET[9] CBUF_VBUF_READ_START_ERR_FOUND and INTR0_ENABLE_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_ENABLE_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND	This flag indicates when at least one of the CBUF read accesses does not start at the VBUF start address(1).
INTR0_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND	INTR0_ENABLE_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND and INTR0_ENABLE_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND	This flag indicates when at least one of the CBUF read addresses is out of the CBUF address range(1).
INTR0_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/ INTR1_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND	INTR0_ENABLE_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND and INTR0_ENABLE_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND	This flag indicates that at least one CBUF write address is not incrementing in raster scan order(1).
INTR0_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND	INTR0_ENABLE_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_ENABLE_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND and INTR0_ENABLE_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_ENABLE_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND	This flag indicates when at least one of the CBUF write accesses does not start at the VBUF start address(1).

Table 15-394. OCMC_RAM1 Events (continued)

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND	INTR0_ENABLE_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND and INTR0_ENABLE_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND	This flag indicates when at least one of the CBUF write addresses is out of the CBUF address range(1).
INTR0_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/ INTR1_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND	INTR0_ENABLE_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/ INTR1_ENABLE_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND and INTR0_ENABLE_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/ INTR1_ENABLE_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND	This flag indicates when a virtual address error is detected. This is a general interrupt event which is not associated with any specific CBUF(1).
INTR0_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[3] OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[3] OUT_OF_RANGE_ERR_FOUND	INTR0_ENABLE_SET[3] OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_SET[3] OUT_OF_RANGE_ERR_FOUND and INTR0_ENABLE_CLEAR[3] OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_CLEAR[3] OUT_OF_RANGE_ERR_FOUND	General interrupt for an access made with illegal VBUF address(1).
INTR0_STATUS_RAW_SET[2] ADDR_ERR_FOUND/ INTR1_STATUS_RAW_SET[2] ADDR_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[2] ADDR_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[2] ADDR_ERR_FOUND	INTR0_ENABLE_SET[2] ADDR_ERR_FOUND/ INTR1_ENABLE_SET[2] ADDR_ERR_FOUND and INTR0_ENABLE_CLEAR[2] ADDR_ERR_FOUND/ INTR1_ENABLE_CLEAR[2] ADDR_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[2] CLEAR_ADDR_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.

Table 15-394. OCMC_RAM1 Events (continued)

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[1] DED_ERR_FOUND/ INTR1_STATUS_RAW_SET[1] DED_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[1] DED_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[1] DED_ERR_FOUND	INTR0_ENABLE_SET[1] DED_ERR_FOUND/ INTR1_ENABLE_SET[1] DED_ERR_FOUND and INTR0_ENABLE_CLEAR[1] DED_ERR_FOUND/ INTR1_ENABLE_CLEAR[1] DED_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT[19:16] DED_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[1] CLEAR_DED_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.
INTR0_STATUS_RAW_SET[0] SEC_ERR_FOUND/ INTR1_STATUS_RAW_SET[0] SEC_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[0] SEC_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[0] SEC_ERR_FOUND	INTR0_ENABLE_SET[0] SEC_ERR_FOUND/ INTR1_ENABLE_SET[0] SEC_ERR_FOUND and INTR0_ENABLE_CLEAR[0] SEC_ERR_FOUND/ INTR1_ENABLE_CLEAR[0] SEC_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[0] CLEAR_SEC_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.

(1) The LAST_ILLEGAL_OCMC_ADDR register stores the last illegal L3_MAIN address caused the assertion of this event.

15.6.3.5 OCM Subsystem Memory Regions

The SRAM associated with the OCMC_RAM1 is accessible through the L3_MAIN interconnect. The start address is 0x4030 0000 and the end address is 0x4037 FFFF. That is address space of 512KiB. The configuration registers of the OCMC_RAM1 are accessible through the L4_PER3 starting at address 0x4880 4000.

15.6.3.6 OCM Controller Modes Of Operation

The OCM controller supports four modes of operation. Each of these modes is selected through the CFG_OCMC_ECC[2:0] CFG_OCMC_MODE bit field. The four supported modes are the following:

- Non-ECC mode (Data Access) - Accesses to the SRAM are non-ECC-enabled and an ECC is not calculated.
- Non-ECC mode (Code Access) - The L3_MAIN address is mapped to the SRAM memory space where the ECC code is stored. This mode allows read and write access to the 9-bit ECC word associated with each 128-bit data word. This mode is used for test purposes.
- Full-ECC mode - Accesses to the SRAM are ECC-enabled and a 9-bit ECC is calcualted for each 128 bits of data.
- Block-ECC mode - A 9-bit ECC is calcualted only for a 128KiB block of the SRAM. Accesses outside the 128KiB ECC-enabled block are non-ECC data acceses. In other words, a 9-bit ECC will be calculated not for each 128-bit data word of the whole SRAM space, but for each 128-bit data word within the boundaries of this 128KiB block of the SRAM. The selection of a 128KiB ECC-enabled block is done using bits[19:0] of the CFG_OCMC_ECC_MEM_BLK register. Each bit specifies which 128KiB block of the SRAM is ECC-enabled. 0x1 is the active value for each bit. In addition, more than one 128KiB ECC-enabled block can be selected.

The default mode of operation for the OCM controller is the non-ECC data access mode.

15.6.3.7 ECC Associated FIFOs

There are three FIFOs used when ECC mode is enabled. Each FIFO is four level deep. The FIFOs are the following:

- Address FIFO for single errors also referred to as SEC FIFO
- Address FIFO for double errors also referred to as DED FIFO
- Address FIFO for address errors also referred to as ADDRERR FIFO

The SEC FIFO stores the SRAM addresses at which a single error is detected. The FIFO is able to store up to four unique addresses of the single errors occured. If there are more than four single errors associated with unique addresses, then only the first four addresses are stored in the FIFO. In case of occurrence of multiple correctable errors, the addresses are stored in the order the errors occurred. The SEC FIFO can be optionally configured to store all addresses of the single errors occured including also the repeated addresses. This is done by setting to 0x0 the CFG_OCMC_ECC_ERROR[24] CFG_DISCARD_DUP_ADDR bit. The SEC FIFO can be cleared by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[0] CLEAR_SEC_ERR_CNT bit or by reding FIFO's content one by one through the STATUS_SEC_ERROR_TRACE[17:0] ADDRESS_128BIT bit field which points to the SEC FIFO. In addition, the STATUS_SEC_ERROR_TRACE[18] VALID bit shows whether the FIFO is empty or not. A value of 0x1 means that the SEC FIFO is not empty and valid address can be read.

The DED FIFO stores the SRAM addresses when a double error is detected. The FIFO is able to store up to four unique addresses, but it can also be configured to store the repeated addresses by setting to 0x0 the CFG_OCMC_ECC_ERROR[24] CFG_DISCARD_DUP_ADDR bit. The STATUS_DED_ERROR_TRACE[17:0] ADDRESS_128BIT bit field points to the DED FIFO. The STATUS_DED_ERROR_TRACE[18] VALID bit shows whether the FIFO is empty or not. The DED FIFO can be cleared by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[1] CLEAR_DED_ERR_CNT bit or by reading its content one by one through the STATUS_DED_ERROR_TRACE[17:0] ADDRESS_128BIT.

The ADDRERR FIFO stores the SRAM addresses where the single error occured is an addres error. The STATUS_ADDR_TRANSLATION_ERROR_TRACE[17:0] ADDRESS_128BIT bit field points to the ADDRERR FIFO. The STATUS_ADDR_TRANSLATION_ERROR_TRACE[18] VALID bit shows whether the FIFO is empty or not. The ADDRERR FIFO can be cleared by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[2] CLEAR_ADDR_ERR_CNT bit or by reading its content one by one through the STATUS_ADDR_TRANSLATION_ERROR_TRACE[17:0] ADDRESS_128BIT pointer. The ADDRERR FIFO is also able to store up to four unique addresses and can also be configured to store repeated addresses by setting to 0x0 the CFG_OCMC_ECC_ERROR[24] CFG_DISCARD_DUP_ADDR bit.

15.6.3.8 ECC Counters And Corrected Bit Distribution Register

There are three counters which are used to count different types of errors occured when the ECC mode is enabled. The counters are the following:

- SEC Counter - STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT. This is the counter for the single errors occured. It keeps track of all single errors. That is, even for those with error addresses that have already been logged.
- DED Counter - STATUS_ERROR_CNT[19:16] DED_ERROR_CNT. This is the counter for the double error detections.
- ADDRERR Counter - STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT. This is the counter for the address errors found when a single error occurs. That is, when the single error is an addres error.

When a single error in the 128-bit data word occurs and this error is corrected, the OCM controller indicates for the corrected bit of this 128-bit word by setting to 0x1 a corresponding bit in the corrected bit distribution register. This is a 128-bit register composed by the following registers:

- STATUS_SEC_ERROR_DISTR_0[31:0] SEC_BIT_ERROR_FOUND - Bits [31:0] of the corrected 128-bit data word.
- STATUS_SEC_ERROR_DISTR_1[31:0] SEC_BIT_ERROR_FOUND - Bits [63:32] of the corrected 128-bit data word.
- STATUS_SEC_ERROR_DISTR_2[31:0] SEC_BIT_ERROR_FOUND - Bits [95:64] of the corrected 128-bit data word.

- STATUS_SEC_ERROR_DISTR_3[31:0] SEC_BIT_ERROR_FOUND - Bits [127:96] of the corrected 128-bit data word.

When a single error in the ECC itself occurs, the OCM controller indicates for this error by setting to 0x1 a corresponding bit in the STATUS_SEC_ERROR_DISTR_4[7:0] SEC_ECC_CODE_ERROR_FOUND bit field. The parity bit is not associated with this bit field.

15.6.3.9 ECC Support

The ECC mode is enabled through the CFG_OCMC_ECC[2:0] CFG_OCMC_MODE bit field. When enabled a 9-bit Hamming ECC is calculated and stored for each consecutive 128-bit block of the SRAM. The ECC is calculated based on a codeword constructed by concatenating the 128 bits of data with the address bits A21 through A4 of the L3_MAIN. The ECC generated is Hamming(155,146) code and has a Hamming distance of 4. The OCM controller uses this code to validate the content of the SRAM, to correct a single bit error that occurs within the 128-bit boundary or to determine if a non-correctable error has occurred within the 128-bit boundary.

During write transactions and when ECC is enabled, for every 128-bit data word, the ECC is calculated and stored in a 9-bit field of the SRAM associated only with the address where that 128-bit data word is written. If an initiator performs a write transaction which is less than 128 bits or it is non-128-bit aligned transaction, then the content of all 128 bits is read, the new sub-quanta of data is inserted and the ECC is calculated based on all 128 bits.

During read transactions and when ECC is enabled, the ECC is calcualated based on the memory address (bits A21 through A4) and the 128-bit data word read from the SRAM. This ECC is then compared to the ECC stored at the address when the data was written to the SRAM. If the two ECCs are matching then the data is transferred to the requesting initiator without further exceptions. If the two ECCs are not matching then a check is made to determine if the error is correctable or not. If the error is not correctable, that is a double error, then the address of the erroneous word is stored in the DED FIFO, the STATUS_ERROR_CNT[19:16] DED_ERROR_CNT counter is incremented by 1 and the double error flag is asserted. The double error flag is indicated by the INTR0_STATUS_RAW_SET[1] DED_ERR_FOUND/ INTR1_STATUS_RAW_SET[1] DED_ERR_FOUND bits, but its assertion depends on the threshold configured through the CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX bit field. For more information see, Table 15-394, *OCMC_RAM1 Events*.

In case of a single error, the OCM controller first determines whether the erroneous bit is in the data, address or the ECC itself. In this case the following applies:

- If the single error is located in the data read, then the erroneous bit is corrected and the data is passed to the requesting initiator. The erroneous bit is corrected also in the SRAM location by the auto re-write feature of the OCM controller if this feature is enabled by setting to 0x1 the CFG_OCMC_ECC[3] CFG_ECC_SEC_AUTO_CORRECT bit field. In addition, the address of the corrected data word is pushed to the SEC FIFO and the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counter is incremented by 1. The single error flag is asserted too, but only if the value of the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counter reaches the threshold configured by the CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX bit field. The single error flag is indicated by the INTR0_STATUS_RAW_SET[0] SEC_ERR_FOUND/INTR1_STATUS_RAW_SET[0] SEC_ERR_FOUND bits. For more information see, Table 15-394, *OCMC_RAM1 Events*.
- If the single error is located in the address portion of the quanta, then the data is passed to the requesting initiator unchanged and the STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT and STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counters are incremented by 1. The address associated with this error is stored in the ADDRERR FIFO and the address error flag is asserted. This flag is indicated by the INTR0_STATUS_RAW_SET[2] ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET[2] ADDR_ERR_FOUND bits, but its assertion depends on the threshold configured through the CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX bit field. For more information see, Table 15-394, *OCMC_RAM1 Events*.
- If the single error is located in the ECC itself, then the data is passed to the initiator unchanged but the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counter is incremented by 1 and the address associated with this error is stored in the SEC FIFO.

Table 15-395 summarizes the actions taken by the OCM controller for the different error types.

Table 15-395. OCMC Error Handling In Case Of Different Error Types

Error Type	Data Returned	SRAM Data/ECC Update	SEC Counter	SEC FIFO	DED Counter	DED FIFO	ADDRERR Counter	ADDRERR FIFO	Error Bit Distribution
Single data error	Corrected	Data corrected/ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the corrected bit distribution register is updated
Single address error	Unchanged	ECC re-generated	Incremented by 1	-	-	-	Incremented by 1	Address written	-
Single ECC error	Unchanged	ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the STATUS_SEC_ERROR_DISTR_4[7:0] SEC_ECC_CODE_ERROR_FOUND bit field is updated
Double error	Unchanged	-	-	-	Incremented by 1	Address written	-	-	-

If ECC has to be used, before performing SRAM read/write operations the following steps should be performed:

- Configuring the ECC registers
- Enabling the ECC
- Initializing the SRAM with data
- Clearing the status flags

Table 15-396 describes in detail the steps to be performed.

Table 15-396. OCMC ECC Configuration

Step	Associated Register/ Bit Field	Value
(Optional) Enable the error response on L3_MAIN for a non-correctable error	CFG_OCMC_ECC[4] CFG_ECC_ERR_SRESP_EN	0x1
(Optional) Enable data auto correction in case of a single error	CFG_OCMC_ECC[3] CFG_ECC_SEC_AUTO_CORRECT	0x1
Enable the memory blocks to be ECC protected, if ECC block mode is used	CFG_OCMC_ECC_MEM_BLK[19:0] CFG_ECC_ENABLED_128K_BLK	0x-
(Optional) Configure the address errors count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX	0x-
(Optional) Configure the DED count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX	0x-
(Optional) Configure the SEC count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX	0x-
Enable ECC	CFG_OCMC_ECC[2:0] CFG_OCMC_MODE	0x2 for full ECC or 0x3 for block ECC mode
Initialize the memory with data		
Clear the error counters in the STATUS_ERROR_CNT register	CFG_OCMC_ECC_CLEAR_HIST[2:0]	0x7

Table 15-396. OCMC ECC Configuration (continued)

Step	Associated Register/ Bit Field	Value
Clear the SEC bit distribution history from the following registers:	CFG_OCMC_ECC_CLEAR_HIST[3] CLEAR_SEC_BIT_DISTR	0x1
• STATUS_SEC_ERROR_DISTR_0

• STATUS_SEC_ERROR_DISTR_3		
• STATUS_SEC_ERROR_DISTR_4		

15.6.3.10 Circular Buffer (CBUF) Support

The OCM controller provides up to 12 programmable circular buffers that are mapped to virtual video frames to support sliced based on-the-fly video frame processing. Each circular buffer must be programmed with the following:

- Unique virtual frame start address - configured through CBUF_i_VBUF_START_ADDR[31:4] ADDR.
- Unique virtual frame end address - configured through CBUF_i_VBUF_END_ADDR[31:4] ADDR.
- SRAM start address - configured through CBUF_i_OCMC_START_ADDR[31:4] ADDR.
- SRAM size allocated for that circular buffer - configured through CBUF_i_OCMC_BUF_SIZE[19:4] BUF_SIZE.

The circular buffer mode is enabled when the CFG_OCMC_CBUF_EN[0] CBUF_MODE_EN bit is set to 0x1. In addition, to enable certain circular buffer the corresponding bit in the CFG_OCMC_CBUF_EN[27:16] bit field must be set to 0x1. For example, to enable CBUF_0 both the CFG_OCMC_CBUF_EN[0] CBUF_MODE_EN and CFG_OCMC_CBUF_EN[16] CBUF_EN_0 bits must be set to 0x1.

The data transfers are made to the virtual frame addresses. The OCM controller translates these virtual addresses to SRAM addresses allocated for the CBUF. The address translation is done on-the-fly without leading to any additional latency and therefore has no performance impact on the overall operation of the OCM controller.

The L3_MAIN address range associated with the virtual frame addresses is the following:

- For OCMC_RAM1 the start address is 0x4180 0000 and the end address is 0x41FF FFFF.

When an initiator performs an access to these L3_MAIN addresses, these virtual frame addresses will be translated automatically by the OCM controller into SRAM addresses. Figure 15-109 shows the address mapping of the virtual frame addresses to CBUF addresses.

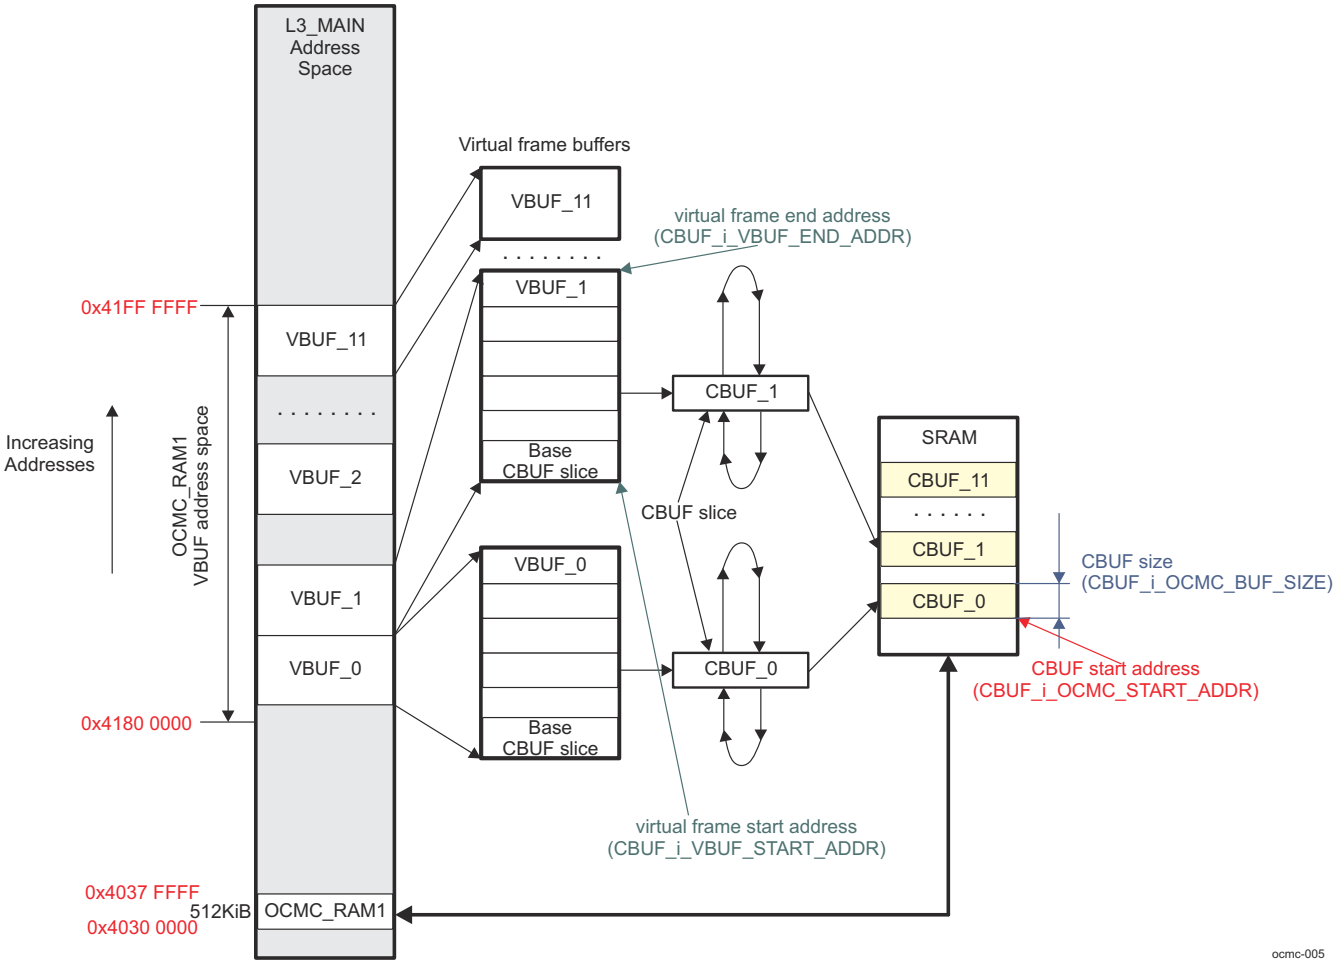

Figure 15-109. VBUF to CBUF Address Mapping

It must be taken into account that the start address of a virtual frame always begins at the start of the CBUF. Since the virtual frame buffer size is not necessarily to be a multiple of the CBUF size, the last VBUF write location may not be the last line of the CBUF. As the CBUF read and write pointers are independently managed the initiators that are writing to and reading from the CBUF should be coordinated in order to avoid overflow and underflow conditions.

15.6.3.11 CBUF Mode Error Handling

For each L3_MAIN write or read access associated with the virtual frame buffer, the OCM controller performs various address error checks to prevent illegal CBUF accesses from causing false overflow and underflow conditions. Once the L3_MAIN VBUF address is determined as valid, the OCM controller further checks for overflow and underflow conditions to properly handle the access to the CBUF during each one of these conditions and to notify for error condition an external host.

For more information regarding all CBUF events see, Table 15-394, *OCMC_RAM1 Events*.

15.6.3.11.1 VBUF Address Not Mapped to a CBUF Memory Space

The L3_MAIN VBUF address should be mapped to a valid CBUF region. If this address is mapped to none of the configured CBUF regions, then the OCM controller generates a virtual address error or out of range CBUF address error event. It is possible both virtual address error and out of range CBUF address error to be generated. The L3_MAIN VBUF address caused these two events can be read through the LAST_ILLEGAL_OCMC_ADDR[31:0] ADDR bit field.

Virtual address error is generated when the L3_MAIN VBUF address is lower than the virtual frame start address. This is indicated by asserting the INTR0_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND bit.

The out of range CBUF address error is generated when the L3_MAIN VBUF address is greater than the virtual frame end address. This error is an indication of an unexpected change in the frame size or a long frame and should be handled immediately to prevent further memory corruption. The out of range CBUF address error can be caused when performing write or read access. The out of range CBUF write address error is indicated by the STATUS_CBUF_WR_OUT_OF_RANGE_ERR[11:0] CBUF_ERR bit field. The out of range CBUF read address error is indicated by the STATUS_CBUF_RD_OUT_OF_RANGE_ERROR[11:0] CBUF_ERR bit field. Each bit in these registers is associated only with one CBUF. Bit 0 corresponds to CBUF_0, bit 1 corresponds to CBUF_1 and so on. A value of 0x1 for each bit means that there is an error (CBUF address is out of CBUF range) for the corresponding CBUF. Writing 0x1 for each bit clears the status.

The INTR0_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_WR_OUT_OF_RANGE_ERR[11:0] CBUF_ERR bit field is set to 0x1.

The INTR0_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_RD_OUT_OF_RANGE_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

15.6.3.11.2 VBUF Access Not Starting At The Base Address

After (hardware of software) reset or on a new frame start condition, a frame write or read access for any VBUF must start from its virtual frame start address (CBUF_i_VBUF_START_ADDR[31:4] ADDR). If this is not met the OCM controller ignors all accesses which don't start at address CBUF_i_VBUF_START_ADDR[31:4] ADDR and also generates an interrupt. The STATUS_CBUF_WR_VBUF_START_ERR[11:0] CBUF_ERR register contains the status bits of this interrupt which are associated with frame write access. The STATUS_CBUF_VBUF_RD_START_ERROR[11:0] CBUF_ERR register contains the status bits associated with frame read access. Each bit in these two registers is associated only with one CBUF. A value of 0x1 for each bit means that the read/write access does not start at the VBUF start address.

While this error condition exists, no updates to the CBUF channel status registers are made. An exception to this constraint is when the last read/write access is still within the base CBUF slice. The enforcing of a frame starting at VBUF starting address is not done in this case to allow random access within the same CBUF. However, this will be flagged and handled as a short frame occurrence.

The INTR0_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_WR_VBUF_START_ERR[11:0] CBUF_ERR bit field is set to 0x1.

The INTR0_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/INTR1_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_VBUF_RD_START_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

15.6.3.11.3 Illegal Address Change Between Two Same Type Accesses

The OCM controller requires both read and write accesses to a virtual frame buffer to be performed in the positive raster scan order, that is, successive write or read accesses should be to a higher address except on a new frame start for which the address jumps back down to the beginning of the virtual frame buffer. The OCM controller checks to make sure that a virtual address meets one of the following conditions:

- It is within the same CBUF slice as the last access of the same type (read or write)
- It is within the next CBUF slice of the last access of the same type (read or write)
- The virtual address is to the VBUF frame start address

Based on these constraints, the OCM controller generates an write/read address sequence error interrupt and invalidates the access, that is, writes are disabled and reads return unknown data, if the following two conditions are met:

- The current access address is not to a current or next CBUF slice space
- The current access address is not to the base of the virtual frame buffer (the first CBUF slice)

The random accesses within the current CBUF slice are permited to allow some variations in the line width of the captured video which often happens with weak video signal conditions.

To avoid illegal CBUF slice backward switching, the modules capturing the input video and sending it to the CBUF of the OCM controller should limit the maximum width of a line width to be less than the stride size (in pixels). This guarantees that a start of a new line does not point back to the previous CBUF slice.

If a write or read address sequence error event is detected on an access, the OCM controller will simply invalidate the accesses and will not update the CBUF status registers.

The bits in the STATUS_CBUF_WR_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field indicate write address sequence error event.

The bits in the STATUS_CBUF_RD_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field indicate read address sequence error event.

In both the registers each bit is associated only with one CBUF.

The INTR0_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/INTR1_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_WR_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

The INTR0_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_RD_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

15.6.3.11.4 Illegal Frame SIze (Short Frame Detection)

If a frame write access for any VBUF begins from its virtual frame start address without a CBUF software reset and the last write address is not the virtual frame end address or is in the last CBUF slice, then the previous frame is considered to be short. This includes the case where a new frame write happens twice without a new frame read in between, which is an indication of an extremely short frame. When a short frame event is detected, the OCM controller generates a short frame detection interrupt and temporarily disables overflow checking on the write access, including also the current access, until a frame read happens in order to avoid false overflow indication on a suspended read side following the short frame detection.

If the last write address is in the last CBUF slice the short frame detection can be ignored if the CFG_OCMC_CBUF_ERR_HANDLER[1] SHORT_FRAME_PREV_EOF_SEL bit is set to 0x1.

The STATUS_CBUF_SHORT_FRAME_DETECT[11:0] CBUF_ERR bit field has status flags to indicate a short frame detection for each CBUF. When a short frame condition occurs the corresponding bit is set to 0x1.

The INTR0_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_SHORT_FRAME_DETECT[11:0] CBUF_ERR bit field is set to 0x1.

In addition, the short frame detection enabling/disabling is controlled by the CFG_OCMC_CBUF_ERR_HANDLER[0] SHORT_FRAME_DETECT_CHECK_EN bit.

15.6.3.11.5 CBUF Overflow

For each valid CBUF write access, the write address is compared to the last read address for an overflow condition. If an overflow is detected, the corresponding CBUF overflow status bit in the STATUS_CBUF_OVERFLOW_MID or STATUS_CBUF_OVERFLOW_WRAP registers is set to 0x1 and an interrupt is generated. This interrupt condition exists until the corresponding overflow status bit is cleared.

There are two types of overflow conditions referred to as Cbuf_overflow_wrap and Cbuf_overflow_mid.

Cbuf_overflow_wrap occurs in case at least one of the following two:
- VBUF write address – VBUF frame start address < CBUF size
- VBUF write address – VBUF frame start address > VBUF last read address – Current VBUF start address

Cbuf_overflow_mid occurs in case at least one of the following two:
- VBUF write address – VBUF frame start address > CBUF size
- VBUF write address – VBUF last read address > CBUF size

If an overflow condition is detected on a CBUF write access, the OCM controller generates a CBUF overflow (Cbuf_overflow_wrap or Cbuf_overflow_mid) interrupt and enter an overflow error handling state. In this state, the OCM controller do the following in the default error handling configuration:
- When a Cbuf_Overflow_Wrap condition occurs (write buffer wraparound with read from previous frame still remaining), writes are disabled but reads are serviced normally. This mechanism preserves the back end of the previous frame and discards the new frame which is already showing signs of overflowing. Writes will be re-enabled automatically on write to the virtual frame start address which indicates the next frame after the overflowed frame has begun. The overflow (and underflow) check for this CBUF will be disabled until detection of write to/read from the virtual frame start address. The module which reads should not start reading the next frame (which is being discarded) or stop reading the frame if the read of this new frame has already started. This mechanism allows both write and read sides to re-synchronize on the next frame after one-frame drop.
- When a Cbuf_Overflow_Mid condition occurs, writes and reads are serviced normally allowing the read side to catch up to the write side. The overflow (and underflow) check will be disabled until first a write to the virtual frame start address and then a read from the virtual frame start address is detected. This mechanism allows the frame with a “momentary” overflow condition to be saved. The reader side has an option to stop reading and discarding the data by just resetting its CBUF read pointer at the next frame start, if the read side is too far back.

These steps are taken to minimize the frame loss due to an overflow condition. To support the previously described behavior but to allow software to override the default error handling behavior the following controls are available:
- CFG_OCMC_CBUF_ERR_HANDLER[7:6] OVERFLOW_CHECK_REENABLE_SEL
- CFG_OCMC_CBUF_ERR_HANDLER[5:4] OVERFLOW_WRITE_HANDLER_SEL

In addition, the overflow check can be enabled or disabled through the CFG_OCMC_CBUF_ERR_HANDLER[2] OVERFLOW_ERR_CHECK_EN bit.

15.6.3.11.6 CBUF Underflow

According to the CBUF operation a read request can only be made when there are enough number of video lines written to the CBUF. Therefore, there should not be any underflow conditions due to normal processing speed variations. An underflow condition occurs when the VBUF read address is greater than the last VBUF write address. To detect an abnormal failure in the read/write mechanism which could cause an underflow condition, each valid CBUF read access is checked for an underflow condition and if detected, an underflow interrupt is generated for the selected CBUF. The STATUS_CBUF_UNDERFLOW[11:0] CBUF_ERR bit field has status flags indicating when underflow occurs. This interrupt condition exists until the corresponding underflow status bit in the STATUS_CBUF_UNDERFLOW register is cleared.

If an underflow is detected on a CBUF read access, the OCM controller generates an underflow interrupt and continues to perform reads and writes normally, but the return data will not be correct while the underflow condition exists.

To avoid a false underflow detection at the end of a frame (due to external decoders sending short last line or due to interlaced input video having different number of lines in even/odd fields), the CFG_OCMC_CBUF_ERR_HANDLER[8] UNDERFLOW_LAST_CBUF_SLICE_DISABLE bit can be set to 0x1 which disables the underflow checking in the last CBUF slice.

The INTR0_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND/INTR1_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_UNDERFLOW[11:0] CBUF_ERR bit field is set to 0x1.

In addition, the underflow check can be enabled or disabled through the CFG_OCMC_CBUF_ERR_HANDLER[3] UNDERFLOW_ERR_CHECK_EN bit.

15.6.3.12 Status Reporting

The OCM controller keeps a history of last valid write and read addresses for each CBUF. The CBUF_k_LAST_WR_ADDR register stores the address for the last valid write and the CBUF_k_LAST_RD_ADDR register stores the address for the last valid read access.

The OCMC_ECC generates also a general VBUF mode error event for an access made with illegal VBUF address. The INTR0_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND bit indicates for this event.

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	SW_RST	Software reset of the OCM controller configuration and history logic (does not reset L4 interface) 0x0: Normal operation (OCM controller is not reset) 0x1: Reset the OCM controller (except its registers). This bit must be set back to 0x0 to resume the normal operation of the OCM Controller.	RW	0x0

Table 15-405. OCMC_MEM_SIZE_READ

Address Offset	0x0000 000C		
Physical Address	0x4880 400C	**Instance**	OCMC_RAM1
Description	This register provides the status of the OCM Controller configuration.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																VBUF_ADDR_MSB				RESERVED		MEM_CBUF_ENABLE	MEM_ECC_ENABLE	RESERVED			MEM_SIZE_128K_CNT				

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0
16:12	VBUF_ADDR_MSB	This bit field returns the MSB bit of the valid VBUF address range. The default value of 23 means that the valid VBUF address range is from 0x8000 0000 to 0x80FF FFFF	R	0x-
11:10	RESERVED		R	0x0
9	MEM_CBUF_ENABLE	Indicates whether CBUF is supported or not. 0x0: CBUF not supported 0x1: CBUF supported	R	0x-
8	MEM_ECC_ENABLE	Indicates whether ECC is supported or not. 0x0: ECC not supported 0x1: ECC supported	R	0x-
7:5	RESERVED		R	0x0
4:0	MEM_SIZE_128K_CNT	This bit field indicates how many 128KiB memory blocks are present in the SRAM. Access beyond the memory size reported in the MEM_SIZE_128K_CNT bit field results in an address error interrupt. 0x1: One 128KiB memory block 0x2: Two 128KiB memory blocks ... 0x14: 20 memory blocks of 128KiB	R	0x-

Table 15-455. CFG_OCMC_CBUF_RESET

Address Offset	0x0000 0204		
Physical Address	0x4880 4204	**Instance**	OCMC_RAM1
Description	Writing 1 to bit n will set a reset bit to clear the corresponding CBUF_n address translation logic. Sliding CBUF frame tracking will be cleared so that the CBUF now points to the base of the virtual frame buffer. Normally, a reset is not required since the CBUF logic will clear itself when a VBUF access is to the base of the virtual frame.

Chapter 16

DMA Controllers

This chapter describes the features and operation of the device System DMA (DMA_SYSTEM) and Enhanced DMA (EDMA) controllers.

16.1 System DMA

This chapter describes the system direct memory access (DMA_SYSTEM) module.

16.1.1 DMA_SYSTEM Module Overview

The system direct memory access (DMA_SYSTEM) module, also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
  - Memory and memory
  - Memory and peripheral device
- 32 logical DMA channels supporting:
  - Multiple concurrent transfers
  - Independent transfer profile for each channel
  - 8-bit, 16-bit, or 32-bit data element transfer size
  - Software-triggered or hardware-synchronized transfers
  - Flexible source and destination address generation
  - Burst read and write - max burst size is 16
  - Chained multiple-channel transfers
  - Endianism conversion
  - Draining
  - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 Hardware DMA requests
- DMA_CROSSBAR
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 × 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support

Figure 16-1 shows an overview of the DMA_SYSTEM module.

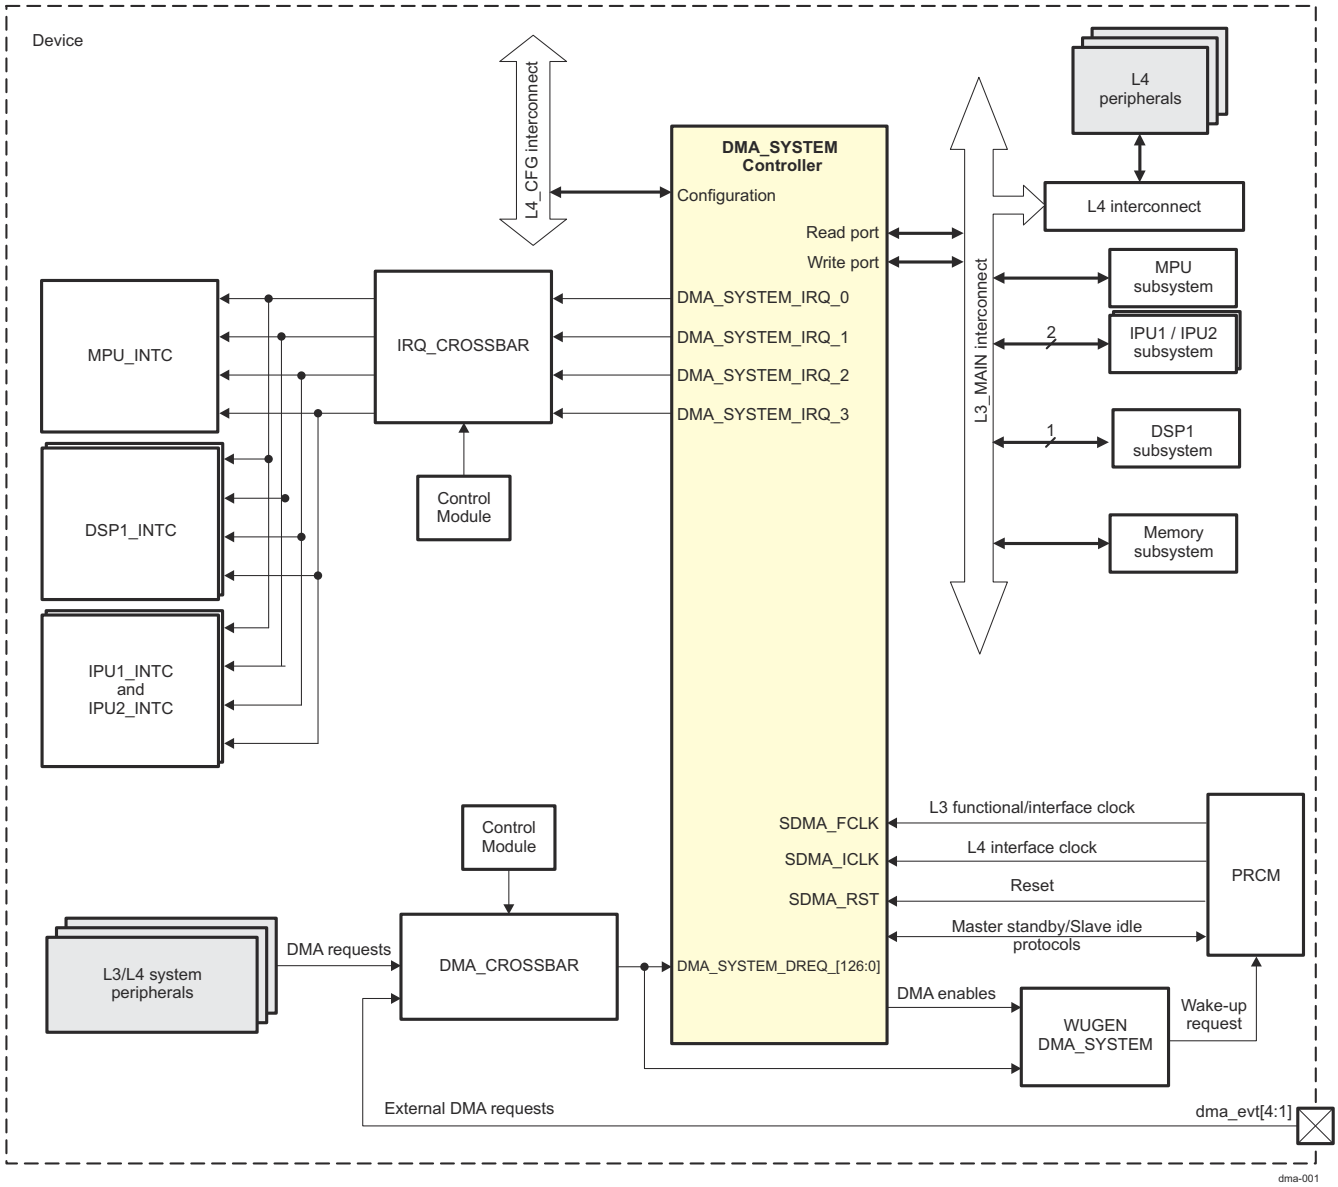

Figure 16-1. DMA_SYSTEM Overview

The DMA_SYSTEM module has three ports: one read, one write, and one configuration port, and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the DMA_SYSTEM through the L4_CFG interconnect.

16.1.2 DMA_SYSTEM Controller Environment

The DMA_SYSTEM controller supports external DMA requests through the dma_evt[4:1] pins (see Table 16-1). A logical channel can be configured to respond to an external synchronization request.

Table 16-1. External DMA_SYSTEM Request Signals

Pin Name	DMA_CROSSBAR Input	Signal Name	I/O(1)	Description	Module Reset Value
dma_evt1	DMA_CROSSBAR_2	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
dma_evt2	DMA_CROSSBAR_3	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z
dma_evt3	DMA_CROSSBAR_167	EXT_SYS_DREQ_2	I	External DMA request 2 (system expansion)	Z
dma_evt4	DMA_CROSSBAR_168	EXT_SYS_DREQ_3	I	External DMA request 3 (system expansion)	Z

(1) I = Input, O = Output

Figure 16-2 shows an example of how to use the external hardware DMA request pins in the DMA_SYSTEM environment.

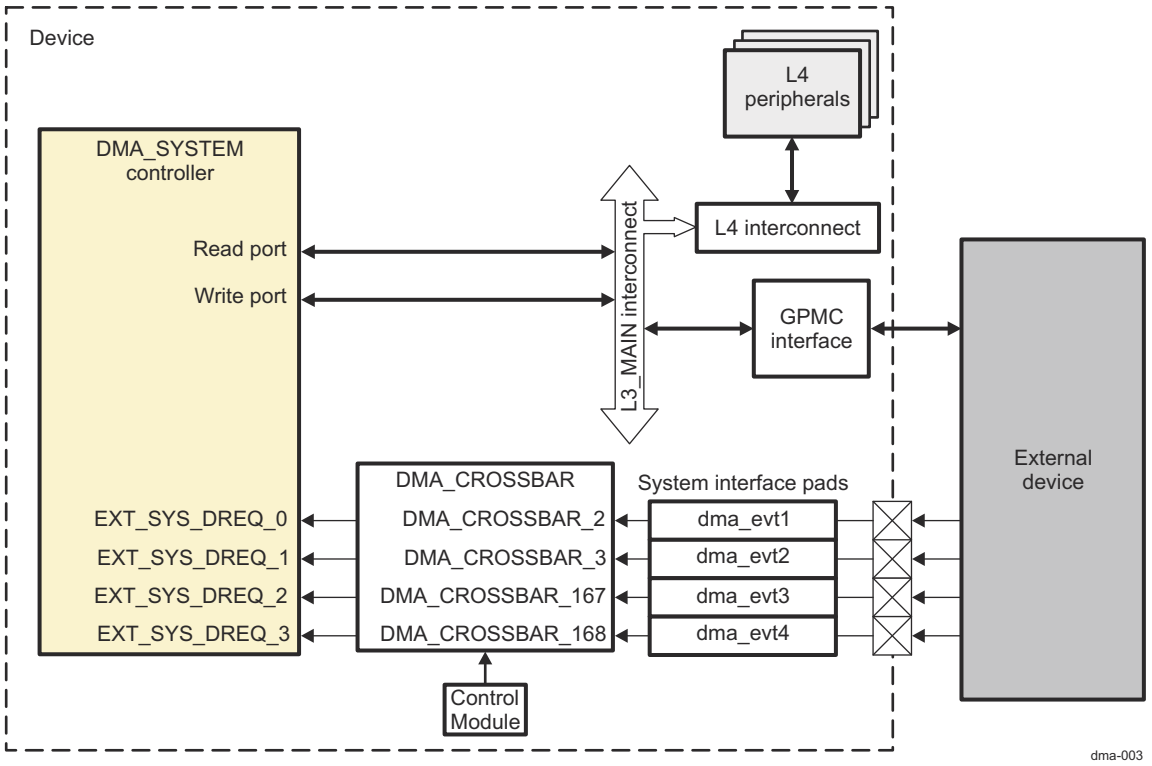

Figure 16-2. Example of External DMA Requests Use

An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, see *Pad Configuration Registers* in the *Control Module*.

All 127 DMA request lines are transition sensitive.

For a transition-sensitive DMA request (see Figure 16-3), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (DMA_L3_GICLK):

- When the deassertion time is less than one clock cycle, the DMA_SYSTEM may not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

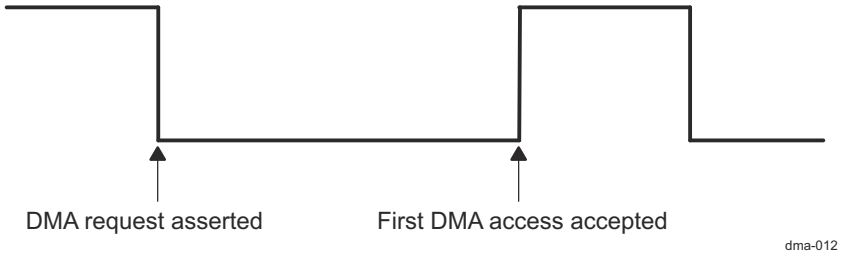

Figure 16-3. Transition-Sensitive DMA Request Scheme

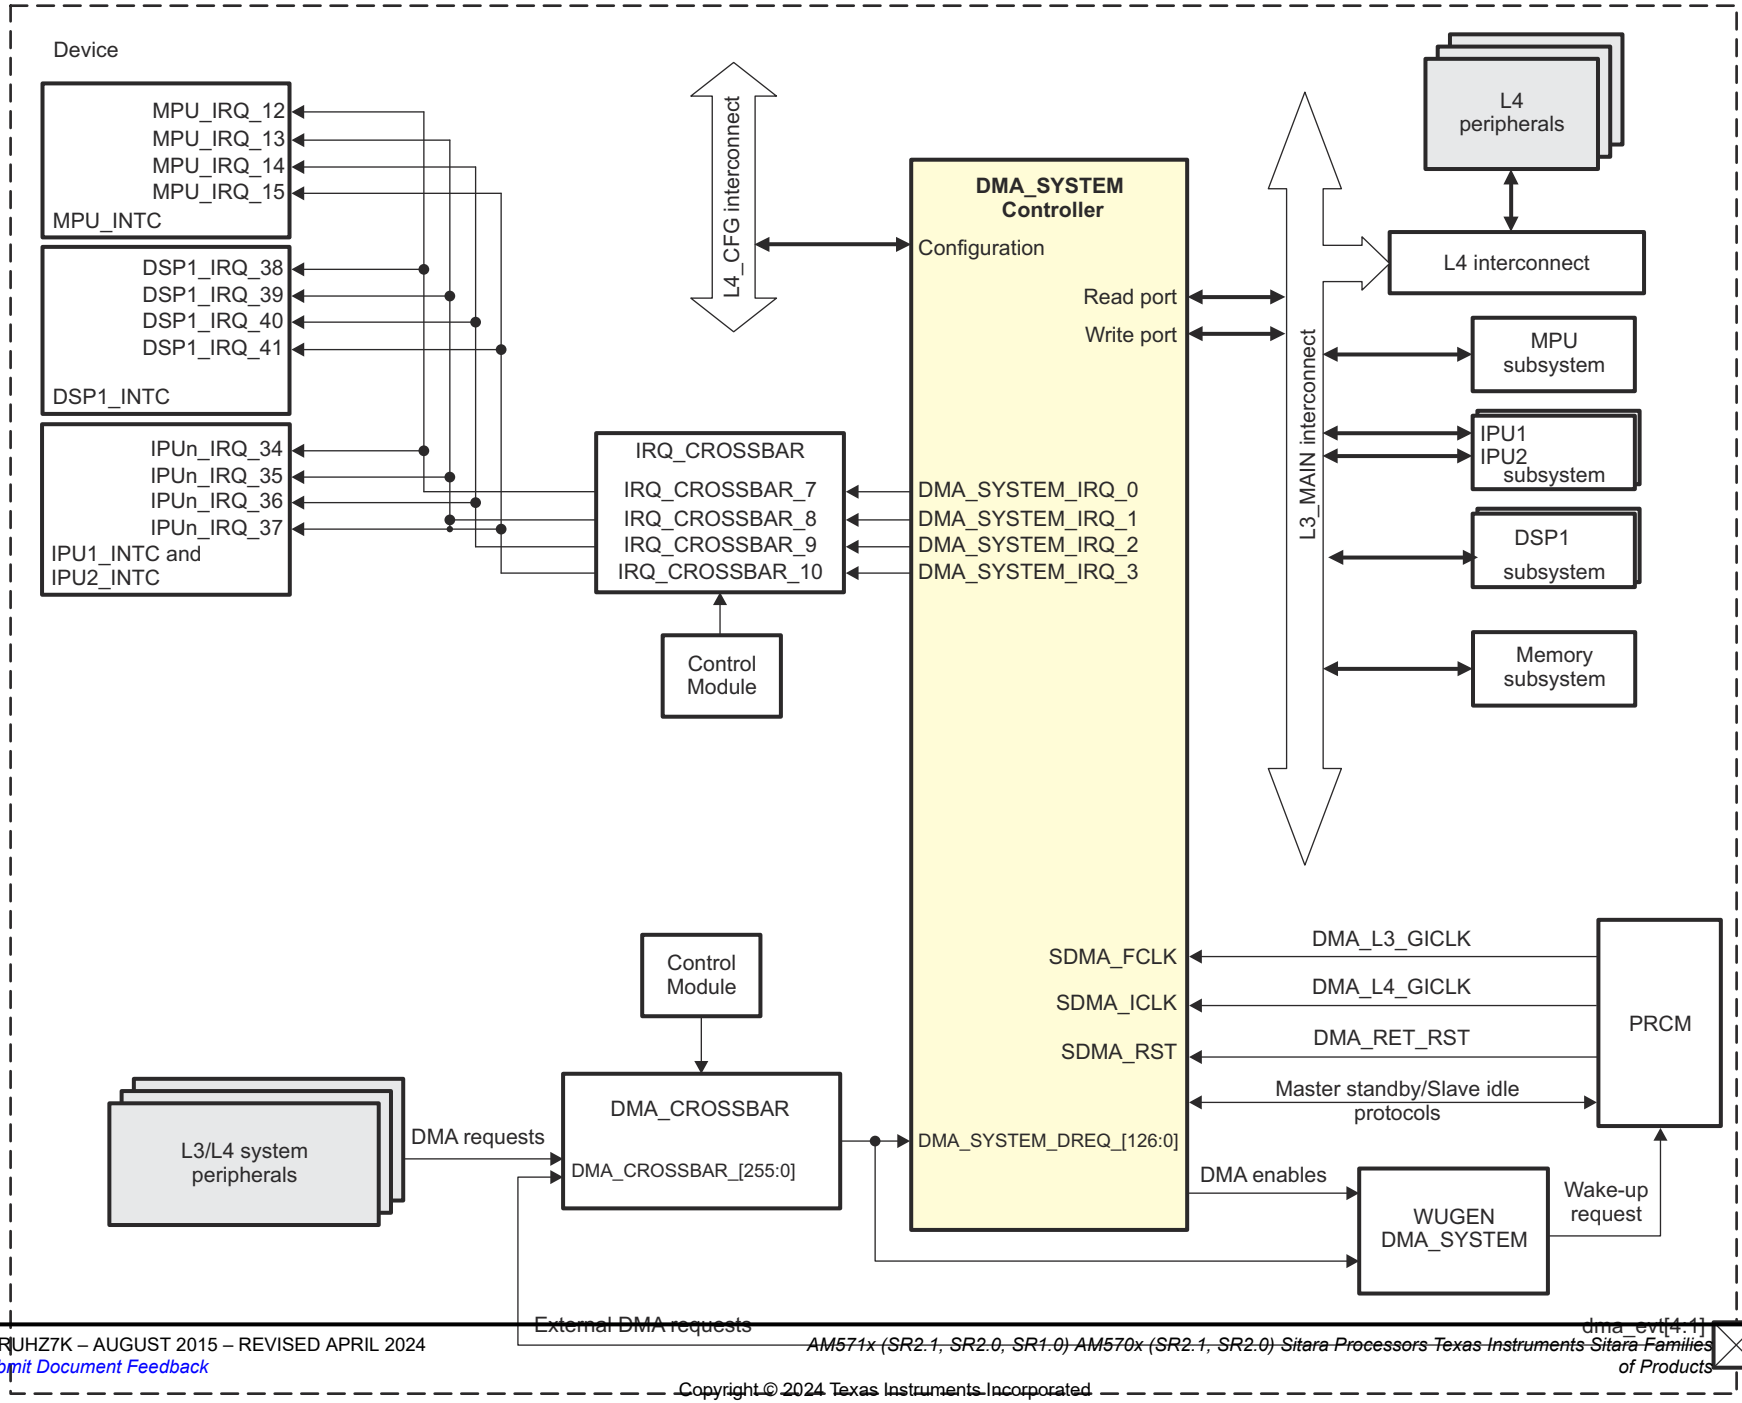
16.1.3 DMA_SYSTEM Module Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 16-4 shows the DMA_SYSTEM controller integration.



dma-002

Note

For more information about the system DMA wake-up generator (WUGEN_DMA_SYSTEM), the master standby/slave idle protocols, and the wake-up request, see *Clock Management*, in *Power, Reset, and Clock Management*.

Table 16-2 through Table 16-4 summarize the integration of the module in the device.

Table 16-2. DMA_SYSTEM Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
DMA_SYSTEM	PD_COREAON	L3_MAIN and L4_CFG

Table 16-3. DMA_SYSTEM Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DMA_SYSTEM	SDMA_FCLK	DMA_L3_GICLK	PRCM	Functional clock for all internal logic and for the two master read and write ports. For information about the power, reset, and clock management (PRCM) clock gating and management, see *Power, Reset, and Clock Management*.
	SDMA_ICLK	DMA_L4_GICLK		Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see *Power, Reset, and Clock Management*.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DMA_SYSTEM	SDMA_RST	DMA_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the DMA_SYSTEM module, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see *Power, Reset, and Clock Management*.

Table 16-4. DMA_SYSTEM Hardware Requests

Interrupt Requests					
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR INPUT**	**Default Mapping**	**Destination**	**Description**
DMA_SYSTEM	DMA_SYSTEM_IRQ_0	IRQ_CROSSBAR_7	MPU_IRQ_12	Cortex-A15 MPU INTC	DMA_SYSTEM interrupt request 0. For information about the MPU_INTC, see *Interrupt Requests to MPU_INTC*.
			IPU1_IRQ_34	IPU1 INTC	DMA_SYSTEM interrupt request 0. For information about the IPU1_INTC, see *Interrupt Requests to IPU1_Cx_INTC*.
			IPU2_IRQ_34	IPU2 INTC	DMA_SYSTEM interrupt request 0. For information about the IPU2_INTC, see *Interrupt Requests to IPU2_Cx_INTC*.
			DSP1_IRQ_38	DSP1 INTC	DMA_SYSTEM interrupt request 0. For information about the DSP1_INTC, see *Interrupt Requests to DSP1_INTC*.
	DMA_SYSTEM_IRQ_1	IRQ_CROSSBAR_8	MPU_IRQ_13	Cortex-A15 MPU INTC	DMA_SYSTEM interrupt request 1
			IPU1_IRQ_35	IPU1 INTC	
			IPU2_IRQ_35	IPU2 INTC	
			DSP1_IRQ_39	DSP1 INTC	
	DMA_SYSTEM_IRQ_2	IRQ_CROSSBAR_9	MPU_IRQ_14	Cortex-A15 MPU INTC	DMA_SYSTEM interrupt request 2
			IPU1_IRQ_36	IPU1 INTC	
			IPU2_IRQ_36	IPU2 INTC	
			DSP1_IRQ_40	DSP1 INTC	
	DMA_SYSTEM_IRQ_3	IRQ_CROSSBAR_10	MPU_IRQ_15	Cortex-A15 MPU INTC	DMA_SYSTEM interrupt request 3
			IPU1_IRQ_37	IPU1 INTC	
			IPU2_IRQ_37	IPU2 INTC	
			DSP1_IRQ_41	DSP1 INTC	

Note

The "**Default Mapping**" column in Table 16-4 *Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR or DMA_CROSSBAR modules.

For more information about the IRQ_CROSSBAR and DMA_CROSSBAR modules, see sections: *IRQ_CROSSBAR Module Functional Description* and *DMA_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, refer to *Interrupt Controllers* in the device TRM.

Note

For a description of the interrupt source, see Section 16.1.4.2, *DMA_SYSTEM Controller Interrupt Requests*.

16.1.3.1 DMA Requests to the DMA_SYSTEM Controller

Table 16-5 lists the default DMA sources for the DMA_SYSTEM controller. In addition, the DMA_SYSTEM inputs (DMA_SYSTEM_DREQ_[126:0]) can alternatively be sourced through the associated DMA_CROSSBAR from one of the 256 multiplexed device DMA sources listed in Table 16-6. The CTRL_CORE_DMA_SYSTEM_DREQ_y_z registers (where *y* and *z* are indexes of DMA_SYSTEM input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

Table 16-5. DMA_SYSTEM Default Request Mapping

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_SYSTEM_DREQ_0	1	CTRL_CORE_DMA_SYSTEM_DREQ_0_1[7:0]	1	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_1	2	CTRL_CORE_DMA_SYSTEM_DREQ_0_1[23:16]	2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion)
DMA_SYSTEM_DREQ_2	3	CTRL_CORE_DMA_SYSTEM_DREQ_2_3[7:0]	3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion)
DMA_SYSTEM_DREQ_3	4	CTRL_CORE_DMA_SYSTEM_DREQ_2_3[23:16]	4	GPMC_DREQ	GPMC data transmit request from prefetch engine
DMA_SYSTEM_DREQ_4	5	CTRL_CORE_DMA_SYSTEM_DREQ_4_5[7:0]	5	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_5	6	CTRL_CORE_DMA_SYSTEM_DREQ_4_5[23:16]	6	DISPC_DREQ	Frame update request
DMA_SYSTEM_DREQ_6	7	CTRL_CORE_DMA_SYSTEM_DREQ_6_7[7:0]	7	CT_TBR_DREQ	DEBUG subsystem CT_TBR request
DMA_SYSTEM_DREQ_7	8	CTRL_CORE_DMA_SYSTEM_DREQ_6_7[23:16]	8	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_8	9	CTRL_CORE_DMA_SYSTEM_DREQ_8_9[7:0]	9	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_9	10	CTRL_CORE_DMA_SYSTEM_DREQ_8_9[23:16]	10	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_10	11	CTRL_CORE_DMA_SYSTEM_DREQ_10_11[7:0]	11	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_11	12	CTRL_CORE_DMA_SYSTEM_DREQ_10_11[23:16]	12	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_12	13	CTRL_CORE_DMA_SYSTEM_DREQ_12_13[7:0]	13	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_13	14	CTRL_CORE_DMA_SYSTEM_DREQ_12_13[23:16]	14	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_14	15	CTRL_CORE_DMA_SYSTEM_DREQ_14_15[7:0]	15	MCSPI3_DREQ_TX0	McSPI3 transmit request channel 0
DMA_SYSTEM_DREQ_15	16	CTRL_CORE_DMA_SYSTEM_DREQ_14_15[23:16]	16	MCSPI3_DREQ_RX0	McSPI3 receive request channel 0
DMA_SYSTEM_DREQ_16	17	CTRL_CORE_DMA_SYSTEM_DREQ_16_17[7:0]	17	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_17	18	CTRL_CORE_DMA_SYSTEM_DREQ_16_17[23:16]	18	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_18	19	CTRL_CORE_DMA_SYSTEM_DREQ_18_19[7:0]	19	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_19	20	CTRL_CORE_DMA_SYSTEM_DREQ_18_19[23:16]	20	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_20	21	CTRL_CORE_DMA_SYSTEM_DREQ_20_21[7:0]	21	Reserved	Reserved by default but can be remapped to a valid DMA source

Table 16-5. DMA_SYSTEM Default Request Mapping (continued)

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_SYSTEM_DREQ_21	22	CTRL_CORE_DMA_SYSTEM_DREQ_20_21[23:16]	22	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_22	23	CTRL_CORE_DMA_SYSTEM_DREQ_22_23[7:0]	23	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_23	24	CTRL_CORE_DMA_SYSTEM_DREQ_22_23[23:16]	24	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_22	23	CTRL_CORE_DMA_SYSTEM_DREQ_22_23[7:0]	23	MCSPI3_DREQ_TX1	McSPI module 3 - transmit request channel 1
DMA_SYSTEM_DREQ_23	24	CTRL_CORE_DMA_SYSTEM_DREQ_22_23[23:16]	24	MCSPI3_DREQ_RX1	McSPI module 3 - receive request channel 1
DMA_SYSTEM_DREQ_24	25	CTRL_CORE_DMA_SYSTEM_DREQ_24_25[7:0]	25	I2C3_DREQ_TX	I2C3 transmit request
DMA_SYSTEM_DREQ_25	26	CTRL_CORE_DMA_SYSTEM_DREQ_24_25[23:16]	26	I2C3_DREQ_RX	I2C3 receive request
DMA_SYSTEM_DREQ_26	27	CTRL_CORE_DMA_SYSTEM_DREQ_26_27[7:0]	27	I2C1_DREQ_TX	I2C1 transmit request
DMA_SYSTEM_DREQ_27	28	CTRL_CORE_DMA_SYSTEM_DREQ_26_27[23:16]	28	I2C1_DREQ_RX	I2C1 receive request
DMA_SYSTEM_DREQ_28	29	CTRL_CORE_DMA_SYSTEM_DREQ_28_29[7:0]	29	I2C2_DREQ_TX	I2C2 transmit request
DMA_SYSTEM_DREQ_29	30	CTRL_CORE_DMA_SYSTEM_DREQ_28_29[23:16]	30	I2C2_DREQ_RX	I2C2 receive request
DMA_SYSTEM_DREQ_30	31	CTRL_CORE_DMA_SYSTEM_DREQ_30_31[7:0]	31	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_31	32	CTRL_CORE_DMA_SYSTEM_DREQ_30_31[23:16]	32	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_32	33	CTRL_CORE_DMA_SYSTEM_DREQ_32_33[7:0]	33	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_33	34	CTRL_CORE_DMA_SYSTEM_DREQ_32_33[23:16]	34	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_SYSTEM_DREQ_34	35	CTRL_CORE_DMA_SYSTEM_DREQ_34_35[7:0]	35	MCSPI1_DREQ_TX0	McSPI1 transmit request channel 0
DMA_SYSTEM_DREQ_35	36	CTRL_CORE_DMA_SYSTEM_DREQ_34_35[23:16]	36	MCSPI1_DREQ_RX0	McSPI1 receive request channel 0
DMA_SYSTEM_DREQ_36	37	CTRL_CORE_DMA_SYSTEM_DREQ_36_37[7:0]	37	MCSPI1_DREQ_TX1	McSPI1 transmit request channel 1
DMA_SYSTEM_DREQ_37	38	CTRL_CORE_DMA_SYSTEM_DREQ_36_37[23:16]	38	MCSPI1_DREQ_RX1	McSPI1 receive request channel 1
DMA_SYSTEM_DREQ_38	39	CTRL_CORE_DMA_SYSTEM_DREQ_38_39[7:0]	39	MCSPI1_DREQ_TX2	McSPI1 transmit request channel 2
DMA_SYSTEM_DREQ_39	40	CTRL_CORE_DMA_SYSTEM_DREQ_38_39[23:16]	40	MCSPI1_DREQ_RX2	McSPI1 receive request channel 2
DMA_SYSTEM_DREQ_40	41	CTRL_CORE_DMA_SYSTEM_DREQ_40_41[7:0]	41	MCSPI1_DREQ_TX3	McSPI1 transmit request channel 3
DMA_SYSTEM_DREQ_41	42	CTRL_CORE_DMA_SYSTEM_DREQ_40_41[23:16]	42	MCSPI1_DREQ_RX3	McSPI1 receive request channel 3
DMA_SYSTEM_DREQ_42	43	CTRL_CORE_DMA_SYSTEM_DREQ_42_43[7:0]	43	MCSPI2_DREQ_TX0	McSPI2 transmit request channel 0

Table 16-5. DMA_SYSTEM Default Request Mapping (continued)

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_SYSTEM_DREQ_43	44	CTRL_CORE_DMA_SYSTEM_DREQ_42_43[23:16]	44	MCSPI2_DREQ_RX0	McSPI2 receive request channel 0
DMA_SYSTEM_DREQ_44	45	CTRL_CORE_DMA_SYSTEM_DREQ_44_45[7:0]	45	MCSPI2_DREQ_TX1	McSPI2 transmit request channel 1
DMA_SYSTEM_DREQ_45	46	CTRL_CORE_DMA_SYSTEM_DREQ_44_45[23:16]	46	MCSPI2_DREQ_RX1	McSPI2 receive request channel 1

16.1.3.2 Mapping of DMA Requests to DMA_CROSSBAR Inputs

Note

For information about the DMA_CROSSBAR module, refer to *DMA_CROSSBAR Module Functional Description* in *Control Module*.

Table 16-6 shows the mapping of device DMA requests to DMA_CROSSBAR inputs.

Table 16-6. Connection of The Device DREQs to The DMA_CROSSBAR Inputs

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_0	Reserved	Reserved
DMA_CROSSBAR_1	Reserved	Reserved
DMA_CROSSBAR_2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion) - coming from SOC IOs - level sentitive only
DMA_CROSSBAR_4	GPMC_DREQ	GPMC request from prefetch engine
DMA_CROSSBAR_5	Reserved	Reserved
DMA_CROSSBAR_6	DISPC_DREQ	The line trigger signal to synchronize a memory to memory logical channel in the DMA4 (system DMA) is generated by the Display Controller IP.
DMA_CROSSBAR_7	CT_TBR_DREQ	DMA request coming from CT_TBR in DEBUGSS (used to be External DMA request 2 - coming from SOC IOs)
DMA_CROSSBAR_8 to DMA_CROSSBAR_14	Reserved	Reserved
DMA_CROSSBAR_15	MCSPI3_DREQ_TX0	McSPI module 3 - transmit request channel 0
DMA_CROSSBAR_16	MCSPI3_DREQ_RX0	McSPI module 3 - receive request channel 0
DMA_CROSSBAR_17 to DMA_CROSSBAR_22	Reserved	Reserved
DMA_CROSSBAR_23	MCSPI3_DREQ_TX1	McSPI module 3 - transmit request channel 1
DMA_CROSSBAR_24	MCSPI3_DREQ_RX1	McSPI module 3 - receive request channel 1
DMA_CROSSBAR_25	I2C3_DREQ_TX	I2C module 3 - transmit request
DMA_CROSSBAR_26	I2C3_DREQ_RX	I2C module 3 - receive request
DMA_CROSSBAR_27	I2C1_DREQ_TX	I2C module 1 - transmit request
DMA_CROSSBAR_28	I2C1_DREQ_RX	I2C module 1 - receive request
DMA_CROSSBAR_29	I2C2_DREQ_TX	I2C module 2 - transmit request
DMA_CROSSBAR_30	I2C2_DREQ_RX	I2C module 2 - receive request
DMA_CROSSBAR_31 to DMA_CROSSBAR_34	Reserved	Reserved
DMA_CROSSBAR_35	MCSPI1_DREQ_TX0	McSPI module 1 - transmit request channel 0
DMA_CROSSBAR_36	MCSPI1_DREQ_RX0	McSPI module 1 - receive request channel 0
DMA_CROSSBAR_37	MCSPI1_DREQ_TX1	McSPI module 1 - transmit request channel 1
DMA_CROSSBAR_38	MCSPI1_DREQ_RX1	McSPI module 1 - receive request channel 1
DMA_CROSSBAR_39	MCSPI1_DREQ_TX2	McSPI module 1 - transmit request channel 2
DMA_CROSSBAR_40	MCSPI1_DREQ_RX2	McSPI module 1 - receive request channel 2
DMA_CROSSBAR_41	MCSPI1_DREQ_TX3	McSPI module 1 - transmit request channel 3
DMA_CROSSBAR_42	MCSPI1_DREQ_RX3	McSPI module 1 - receive request channel 3
DMA_CROSSBAR_43	MCSPI2_DREQ_TX0	McSPI module 2 - transmit request channel 0
DMA_CROSSBAR_44	MCSPI2_DREQ_RX0	McSPI module 2 - receive request channel 0
DMA_CROSSBAR_45	MCSPI2_DREQ_TX1	McSPI module 2 - transmit request channel 1

Table 16-6. Connection of The Device DREQs to The DMA_CROSSBAR Inputs (continued)

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_46	MCSPI2_DREQ_RX1	McSPI module 2 - receive request channel 1
DMA_CROSSBAR_47	MMC2_DREQ_TX	MMC/SD2 transmit request
DMA_CROSSBAR_48	MMC2_DREQ_RX	MMC/SD2 receive request
DMA_CROSSBAR_49	UART1_DREQ_TX	UART module 1 - transmit request
DMA_CROSSBAR_50	UART1_DREQ_RX	UART module 1 - receive request
DMA_CROSSBAR_51	UART2_DREQ_TX	UART module 2 - transmit request
DMA_CROSSBAR_52	UART2_DREQ_RX	UART module 2 - receive request
DMA_CROSSBAR_53	UART3_DREQ_TX	UART module 3 - transmit request (Also infrared - IRDA)
DMA_CROSSBAR_54	UART3_DREQ_RX	UART module 3 - receive request (Also infrared - IRDA)
DMA_CROSSBAR_55	UART4_DREQ_TX	UART module 4 – transmit request
DMA_CROSSBAR_56	UART4_DREQ_RX	UART module 4 – receive request
DMA_CROSSBAR_57	MMC4_DREQ_TX	MMC/SD4 transmit request
DMA_CROSSBAR_58	MMC4_DREQ_RX	MMC/SD4 receive request
DMA_CROSSBAR_59	Reserved	Reserved
DMA_CROSSBAR_60	Reserved	Reserved
DMA_CROSSBAR_61	MMC1_DREQ_TX	MMC/SD1 transmit request
DMA_CROSSBAR_62	MMC1_DREQ_RX	MMC/SD1 receive request
DMA_CROSSBAR_63	UART5_DREQ_TX	UART module 5 – transmit request (used to be External DMA request 3 - coming from SOC IOs)
DMA_CROSSBAR_64	UART5_DREQ_RX	UART module 5 – receive request (used to be USIM receive request)
DMA_CROSSBAR_65 to DMA_CROSSBAR_69	Reserved	Reserved
DMA_CROSSBAR_70	MCSPI4_DREQ_TX0	McSPI module 4 - transmit request channel 0
DMA_CROSSBAR_71	MCSPI4_DREQ_RX0	McSPI module 4 - receive request channel 0
DMA_CROSSBAR_72 to DMA_CROSSBAR_75	Reserved	Reserved
DMA_CROSSBAR_76	DSS_DREQ	Display subsystem HDMI Audio DMA request
DMA_CROSSBAR_77	MMC3_DREQ_TX	MMC/SD3 transmit request
DMA_CROSSBAR_78	MMC3_DREQ_RX	MMC/SD3 receive request
DMA_CROSSBAR_79	UART6_DREQ_TX	UART module 6 – transmit request (used to be USIM transmit request)
DMA_CROSSBAR_80	UART6_DREQ_RX	UART module 6 – receive request (used to be USIM receive request)
DMA_CROSSBAR_81 to DMA_CROSSBAR_123	Reserved	Reserved
DMA_CROSSBAR_124	I2C4_DREQ_TX	I2C module 4 - transmit request
DMA_CROSSBAR_125	I2C4_DREQ_RX	I2C module 4 - receive request
DMA_CROSSBAR_126	Reserved	Reserved
DMA_CROSSBAR_127	Reserved	Reserved
DMA_CROSSBAR_128	McASP1_DREQ_RX	McASP receive event
DMA_CROSSBAR_129	McASP1_DREQ_TX	McASP transmit event

DMA_CROSSBAR_203	PWMSS3_DREQ_eCAP2_EVT	eCAP2 event/interrupt
DMA_CROSSBAR_204	I2C6_DREQ_TX(1)	I2C6 DMA Transmit request
DMA_CROSSBAR_205	I2C6_DREQ_RX (1)	I2C6 DMA Receive request
DMA_CROSSBAR_206 to DMA_CROSSBAR_255	Reserved	Reserved

(1) VCP1, VCP2 and I2C6 are not supported on the AM571x / AM570x family of devices.

16.1.4 DMA_SYSTEM Functional Description

The DMA_SYSTEM module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-5 shows the DMA_SYSTEM controller top-level block diagram.

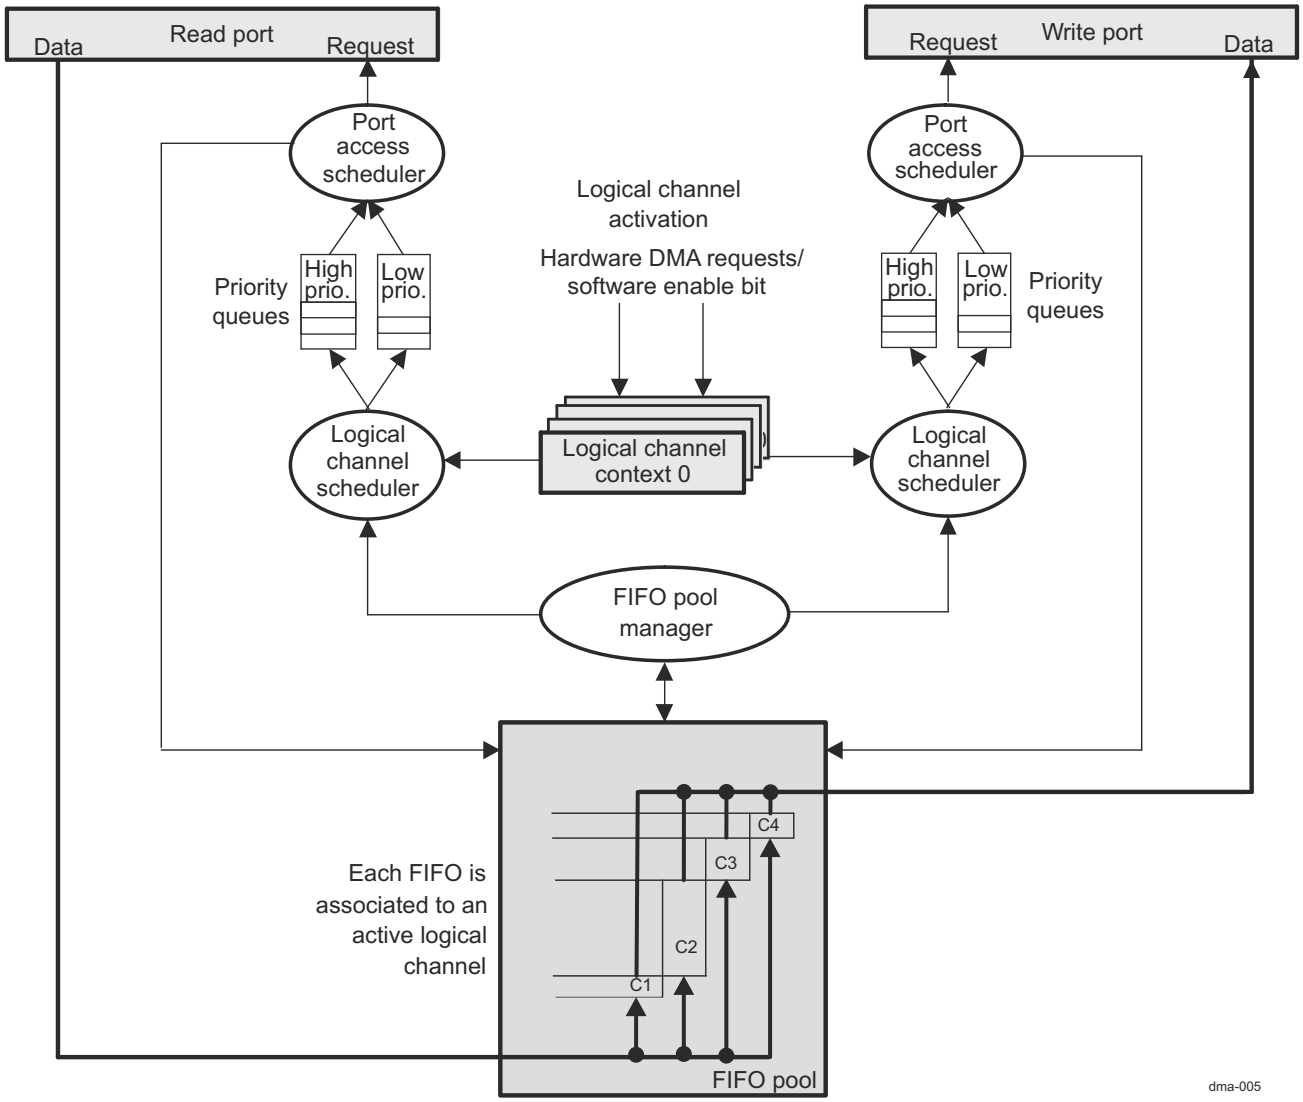

Figure 16-5. DMA_SYSTEM Controller Top-Level Block Diagram

16.1.4.1 DMA_SYSTEM Controller Power Management

Table 16-7 describes power-management features available for the DMA_SYSTEM controller.

Note

- For information about source clock gating and sleep/wake-up transitions, see secton *Clock Management*, in *Power, Reset, and Clock Management*.
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see *Module Level Clock Management*, in *Power, Reset, and Clock Management*.

Table 16-7. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	DMA4_OCP_SYSCONFIG[0] AUTOIDLE bit	This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity.
Slave idle modes	DMA4_OCP_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	DMA4_OCP_SYSCONFIG[9:8] CLOCKACTIVITY bit field	For configuration details, see Table 16-8.
Master standby modes	DMA4_OCP_SYSCONFIG[13:12] MIDLEMODE bit field	Force-standby, no-standby, and smart-standby modes are available.
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

Table 16-8. Clock Activity Settings

SDMA_CLOCKACTIVITY Values	Clock State When Module is in IDLE State	
	SDMA_ICLK	SDMA_FCLK
00	Off	Off
10	Off	On
01	On	Off
11	On	On

CAUTION

Because the PRCM module cannot read CLOCKACTIVITY settings through hardware, software must ensure consistent programming between the SDMA_CLOCKACTIVITY and DMA_SYSTEM clock PRCM control bits. For a description of the ClockActivity feature, see *Module Level Clock Management*, in *Power, Reset, and Clock Management*.

16.1.4.2 DMA_SYSTEM Controller Interrupt Requests

DMA4 has four interrupt lines (Lj, where j = 0, 1, 2, 3). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The DMA4_IRQSTATUS_Lj CH_31_0_Lj field shows the status of the different sources of interrupt. If the DMA4_IRQENABLE_Lj bit is 1, channel *i* is the source of interrupt in line *j*. In contrast to the DMA4_CSRi registers, the DMA4_IRQSTATUS_Lj registers are updated regardless of the corresponding bits in the DMA4_IRQENABLE_Lj registers.
- The DMA4_IRQENABLE_Lj CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the DMA4_IRQENABLE_Lj bit is set to 0, channel interrupt *i* of the line *j* is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the DMA4_CICRi register. Each status bit is updated in the DMA4_CSRi register only when the corresponding enable bit is enabled in the DMA4_CICRi register.

To determine an interrupt source when an interrupt rises on an interrupt line L*j*:

- Identify the channel (LCH*i*) generating the interrupt.

  Read DMA4_IRQSTATUS_Lj.LCH*i* (LCH0 to LCH31). If LCH*i* = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.

  Read the LCH*i* DMA4_CSRi. For example, if the drop event (the DMA4_CSRi[1] DROP bit) is 1, a request collision will occur.

The interrupt event status bit in the DMA4_CSRi register is immediately reset after it is written to 1.

The interrupt status bit in the DMA4_IRQSTATUS_Lj register is cleared after it is written to 1.

16.1.4.2.1 Interrupt Generation

The DMA_SYSTEM module has four interrupt request output lines, DMA_SYSTEM_IRQ_0 to DMA_SYSTEM_IRQ_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in Table 16-9 occurs.

Table 16-9. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error is returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CENi[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFNi[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDPi[1:0] DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Drain end	Drain is completed (DMA4_CCRi[10] WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the DMA4_IRQENABLE_Lj register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel DMA4_CICRi register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the DMA4_IRQSTATUS_Lj register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel DMA4_CSRi register.

16.1.4.3 Logical Channel Transfer Overview

As Figure 16-5 shows, the DMA_SYSTEM module has one read port and one write port operating independently of one another. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

  A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.
- Logical channel activation

  A logical channel becomes active as follows:
  - For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
  - For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel
- Logical channel transfer composition

  A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, the transfer size, start address alignment, addressing mode, and configured maximum burst size, each transaction can be a single access or a burst of accesses.
- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE_PRIORITY and READ_ PRIORITY) in the logical channel DMA4_CCRi register determine whether a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the DMA4_GCR[23:16] ARBITRATION_RATE bit field.

Note

The DMA4_GCR[23:16] ARBITRATION_RATE bit field does not depend on the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field. The ARBITRATION_RATE bit field depends on the DMA4_CCRi[26] WRITE_PRIORITY bit and the DMA4_CCRi[6] READ_PRIORITY bit.

- Read/write port access scheduling policy

  When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

  When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The DMA_SYSTEM module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting
- At least one free thread ID is available

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

Note

If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 × M, 4 × M, 8 × M or 16 × M, where M can be 8, 16, or 32 bits).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see Section 16.1.4.2.1, *Interrupt Generation*).

16.1.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the DMA4_GCR[7:0] MAX_CHANNEL_FIFO_DEPTH bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) 1.

16.1.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

transfer block size = FN × EN × ES

The FN, EN, and ES are common for the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI must be such that, when added to the logical channel address pointer, it results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

Note

The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see Section 16.1.4.2.1, *Interrupt Generation*).

The DMA4_CFNi register configures the FN in a block.

The DMA4_CENi register configures the EN.

The DMA4_CSDPi register configures the ES.

The DMA4_CSSAi and DMA4_CDSAi registers configure the source and destination start addresses.

The DMA4_CCRi register configures the source and destination addressing modes.

The DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

Note

Constant addressing mode with DMA4 to/from DDR memory is not supported on the device. To fill the DDR memory with a single value, the constant fill feature of the DMA4 must be used, instead of a constant-addressing mode transfer.

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter ≠ 0):

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter ≠ 0):

$$A(n + 1) = A(n) + ES + (FI\ 1)$$

Calculate the element and frame index as follows:

Equation 5. EIement index

$$EI = [(Stride\ EI\ 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride\ FI\ 1) * ES] + 1$$

where:

A(n): Byte address of the element *n* within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element *n* to the start of next element, *n+1*.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, DMA4_CENi.

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, DMA4_CFNi.

Figure 16-6 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is

used in the 90-degree clockwise image rotation example shown in Figure 16-10.) The double-index addressing example shown in Figure 16-6 uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

Figure 16-6 through Figure 16-9 show examples of addressing mode configurations. Table 16-10 lists parameter values for the examples.

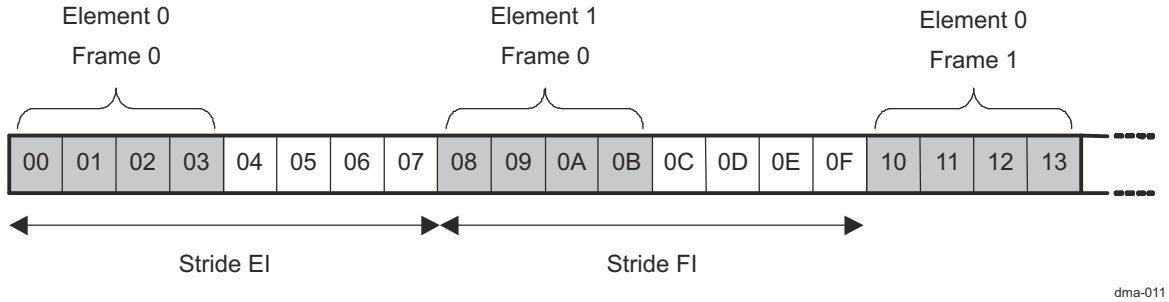

Figure 16-6. Example Showing Double-Index Addressing, Elements, Frames, and Strides

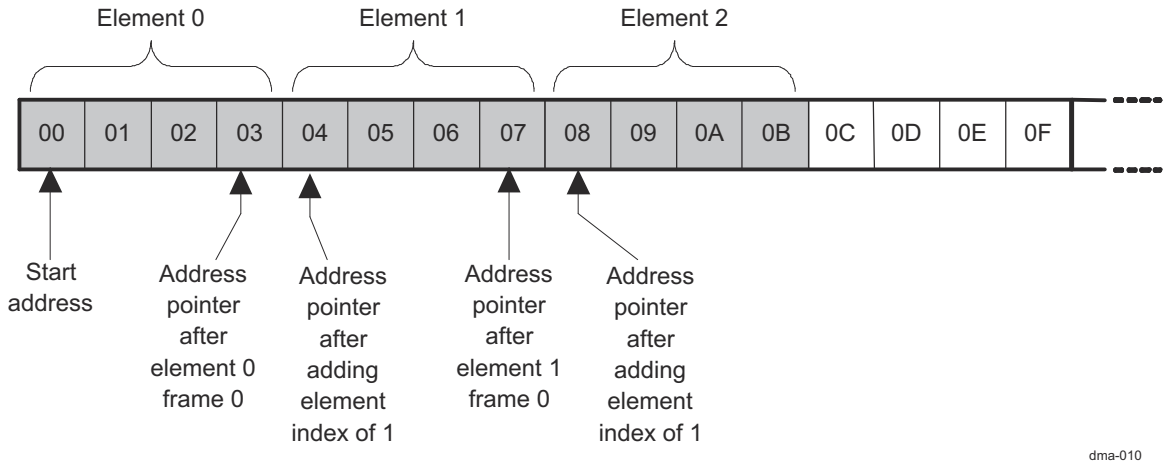

Figure 16-7. Addressing Mode Example (a)

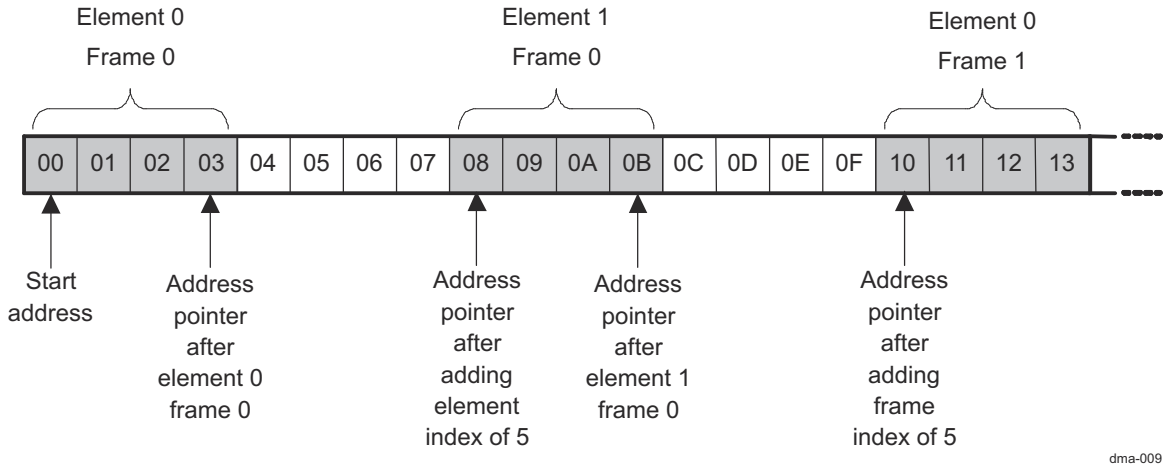

Figure 16-8. Addressing Mode Example (b)

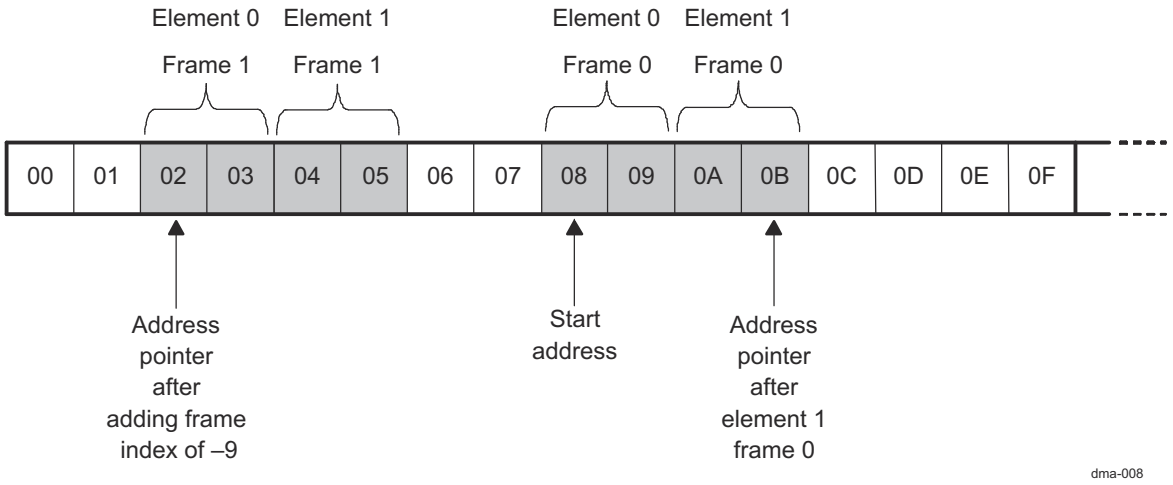

Figure 16-9. Addressing Mode Example (c)

Table 16-10. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of (360 – xx) degrees on source, and swapping the width (x) and height (y) of the image in them. The opposite is also true. Table 16-11 lists the equations for 90-, 180-, and 270-degree rotations.

Table 16-11. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	ES*(y–1)	ES*(x*y–1)	ES*y*(x–1)
	EI	ES*(y–1) + 1	1–2*ES	1–ES*(y + 1)
	FI	1 ES*[(x–1)*y + 2]	1–2*ES	1+ES*(x–1)*y
Double indexing on source (read)	Base address	ES*x*(y–1)	ES*(x*y–1)	ES*(x–1)
	EI	1–ES*(x + 1)	1–2*ES	ES*(x–1) + 1
	FI	1+ES*(y–1)*x	1–2*ES	1 ES*[(y–1)*x + 2]

Table 16-12 and Figure 16-10 show the configuration required to perform a 90-degree clockwise rotation of a 240 × 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line-by-line starting at the left end of the top line.

Note

The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

Section 16.1.5.7, *90-Degree Clockwise Image Rotation*, describes how to program an example of a 90-degree clockwise image rotation.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 16-12. Example Parameter Values for a 90-Degree Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	–[(SW-1)*SH + 1] = 38,241 elements
Start address	0x100000	0x200000 + (SH 1) x ES = 0x20027C
EN	SW	SW
EI	[(Stride EI 1) * ES] + 1 = 1	[(Stride EI 1) * ES] + 1 = 637
FN	SH	SH
FI	[(Stride FI 1) * ES] + 1= 1	[(Stride FI 1) * ES] + 1 = 152,967

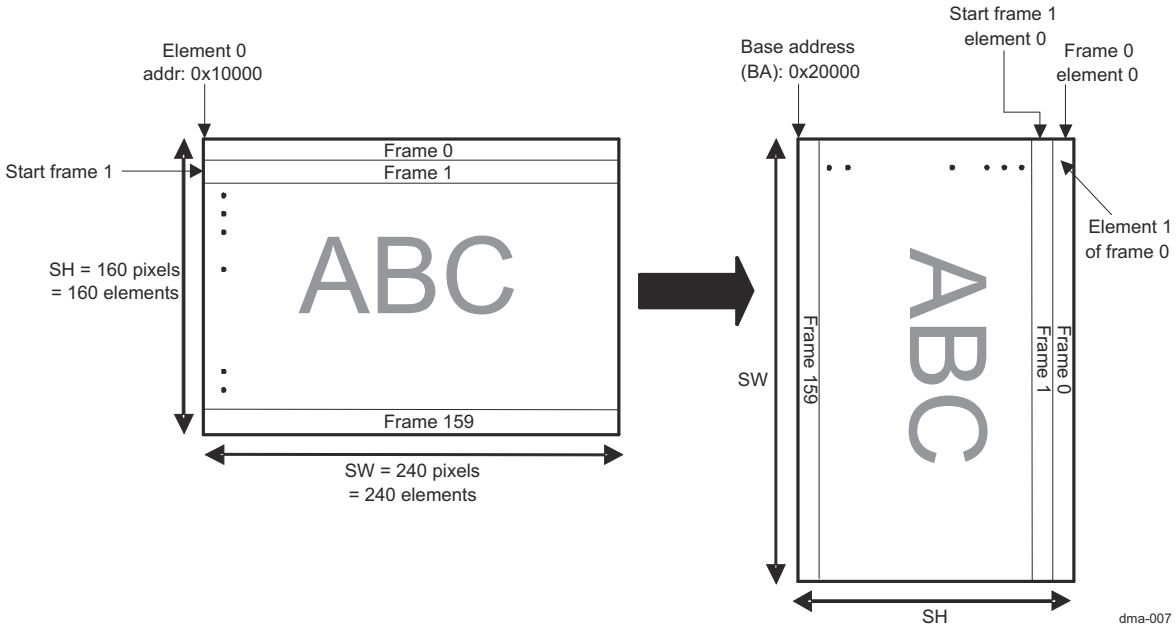

Figure 16-10. Example of a 90-Degree Clockwise Image Rotation

16.1.4.6 Packed Accesses

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).
- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

16.1.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the DMA4_CSDPi register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

Note

If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

16.1.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the DMA4_CSDPi register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the DMA_SYSTEM module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel DMA4_CSDPi register.

Note

Because the device is little-endian by construction, the DMA_SYSTEM endianism registers must never be set to big-endian.

If DMA_SYSTEM is used to execute endian conversion by setting the source and destination to different endianism values, it is important to consider that the L3_MAIN interconnect also executes endian conversion if the DMA_SYSTEM and the source or destination have a different data bus width.

16.1.4.9 Transfer Synchronization

A logical channel can be programmed for software-triggered or hardware synchronized transfers.

16.1.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA DMA4_CCRi[4:0] and DMA4_CCRi[20:19] bit fields to 0. The transfer starts as soon as the DMA DMA4_CCRi[7] bit is set (when it enters the scheduling process).

16.1.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel DMA4_CCRi register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see Table 16-9).

Specify the DMA request number in the DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields. After the DMA4_CCRi[7] ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

Note

The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, the DMA4_CCRi[4:0] SYNCHRO_CONTROL bit field must be set to 0x2 (DMA request number + 1).

Note

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel DMA4_CCRi register and the DMA4_CCRi[5] FS and DMA4_CCRi[18] BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit through either the channel DMA4_CDFIi register (source synchronized) or the DMA4_CSFIi register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

Block_size = Number_of_Frame_in_Block * Number_of_Element_in_Frame * Element_Size

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see Section 16.1.4.13, *Reprogramming an Active Channel*).

For a source synchronized transfer, buffering can be enabled or disabled by setting the DMA4_CCRi[25] BUFFERING_DISABLE bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

Note

Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel DMA4_CCRi[23] PREFETCH bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see Section 16.1.4.4, *FIFO Queue Memory Pool*).

Buffering disable is not allowed for a destination-synchronized transfer.

Note

Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the DMA4_CSDPi[17:16] WRITE_MODE bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The DMA4_CCRi[25] BUFFERING_DISABLE bit must be filled with an allowed value, as specified in Table 16-13.

Table 16-13. Buffering Disable

	BUFFERING_DISABLE	
	(0: Buffering enable, 1: Buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

- Synchronized transfer monitoring using CDAC (DMA4_CDACi):

Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see Section 16.1.5.4, *Synchronized Transfer Monitoring Using CDAC*).

Note

For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

16.1.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

Note

Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see Section 16.1.5.5, *Concurrent Software and Hardware Synchronization*):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register DMA4_GCR[13:12] .

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the DMA4_GCR [13:12] value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 => No ThreadID is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x1 => Read ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 => Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 => No ThreadID is reserved for high-priority channels
- DMA4_GCR[13:12] = 0x1 => Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 => Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 => Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the DMA4_GCR[13:12] value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit (DMA4_CCRi[26]) is added for write priority, and the previous priority bit becomes read priority bit (DMA4_CCRi[6]).

Note

The device has one priority bit per logical channel, not one priority bit per port.

16.1.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the DMA4_GCR register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the DMA4_GCR[15:14] HI_LO_FIFO_BUDGET field. The maximum channel FIFO depth is limited by the HI_LO_FIFO_BUDGET field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user must perform the following equation:

- For a high-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of High Channel =< High Budget FIFO
- For a low-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of Low Channel =< Low Budget FIFO

Note

Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

16.1.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel DMA4_CLNK_CTRLi register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it may be all, none, or simply the first one). The DMA request line number must be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the

DMA4_CLNK_CTRLi[15] ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

Note

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information about the programming model, see Section 16.1.5, *DMA_SYSTEM Basic Programming Model*.

16.1.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the DMA4_CCRi[7] ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the DMA4_CCRi register (DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

16.1.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

maximum_transfer_size =peripheral_FIFO_depth x number_of_frame_in_block

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

Example:

Consider a camera interface with a FIFO_depth of 128 words and a FIFO_element_number_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is $128x2^{16}$ words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (maximum_transfer_size = 2^{24} x 2^{16} words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: The Peripheral_element_number_threshold (the number of elements in a packet) shares the DMA4_CSFIi and DMA4_CDFIi configuration registers. If the peripheral is the source target, the addressing mode is constant, and the DMA4_CSFIi[15:0] bit field is used to specify the packet data size in the DMA4_CSFIi register. The user must set the DMA.SDMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the DMA4_CDFIi[15:0], is used to specify the packet data size (PKT_ELNT_NBR), and the bit field [31:16] is unused. To specify the packet data size in the DMA4_CDFIi register, the user must set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0.

  Note

  The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet_Data_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary and stops at the block boundary for the last packet DMA Request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting.

  The packet synchronization mode is active when DMA4_CCRi[5] FS = DMA4_CCRi[18] BS = 1. Then:
  - If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 0, the DMA4_CDFIi[15:0] bit field gives the number of elements in the packet and the DMA4_CDFIi[31:16] bit field is unused for the packet size.
  - If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 1, the DMA4_CSFIi[15:0] bit field gives the number of elements in the packet and the DMA4_CSFIi[31:16] bit field is unused for the packet size.

Note

The maximum transfer size, regardless of the packet size, is always:

Block_size = Number_of_Frame_in_Block x Number_of_Element_in_Frame x Element_Size.

If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

16.1.4.15 Graphics Acceleration Support

The DMA_SYSTEM supports two graphic acceleration features: transparent copy and constant fill.

Only one of these features can be enabled at a time through the DMA4_CCRi register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the DMA4_COLORi register so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-11 shows the 2-D graphic transparent color block diagram.

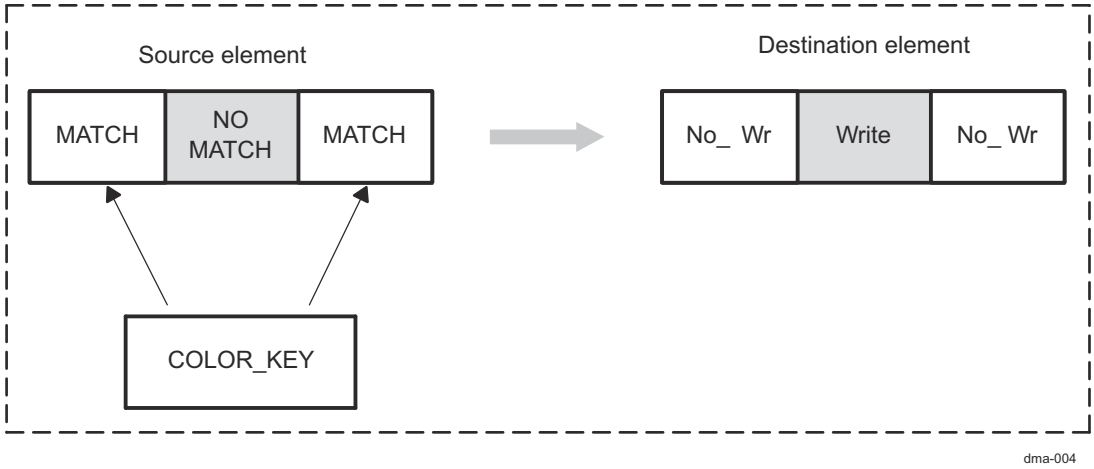

Figure 16-11. 2-D Graphic Transparent Color Block Diagram

The constant fill feature provides the ability to specify a particular color through the DMA4_COLORi register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8, 16, and 24 bpp, depending on what is specified as the DMA transfer ES through the DMA4_CSDPi register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSBs) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

16.1.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the DMA4_CCRi[22] SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor

mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

16.1.4.17 Posted and Nonposted Writes

A logical channel can be configured in its DMA4_CSDPi[17:16] bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (may improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write completes before transfer can complete.

16.1.4.18 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware-source-synchronized with buffering enabled (DMA4_CCRi[25] BUFFERING_DISABLE = 0). If this is the case, the FIFO is drained to prevent the loss of data. For more information about this feature, see Section 16.1.4.19, *FIFO Draining Mechanism*.

16.1.4.19 FIFO Draining Mechanism

When a source-synchronized channel is disabled during a transfer, the current hardware request (element/packet/frame/block) service completes and the channel DMA4_CCRi[9] RD_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the DMA4_CCRi[10] WR_ACTIVE bit is set to 0 (channel is no longer active on the write port) and if the DMA4_CICRi[12] DRAIN_END_IE is set to 1, the DMA4_CSRi[12] DRAIN_END status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for the DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE bits to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and DMA4_CCRi[25] BUFFERING_DISABLE = 0
  and
- If the channel is not a solid fill channel
  and
- If the channel is not a transparent and copy channel
  and
- If the channel is a hardware, synchronized channel

Note

For a self-linked or chain-linked channel, the user must disable the DMA4_CLNK_CTRLi[15] ENABLE_LINK bit before disabling the channel.

In all other cases, the channel undergoes an abort.

16.1.4.20 Linked List

16.1.4.20.1 Overview

The DMA_SYSTEM supports the logical transfer-descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter-gather transfers with minimum MPU support by removing successive channel configuration processing and associated

interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

16.1.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register (DMA4_CNDPi) and a channel-descriptor parameter register (DMA4_CDPi). The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

16.1.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable, depending on the descriptor type and the Nxt_Dv and Nxt_Sv bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- Src_Element_index and Dst_Element_index are concatenated in the same 32-bit location.
- DMA4_CICRi (interrupt event mask)
- CFN (frame number)
- Bit fields:
  - P: Corresponds to the PAUSE_LINK_LIST bit:
    - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
    - The user must not set the PAUSE_LINK_LIST bit through the configuration port. Otherwise, behavior is undefined.
    - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (descriptor load or data load).
  - B: Corresponds to the end-of-block enable bit (BLOCK_IE) of the DMA4_CICRi register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where DMA4_CICRi is fully specified.
  - Nxt_Dv, Nxt_Sv: Mapped in the DMA4_CDPi register. They indicate one of the following possibilities:
    - Next descriptor contains an updated destination or source address.
    - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
    - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.

– Next_Descriptor_Type: Specifies the next descriptor type that corresponds to the NEXT_DESCRIPTOR_TYPE bit field in the DMA4_CDPi register

16.1.4.20.3.1 Type 1

A type 1 descriptor includes the overall channel configuration register value to be loaded (global registers are not part of the type 1 descriptor). This descriptor is used primarily when major changes are required:

- Channel read or write access profiles must be modified; for example, bursting and packing (included in the DMA4_CSDPi register)
- Attach a new DMA request to the same channel or change the priority or access privilege (included in the DMA4_CCRi register)
- Enable solid or transparent color fill (included in the DMA4_CCRi and DMA4_COLORi registers)
- Enable a channel link (included in the DMA4_CLNK_CTRLi register)

Table 16-14 shows a type 1 descriptor.

16.1.4.20.3.2 Type 2

A type 2 descriptor includes the overall logical channel transfer address register and transfer format register to be loaded. This descriptor enables 2D addressing linked-list transfer (for example, a multimedia application where 2D objects are moved in a link). Table 16-15 shows a type 2 descriptor with source and destination address updates. Table 16-16 shows a type 2 descriptor with one source or destination address update.

16.1.4.20.3.3 Type 3

A type 3 descriptor is limited to a few logical channel transfer address registers and transfer format registers to be loaded. This descriptor enables simple 1D addressing link transfer (for example, scatter-gather or ping-pong memory movement using a linked list). Table 16-17 shows a type 3 descriptor with source and destination address updates. Table 16-18 shows a type 3 descriptor with one source or address destination update.

16.1.4.20.4 Linked-List Control and Monitoring

16.1.4.20.4.1 Transfer Mode Setting

Four descriptor types are available in DMA4_CDPi[9:8] TRANSFER_MODE to distinguish the different transfer modes:

- DMA4_CDPi[9:8] TRANSFER_MODE = 00: The current channel is using normal mode.
- DMA4_CDPi[9:8] TRANSFER_MODE = 01: The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is normal mode (DMA4_CDPi[9:8] TRANSFER_MODE = 0).

16.1.4.20.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the DMA4_CCRi[7] ENABLE bit to 1). The DMA4_CDPi[10] FAST bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

16.1.4.20.4.3 Monitoring a Linked-List Progression

In addition to the DMA4_CCENi (remaining elements) and DMA4_CCFNi (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, DMA4_CCDNi (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the DMA4_CCDNi register to 0 during the initial configuration. When the DMA4_CCDNi register is updated, the DMA4_CCFNi and the DMA4_CCENi registers are updated. The user must also initialize the DMA4_CCFNi and DMA4_CCENi registers to 0xFFFF and to 0xFFFFFF, respectively, to track the effective transfer start of synchronized transfer.

16.1.4.20.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled during the initial configuration in CICR. The DMA4_CICRi register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the DMA4_CICRi and DMA4_CSRi registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update BLOCK_IE (full DMA4_CICRi update), a dedicated BLOCK_IE bit field is also available in a type 3 descriptor.

16.1.4.20.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the DMA4_CDPi[7] PAUSE_LINK_LIST bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel DMA4_CDPi[7] PAUSE_LINK_LIST bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the DMA4_CDPi[7] PAUSE_LINK_LIST bit through the configuration port; otherwise, transfer behavior is undefined.

A PAUSE_LINK_LIST bit (P) is set to 1 in the descriptor.
  - The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
  - The linked list can be resumed by resetting the DMA4_CDPi[7] PAUSE_LINK_LIST bit (through the configuration port).

16.1.4.20.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped for a drain or an abort. These cases are exclusive.

16.1.4.20.4.6.1 Drain

- Drain conditions:

  A channel is a drain candidate if it is a hardware-source-synchronized transfer with DMA4_CCRi[25] BUFFERING_DISABLE = 0 and should not be doing any of the graphics operation (transparent copy or solid-color fill).
- Drain trigger:

  A drain candidate channel is drained if it is disabled (DMA4_CCRi[7] ENABLE = 0) or if it receives a transaction error on the read port.
- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
  - During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
  - During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a DRAIN_END interrupt can be asserted.

16.1.4.20.4.6.2 Abort

- Abort condition:

  A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with DMA4_CCRi[25] BUFFERING_DISABLE = 1.
- Abort trigger:

  A channel is an abort candidate if it is disabled (DMA4_CCRi[7] ENABLE = 0), if it receives a transaction error on the read or write port, or if there is a MISALIGNMENT_ERROR.
- Abort behavior with a type 1, 2, or 3 descriptor:

  If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.

  In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

16.1.4.20.4.7 Status Bit Behavior

This section describes the behavior of the DMA4_CSRi[6] SYNC, DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE status bits:

- For a hardware-synchronized channel in linked-list mode, the DMA4_CSRi[6] SYNC bit becomes active (DMA4_CSRi[6] SYNC = 1) when the first data load transaction is scheduled and remains active until the last data load transaction in the block (not super block) is descheduled (DMA4_CSRi[6] SYNC = 0). The SYNC bit is not active during the descriptor load phase.
- The DMA4_CCRi[9] RD_ACTIVE bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
  - When (during the descriptor load phase) the last descriptor write request is descheduled
  - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
  - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch

- The DMA4_CCRi[10] WR_ACTIVE bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
  - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
  - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with DMA4_CCRi[25] BUFFERING_DISABLE = 0) or hardware-destination-synchronized transfer.

16.1.4.20.4.8 Linked-List Channel Linking

Channel linking for inter- and intra-super blocks is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]->CHx[DataN + 1]

CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]-CHx[DataN+1] -> CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] ->.-> CHx[DESp]->CHx[Data(p + 1)] -> CHz[Data1]-> CHz[DES1] -> .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

Note

In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

Note

If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx is disabled after the corresponding data load and enables the channel CHz.

16.1.5 DMA_SYSTEM Basic Programming Model

16.1.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the DMA4_GCR register, and any required interrupts must be enabled through the DMA4_IRQENABLE_Lj registers and the logical channel DMA4_CICRi registers.

Software clears the DMA4_CSRi register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

16.1.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     - Transfer ES (8, 16, or 32 bits) in the DMA DMA4_CSDPi[1:0] bit field.
     - Read and write port access types (single/burst), DMA DMA4_CSDPi[8:7] and DMA4_CSDPi[15:14] bit fields
     - Source and destination endianism, DMA DMA4_CSDPi[21] and DMA4_CSDPi[19] bits
     - Write mode (posted or nonposted) and DMA DMA4_CSDPi[17:16] bit field
     - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA DMA4_CSDPi[6] and DMA4_CSDPi[13] bits
   - DMA4_CENi: EN
   - DMA4_CFNi: FN per transfer block
   - DMA4_CSSAi and DMA4_CDSAi: Source and destination start address (aligned with transfer ES)
   - DMA4_CCRi:
     - Read and write port addressing modes, DMA DMA4_CCRi[13:12] and DMA4_CCRi[15:14] bit field
     - Priority bit for both read and write ports, DMA DMA4_CCRi[6] and DMA4_CCRi[26] bits
     - DMA request number (set to 0 for a software-triggered transfer) and DMA register bit fields DMA4_CCRi[4:0] = 0 and DMA4_CCRi[20:19] = 0
   - DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi: Source and destination element and frame indexes (depending on addressing mode)
2. Start the transfer through the enable bit in the channel DMA4_CCRi register and DMA DMA4_CCRi[7] bit

The following example performs a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000):

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t
      *)malloc(sizeof(DMA4_t));
/* Init. parameters
      */
DMA4->DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; //
      DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; //
      DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; //
      DMA4_CSDPi[21]
DMA4->DestinationEndianism = 0; //
      DMA4_CSDPi[19]
DMA4->WriteMode = 0; //
      DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0; //
      DMA4_CSDPi[6]
DMA4->DestinationPacked = 0; //
      DMA4_CSDPi[13]
```

```
DMA4->NumberOfElementPerFrame = 240; //
      DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; //
      DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; //
      DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; //
      DMA4_CDSAi
DMA4->SourceElementIndex = 1; //
      DMA4_CSEIi
DMA4->SourceFrameIndex = 1; //
      DMA4_CSFIi
DMA4->DestinationElementIndex = 1; //
      DMA4_CDEIi
DMA4->DestinationFrameIndex = 1; //
      DMA4_CDFIi
DMA4->ReadPortAccessMode = 1; //
      DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1; //
      DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; //
      DMA4_CCRi[6]
DMA4->WritePriority = 0; //
      DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; //
      DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; //
      DMA4_CCRi[20:19]
/* 1) Configure the transfer
      parameters in the logical DMA registers
      */
/*---------------------------------------------------------------------*/
/*

DMA4_CDFI_CH10 =
      DMA4->DestinationFrameIndex;
/* 2) Start the DMA transfer by
      Setting the enable bit CCR[7]=1 */

/*----------------------------------------------------------------*/

//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */
```

16.1.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the DMA4_CDACi register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization DMA4_CCRi[5] FS bit and the block synchronization DMA4_CCRi[18] BS bit must be programmed. For all the following synchronized transfers (element, packet, and frame or block-synchronized transfers), the user must first set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1 when the source triggers on the DMA request and set it the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0 when the destination triggers on the DMA request.

Note

The user must take care when setting the DMA4_CCRi[23] PREFETCH bit it is in conjunction with DMA4_CCRi[24] SEL_SRC_DST_SYNC bit.

- To configure an LCh to transfer one element per DMA request:
  1. Set the number of DMA request associated with the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  4. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  5. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.

6. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
7. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
8. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
9. Set both FS and BS to 0 in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
10. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

- To configure an LCh to transfer one frame per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  5. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  6. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  7. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  8. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  9. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  10. Set FS to 1 and BS to 0, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  11. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one block per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
  5. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  6. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  7. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  8. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  9. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  10. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  11. Set FS to 0 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  12. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one packet per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set DMA4_CCRi [24] SEL_SRC_DST_SYNC to 1 and set the packet element number in the DMA4_CSFIi register and set the addressing mode of source to constant addressing in DMA4_CCRi[13:12] SRC_AMODE bit field; else, if the packet requestor is in the destination, set the DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 and set the packet element number in the DMA4_CDFIi register and set the addressing mode of destination to constant addressing in DMA4_CCRi[15:14] DST_AMODE bit field.
  4. Set the number of elements per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  5. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
  6. Set the element number in the packet in the DMA4_CSFIi[15:0] PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the DMA4_CDFIi[15:0] PKT_ELNT_NBR if constant addressing mode is used in the destination side.

7. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
8. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
9. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
10. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
11. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
12. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
13. Set FS to 1 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
14. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

Note

It is possible to stop a transfer by disabling the channel by resetting the DMA4_CCRi[7] ENABLE bit.

16.1.5.4 Synchronized Transfer Monitoring Using CDAC

The DMA4_CDACi register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the DMA4_CDACi register.
2. Enable the channel.
3. If a time-out occurs, read DMA4_CDACi register.
4. If DMA4_CDACi != 0 (it is the value configured in DMA4_CDACi):

   This indicates that the corresponding transfer has started. The user can then rely on DMA4_CCENi and DMA4_CCFNi element and frame counters.

   Otherwise, if DMA4_CDACi = 0 (it is the value configured in the DMA4_CDACi):

   This indicates that the corresponding transfer did not start.

16.1.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.
- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:

   Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field to 0x1.
2. Specify channel priority:

   Channel 4 is a write high priority channel: set DMA4_CCRi[26] WRITE_PRIORITY = 1.

   Channel 5 is a read high priority channel: set DMA4_CCRi[6] READ_PRIORITY = 1.

16.1.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers described in Section 16.1.5.5, *Concurrent Software and Hardware Synchronization*.
2. For each channel in the chain, configure the DMA4_CLNK_CTRLi register as follows:
   - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit field.
   - Include the logical channel to the chain and enable link by setting the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit.
   - For a non-looping chain, the last logical channel in the chain must have the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit set to 0 to indicate the end of the chain.
3. Enable the transfer through the enable bit in the first logical channel DMA4_CCRi[7] ENABLE bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLINK_CTRL_CH10 =
      0x0000800A;
```

16.1.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in Section 16.1.4.5, *Addressing Modes*, can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     - Transfer ES = 32-bit (32 bpp), DMA4_CSDPi[1:0] DATA_TYPE bit field
     - Read and write port access types = maximum burst size supported by memory device, DMA4_CSDPi[8:7] SRC_BURST_EN and DMA4_CSDPi[15:14] DST_BURST_EN bit fields
     - Source and destination endianism, DMA4_CSDPi[21] SRC_ENDIAN and DMA4_CSDPi[19] DST_ENDIAN bits
     - Write mode = posted with last element nonposted, DMA4_CSDPi[17:16] WRITE_MODE bit field
     - Source and destination packed = Yes (although destination writes do not benefit because EI1), DMA4_CSDPi[6] SRC_PACKED and DMA4_CSDPi[13] DST_PACKED bits
   - DMA4_CENi: EN = 240
   - DMA4_CFNi: FN per transfer block = 160
   - DMA4_CSSAi: Source start address = 0x100000
   - DMA4_CDSAi: destination start address = 0x20013E
   - DMA4_CCRi:
     - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, DMA4_CCRi[13:12] SRC_AMODE and DMA4_CCRi[15:14] DST_AMODE bit fields
     - Low or high priority, DMA4_CCRi[6] READ_PRIORITY bit
     - DMA request number = 0 (for software-triggered transfer), DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields
   - DMA4_CSEIi: Source EI = 1
   - DMA4_CSFIi: Source frame index = 1

- DMA4_CDEIi: destination EI = 637
- DMA4_CDFIi: destination frame index = 152967

2. Start the transfer through the enable bit in the channel DMA4_CCRi register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in Section 16.1.5.2, *Software-Triggered (Nonsynchronized) Transfer*:

```
/* Init. parameters */
DMA4->DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]

DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]

DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]

DMA4->DestinationEndianism = 0; // DMA4_CSDPi[19]

DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked
      = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; //
      DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi

DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi

DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi

DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi

DMA4->SourceElementIndex = 1; // DMA4_CSEIi

DMA4->SourceFrameIndex = 1; // DMA4_CSFIi

DMA4->DestinationElementIndex = 637; // DMA4_CDEIi

DMA4->DestinationFrameIndex = -152967; // DMA4_CDFIi

DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]

DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]

DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority =
      0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]

DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]
```

16.1.5.8 Graphic Operations

- Transparent copy:
  1. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 1
  2. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 0
  3. Set the value of the key color in the DMA4_COLORi[15:0] COLOR_KEY bit field

  To perform this graphic operation, the following lines can be added to the example of Section 16.1.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

```
DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;

DMA4_COLOR_CH10 = 0x00000003;
```

- Solid Color fill:
  1. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 1
  2. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 0
  3. Set the value of key the color in the DMA4_COLORi[15:0] SOLID_COLOR bit field

To perform this graphic operation, the following lines can be added to the example of Section 16.1.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

```
DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;

DMA4_COLOR_CH10 = 0x00000003;
```

16.1.5.9 Linked-List Programming Guidelines

- With the exception of the DMA4_CCRi[7] ENABLE bit and the DMA4_CDPi[7] PAUSE_LINK_LIST bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
  - For type 2, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi
    - DMA4_CLNK_CTRLi
  - For type 3, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi
    - DMA4_CLNK_CTRLi
    - DMA4_CICRi
    - DMA4_CFNi
- In case of a linked list with descriptor types 2 and 3, the content of the DMA4_CCRi register must not change during super-block life.
- The PAUSE_LINK_LIST bit must not be set in the initialization phase.

16.1.6 DMA_SYSTEM Register Manual

16.1.6.1 DMA_SYSTEM Instance Summary

Table 16-19. DMA_SYSTEM Instance Summary

Module Name	Base Address	Size
DMA_SYSTEM	0x4A05 6000	4 KiB

16.1.6.2 DMA_SYSTEM Registers

16.1.6.2.1 DMA_SYSTEM Register Summary

Index *i* represents the logical channel number (where i = 0 to 31). The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_CCR10 (channel 10) register has an offset address of 10 × 0x60 = 0x3C0, and thus a physical address of 0x4A05 6080 + 0x3C0 = 0x4A05 6440.

Index *j* represents the interrupt line number (where j = 0 to 3) The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_IRQSTATUS_L3 (line 3) register has an offset address of 3 × 0x4 = 0xC, and thus a physical address of 0x4A05 6008 + 0xC = 0x4A05 6014.

16.1.6.2.2 DMA_SYSTEM Register Description

Note

Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

Description	This register contains the DMA revision code		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	Reserved, Write 0's for future compatibility. Read returns 0	R	TI internal Data

Table 16-22. DMA4_IRQSTATUS_Lj

Address Offset	0x0000 0008 + (0x4 * j)	**Index**	j = 0 to 3
Physical Address	0x4A05 6008 + (0x4 * j)	**Instance**	DMA_SYSTEM
Description	The interrupt status register regroups all the status of the DMA_SYSTEM channels that can generate an interrupt over line Lj.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CH_31_0_Lj																															

Bits	Field Name	Description	Type	Reset
31:0	CH_31_0_Lj	Channel 31 Interrupt on Lj: When an interrupt is seen on the line Lj the status of a interrupting channel i is read in the bit field i. Read 0x0: Channel Interrupt Lj false Write 0x0: Channel Interrupt Lj status bit unchanged Write 0x1: Channel Interrupt Lj status bit is reset Read 0x1: Channel Interrupt Lj true (pending)	RW W1toClr	0x0000 0000

Table 16-23. DMA4_IRQENABLE_Lj

Address Offset	0x0000 0018 + (0x4 * j)	**Index**	j = 0 to 3
Physical Address	0x4A05 6018 + (0x4 * j)	**Instance**	DMA_SYSTEM
Description	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on line Lj		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CH_31_0_Lj_EN

Bits	Field Name	Description	Type	Reset
31:0	CH_31_0_Lj_EN	Channel Interrupt on Lj mask/unmask : to Mask/Unmask a channel i interrupt on Lj the user writes 0/1 on the bit field i. 0x0: Channel Interrupt Lj is masked 0x1: Channel Interrupt Lj generates an interrupt when it occurs	RW	0x0000 0000

Table 16-24. DMA4_SYSSTATUS

Address Offset	0x0000 0028		
Physical Address	0x4A05 6028	**Instance**	DMA_SYSTEM
Description	The register provides status information about the module excluding the interrupt status information (see interrupt status register)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															RESETDONE

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved for module-specific status information	R	0x0000 0000
0	RESETDONE	Internal reset monitoring Read 0x0: Internal module reset is on-going Read 0x1: Reset completed	R	1

Table 16-25. DMA4_OCP_SYSCONFIG

Address Offset	0x0000 002C		
Physical Address	0x4A05 602C	**Instance**	DMA_SYSTEM
Description	DMA system configuration register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

2	HALF_FRAME_INTERRUPT_CPBLTY	Detection capability of the half of frame end. Read 0x0: Does not support half of frame interrupt generation capability Read 0x1: Supports half of frame interrupt generation capability	R	1
1	EVENT_DROP_INTERRUPT_CPBLTY	Request collision detection capability. Read 0x0: Does not support event drop interrupt generation capability Read 0x1: Supports event drop interrupt generation capability	R	1
0	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0

Table 16-30. DMA4_GCR

Address Offset	0x0000 0078		
Physical Address	0x4A05 6078	**Instance**	DMA_SYSTEM
Description	FIFO sharing between high and low priority channel. The Maximum per channel FIFO depth is bounded by the low and high channel FIFO budget. The high respectively low priority channels maximum burst size must be less than the min (high respectively low priority channel FIFO budget, per channel maximum FIFO depth)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							CHANNEL_ID_GATE	ARBITRATION_RATE								HI_LO_FIFO_BUDGET		HI_THREAD_RESERVED		RESERVED				MAX_CHANNEL_FIFO_DEPTH							

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00
24	CHANNEL_ID_GATE	Gates the Channel ID bus monitoring on both Read and Write ports 0x0: Gates the Channel ID qualifiers on both Read and Write Ports 0x1: Does not gate the Channel ID qualifiers on both Read and Write Ports	RW	0x0
23:16	ARBITRATION_RATE	Arbitration switching rate between prioritized and regular channel queues	RW	0x01

Bits	Field Name	Description	Type	Reset
15:14	HI_LO_FIFO_BUDGET	Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO 0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels	RW	0x0
13:12	HI_THREAD_RESERVED	Allow thread reservation for high priority channel on both read and write ports. 0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.	RW	0x0
11:8	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

Table 16-31. DMA4_CCRi

Address Offset	0x0000 0080 + (0x60 * i)	**index:**	i = 0 to 31
Physical Address	0x4A05 6080 + (0x60 * i)	**Instance**	DMA_SYSTEM
Description	Channel Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED	RESERVED	WRITE_PRIORITY	BUFFERING_DISABLE	SEL_SRC_DST_SYNC	PREFETCH	SUPERVISOR	RESERVED	SYNCHRO_CONTROL_UPPER	BS	TRANSPARENT_COPY_ENABLE	CONST_FILL_ENABLE	DST_AMODE	SRC_AMODE	RESERVED	WR_ACTIVE	RD_ACTIVE	SUSPEND_SENSITIVE	ENABLE	READ_PRIORITY	FS	SYNCHRO_CONTROL

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
29:27	RESERVED	Reserved for non-GP devices	RW	0x0
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the write side during the arbitration process. 0x1: Channel has high priority on write sided during the arbitration process.	RW	0
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: Buffering is enabled across element/packet when source is synchronized to element, packet, frame or blocks. 0x1: Buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks.	RW	-
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register. 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register.	RW	-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests. 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is software user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported.	RW	0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled. 0x1: Supervisor mode is enabled.	RW	0
21	RESERVED	Reserved for non-GP devices	RW	0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as 2 MSB, with the 5 bits of the synchro channel bit field.	RW	0b00
18	BS	Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer.	RW	-

Bits	Field Name	Description	Type	Reset
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled. 0x1: Transparent copy mode is enabled.	RW	-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled. 0x1: Constant fill mode is enabled.	RW	0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
11	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
10	WR_ACTIVE	Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port. Read 0x1: Channel is currently active on the write port.	R	0
9	RD_ACTIVE	Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port. Read 0x1: Channel is currently active on the read port.	R	0
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions.	RW	0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled. 0x1: The logical channel is enabled.	RW	0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the read side during the arbitration process. 0x1: Channel has high priority on read sided during the arbitration process.	RW	0
5	FS	Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS = 0 and BS = 0: An element is transferred once a DMA request is made. FS = 0 and BS = 1: An entire block is transferred once a DMA request is made. FS = 1 and BS = 0: An entire frame is transferred once a DMA request is made. FS = 1 and BS = 1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	-

Bits	Field Name	Description	Type	Reset
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used in conjunction with the second_level_ synchro_control_upper (as 2 MSB) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127)There are 127 possible DMA request to assign to any LCH. **Note:** The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).	RW	0b00000

Table 16-32. DMA4_CLNK_CTRLi

16.2 Enhanced DMA

This chapter describes the Enhanced Direct Memory Access (EDMA) controller.

16.2.1 EDMA Module Overview

The enhanced direct memory access module, also called EDMA, performs high-performance data transfers between two slave points, memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. EDMA transfer is programmed through a logical EDMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The EDMA can also perform transfers between external memories and between Device subsystems internal memories, with some performance loss caused by resource sharing between the read and write ports.

EDMA controller is based on two major principal blocks:
- EDMA third-party channel controller (EDMA_TPCC)
- EDMA third-party transfer controller (EDMA_TPTC)

The **TPCC** is a high flexible Channel Controller. It serves as an user interface and an event interface for the EDMA controller. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The **TPTC** performs read and write transfers by EDMA ports to the slave peripherals as programmed in the "Active" and "Pending" set of the registers. The transfer controllers are responsible for data movement and issue read/write commands to the source and destination addresses that are programmed for a given transfer in the EDMA_TPCC.

The SoC integrates the following EDMA instances:

- One system-level EDMA
- One DSP internal EDMA (per DSP)
- One EVE internal EDMA (per EVE)

Each of these EDMA modules consists of:

- One TPCC instance
- Two TPTC instances

Note

All EDMA modules in the SoC are functionally identical. Note that some of the configuration parameters may be different for the various EDMA instances (see Section 16.2.1.3, *EDMA Controllers Configuration*).

This chapter is mostly focused on describing the system-level EDMA module (in terms of configuration and integration in the SoC). For details on DSPx_EDMA / EVEx_EDMA integration, see their respective chapters.

Figure 16-12 shows an overview of the EDMA module.

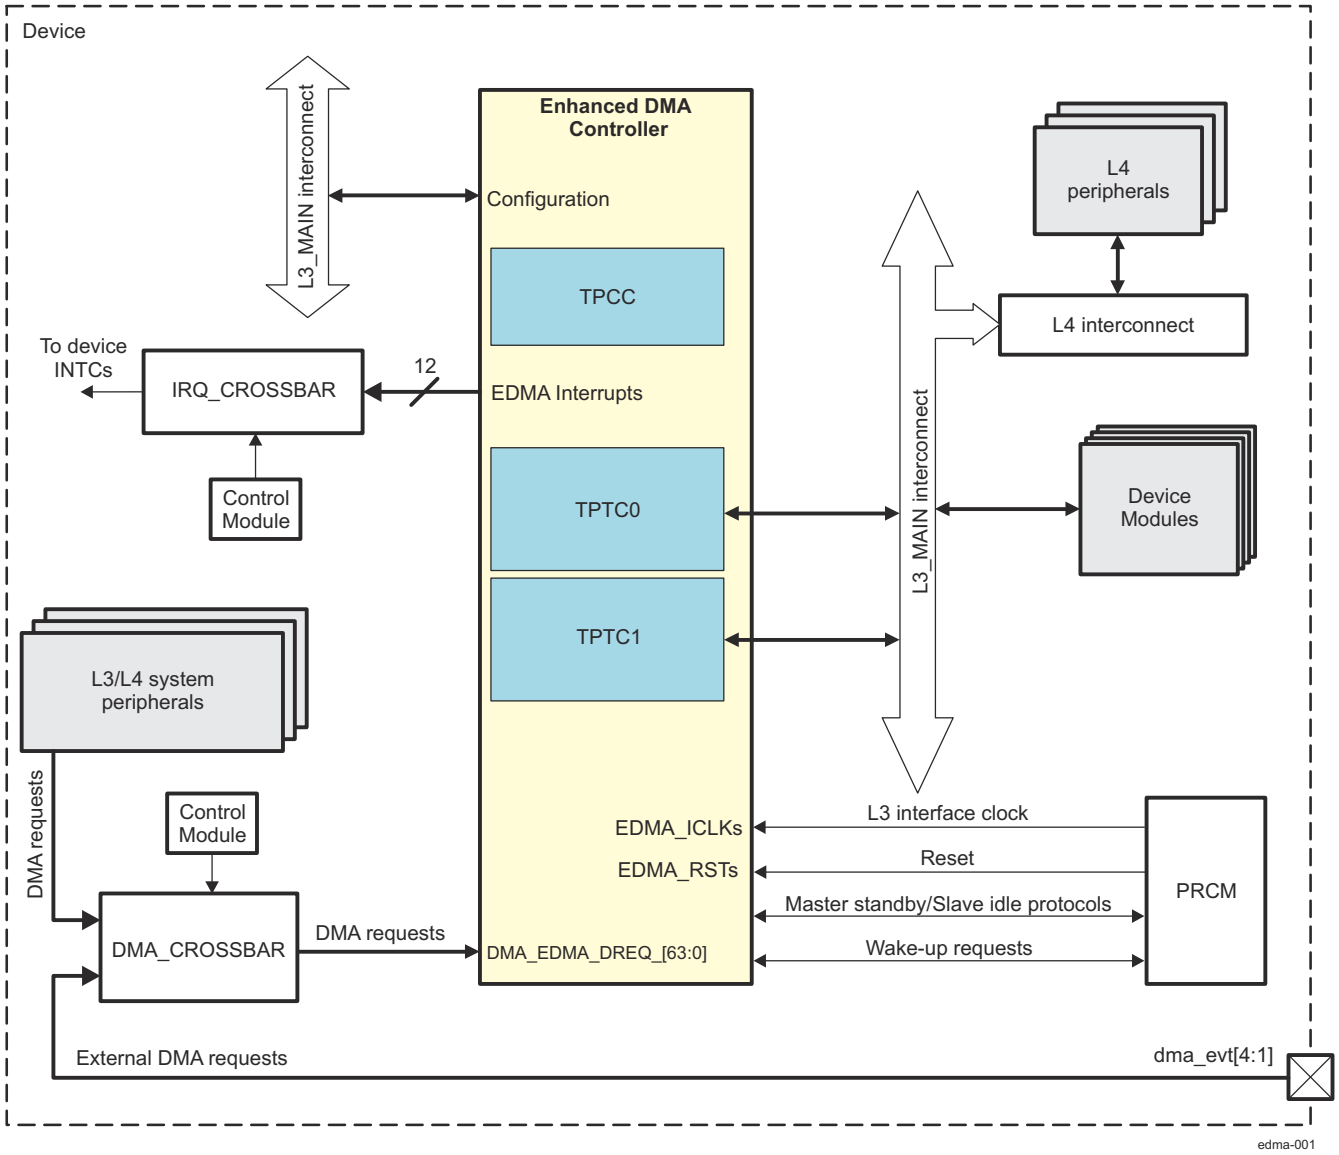

Figure 16-12. EDMA module Overview

The device CPUs can configure the EDMA controller blocks through the L3_MAIN interconnect.

16.2.1.1 EDMA Features

The **EDMA_TPCC** channel controller has following features:

- Fully orthogonal transfer description:
  - Three transfer dimensions.
  - A-synchronized transfers: one-dimension serviced per event.
  - AB-synchronized transfers: two-dimensions serviced per event.
  - Independent indexes on source and destination.
  - Chaining feature allows a 3-D transfer based on a single event.
- Flexible transfer definition:
  - Increment or FIFO transfer addressing modes.
  - Linking mechanism allows automatic PaRAM set update.
  - Chaining allows multiple transfers to execute with one event.
- Interrupt generation for the following:

  - Transfer completion.
  - Error conditions.
- Debug visibility:
  - Queue water marking/threshold.
  - Error and status recording to facilitate debug.
- 64 DMA request channels:
  - Event synchronization.
  - Manual synchronization (CPU(s) write to event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH).
  - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:
  - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
  - Support for programmable QDMA channel to PaRAM mapping.
- 512 PaRAM sets:
  - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Two transfer controllers/event queues.
- 16 event entries per event queue.
- Memory protection support:
  - Proxy memory protection for TR submission.
  - Active memory protection for accesses to PaRAM and registers.

The **EDMA_TPTC** transfer controller has the following features:

- Two transfer controllers (TC).
- 128-bit wide read and write ports per TC.
- Up to four in-flight transfer requests (TRs).
- Programmable priority level.
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA_TPCC manages the 3rd dimension).
- Support for increment or constant addressing mode transfers.
- Interrupt and error support.
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness.

16.2.1.2

EDMA controller uses the shared MMU1 module for transfering to and from DSP module. This provides several benefits including:

- Protection of Host CPU memory regions from accidental corruption by EDMA TPTCs.
- Direct allocation of buffers in user space without the need for translation between CPU and DSP applications utilizing EDMA TPTCs.

Accesses by the EDMA TPTCs (both TPTC0 and TPTC1) may optionally be routed through the MMU1.

The TPTC0 and TPTC1 routing allows EDMA transfer controller to be used to perform transfers using only the virtual addresses of the associated buffers.

For more information about MMU1 module refer to Chapter 20 *Memory Management Units*.

16.2.1.3 EDMA Controllers Configuration

Table 16-52 summarizes the configuration for each of the EDMA channel controllers present on the SoC.

Table 16-52. EDMA Channel Controllers Configuration

Parameter	SYS_EDMA CC Configuration	DSPx_EDMA CC Configuration	EVEx_EDMA CC Configuration
Number of DMA channels (NUM_DMACH)	64	64	16
Number of QDMA channels (NUM_QDMACH)	8	8	8
Number of interrupt channels (NUM_INTCH)	64	64	16

Table 16-52. EDMA Channel Controllers Configuration (continued)

Parameter	SYS_EDMA CC Configuration	DSPx_EDMA CC Configuration	EVEx_EDMA CC Configuration
Number of PaRAM set entries (NUM_PARAMENTRY)	512	128	128
Number of event queues (NUM_EVQUE)	2	2	2
Number of transfer controllers (NUM_TC)	2	2	2
Memory protection existence (MPEXIST)	Yes	Yes	Yes
Number of memory protection and shadow regions (NUM_REGIONS)	8	8	8
Channel mapping existence (CHMAPEXIST)	Yes	Yes	Yes

Table 16-53 summarizes the configuration of each of the EDMA transfer controllers present on the SoC.

Table 16-53. EDMA Transfer Controllers Configuration

Parameter	SYS_EDMA TC0 / TC1 Configuration	DSPx_EDMA TC0 / TC1 Configuration	EVEx_EDMA TC0 / TC1 Configuration
Data FIFO size (FIFOSIZE)	1024 bytes	2048 bytes	2048 bytes
Bus width (BUSBYTE)	16 bytes	16 bytes	16 bytes
Number of destination FIFO register sets (DSTREGDEPTH)	4 entries	4 entries	4 entries
Default burst size (DBS)	Defined by CTRL_CORE_CONTROL_IO_1 register	Defined by DSP_SYS_BUS_CONFIG register	Defined by EVE_BUS_CONFIG register

16.2.2 EDMA Controller Environment

The EDMA controller supports external DMA requests through the dma_evt[4:1] pins (see Table 16-54). A logical channel can be configured to respond to an external synchronization request.

Table 16-54. External EDMA Request Signals

Pin Name	DMA_CROSSBAR Input	Signal Name	I/O(1)	Description	Module Reset Value
dma_evt1	DMA_CROSSBAR_2	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
dma_evt2	DMA_CROSSBAR_3	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z
dma_evt3	DMA_CROSSBAR_167	EXT_SYS_DREQ_2	I	External DMA request 2 (system expansion)	Z
dma_evt4	DMA_CROSSBAR_168	EXT_SYS_DREQ_3	I	External DMA request 3 (system expansion)	Z

(1) I = Input, O = Output

Figure 16-13 shows an example of how to use the external hardware DMA request pins in the EDMA environment.

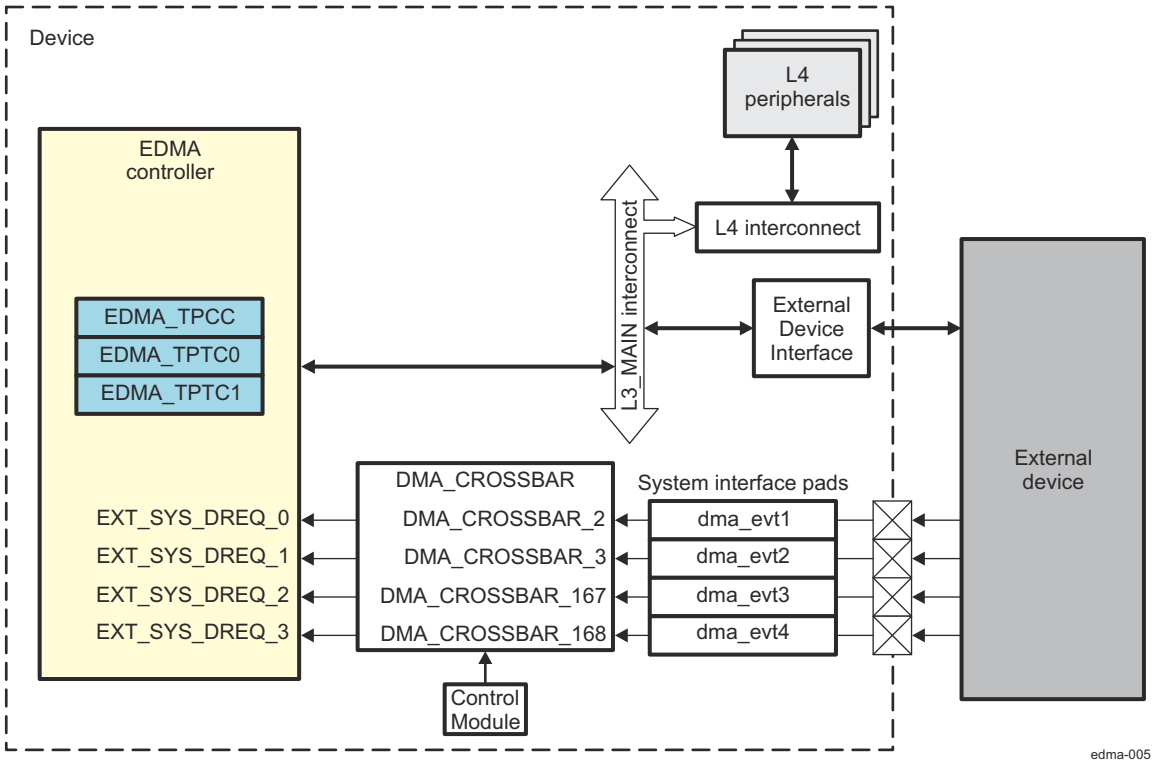

Figure 16-13. Example of External DMA Requests Use

An external device can use the external DMA request pins to start a logical channel transfer. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, refer to *Control Module*.

All 64 DMA request lines are transition sensitive.

16.2.3 EDMA Controller Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 16-14 shows the EDMA controller integration.

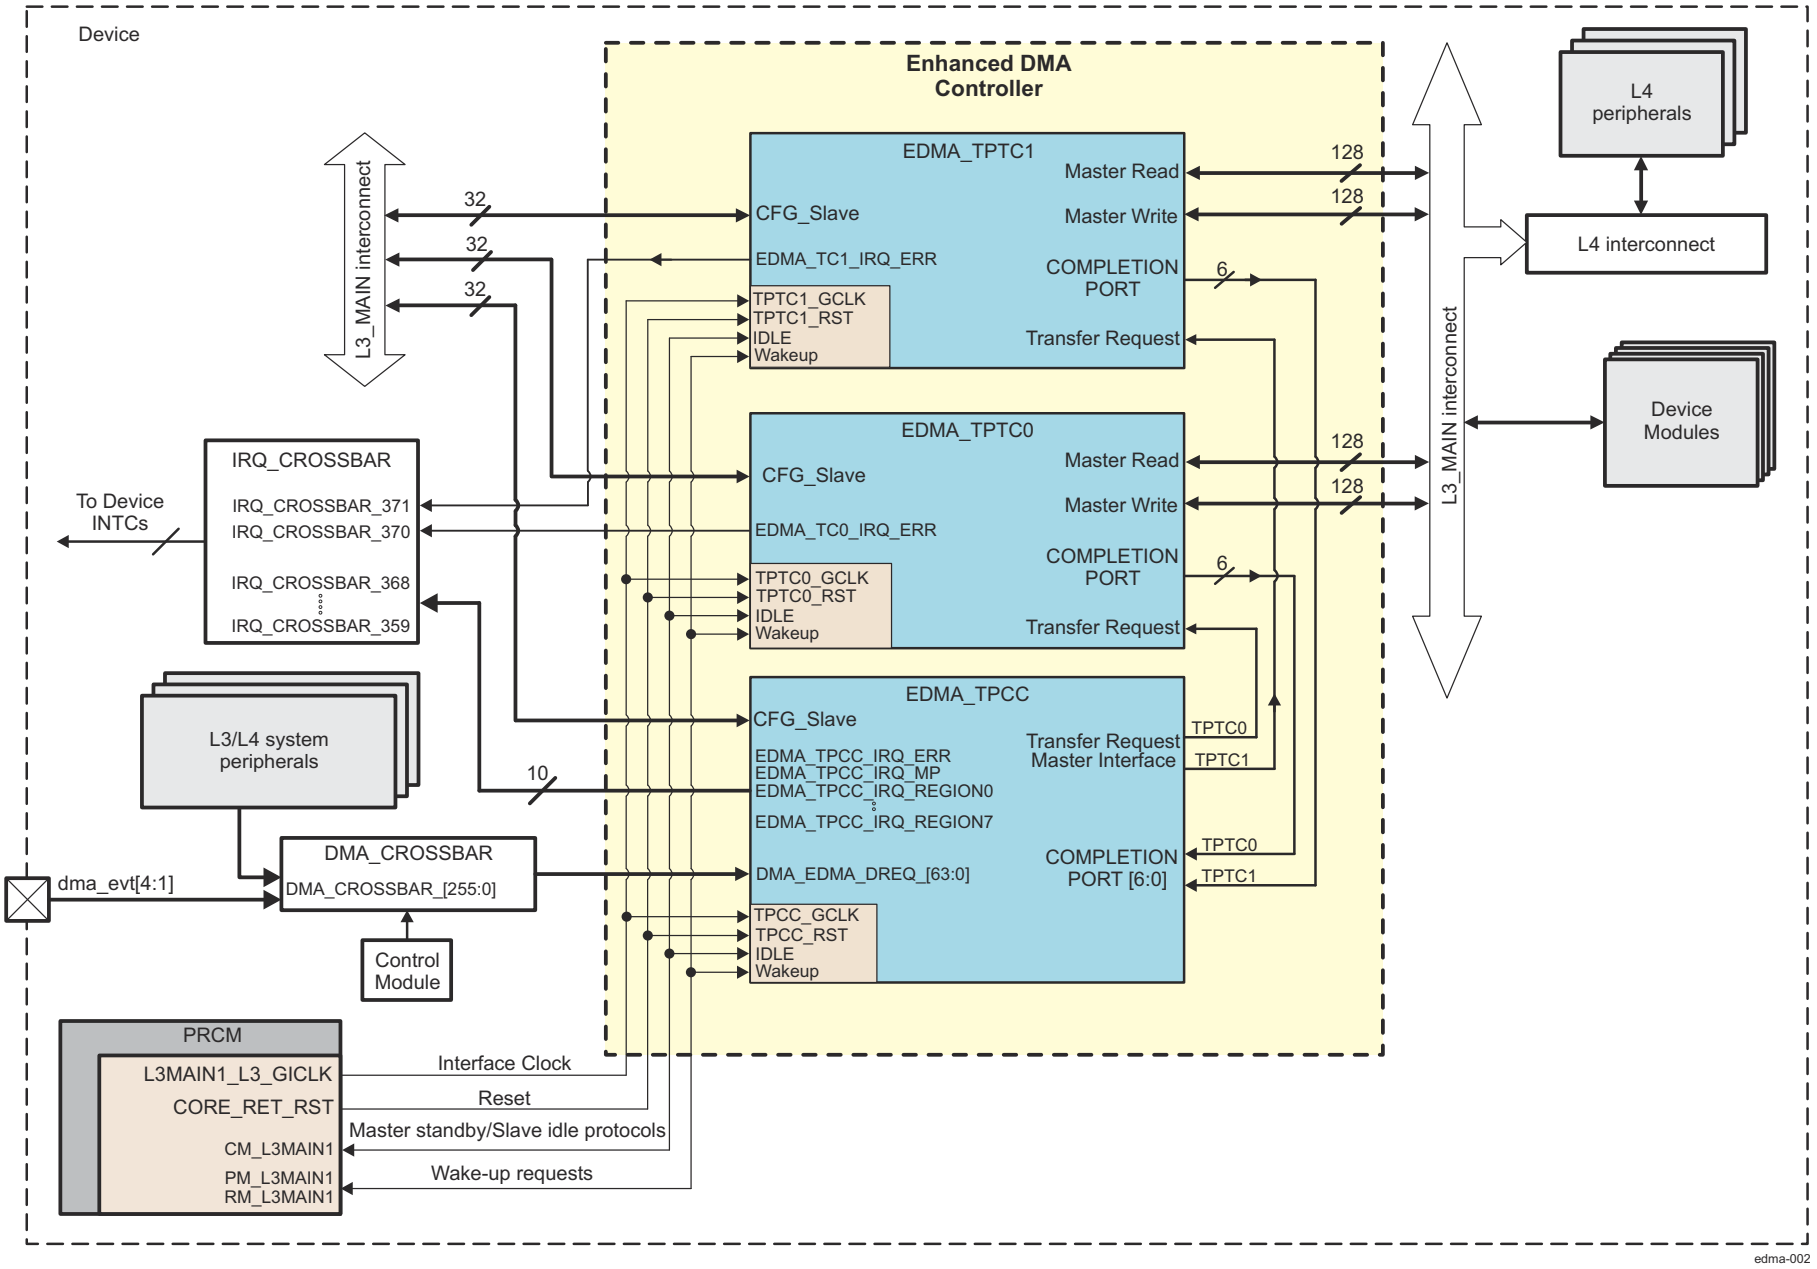

Figure 16-14. EDMA Controller Integration

Table 16-55 through Table 16-57 summarize the integration of the module in the device.

Table 16-55. EDMA Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
EDMA_TPCC	PD_COREAON	L3_MAIN
EDMA_TPTC0		
EDMA_TPTC1		

Table 16-56. EDMA Clocks and Resets

Clocks

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EDMA_TPCC	EDMA_TPCC_GCLK	L3MAIN1_L3_GICLK	PRCM	Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see *Power, Reset, and Clock Management*.
EDMA_TPTC0	EDMA_TPTC0_GCLK			
EDMA_TPTC1	EDMA_TPTC1_GCLK			

Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EDMA_TPCC	EDMA_TPCC_RST	CORE_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the EDMA contrller modules, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see *Power, Reset, and Clock Management*.
EDMA_TPTC0	EDMA_TPTC0_RST			
EDMA_TPTC1	EDMA_TPTC1_RST			

Table 16-57. EDMA Hardware Requests

Interrupt Requests

Module Instance	Source Signal Name	Destination IRQ_CROSSBAR INPUT	Default mapping	Description
EDMA_TPCC	EDMA_TPCC_IRQ_ERR	IRQ_CROSSBAR_359	-	TPCC error interrupt. This IRQ source signal is not mapped by default to any device INTC. For more information about INTC refer to *Interrupt Controllers*.
	EDMA_TPCC_IRQ_MP	IRQ_CROSSBAR_360	-	TPCC memory protection interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION0	IRQ_CROSSBAR_361	-	TPCC Region 0 interrupt. This IRQ source signal is not mapped by default to any device INTC.

Table 16-57. EDMA Hardware Requests (continued)

	EDMA_TPCC_IRQ_REGION1	IRQ_CROSSBAR_362	-	TPCC Region 1 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION2	IRQ_CROSSBAR_363	-	TPCC Region 2 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION3	IRQ_CROSSBAR_364	-	TPCC Region 3 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION4	IRQ_CROSSBAR_365	-	TPCC Region 4 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION5	IRQ_CROSSBAR_366	-	TPCC Region 5 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION6	IRQ_CROSSBAR_367	-	TPCC Region 6 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION7	IRQ_CROSSBAR_368	-	TPCC Region 7 interrupt. This IRQ source signal is not mapped by default to any device INTC.
EDMA_TPTC0	EDMA_TC0_IRQ_ERR	IRQ_CROSSBAR_370	-	TPTC0 error interrupt. This IRQ source signal is not mapped by default to any device INTC.
EDMA_TPTC1	EDMA_TC1_IRQ_ERR	IRQ_CROSSBAR_371	-	TPTC1 error interrupt. This IRQ source signal is not mapped by default to any device INTC.

Note

The "**Default Mapping**" column in Table 16-57 *EDMA Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR or DMA_CROSSBAR modules.
For more information about the IRQ_CROSSBAR and DMA_CROSSBAR modules, see sections: *IRQ_CROSSBAR Module Functional Description* and *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For a description of the interrupt source, see *EDMA interrupts*.

16.2.3.1 EDMA Requests to the EDMA Controller

Table 16-58 lists the default DMA sources for the EDMA controller. In addition, the EDMA inputs (DMA_EDMA_DREQ_[63:0]) can alternatively be sourced through the associated DMA_CROSSBAR from one of the 256 multiplexed device DMA sources listed in Table 16-6. The CTRL_CORE_DMA_EDMA_DREQ_y_z registers (where *y* and *z* are indexes of EDMA input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

Table 16-58. EDMA Default Request Mapping

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_0	1	CTRL_CORE_DMA_EDMA_DREQ_0_1[7:0]	1	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_1	2	CTRL_CORE_DMA_EDMA_DREQ_0_1[23:16]	2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion)
DMA_EDMA_DREQ_2	3	CTRL_CORE_DMA_EDMA_DREQ_2_3[7:0]	3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion)
DMA_EDMA_DREQ_3	4	CTRL_CORE_DMA_EDMA_DREQ_2_3[23:16]	4	GPMC_DREQ	GPMC data transmit request from prefetch engine
DMA_EDMA_DREQ_4	5	CTRL_CORE_DMA_EDMA_DREQ_4_5[7:0]	5	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_5	6	CTRL_CORE_DMA_EDMA_DREQ_4_5[23:16]	6	DISPC_DREQ	Frame update request
DMA_EDMA_DREQ_6	7	CTRL_CORE_DMA_EDMA_DREQ_6_7[7:0]	7	CT_TBR_DREQ	DEBUG subsystem CT_TBR request
DMA_EDMA_DREQ_7	8	CTRL_CORE_DMA_EDMA_DREQ_6_7[23:16]	8	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_8	9	CTRL_CORE_DMA_EDMA_DREQ_8_9[7:0]	9	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_9	10	CTRL_CORE_DMA_EDMA_DREQ_8_9[23:16]	10	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_10	11	CTRL_CORE_DMA_EDMA_DREQ_10_11[7:0]	11	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_11	12	CTRL_CORE_DMA_EDMA_DREQ_10_11[23:16]	12	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_12	13	CTRL_CORE_DMA_EDMA_DREQ_12_13[7:0]	13	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_13	14	CTRL_CORE_DMA_EDMA_DREQ_12_13[23:16]	14	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_14	15	CTRL_CORE_DMA_EDMA_DREQ_14_15[7:0]	15	MCSPI3_DREQ_TX0	McSPI3 transmit request channel 0
DMA_EDMA_DREQ_15	16	CTRL_CORE_DMA_EDMA_DREQ_14_15[23:16]	16	MCSPI3_DREQ_RX0	McSPI3 receive request channel 0
DMA_EDMA_DREQ_16	17	CTRL_CORE_DMA_EDMA_DREQ_16_17[7:0]	17	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_17	18	CTRL_CORE_DMA_EDMA_DREQ_16_17[23:16]	18	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_18	19	CTRL_CORE_DMA_EDMA_DREQ_18_19[7:0]	19	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_19	20	CTRL_CORE_DMA_EDMA_DREQ_18_19[23:16]	20	Reserved	Reserved by default but can be remapped to a valid DMA source

16.2.4 EDMA Controller Functional Description

This chapter discusses the architecture of the EDMA controller.

16.2.4.1 Block Diagram

Figure 16-15 shows the functional block diagram of the EDMA controller.

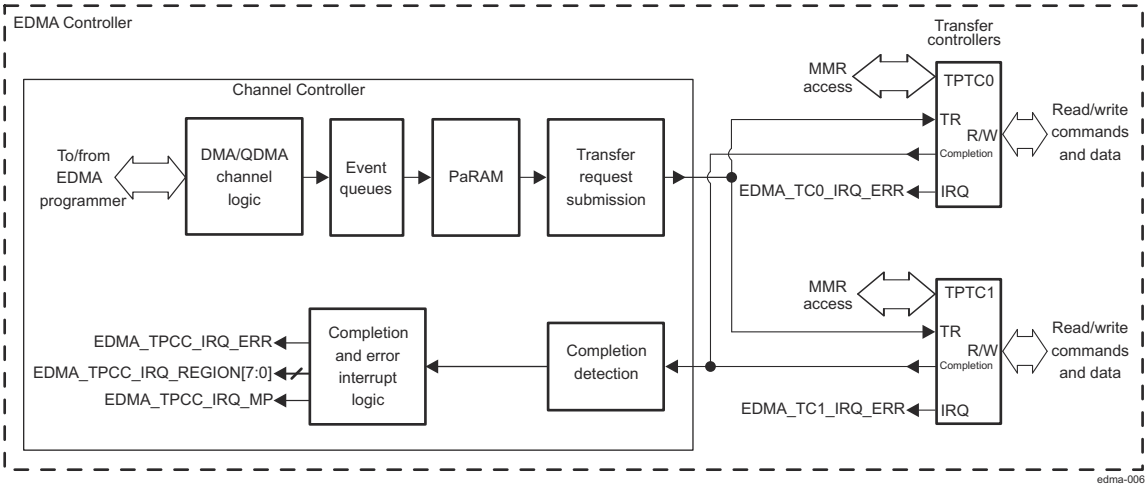

Figure 16-15. EDMA Controller Block Diagram

16.2.4.1.1 Third-Party Channel Controller

The TPCC is the EDMA transfer scheduler responsible for scheduling, arbitrating, and issuing user programmed transfers to the two TPTCs.

Figure 16-16 shows a functional block diagram of the EDMA channel controller (EDMA_TPCC).

The main blocks of the EDMA_TPCC are as follows:

- Parameter RAM (PaRAM): The PaRAM maintains parameter sets for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets. EDMA_TPCC processes and sets based on a trigger event and submits a transfer request (TR) to the transfer controllers.
- EDMA event and interrupt processing registers: Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- Completion detection: The completion detect block detects completion of transfers by the EDMA_TPTCs or slave peripherals. The completion of transfers can be used optionally to chain trigger new transfers or to assert interrupts.
- Event queues: Event queues form the interface between the event detection logic and the transfer request submission logic.
- Memory protection registers: Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

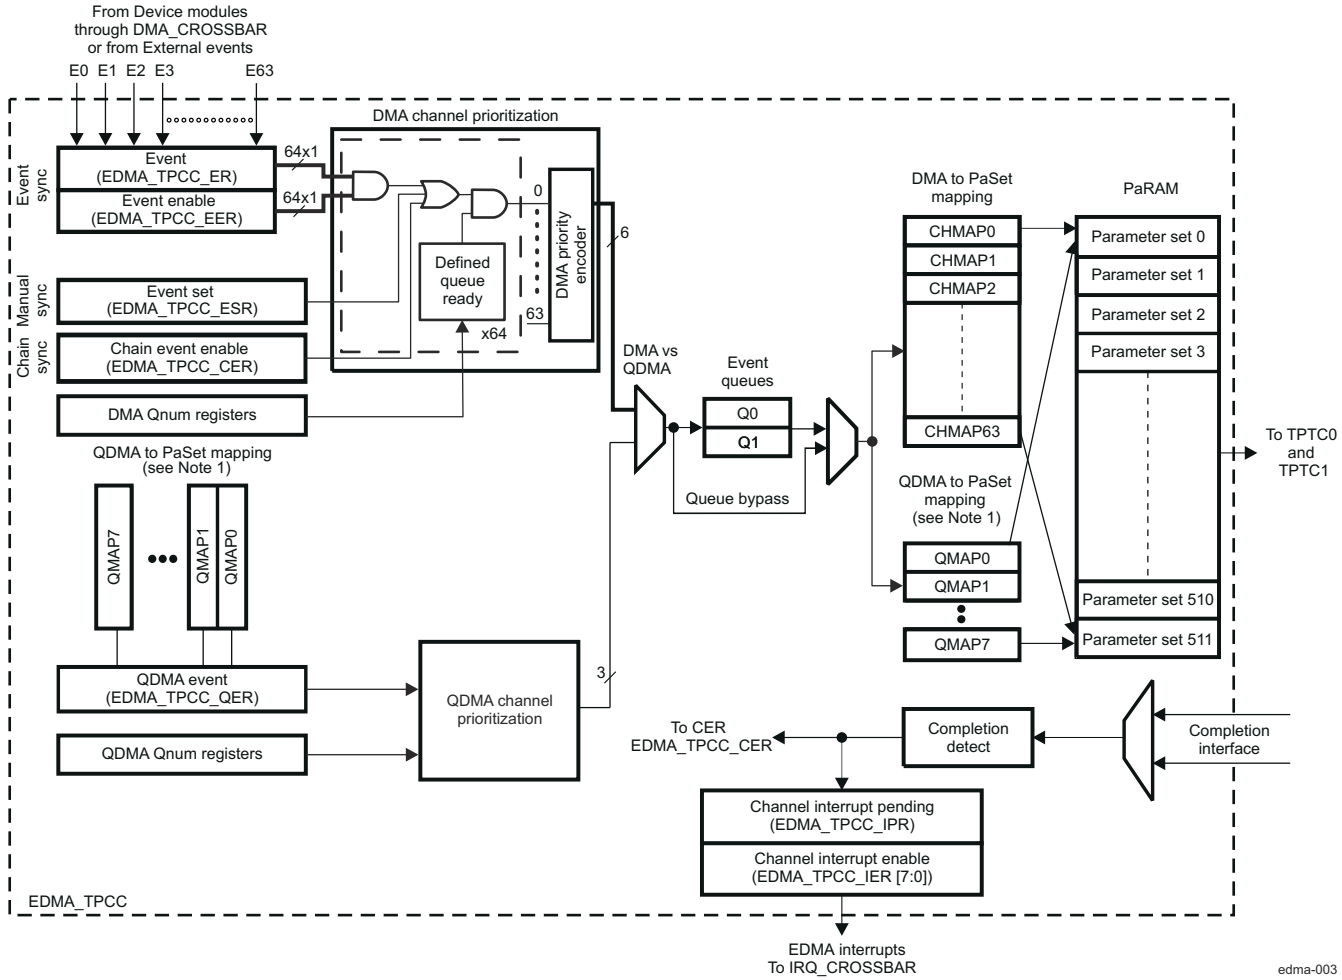
Other functions include the following:

- Region registers: Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA programmers own (for example, MPU or DSPs).
- Debug registers: Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA_TPCC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main difference between a DMA channel and a QDMA channel is the method that the system uses to trigger transfers.

Figure 16-16 is a block diagram of the EDMA_TPCC.



A. Although it is depicted twice in Figure 16-16, there is only one physical register set for the QDMA to PaRAM set mapping block.

Figure 16-16. EDMA Channel Controller Block Diagram

The EDMA_TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels are triggered by external events (such as McSPI modules TX event and McSPI modules RX event) by the event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH, or through chaining register EDMA_TPCC_CER.
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed [64:1] and [8:1] priority encoder for these events, respectively (a low channel number corresponds to a high priority).

DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controllers, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the transfer request TR bus or PaRAM processing are busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the EDMA_TPTC is available for a new TR to be programmed into the EDMA_TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaRAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaRAM entry in anticipation of the next trigger event for that PaRAM entry.

The EDMA_TPCC also has an error detection logic that causes an error interrupt generation on various error conditions (for example: missed events EDMA_TPCC_EMR and EDMA_TPCC_EMRH registers, exceeding event queue thresholds in EDMA_TPCC_CCERR register, etc.).

16.2.4.1.2 Third-Party Transfer Controller

The TPTC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

Figure 16-17 shows a functional block diagram and of the EDMA transfer controller (EDMA_TPTC) and its connection to the EDMA_TPCC.

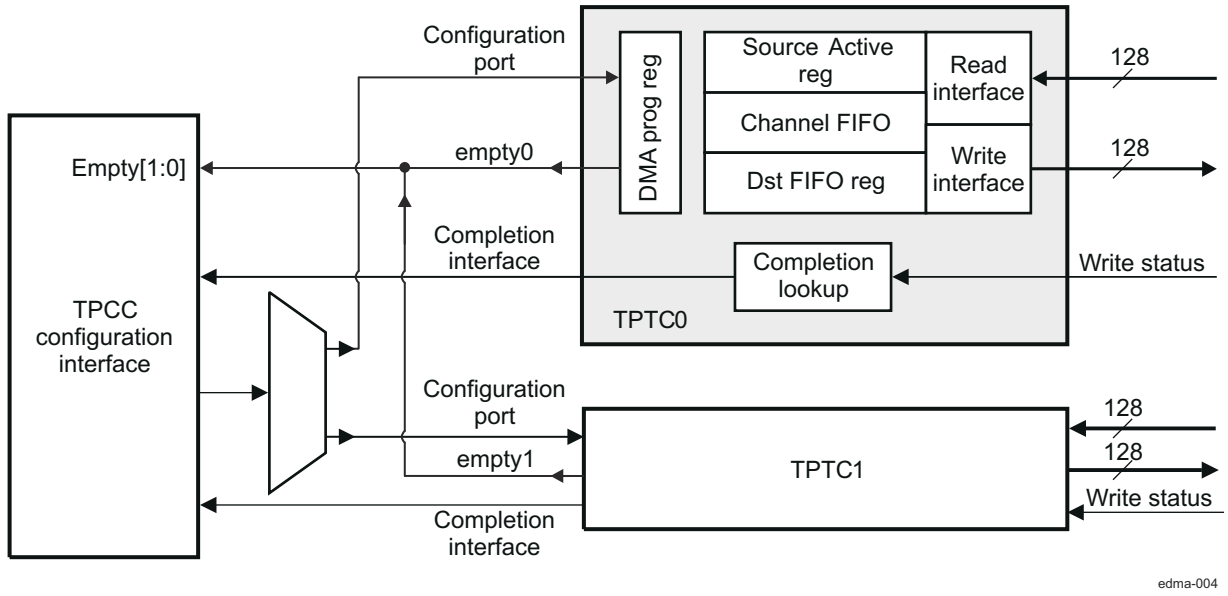


Figure 16-17. TPTC Block Diagram

Note

The port data bus width of the instances of the TPTC is fixed at 128 bits.

Two instances of the EDMA_TPTC generate concurrent traffic on the L3_MAIN interconnect. Each TC controller consists of the following components:

- DMA Program Register Set: Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the Program Register Set, not the active register set. For typical standalone operation, the CPU programs the Program Register while the TC services the Active register set. The Program Register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- Source Active Register Set : Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress in the Read Controller. The Active register set is split into independent Source and Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.

- Destination FIFO Register Set: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.
- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- Read Controller/Interconnect Read Interface: The Interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 128 bytes and available landing space in the channel FIFO.
- Write controller/Interconnect Write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 128 bytes and available data in the channel FIFO.
- Completion interface: sends completion codes to the EDMA_TPCC when a transfer completes and generates interrupts and chained events in the TPCC module.
- Configuration port: Slave interface that provides read/write access to program registers and read access to all memory-mapped TPTC registers.

When one EDMA_TPTC module is idle and receive its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA_TPCC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands controlled by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

16.2.4.2 Types of EDMA controller Transfers

An EDMA transfer is always defined in terms of three dimensions. Figure 16-18 shows the three dimensions used by EDMA controller transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of EDMA_TPCC_ABCNT_n[15:0] ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of EDMA_TPCC_ABCNT_n[31:16] BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using bit-fields EDMA_TPCC_BIDX_n[15:0] SBIDX or EDMA_TPCC_BIDX_n[31:16] DBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. The Count for 3rd Dimension is defined in register EDMA_TPCC_CCNT_n[15:0] CCNT. Each transfer in the 3rd dimension is separated from the previous by an index programmed using EDMA_TPCC_CIDX_n[15:0] SCIDX or EDMA_TPCC_CIDX_n[31:16] DCIDX.

Note

The reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (EDMA_TPCC_OPT_n[2] SYNCDIM bit). For these three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

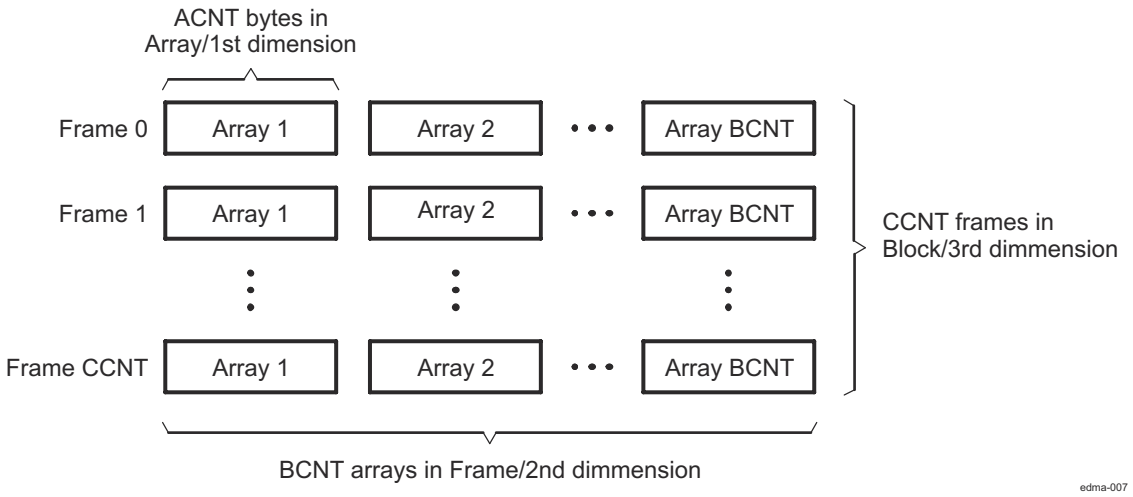

Figure 16-18. Definition of ACNT, BCNT, and CCNT

16.2.4.2.1 A-Synchronized Transfers

In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of EDMA_TPCC_ABCNT_n[15:0] ACNT bytes, or one array of ACNT bytes. Each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0]SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX, as shown in Figure 16-19, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) in EDMA_TPCC_BIDX_n register.

Frames are always separated by EDMA_TPCC_CIDX_n[15:0] SCIDX and EDMA_TPCC_CIDX_n[31:16] DCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in Figure 16-19, SRCCIDX / DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 16-19 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Figure 16-19 for details on parameter set updates.

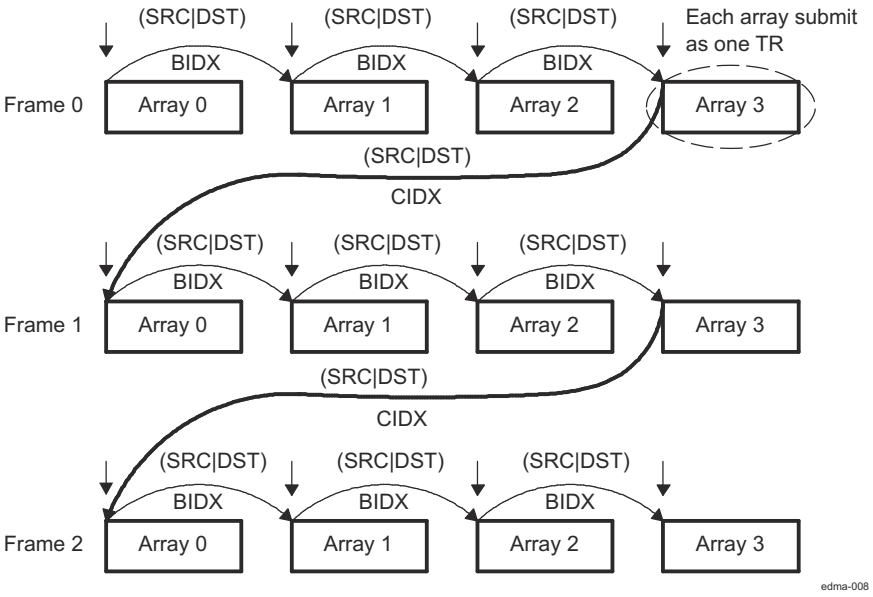

Figure 16-19. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

16.2.4.2.2 AB-Synchronized Transfers

In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. Each event/TR packet conveys information for one entire frame of BCNT_n arrays of ACNT_n bytes. Thus, EDMA_TPCC_CCNT_n events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX as shown in Figure 16-20. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add EDMA_TPCC_CIDX_n[15:0] SCIDX / EDMA_TPCC_CIDX_n[31:16] DCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 16.2.4.3.6 *Parameter Set Updates* for details on parameter set updates.

Figure 16-20 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of *n* (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

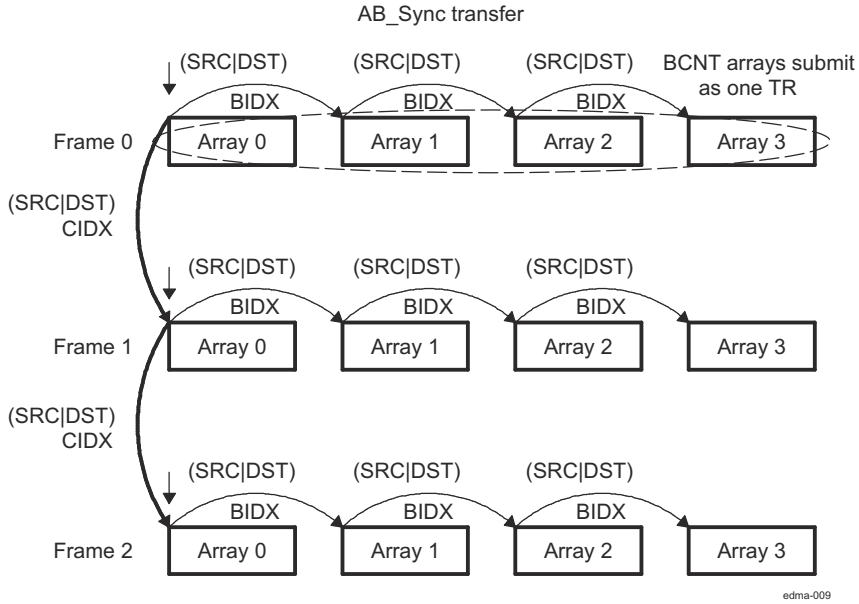

Figure 16-20. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

Note

ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

Note

VCP does not support Const/FIFO mode DMA transfers. The EDMA should be configured for AB-Synchronized transfer with ACNT = 8, BCNT = number of elements.

16.2.4.3 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table in EDMA_TPCC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0, they should be remapped before use by EDMA_TPCC_DCHMAPN_m and EDMA_TPCC_QCHMAPN_j registers.

Table 16-59. EDMA Parameter RAM Contents

PaRAM Set Number	Base Address	Parameters(1)
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...	...	...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...	...	...
510	EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh	PaRAM set 510
511	EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh	PaRAM set 511

(1) The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

16.2.4.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in Figure 16-21 and described in Table 16-60. Each PaRAM set consists of 16-bit and 32-bit parameters.

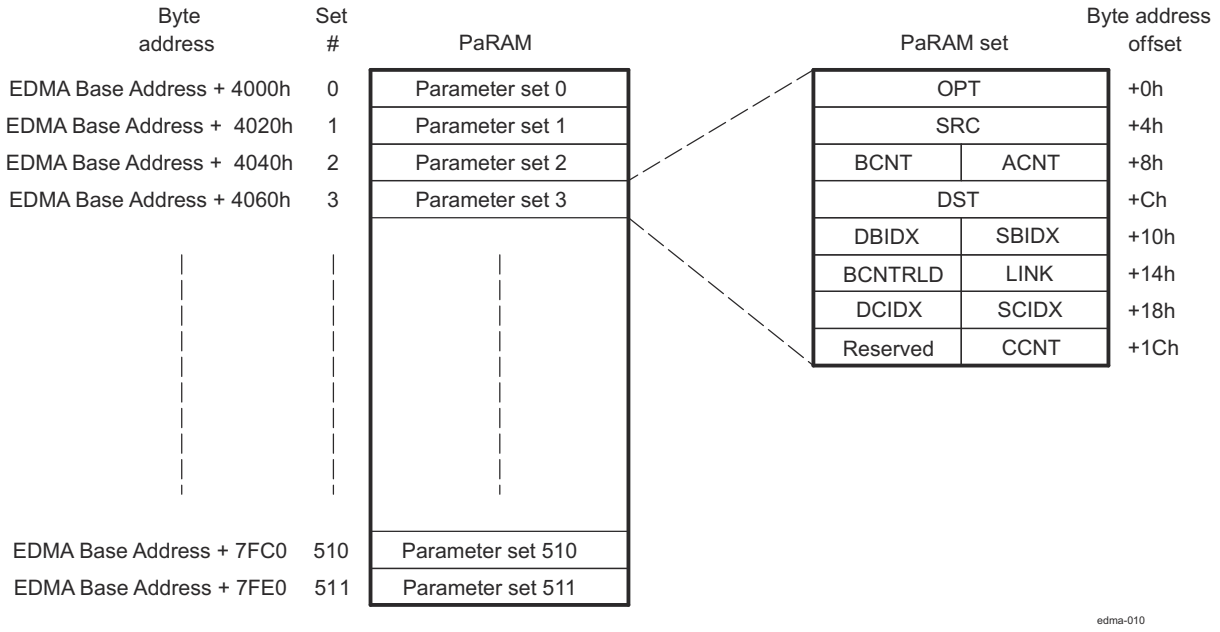

Figure 16-21. PaRAM Set

Table 16-60. EDMA Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options EDMA_TPCC_OPT_n register	Transfer configuration options
4h	SRC	Channel Source Address EDMA_TPCC_SRC_n register	The byte address from which data is transferred
8h(1)	ACNT	Count for 1st Dimension EDMA_TPCC_ABCNT_n[15:0] ACNT bit-field.	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension EDMA_TPCC_ABCNT_n[31:16] BCNT bit-field.	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address EDMA_TPCC_DST_n register	The byte address to which data is transferred
10h(1)	SBIDX	Source BCNT Index EDMA_TPCC_BIDX_n[15:0] SBIDX bit-field.	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DBIDX	Destination BCNT Index EDMA_TPCC_BIDX_n[31:16] DBIDX bit-field.	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h(1)	LINK	Link Address EDMA_TPCC_LNK_n[15:0] LINK bit-field	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload EDMA_TPCC_LNK_n[31:16] BCNTRLD bit-field	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h(1)	SCIDX	Source CCNT index. EDMA_TPCC_CIDX_n[15:0] SCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DCIDX	Destination CCNT index. EDMA_TPCC_CIDX_n[31:16] DCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension. EDMA_TPCC_CCNT_n[15:0] CCNT bit-field.	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	Reserved	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

(1) If OPT, SRC, or DST is the trigger word for a QDMA transfer, then a 32-bit access to that field is required. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor will swap addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

16.2.4.3.2 EDMA Channel PaRAM Set Entry Fields

16.2.4.3.2.1 Channel Options Parameter (OPT)

For detailed information about the channel options parameter, see the EDMA_TPCC_OPT_n register description in Section 16.2.7.2.2.1, *EDMA_TPCC Register Description*.

16.2.4.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, it must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 16.2.4.12.3 *Error Generation* for additional details.

16.2.4.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, it must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 16.2.4.12.3 *Error Generation* for additional details.

16.2.4.3.2.4 Count for 1st Dimension (ACNT)

EDMA_TPCC_ABCNT_n[15:0] ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA_TPTC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 16.2.4.3.5 *Dummy Versus Null Transfer Comparison* and Section 16.2.4.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

16.2.4.3.2.5 Count for 2nd Dimension (BCNT)

EDMA_TPCC_ABCNT_n[15:0] BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 16.2.4.3.5 *Dummy Versus Null Transfer Comparison* and Section 16.2.4.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

16.2.4.3.2.6 Count for 3rd Dimension (CCNT)

EDMA_TPCC_CCNT_n[15:0] CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

A CCNT value of 0 is considered either a null or dummy transfer.

Refer to Section 16.2.4.3.5 *Dummy Versus Null Transfer Comparison* and Section 16.2.4.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

16.2.4.3.2.7 BCNT Reload (BCNTRLD)

EDMA_TPCC_LNK_n[31:16] BCNTRLD is a 16-bit unsigned value used to reload the EDMA_TPCC_ABCNT_n[15:0] BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA_TPCC decrements the BCNT value by 1 on

each TR submission. When BCNT reaches 0, the EDMA_TPCC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA_TPCC submits the BCNT in the TR and the EDMA_TPTC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

16.2.4.3.2.8 Source B Index (SBIDX)

EDMA_TPCC_BIDX_n[15:0] SBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[15:0] SBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

16.2.4.3.2.9 Destination B Index (DBIDX)

EDMA_TPCC_BIDX_n[31:16] DBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[31:16] DBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. Refer to Section 16.2.4.3.2.8 *Source B Index (SBIDX)* for examples.

16.2.4.3.2.10 Source C Index (SCIDX)

EDMA_TPCC_CIDX_n[15:0] SCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for EDMA_TPCC_CIDX_n[15:0] SCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

Note

When SCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 16-19), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 16-20).

16.2.4.3.2.11 Destination C Index (DCIDX)

EDMA_TPCC_CIDX_n[31:16] DCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

Note

When DCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 16-19), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 16-20).

16.2.4.3.2.12 Link Address (LINK)

The EDMA_TPCC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter EDMA_TPCC_LNK_n[15:0] LINK specifies the byte address offset in the PaRAM from which the EDMA_TPCC loads/reloads the next PaRAM set during linking.

It must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA_TPCC ignores the upper 2 bits of the LINK entry, allowing the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if it use the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

It should check that the programed value in the EDMA_TPCC_LNK_n[15:0] LINK field is correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

Value of FFFFh in EDMA_TPCC_LNK_n[15:0] LINK bit-field is referred to as a NULL link that should cause the EDMA_TPCC to perform an internal write of 0 to all entries of the current PaRAM set, except for the EDMA_TPCC_LNK_n[15:0] LINK field is set to FFFFh. Also, see Section 16.2.4.5 *Completion of a DMA Transfer* for details on terminating a transfer.

16.2.4.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA_TPCC, the bit corresponding to the channel is set in the associated event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR). This bit remains set in the associated secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER).
This implies that any future events on the same channel are ignored by the EDMA_TPCC and it is required to clear the bit in EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER for the channel. This is considered an error condition, since events are not expected on a channel that is configured as a null transfer.

16.2.4.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, or EDMA_TPCC_CCNT_n[15:0] CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA_TPCC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR) and the secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes.

16.2.4.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA_TPCC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E*n*) in EDMA_TPCC_EMR to get set and the E*n* bit in EDMA_TPCC_SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 16-61 summarizes the conditions and effects of null and dummy transfer requests.

Table 16-61. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR is set	Yes	No
EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER remains set	Yes	No

Table 16-61. Dummy and Null Transfer Request (continued)

Feature	Null TR	Dummy TR
Link update (STATIC = 0 in EDMA_TPCC_OPT_n)	Yes	Yes
EDMA_TPCC_QER is set	Yes	Yes
EDMA_TPCC_IPR / EDMA_TPCC_IPRH, EDMA_TPCC_CER / EDMA_TPCC_CERH is set using early completion	Yes	Yes

16.2.4.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA_TPCC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of EDMA_TPCC_ABCNT_n[31:16] BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for EDMA_TPCC_ABCNT_n[15:0] ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of EDMA_TPCC_CCNT_n[15:0] CCNT after submission of every transfer request.

Refer to Table 16-62 for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in Section 16.2.4.3.7 *Linking Transfers*.

After the TR is read from the PaRAM (and is in process of being submitted to EDMA_TPTC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.
- AB-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.

Note

PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA_TPTC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 16.2.4.12 *EDMA Transfer Controller (EDMA_TPTC)*. For A-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes (EDMA_TPCC_ABCNT_n[31:16] BCNT = 1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1). For AB-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes of BCNT arrays (EDMA_TPCC_CCNT_n[15:0] CCNT = 1). The EDMA_TPTC is responsible for updating source and destination addresses within the array based on EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_OPT_n[10:8] FWID. For AB-synchronized transfers, the EDMA_TPTC is also responsible to update source and destination addresses between arrays based on EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX.

Table 16-62 shows the details of parameter updates that occur within EDMA_TPCC for A-synchronized and AB-synchronized transfers.

Table 16-62. Parameter Updates in EDMA_TPCC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	**C-Update**	**Link Update**	**B-Update**	**C-Update**	**Link Update**
Condition:	**BCNT > 1**	**BCNT == 1 && CCNT > 1**	**BCNT == 1 && CCNT == 1**	**N/A**	EDMA_TPCC_CCNT_n**[15:0] CCNT > 1**	EDMA_TPCC_CCNT_n**[15:0] CCNT == 1**
SRC	+= SBIDX	+= SCIDX	= Link.EDMA_TPCC_SRC_n	in EDMA_TPTC	+= SCIDX	= Link.EDMA_TPCC_SRC_n
DST	+= DBIDX	+= DCIDX	= Link.EDMA_TPCC_DST_n	in EDMA_TPTC	+= DCIDX	= Link.EDMA_TPCC_DST_n
ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT
BCNT	–= 1	= BCNTRLD	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT	in EDMA_TPTC	N/A	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT
CCNT	None	–= 1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT	in EDMA_TPTC	-=1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT
SBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX	in EDMA_TPTC	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX
DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX

LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0]LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0]LINK
BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD
OPT(1)	None	None	= LINK.EDMA_TPCC_OPT_n	None	None	= LINK.EDMA_TPCC_OPT_n

(1) In all cases, no updates occur if EDMA_TPCC_OPT_n[3] STATIC == 1 for the current PaRAM set.

Note

The EDMA_TPCC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. It should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

16.2.4.3.7 Linking Transfers

The EDMA_TPCC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed that the 16-bit link address field of the current parameter set points to. Linking only occurs when the EDMA_TPCC_OPT_n[3] STATIC bit is cleared.

Note

It should always link a transfer (EDMA or QDMA) to another useful transfer. If it must terminate a transfer, then link the transfer to a NULL parameter set. Refer to Section 16.2.4.3.3 *Null PaRAM Set*.

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the EDMA_TPCC_OPT_n[3] STATIC bit and the EDMA_TPCC_LNK_n[15:0] LINK field. In both cases (null or dummy), if the value of EDMA_TPCC_LNK_n[15:0] LINK is FFFFh, then a null PaRAM set (with all 0s and EDMA_TPCC_LNK_n[15:0] LINK set to FFFFh) is written to the current PaRAM set.
Similarly, if EDMA_TPCC_LNK_n[15:0] LINK is set to a value other than FFFFh, then the appropriate PaRAM location that EDMA_TPCC_LNK_n[15:0] LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA_TPCC reads the entire set (eight words) from the PaRAM set specified by EDMA_TPCC_LNK_n[15:0] LINK and writes all eight words to the PaRAM set that is associated with the current channel. Figure 16-22 shows an example of a linked transfer.

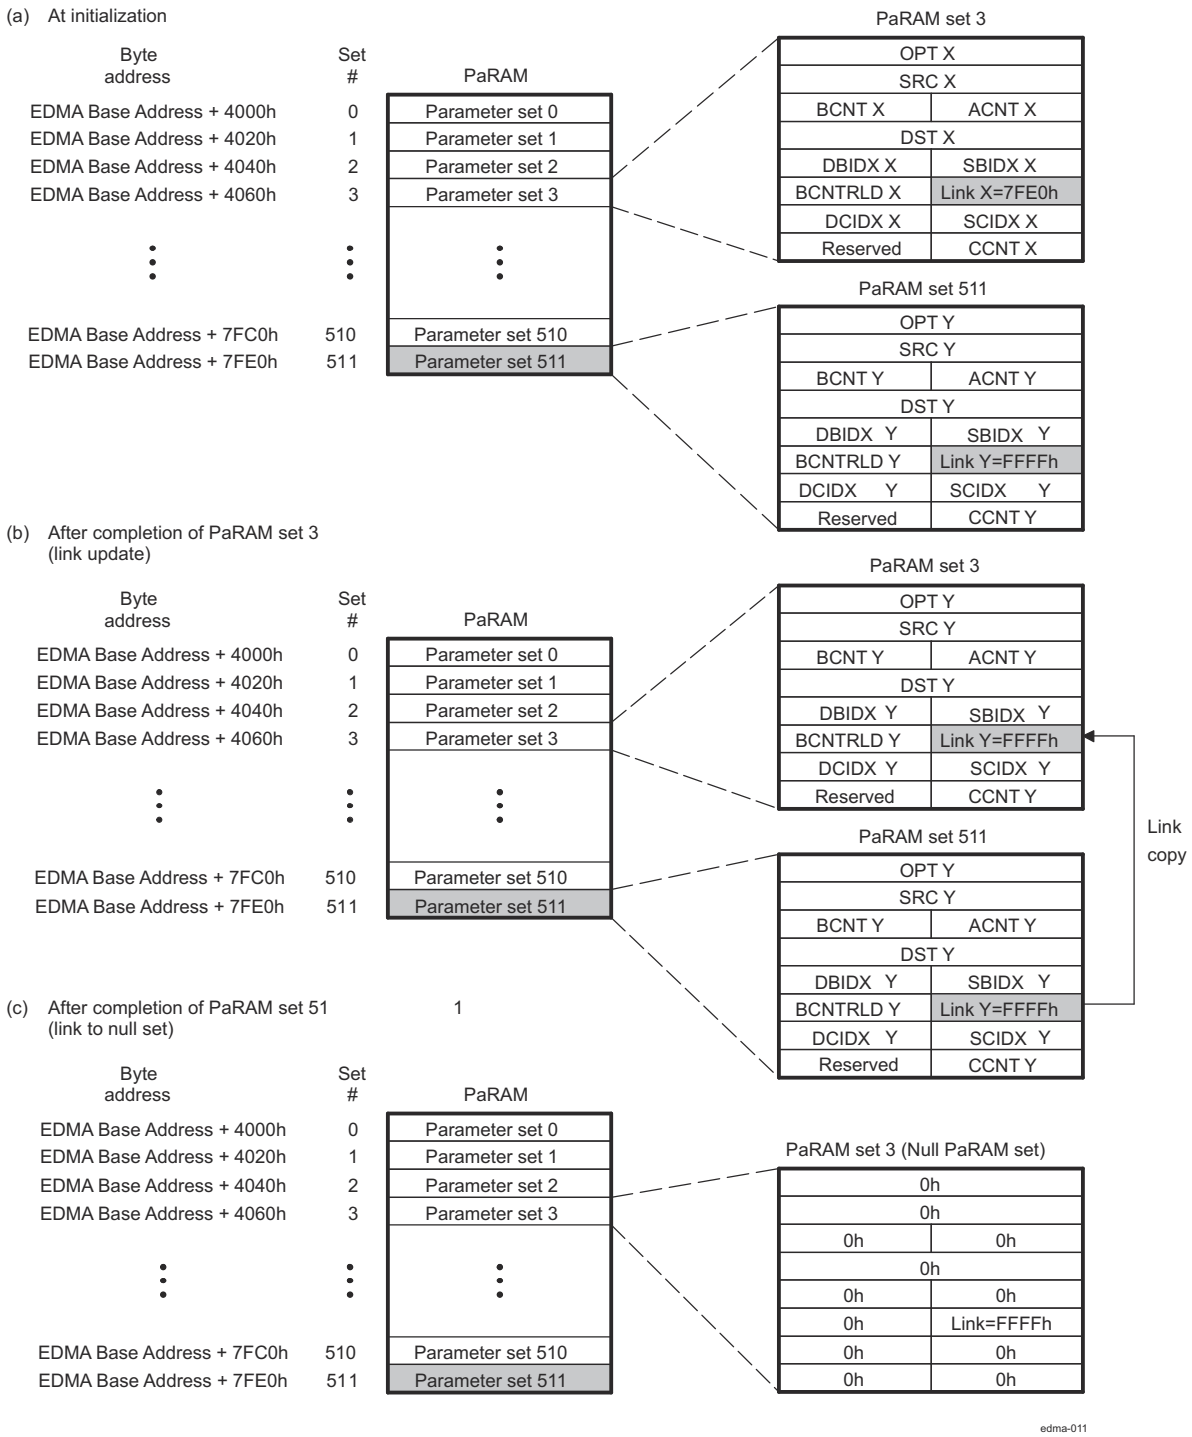

Figure 16-22. Linked Transfer

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (refer to Section 16.2.4.6 *Event, Channel, and PaRAM Mapping*) only use for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by EDMA_TPCC_QCHMAPN_j register), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in EDMA_TPCC_QER because a write to the trigger word was performed. This feature is used

to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. Refer to Section 16.2.4.4.2 *QDMA Channels*.

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 16-23 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

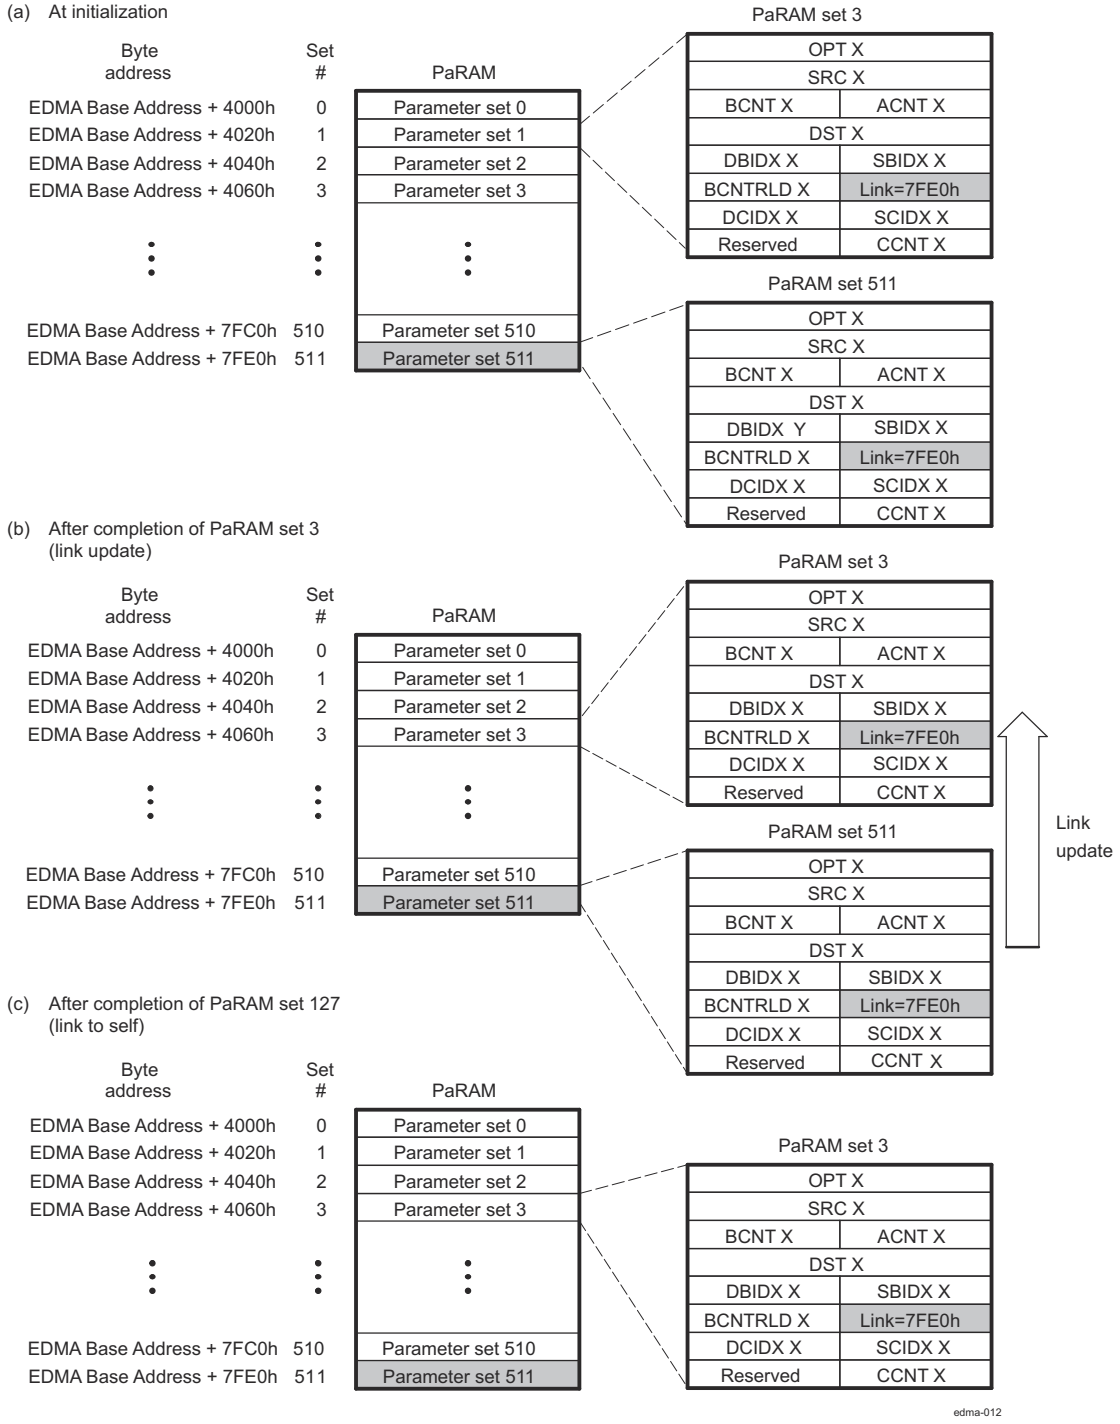

Figure 16-23. Link-to-Self Transfer

Note

If the in EDMA_TPCC_OPT_n[3] STATIC bit is set for a PaRAM set, then link updates are not performed.

16.2.4.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either EDMA_TPCC_OPT_n[0] SAM or EDMA_TPCC_OPT_n[1] DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding EDMA_TPCC_BIDX_n is an even multiple of 32 bytes (256 bits). The EDMA_TPCC does not recognize errors here, but the EDMA_TPTC asserts an error if this is not true. Refer to Section 16.2.4.12.3 *Error Generation*.

Note

The constant addressing (CONST) mode has limited applicability. The EDMA is configured for the constant addressing mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM =0) by appropriately programming the count and indices values.

16.2.4.3.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT. An element-indexed transfer is logically achieved by programming EDMA_TPCC_ABCNT_n[15:0] ACNT to the size of the element and EDMA_TPCC_ABCNT_n[31:16] BCNT to the number of elements that need to be transferred. For example: If there are 16-bit audio data and 256 audio samples that must be transferred to a serial port, therefore the EDMA_TPCC_ABCNT_n[15:0] ACNT = 2 (2 bytes) and EDMA_TPCC_ABCNT_n[31:16] BCNT = 256.

16.2.4.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA_TPCC channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:**The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set registers (EDMA_TPCC_ESR / EDMA_TPCC_ESRH).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

16.2.4.4.1 DMA Channel

16.2.4.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (EDMA_TPCC_ER[31:0] E*n* = 1). For more information about peripheral events to EDMA events mapping, refer to *the device data manual*.
If the corresponding event in the event enable register (EDMA_TPCC_EER) is enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the EDMA_TPCC prioritizes and queues the event in the appropriate

event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA_TPTC and the EDMA_TPCC_ER[31:0] E*n* bit is cleared. At this point, a new event can be safely received by the EDMA_TPCC.

If the PaRAM set associated with the channel is a NULL set (see Section 16.2.4.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register (EDMA_TPCC_EMR[31:0] E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (EDMA_TPCC_ER[31:0] E*n* = 1), regardless of the state of EDMA_TPCC_EER[31:0] E*n*. If the event is disabled when an external event is received (EDMA_TPCC_ER[31:0] E*n* = 1 and EDMA_TPCC_EER[31:0] E*n* = 0), the EDMA_TPCC_ER[31:0] E*n* bit remains set. If the event is subsequently enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the pending event is processed by the EDMA_TPCC and the TR is processed/submitted, after which the EDMA_TPCC_ER[31:0] E*n* bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (EDMA_TPCC_ER[31:0] E*n* != 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EDMA_TPCC_EMR[31:0] E*n* = 1).

16.2.4.4.1.2 Manually-Triggered Transfer Request

The CPU or any peripheral device module initiates a DMA transfer by writing to the event set register EDMA_TPCC_ESR. Writing a 1 to an event bit in the EDMA_TPCC_ESR results in the event being prioritized/ queued in the appropriate event queue, regardless of the state of the EDMA_TPCC_EER[31:0] E*n* bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 16.2.4.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register EDMA_TPCC_ESR[31:0] E*n* = 1 prior to the original being cleared EDMA_TPCC_ESR[31:0] E*n* = 0, then the second event is registered as a missed event in the corresponding bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

16.2.4.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC of the PaRAM set associated with the channel, it results in the corresponding bit in the chained event register EDMA_TPCC_CER to be set EDMA_TPCC_CER[31:0] E[TCC] = 1).

Once a bit is set in EDMA_TPCC_CER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 16.2.4.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_CER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared EDMA_TPCC_CER[31:0] E*n* != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

Note

Chained event registers EDMA_TPCC_CER, event registers EDMA_TPCC_ER, and event set registers EDMA_TPCC_ESR operate independently. An event E*n* can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

16.2.4.4.2 QDMA Channels

16.2.4.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register EDMA_TPCC_QER[31:0] E*n* = 1. A bit corresponding to a QDMA channel is set in the QDMA event register EDMA_TPCC_QER when the following occurs:

- A CPU (or any device module) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register EDMA_TPCC_QCHMAPN_j for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.
- EDMA_TPCC performs a link update on a PaRAM set address that is configured as a QDMA channel matches EDMA_TPCC_QCHMAPN_j settings and the corresponding channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.

Once a bit is set in EDMA_TPCC_QER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If a bit is already set in EDMA_TPCC_QER[31:0] E*n* = 1 and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register EDMA_TPCC_QEMR[7:0] E*n* = 1.

16.2.4.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization.

QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other device modules) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA_TPCC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered).

Note

The CPUs triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register EDMA_TPCC_ESR to kick-off the transfer.

QDMA channels are typically for cases where a single event accomplishes a complete transfer since the CPU (or other device modules) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. QDMA transfers are programmed with EDMA_TPCC_ABCNT_n[31:0] BCNT =1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for A-synchronized transfers, and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if EDMA_TPCC_OPT_n[3] STATIC = 0) for QDMA transfers, it allows to initiate a linked list of QDMAs, so when EDMA_TPCC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel automatically recognizes as a valid QDMA event and initiate another set of transfers as specified by the linked set.

16.2.4.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in Table 16-63 for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (EDMA_TPCC_ABCNT_n[31:0] BCNT and/or EDMA_TPCC_CCNT_n[15:0] CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 16-63. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	EDMA_TPCC_ABCNT_n[31:0] BCNT == 1 && EDMA_TPCC_CCNT_n[15:0] CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

The PaRAM OPT field must program with a specific transfer completion code TCC or EDMA_TPCC_OPT_n[17:12] TCC along with the other EDMA_TPCC_OPT_n fields ([22] TCCHEN, [20] TCINTEN, [23] ITCCHEN, and [21] ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific EDMA_TPCC_OPT_n[17:12] TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register EDMA_TPCC_CER [TCC] and/or interrupt pending register EDMA_TPCC_IPR [TCC] is set.

It can selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[20] TCINTEN, for all but the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[23] ITCCHEN or EDMA_TPCC_OPT_n[21] ITCINTEN), or for all TRs of a parameter set (both). Refer to Section 16.2.4.8 *Chaining EDMA Channels* for details on chaining (intermediate/final chaining) and Section 16.2.4.9 *EDMA Interrupts* for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value must point to another predefined PaRAM set. Alternatively, a non-repetitive transfer must set the link address value to the null link value. The null link value is defined as FFFFh. Refer to Section 16.2.4.3.7 *Linking Transfers* for more details.

Note

Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition must clear before the corresponding channel is used again. Refer to Section 16.2.4.3.5 *Dummy Versus Null Transfer Comparison*.

There are three ways the EDMA_TPCC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

16.2.4.5.1 Normal Completion

In normal completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 0, the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

16.2.4.5.2 Early Completion

In early completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 1, the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

16.2.4.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set Section 16.2.4.3.4 or null set Section 16.2.4.3.3. In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it sets the appropriate bits in the interrupt pending registers EDMA_TPCC_IPR and EDMA_TPCC_IPRH or chained event register EDMA_TPCC_CER and EDMA_TPCC_CERH. The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA_TPCC generates the completion code).

16.2.4.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the dma_evt[4:1] pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_CCNT_n[15:0] CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it. The EDMA event crossbar can be used to select which level events (of which there are more than 64) are mapped to the 64 input events to the EDMA Channel Controller. The default mapping and event crossbar mapping are defined in Section 16.2.3.1, *EDMA Requests to the EDMA Controller*. The event crossbar mapping is controlled by the device Control Modules registers refer to *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

16.2.4.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see Table 16-59). The DMA channel mapping registers EDMA_TPCC_DCHMAPN_m in the EDMA_TPCC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 16-24 illustrates the use of EDMA_TPCC_DCHMAPN_m. There is one EDMA_TPCC_DCHMAPN_m register per channel.

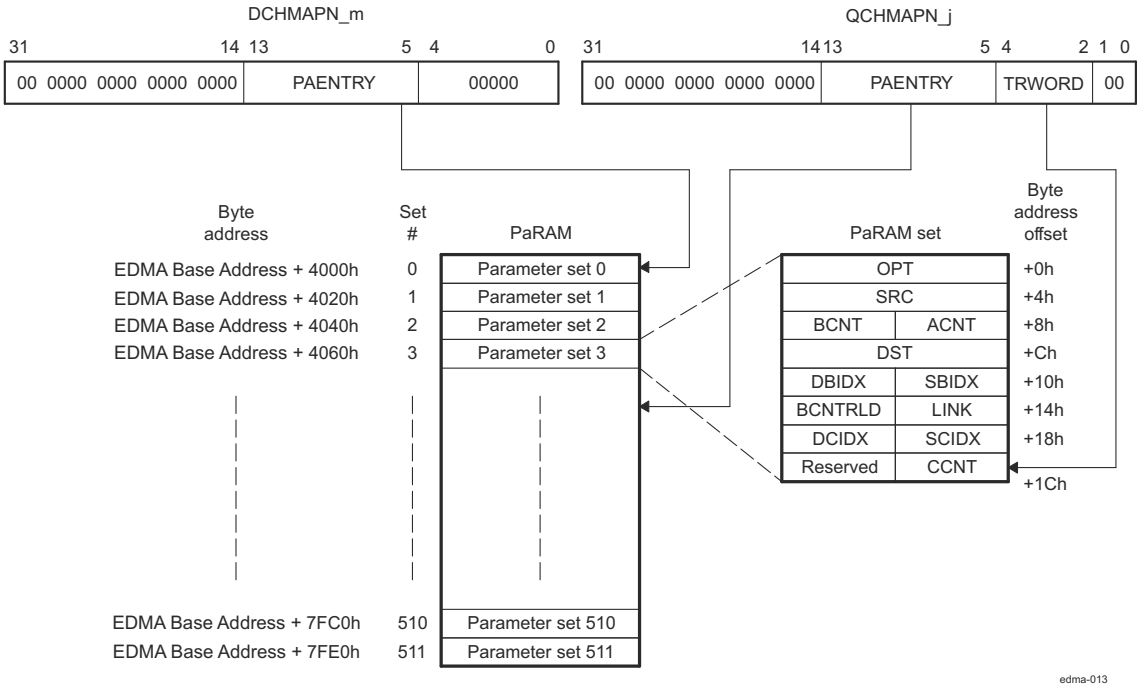

Figure 16-24. DMA Channel and QDMA Channel to PaRAM Mapping

16.2.4.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register EDMA_TPCC_QCHMAPN_j in the EDMA_TPCC allows to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 16-25 illustrates the use of EDMA_TPCC_QCHMAPN_j.

EDMA_TPCC_QCHMAPN_j[4:2] TRWORD bit-field allows to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA_TPCC is a write to the trigger word in the PaRAM set pointed to by EDMA_TPCC_QCHMAPN_j for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0.

It must appropriately re-map PaRAM set 0 before use.

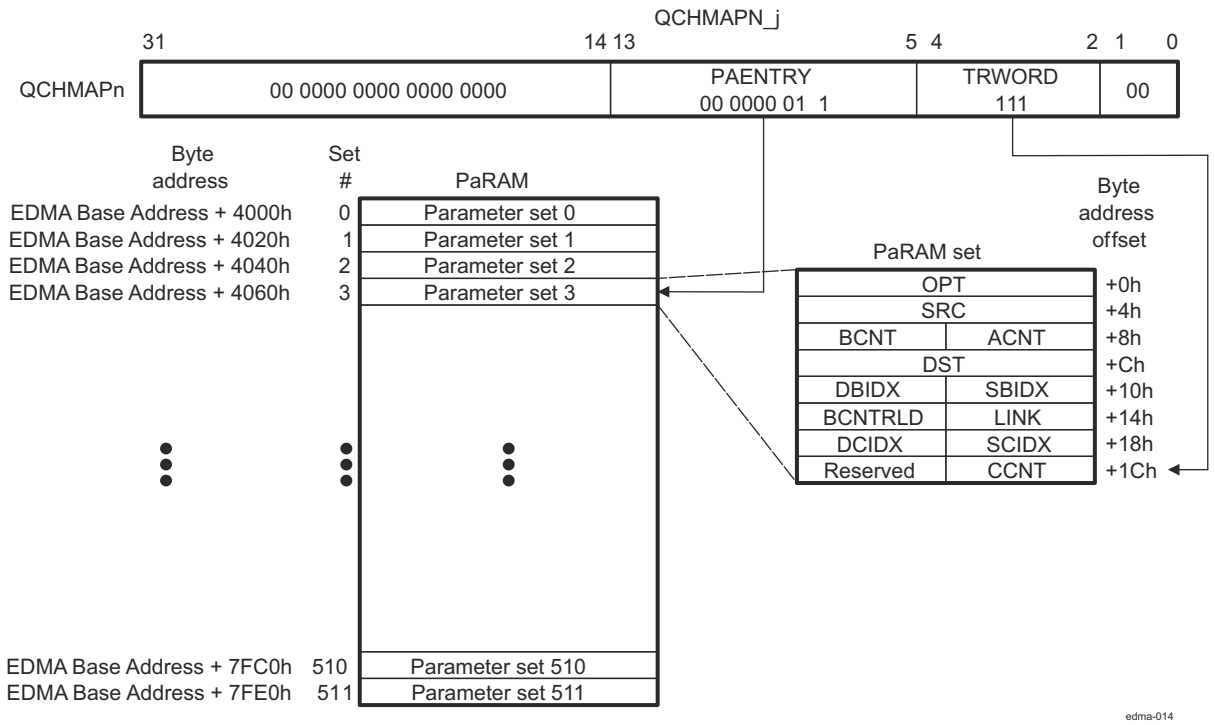

Figure 16-25. QDMA Channel to PaRAM Mapping

16.2.4.7 EDMA Channel Controller Regions

The EDMA channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific device module uses the EDMA controller.

Application software can use regions or to ignore them altogether. It can be used active memory protection in conjunction with regions so that only a specific device module which uses the EDMA (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA initiator only modifies the state of the assigned resources. Memory protection is described in Section 16.2.4.10 *Memory Protection*.

16.2.4.7.1 Region Overview

The EDMA channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA_TPCC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address range(s). For example, the event enable register EDMA_TPCC_EER is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, … EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers EDMA_TPCC_DRAEM_k and the QDMA region access enable registers EDMA_TPCC_QRAEN_k control the underlying control register bits that are accessible via the shadow region address space (except for EDMA_TPCC_IEVAL and EDMA_TPCC_IEVAL_RN_k registers). Table 16-64

lists the registers in the shadow region memory map. Refer to EDMA_TPCC register summary Table 16-80 for the complete global and shadow region memory maps.

Table 16-64. Shadow Region Registers

EDMA_TPCC_DRAEM_k	EDMA_TPCC_DRAEHM_k	EDMA_TPCC_QRAEN_k

Figure 16-26 illustrates the conceptual view of the regions.

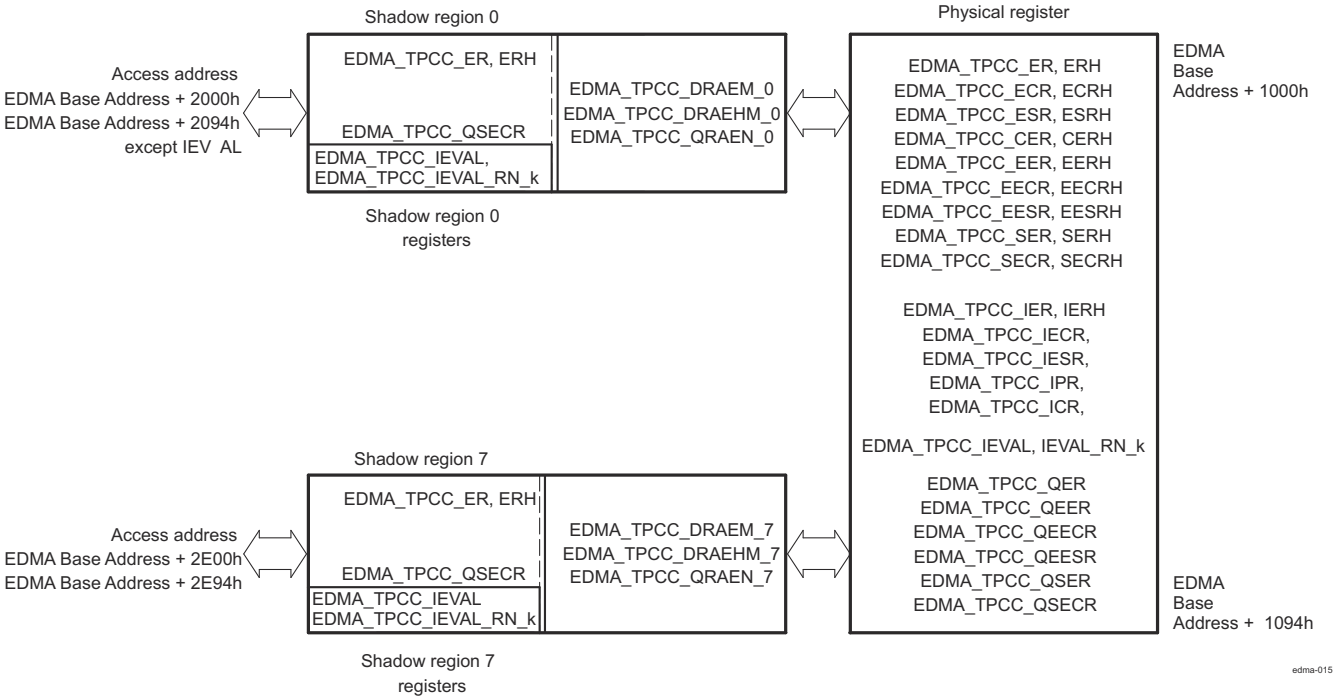

Figure 16-26. Shadow Region Registers

16.2.4.7.2 Channel Controller Regions

There are eight EDMA shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- EDMA_TPCC_DRAEM_k and EDMA_TPCC_DRAEHM_k: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or EDMA_TPCC_OPT_n[17:12] TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAEM/DRAEHM pair. A value of 1 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit implies that the corresponding DMA interrupt channel is accessible; a value of 0 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit forces writes to be discarded and returns a value of 0 for reads.
- EDMA_TPCC_QRAEN_k: One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 EDMA_TPCC_QEER, the corresponding bits in QRAE must be set or writing into EDMA_TPCC_QEESR there will be no the desired effect.
- EDMA_TPCC_MPPAN_k and EDMA_TPCC_MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k registers.

If exclusive access to any given channel / TCC code is required for a region, then only that region's EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k have the associated bit set.

Example 16-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63).

Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47).

EDMA_TPCC_DRAEM_k should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEHM, DRAEM = 0xFFFF0000, 0x0000FFFF QRAEN = 0x0000001
Region 1: DRAEHM, DRAEM = 0x0000FFFF, 0xFFFF0000 QRAEN = 0x00000FE
```

16.2.4.7.3 Region Interrupts

In addition to the EDMA_TPCC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register EDMA_TPCC_IER, DRAEM acts as a secondary interrupt enable for the respective shadow region interrupts. Refer to Table 16-57 *Hardware Request* for more information about EDMA Interrupts.

16.2.4.8 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the ability to chain several events through one event occurrence.

Chaining is different from linking (Section 16.2.4.3.7 *Linking Transfers*). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set. It provides a synchronization event to the chained channel (see Section 16.2.4.4.1.3 *Chain-Triggered Transfer Request*).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* (0-63) needs to be programmed into the EDMA_TPCC_OPT_n[17:12] TCC bit-field of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining EDMA_TPCC_OPT_n[22] TCCHEN = 1 is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If intermediate transfer completion chaining EDMA_TPCC_OPT_n[23] ITCCHEN = 1 is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (EDMA_TPCC_OPT_n[22] TCCHEN = 1 and EDMA_TPCC_OPT_n[23] ITCCHEN = 1) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 16-65 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with EDMA_TPCC_ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0] CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 16-65. Chain Event Triggers

	(Number of chained event triggers on channel 30)	
Options	**A-Synchronized**	**AB-Synchronized**
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 0, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)

Table 16-65. Chain Event Triggers (continued)

	(Number of chained event triggers on channel 30)	
Options	**A-Synchronized**	**AB-Synchronized**
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

16.2.4.9 EDMA Interrupts

The EDMA interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 16-66. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the device interrupt controllers INTCs through the inputs of the IRQ_CROSSBAR module.

Table 16-66. EDMA Transfer Completion Interrupts

Name	Description
EDMA_TPCC_INT0	EDMA_TPCC Transfer Completion Interrupt Shadow Region 0
EDMA_TPCC_INT1	EDMA_TPCC Transfer Completion Interrupt Shadow Region 1
EDMA_TPCC_INT2	EDMA_TPCC Transfer Completion Interrupt Shadow Region 2
EDMA_TPCC_INT3	EDMA_TPCC Transfer Completion Interrupt Shadow Region 3
EDMA_TPCC_INT4	EDMA_TPCC Transfer Completion Interrupt Shadow Region 4
EDMA_TPCC_INT5	EDMA_TPCC Transfer Completion Interrupt Shadow Region 5
EDMA_TPCC_INT6	EDMA_TPCC Transfer Completion Interrupt Shadow Region 6
EDMA_TPCC_INT7	EDMA_TPCC Transfer Completion Interrupt Shadow Region 7

Table 16-67. EDMA Error Interrupts

Name	Description
EDMA_TPCC_ERRINT	EDMA_TPCC Error Interrupt
EDMA_TPCC_MPINT	EDMA_TPCC Memory Protection Interrupt
EDMA_TC0_ERRINT	TC0 Error Interrupt
EDMA_TC1_ERRINT	TC1 Error Interrupt

16.2.4.9.1 Transfer Completion Interrupts

The EDMA_TPCC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA masters). The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA interrupt generation.

The software architecture must either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value is directly mapped to the bits of the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

For example, if EDMA_TPCC_OPT_n[17:12] TCC = 10 0001b, EDMA_TPCC_IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See Section 16.2.4.9.1.1 *Enabling Transfer Completion Interrupts* for details about enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH registers is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 16-68. Transfer Complete Code (TCC) to EDMA_TPCC Interrupt Mapping

TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPR Bit Set	TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPRH Bit Set(1)
0	EDMA_TPCC_IPR[0]	20h	EDMA_TPCC_IPR[32] / EDMA_TPCC_IPRH[0]
1	EDMA_TPCC_IPR[1]	21h	EDMA_TPCC_IPR[33] / EDMA_TPCC_IPRH[1]
2h	EDMA_TPCC_IPR[2]	22h	EDMA_TPCC_IPR[34] / EDMA_TPCC_IPRH[2]
3h	EDMA_TPCC_IPR[3]	23h	EDMA_TPCC_IPR[35] / EDMA_TPCC_IPRH[3]
4h	EDMA_TPCC_IPR[4]	24h	EDMA_TPCC_IPR[36] / EDMA_TPCC_IPRH[4]
...	...	...	...
1Eh	EDMA_TPCC_IPR[30]	3Eh	EDMA_TPCC_IPR[62] / EDMA_TPCC_IPRH[30]
1Fh	EDMA_TPCC_IPR[31]	3Fh	EDMA_TPCC_IPR[63] / EDMA_TPCC_IPRH[31]

(1) Bit fields EDMA_TPCC_IPR [32-63] correspond to bits 0 to 31 in EDMA_TPCC_IPRH, respectively.

The transfer completion code (TCC) can program to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and it intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in EDMA_TPCC_IER / EDMA_TPCC_IERH and in the corresponding shadow region's DMA region access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k).

Interrupt generation can be enabled at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (EDMA_TPCC_OPT_n[20] TCINTEN = 1) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (EDMA_TPCC_OPT_n[21] ITCINTEN = 1) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (EDMA_TPCC_OPT_n[20] TCINTEN = 1, and EDMA_TPCC_OPT_n[21] ITCINTEN = 1) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 16-69 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0]CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 16-69. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 0	1 (Last TR)	1 (Last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 0, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)

Table 16-69. Number of Interrupts (continued)

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	20 (All TRs)	5 (All TRs)

16.2.4.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA_TPCC. This is in addition to setting up the EDMA_TPCC_OPT_n[20] TCINTEN and EDMA_TPCC_OPT_n[21] ITCINTEN bits of the associated PaRAM set.

The EDMA channel controller has interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH and each bit location in EDMA_TPCC_IER / EDMA_TPCC_IERH serves as a primary enable for the corresponding interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

All of the interrupt registers (EDMA_TPCC_IER, EDMA_TPCC_IESR, EDMA_TPCC_IECR, and EDMA_TPCC_IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH and single set of interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH. The programmable DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by EDMA_TPCC_IER / EDMA_TPCC_IERH, see Figure 16-27

The region interrupt outputs are gated by EDMA_TPCC_IER and the specific EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k associated with the region.

Figure 16-27 shows the Interrupt diagram of the EDMA controller.

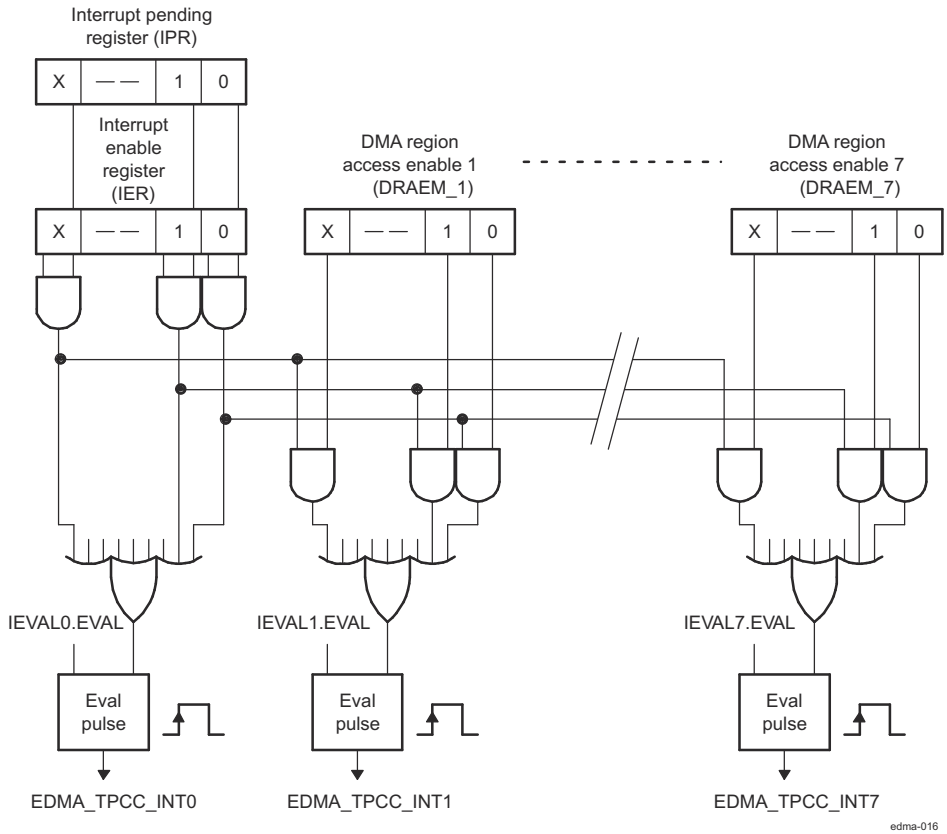

Figure 16-27. Interrupt Diagram

The EDMA_TPCC generates the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA_TPCC_INT0: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_0[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_0[31] E63)
- EDMA_TPCC_INT1: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_1[1] E1) | …| (EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_1[31] E63)
- EDMA_TPCC_INT2: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_2[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_2[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_2[31] E63)....
- Up to EDMA_TPCC_INT7: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_7[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_7[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_7[31] E63)

Note

The EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers are used for dynamic enable/disable of individual interrupts.

Because there is no relation between the EDMA_TPCC_OPT_n[17:12] TCC value and the DMA/QDMA channel, it is possible, the DMA channel 0 to have the EDMA_TPCC_OPT_n[17:12] TCC = 63 in its associated PaRAM set. This mean that if a transfer completion interrupt is enabled (EDMA_TPCC_OPT_n[20] TCINTEN or EDMA_TPCC_OPT_n[21] ITCINTEN is set), then based on the TCC value, EDMA_TPCC_IPRH[31] E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map - program the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to EDMA_TPCC_IPRH bit that is set upon completion).

16.2.4.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (EDMA_TPCC_ICR / EDMA_TPCC_ICRH). For example, a write of 1 to EDMA_TPCC_ICR[0] E0 clears a pending interrupt in EDMA_TPCC_IPR[0] E0.

If an incoming transfer completion code TCC (EDMA_TPCC_OPT_n[17:12] TCC) gets latched to a bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, then additional bits that get set due to a subsequent transfer completion does not result in asserting the EDMA_TPCC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

16.2.4.9.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in EDMA_TPCC_IPR/ EDMA_TPCC_IPRH, thereby enabling recognition of future interrupts. The EDMA_TPCC only asserts additional completion interrupts when all EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, thereby resulting in additional interrupts. Each of the bits in EDMA_TPCC_IPR / EDMA_TPCC_IPRH may need different types of service therefore, the ISR must check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA_TPCC completion interrupt are shown in Example 16-2 and Example 16-3.

The ISR routine in Example 16-2 is more exhaustive and incurs a higher latency.

Example 16-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
2. Performs the operations needed.
3. Writes to the interrupt pending clear register EDMA_TPCC_ICR / EDMA_TPCC_ICRH to clear the corresponding EDMA_TPCC_IPR / EDMA_TPCC_IPRH bit(s).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH again:

a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, assure that all of the enabled interrupts are inactive.

Note

An event may occur during step 4 while the EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

16.2.4.9.3

Example 16-3 is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 16-3. Interrupt Servicing

If any enabled and pending (possibly lower priority) interrupts are left, force the interrupt logic to reassert the interrupt pulse by setting the EDMA_TPCC_IEVAL[0] EVAL bit in the interrupt evaluation register.

The pseudo code is as follows:

1. Enters ISR.
2. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
3. For the condition that is set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH:
   a. Service interrupt as the application requires.
   b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA_TPCC after step 2).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH prior to exiting the ISR:
   a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, then exit the ISR.
   b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, then set EDMA_TPCC_IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

16.2.4.9.4 Interrupt Evaluation Operations

The EDMA_TPCC has interrupt evaluate registers EDMA_TPCC_IEVAL that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k. Writing a 1 to the EDMA_TPCC_IEVAL[0] EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via EDMA_TPCC_IER / EDMA_TPCC_IERH) is still pending EDMA_TPCC_IPR / EDMA_TPCC_IPRH. This register assures that the CPU does not miss the interrupts (or the EDMA master associated with the shadow region) if the software architecture chooses not to use all interrupts. Refer to Example 16-3 about the use of EDMA_TPCC_IEVAL in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register EDMA_TPCC_EEVAL exists in the global region. Writing a 1 to the EDMA_TPCC_EEVAL[0] EVAL bit causes the pulsing of the error interrupt if any pending errors are in EDMA_TPCC_EMR / EDMA_TPCC_EMRH, EDMA_TPCC_QEMR, or EDMA_TPCC_CCERR. See Section 16.2.4.9.5 *Error Interrupts* for additional information regarding error interrupts.

Note

While using EDMA_TPCC_IEVAL for shadow region completion interrupts, check that the EDMA_TPCC_IEVAL operated upon is from that particular shadow region memory map.

16.2.4.9.5 Error Interrupts

The EDMA_TPCC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA_TPCC error interrupt. If the EDMA_TPCC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA_TPCC has a single error interrupt (EDMA_TPCC_ERRINT) that is asserted for all EDMA_TPCC error conditions. There are four conditions that cause the error interrupt:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers EDMA_TPCC_EMR / EDMA_TPCC_EMRH.
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register EDMA_TPCC_QEMR.
- Threshold exceed: for all event queues. These are latched in EDMA_TPCC error register EDMA_TPCC_CCERR.
- TCC error: for outstanding transfer requests that are expected to return completion code EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[23] TCINTEN bit is set to 1, exceeding the maximum limit of 63. This is also latched in the EDMA_TPCC error register EDMA_TPCC_CCERR.

Figure 16-28 illustrates the EDMA_TPCC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA_TPCC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA_TPCC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA_TPCC does not generate additional interrupt.

To reduce the burden on the software, there is an error evaluate register EDMA_TPCC_EEVAL that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register EDMA_TPCC_IEVAL. Unlike the EDMA_TPCC_IEVAL functionality, the EDMA_TPCC_EEVAL register must be written with ‘1’ after any error interrupts are serviced (even when all pending errors are cleared) in order for subsequent errors to trigger a new interrupt.

Note

It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status), it provides a good debug mechanism for unexpected error conditions.

16.2.4.9.6

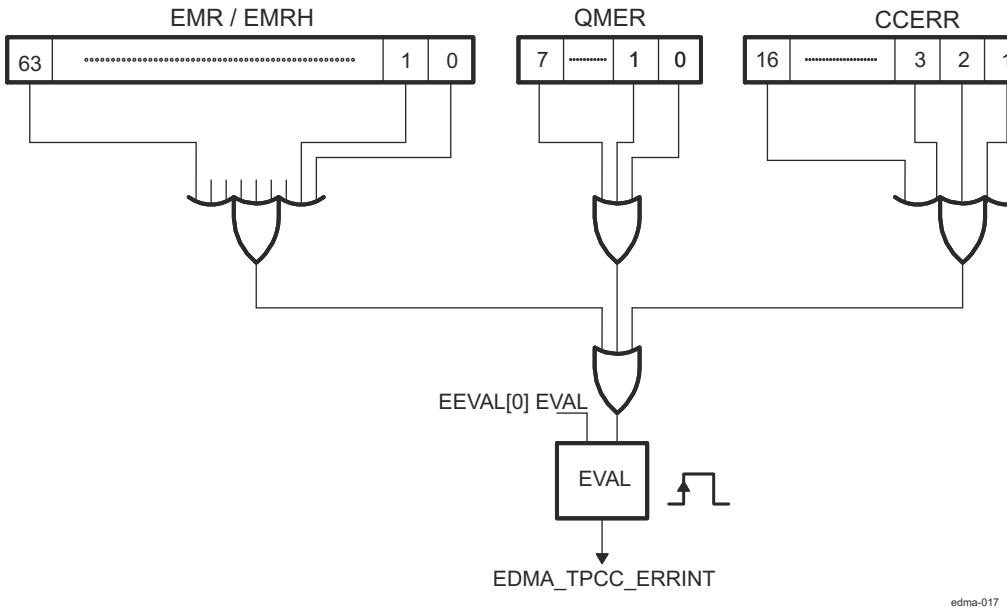

Figure 16-28. Error Interrupt Operation

16.2.4.10 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

16.2.4.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses to the EDMA_TPCC registers. Active memory protection is achieved by a set of memory protection permissions attribute EDMA_TPCC_MPPAN_k registers.

The EDMA_TPCC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to Table 16-80 *EDMA_TPCC Registers Mapping Summary*.

Each of the eight shadow regions has an associated EDMA_TPCC_MPPAN_k registers that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register EDMA_TPCC_MPPAG. The EDMA_TPCC_MPPAG applies to the global region and to the global channel region, except the other EDMA_TPCC_MPPAN_k registers themselves.

Table 16-70 shows the accesses that are allowed or not allowed to the EDMA_TPCC_MPPAG and EDMA_TPCC_MPPAN_k. The active memory protection uses the EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID attributes of the EDMA peripheral modules. TheEDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor).

The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an EDMA peripheral modules.

Table 16-70. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

Table 16-71 describes the EDMA_TPCC_MPPAN_k register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based EDMA_TPCC_MPPAN_k registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight EDMA_TPCC_MPPAN_k region registers (MPPA[0-7]).

Table 16-71. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect(1)	Address Range
EDMA_TPCC_MPPAG	Global Range	0000h-1FFCh	N/A	N/A
EDMA_TPCC_MPPAN_k. MPPAN_0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPAN_1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPAN_2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPAN_3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPAN_4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPAN_5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPAN_6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh

Table 16-71. MPPA Registers to Region Assignment (continued)

Register	Registers Protect	Address Range	PaRAM Protect(1)	Address Range
MPPAN_7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

(1) The PARAM region is divided into 8 regions referred to as an octant.

Example *Access denied.*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[7] NS is set to prevent user level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 0), but it allows supervisor level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

Note

The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EDMA_TPCC_EER is not written too.

Table 16-72. Example Access Denied

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EDMA_TPCC_EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EDMA_TPCC_EESR. This is done by an EDMA connected device module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k (offset 0x082C)	0x0000 04B0	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID0 = 1, EDMA_TPCC_MPPAN_k[1] UW = 0, EDMA_TPCC_MPPAN_k[2] UR = 0, EDMA_TPCC_MPPAN_k[4] SW = 1, EDMA_TPCC_MPPAN_k[5] SR = 1.
	X	Access Denied
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Final value of EDMA_TPCC_EER

Example *Access Allowed*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7 is set to allow user-level accesses (EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1) and supervisor-level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

Note

The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1 and EDMA_TPCC_MPPAN_k. MPPAN_7[10] AID0 = 1, the user-level write access is allowed.
5. The accesse to shadow region registers are masked by their respective EDMA_TPCC_DRAEM_k register. In this example, the EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 is set of 0x9FF00FC2.
6. The value finally written to EDMA_TPCC_EER is 0x8BC00102.

Table 16-73. Example Access Allowed

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7 (offset 0x082C)	0x0000 04B3	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1.
	√ ↓	Access allowed.
EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 (offset 0x0378)	0x9FF0 0FC2 ↓	DMA Region Access Enable Filter
EDMA_TPCC_EESR (offset 0x2E30)	0x8BC0 0102 ↓	Value written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and a Privilege ID of 0.
EDMA_TPCC_EER (offset 0x1020)	↓ 0xBC0 0102	Final value of EER.

16.2.4.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given peripheral module connected to EDMA, to have its permissions travel with the transfer through the EDMA_TPTC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The EDMA_TPCC_OPT_n[31] PRIV bit and EDMA_TPCC_OPT_n[27:24] PRIVID bit is set with the peripheral module's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The EDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor). The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an peripheral module connected to EDMA.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The EDMA_TPCC_OPT_n[31] PRIV is 0 for user-level and the CPU has a EDMA_TPCC_OPT_n[27:24] PRIVID to 0.

The PaRAM set is shown in Figure 16-29.

Figure 16-29. PaRAM Set Content for Proxy Memory Protection Example

(a) EDMA Parameters

Parameter Contents			Parameter	
0010 0007h			Channel Options Parameter (OPT)	
009F 0000h			Channel Source Address (SRC)	
0001h	0004h		Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h			Channel Destination Address (DST)	
0001h	0001h		Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh		BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h		Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h		Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT_n) Content

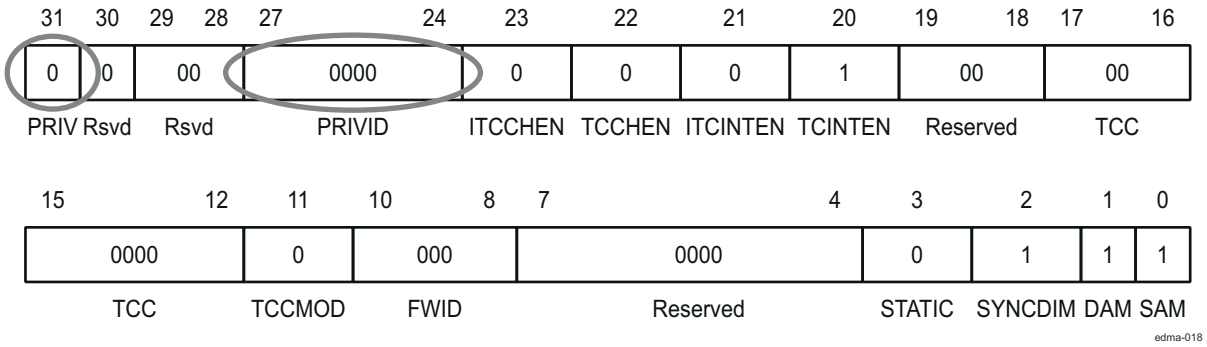

Figure 16-30. Channel Options Parameter (OPT) Example

The EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses EDMA_TPCC_MPPAN_k[4] SW and EDMA_TPCC_MPPAN_k[5] SR, the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (EDMA_TPCC_MPPAN_k[4] SW, EDMA_TPCC_MPPAN_k[5] SR), the user-level write request above is refused. For the transfer to succeed, the source and destination pages must have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID = 0.

Because the privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

Figure 16-31 illustrates the propagation of EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID at the boundaries of all the interacting entities (CPU, EDMA_TPCC, EDMA_TPTCs, and slave memories).

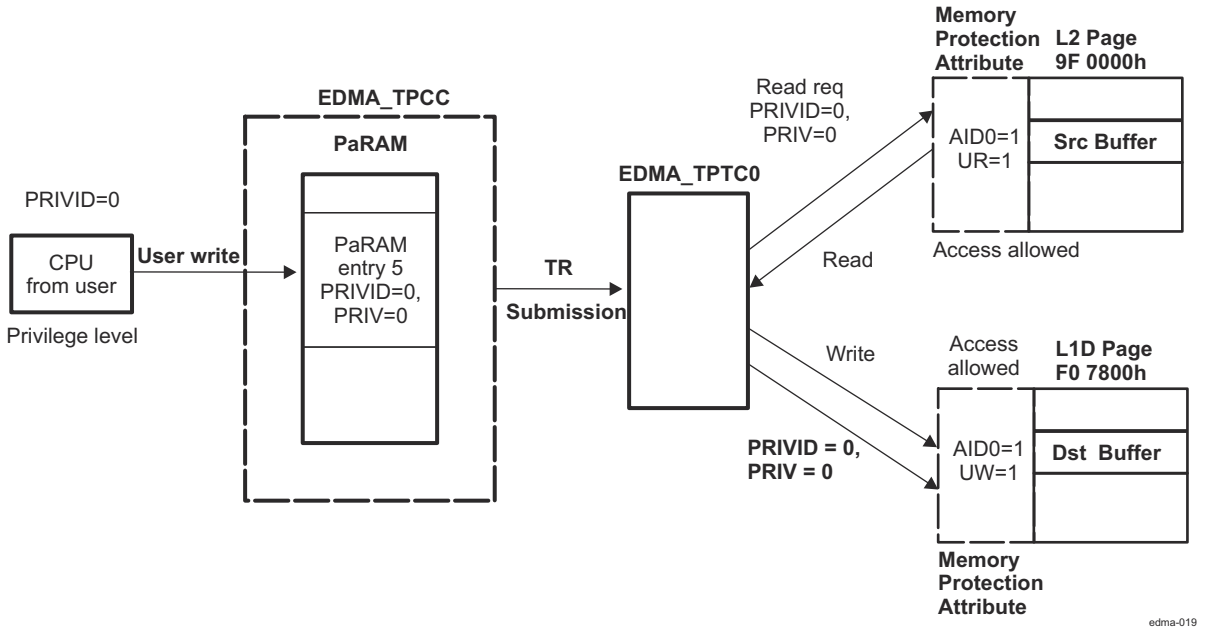

Figure 16-31. Proxy Memory Protection Example

16.2.4.11 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMA_TPCC and the transfer request (TR) submission logic of the EDMA_TPCC. Each queue is 16 entries deep. Each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Queue0, Queue1. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. The transfer requests that are associated with events in Queue1 are submitted to TC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

Queue0 has highest priority and Queue1 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

Refer to Section 16.2.4.11.4 for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers EDMA_TPCC_Q0E_p and EDMA_TPCC_Q1E_p. Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. Refer to Section 16.2.7.2.2.1 *EDMA_TPCC Register Description* for Q0E_p / Q1E_p descriptions of the bit fields.

16.2.4.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register EDMA_TPCC_DMAQNUMN_k and the QDMA queue number register EDMA_TPCC_QDMAQNUM. The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. Refer to Section 16.2.4.11.4 *System-level Performance Considerations*.

Note

If an event is ready to be queued and both the event queue and the EDMA transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA_TPTC. In this case, the event is not logged in the event queue status registers.

16.2.4.11.2 Queue RAM Debug Visibility

There are two event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO. There is a queue status register EDMA_TPCC_QSTATN_i associated with each queue. These along with all of the 16 entries per queue can be read via registers EDMA_TPCC_QSTATN_i and Q0E_p / Q1E_p, respectively.

These registers provide user visibility.

The event queue entry register (Q*x*E*y* Q0E_p / Q1E_p) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA_TPCC memory-mapped register. To see the history of the last 16 TRs that have been processed by the EDMA on a given queue, read the event queue registers. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT*n* EDMA_TPCC_QSTATN_i) includes fields for the start pointer EDMA_TPCC_QSTATN_i[3:0] STRTPTR which provides the offset to the head entry of an event. It also includes a field called EDMA_TPCC_QSTATN_i[12:8] NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The EDMA_TPCC_QSTATN_i[3:0] STRTPTR is used to index appropriately into the 16 event entries. EDMA_TPCC_QSTATN_i[12:8] NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry must be read to determine what's already de-queued and submitted to the associated transfer controller.

16.2.4.11.3 Queue Resource Tracking

The EDMA_TPCC event queue includes watermarking/threshold logic that allows to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The maximum number of events are programed that the queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register EDMA_TPCC_QWMTHRA. The maximum queue usage is recorded actively in the watermark EDMA_TPCC_QSTATN_i[20:16] WM field of the queue status register, that keeps getting updated based on a comparison of number of valid entries, which is also visible in the EDMA_TPCC_QSTATN_i[12:8] NUMVAL bit and the maximum number of entries.

If the queue usage is exceeded, this status is visible in the EDMA_TPCC registers: the QTHRXCD*n* bits in the channel controller error register EDMA_TPCC_CCERR[7:0] and the EDMA_TPCC_QSTATN_i[24] THRXCD bit, where *n* stands for the event queue number. Any bits that are set in EDMA_TPCC_CCERR also generate an EDMA_TPCC error interrupt.

16.2.4.11.4 Performance Considerations

The main system bus infrastructure (L3) arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other masters within the device IRQ_CROSSBAR are programmed using the Control Module registers. The EDMA_TPCC_QUEPRI register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA_TPTC (dictated by the priority set using the Control Module registers, refer to *Control Module Register Manual* in *Control Module* chapter).

16.2.4.12 EDMA Transfer Controller (EDMA_TPTC)

The EDMA channel controller is the user-interface of the EDMA and the EDMA transfer controller (EDMA_TPTC) is the data movement engine of the EDMA controller. The EDMA_TPCC submits transfer requests (TR) to the EDMA_TPTC and the EDMA_TPTC performs the data transfers dictated by the TR, so the EDMA_TPTC is a slave to the EDMA_TPCC.

16.2.4.12.1 Architecture Details

16.2.4.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in Section 16.2.4.12.5 *EDMA_TPTC Configuration*.

The EDMA_TPTC attempts to issue the largest possible command size as limited by the DBS value or the EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_ABCNT_n[31:16] BCNT value of the TR. EDMA_TPTC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

Table 16-74 lists the TR segmentation rules that are followed by the EDMA_TPTC. In summary, if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is larger than the DBS value, then the EDMA_TPTC breaks the

EDMA_TPCC_ABCNT_n[15:0] ACNT array into DBS-sized commands to the source/destination addresses. Each EDMA_TPCC_ABCNT_n[31:16] BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA_TPTC recognizes that the 2D-transfer is organized as a single dimension (EDMA_TPCC_ABCNT_n[15:0] ACNT == EDMA_TPCC_BIDX_n) and the ACNT value is a power of 2.

Table 16-74 lists conditions in which the optimizations are performed.

Table 16-74. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

16.2.4.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 16-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. EDMA_TPTCn_PCNT[15:0] ACNT = 8, EDMA_TPTCn_PCNT[31:16] BCNT = 8, EDMA_TPTCn_PBIDX[15:0] SBIDX = 8, EDMA_TPTCn_PBIDX[31:16] DBIDX = 10, EDMA_TPTCn_PSRC[31:0] SADDR = 64, EDMA_TPTCn_SADST[31:0] DADDR = 191

   Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to EDMA_TPTCn_PCNT[15:0] ACNT = 64, EDMA_TPTCn_PCNT[31:16] BCNT = 1.

   Cmd0 = 64 byte

   Write Controller: Because DBIDX != ACNT, it is not optimized.

   Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.
2. EDMA_TPTCn_PCNT[15:0] ACNT=128, EDMA_TPTCn_PCNT[31:16] BCNT = 1, EDMA_TPTCn_PSRC[31:0] SADDR = 63, EDMA_TPTCn_SADST[31:0] DADDR = 513

   Read Controller: Read address is not aligned.

   Cmd0 = 1 byte, (now the SADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 63 bytes

   Write Controller: The write address is also not aligned.

   Cmd0 = 63 bytes, (now the DADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 1 byte

16.2.4.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA_TPTC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA_TPTC is controlled by the EDMA_TPTCn_RDRATE register. The EDMA_TPTCn_RDRATE register defines the number of cycles that the EDMA_TPTC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA_TPTC consuming all available slave resources. The EDMA_TPTCn_RDRATE[2:0] RDRATE value must be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

16.2.4.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA_TPTC and used by the EDMA_TPTC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

16.2.4.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA_TPTC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.
- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is generated.

16.2.4.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA_TPTC status register EDMA_TPTCn_TCSTAT has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The EDMA_TPTCn_TCSTAT[1] SRCACTV bit indicates whether the source active set is active.
- The EDMA_TPTCn_TCSTAT[6:4] DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The EDMA_TPTCn_TCSTAT[0] PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

Note

If the TRs are in progression, it must realize that there is a chance that the values read from the EDMA_TPTC status registers will be inconsistent since the EDMA_TPTC changes the values of these registers due to ongoing activities.

It is recommended that to ensure no additional submission of TRs to the EDMA_TPTC in order to facilitate ease of debug.

16.2.4.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA_TPTC maintains two important status details in EDMA_TPTCn_TCSTAT that are used during advanced debugging, if necessary. The EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR is a start pointer, the index to the head of the destination FIFO register. The EDMA_TPTCn_TCSTAT[6:4] DSTACTV is a counter for the number of valid (occupied) entries. These registers are used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x0 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x0 implies that no TRs are stored in the destination FIFO register.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x1 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x3 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

16.2.4.12.5 EDMA_TPTC Configuration

Table 16-75 provides the configuration of the individual EDMA transfer controllers present on the device. The DBS for each transfer controller is defined by Control Module register (CTRL_CORE_CONTROL_IO_1) settings.

Table 16-75. EDMA Transfer Controller Configurations

Name	TC0	TC1
EDMA_TPTCn_TCCFG[2:0] FIFOSIZE	1024 bytes	1024 bytes

Table 16-75. EDMA Transfer Controller Configurations (continued)

Name	TC0	TC1
EDMA_TPTCn_TCCFG[5:4] BUSWIDTH	16 bytes	16 bytes
EDMA_TPTCn_TCCFG[9:8] DSTREGDEPTH	4 entries	4 entries
DBS	Defined by CTRL_CORE_CONTROL_IO_1[9:8] TC0_DEFAULT_BURST_SIZE	Defined by CTRL_CORE_CONTROL_IO_1[13:12] TC1_DEFAULT_BURST_SIZE

16.2.4.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA_TPCC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the EDMA_TPCC_ER[31:0]E*n* / EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0] E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[7:0] E*n*) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the EDMA_TPCC_SER[31:0] E*n* \ EDMA_TPCC_SERH[31:0] E*n* (or EDMA_TPCC_QSER[7:0] E*n*) bit is set to inform the event prioritization / processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA_TPCC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA_TPCC clears the EDMA_TPCC_ER[31:0] E*n*/ EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0]E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[31:0] E*n*) bit and the EDMA_TPCC_SER[31:0] E*n* / EDMA_TPCC_SERH[31:0] E*n* bit as soon as it determines the TR is non-null. In the case of a null set, the EDMA_TPCC_SER[31:0] E*n* / EDMA_TPCC_SERH[31:0] E*n* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA_TPCC immediately sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC] - 32).
5. If the TR was programmed for normal completion, the EDMA_TPCC sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC]) when the EDMA_TPTC informs the EDMA_TPCC about completion of the transfer (returns transfer completion codes).
6. The EDMA_TPCC programs the associated EDMA_TPTC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA_TPTC*n*.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA_TPTC*n* then signals completion status to the EDMA_TPCC.

16.2.4.14 EDMA controller Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 16-32 shows the different places EDMA priorities come into play.

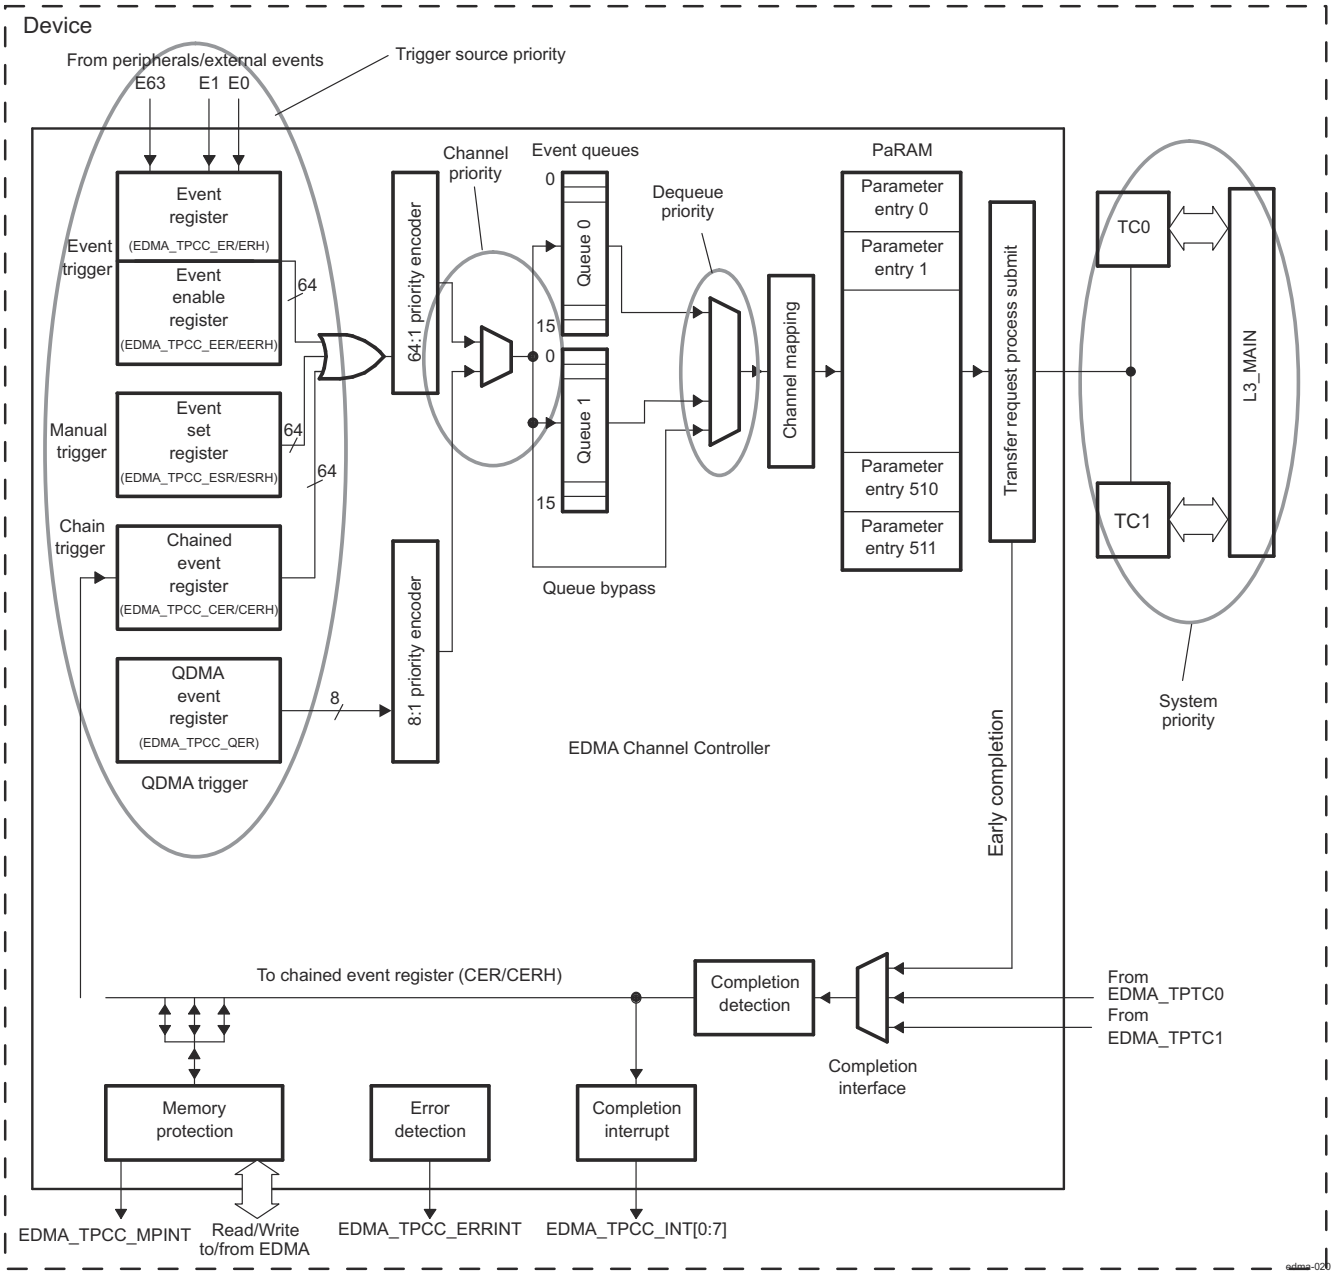

Figure 16-32. EDMA Prioritization

16.2.4.14.1 Channel Priority

The EDMA event registers EDMA_TPCC_ER and EDMA_TPCC_ERH capture up to 64 events, the QDMA event register EDMA_TPCC_QER captures QDMA events for all QDMA channels therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

16.2.4.14.2 Trigger Source Priority

If a EDMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (EDMA_TPCC_ER[31:0] E*n* = 1, EDMA_TPCC_ESR[31:0] E*n* = 1 , EDMA_TPCC_CER[31:0] E*n* = 1) , then the EDMA_TPCC always services these events in the following priority order: event trigger (via EDMA_TPCC_ER) is higher priority than chain trigger (via EDMA_TPCC_CER) and chain trigger is higher priority than manual trigger (via EDMA_TPCC_ESR).

This implies that if for channel 0, both EDMA_TPCC_ER[0] E0 = 1 and EDMA_TPCC_CER[0] E0 = 1 at the same time, then the EDMA_TPCC_ER[0] E0 event is always queued before the EDMA_TPCC_CER[0] E0 event.

16.2.4.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by EDMA_TPCC_DMAQNUMN_k and EDMA_TPCC_QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 1 the lowest.

16.2.4.15 EDMA Power, Reset and Clock Management

16.2.4.15.1 Clock and Power Management

The EDMA channel controller and transfer controller are clocked from L3MIAN1_L3_GICLK interface clock. The EDMA system runs at the L3 clock frequency.

The Auto clock gating for the EDMA_TPCC module is controlled by the EDMA_TPCC_CLKGDIS[0] CLKGDIS bit at the module level.

The L3MIAN1_L3_GICLK interface clock to EDMA controller's modules are controlled by the following registers in the PRCM module:

- PRCM.CM_L3MAIN1_TPCC_CLKCTRL - manages EDMA_TPCC module clock.
- PRCM.CM_L3MAIN1_TPTC1_CLKCTRL - manages EDMA_TPTC0 module clock.
- PRCM.CM_L3MAIN1_TPTC2_CLKCTRL - manages EDMA_TPTC1 module clock.

EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 modules have wakeup depandaces to several device modules. The wakeup dependency based on EDMA modules service requests are controlled by registers in PRCM module:

- PRCM.PM_L3MAIN1_TPCC_WKDEP - controls wakeup dependency based on TPCC service requests.
- PRCM.PM_L3MAIN1_TPTC1_WKDEP - controls wakeup dependency based on TPTC0 service requests.
- PRCM.PM_L3MAIN1_TPTC2_WKDEP - controls wakeup dependency based on TPTC1 service requests.

The EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1 can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the PRCM module. The PRCM acts as a master controller for power management for all peripherals on the device.

The EDMA controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 are separate. In general, it should be verified that there are no pending activities in the EDMA controller

Note

When EDMA controler modules no longer require the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM_L3MAIN1_TPCC_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC1_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the L3MIAN1_L3_GICLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure EDMA modules are ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the EDMA modules. For more information, refer to *Power, Reset, and Clock Management*.

16.2.4.15.2 Reset Considerations

A hardware resets the EDMA (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1) and the EDMA configuration registers. The PaRAM memory contents are undefined after device reset and it should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used. The EDMA modules are reset by CORE_RET_RST reset signal from PRCM.

16.2.4.16 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts.

16.2.5 EDMA Transfer Examples

The EDMA channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

16.2.5.1 Block Move Example

The most basic transfer performed by the EDMA is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 16-33.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 16-34 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, EDMA_TPCC_ABCNT_n[31:16] BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. The QDMA trigger word must be programed to be the highest numbered offset in the PaRAM set that undergoes change.

Figure 16-34 shows the parameters Block Move transfer.

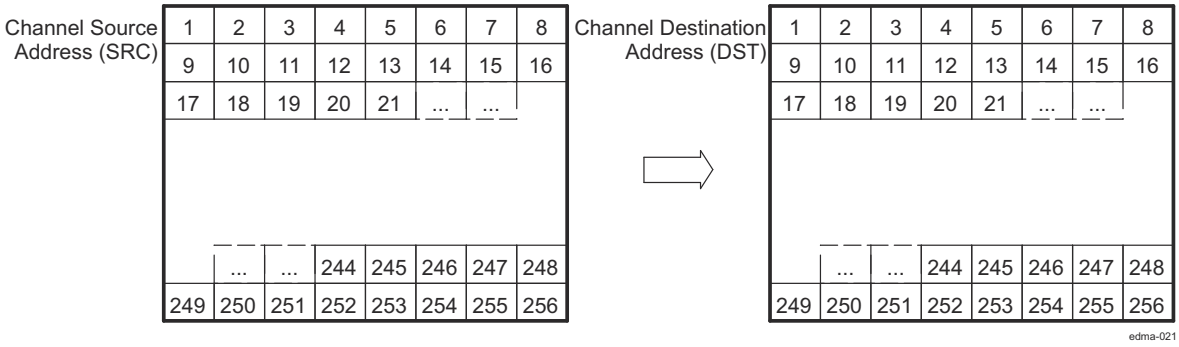

Figure 16-33. Block Move Example

Figure 16-34. Block Move Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents			Parameter	
0010 0008h			Channel Options Parameter (OPT)	
Channel Source Address (SRC)			Channel Source Address (SRC)	
0001h	0100h		Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)			Channel Destination Address (DST)	
0000h	0000h		Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh		BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h		Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h		Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

16.2.5.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA places the subframe in internal L2 SRAM. Figure 16-35 shows the transfer of a subframe from external memory to L2.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 16-36 shows the parameters for Subframe Extraction transfer.

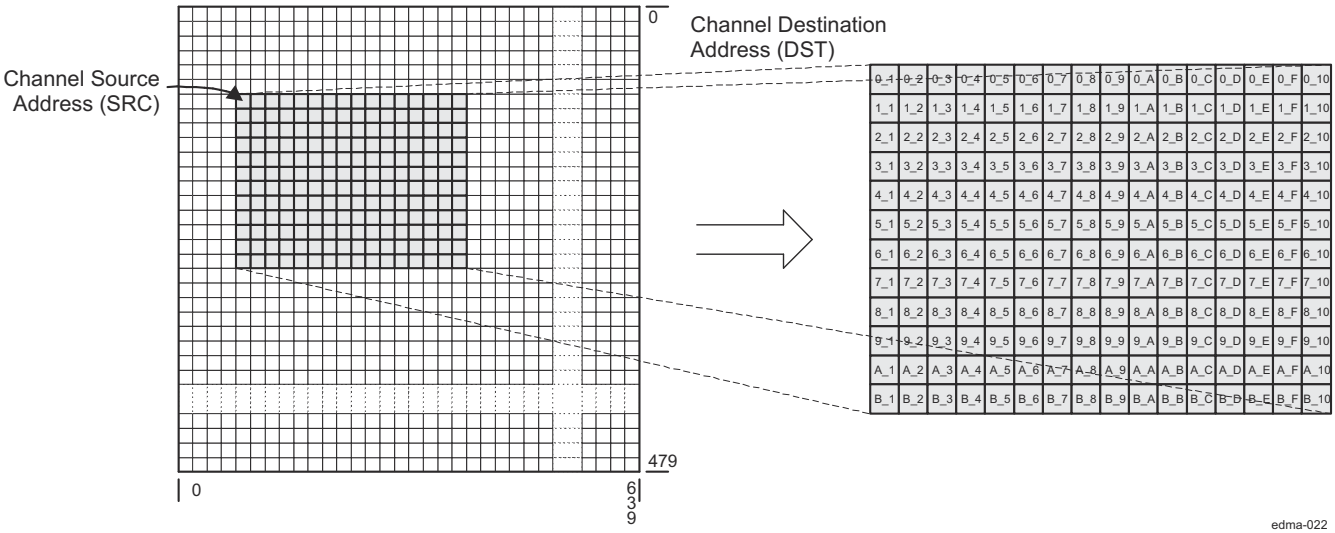

Figure 16-35. Subframe Extraction Transfer

Figure 16-36. Subframe Extraction Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents			Parameter	
0010 000Ch			Channel Options Parameter (OPT)	
Channel Source Address (SRC)			Channel Source Address (SRC)	
000Ch	0020h		Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)			Channel Destination Address (DST)	
0020h	0500h		Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh		BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h		Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h		Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

16.2.5.3 Data Sorting Example

Many applications require the use of multiple data arrays, it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SBIDX - Program this to be the size of the element or ACNT.
- DBIDX - CCNT × ACNT
- SCIDX - ACNT × BCNT
- DCIDX - ACNT

The synchronization type needs to be AB-synchronized and the EDMA_TPCC_OPT_n[3] STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 16-38 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 16-37 shows the Data Sorting transfer

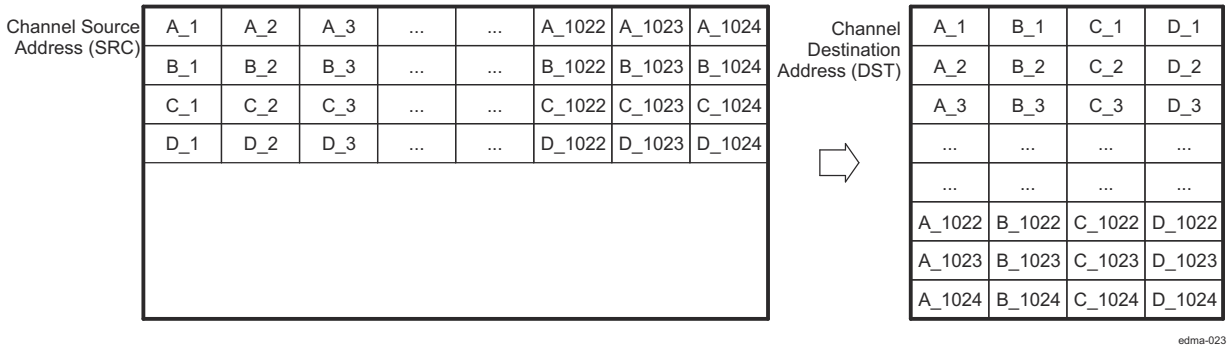

Figure 16-37. Data Sorting Example

Figure 16-38. Data Sorting Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents			Parameter	
0090 0004h			Channel Options Parameter (OPT)	
Channel Source Address (SRC)			Channel Source Address (SRC)	
0400h	0004h		Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)			Channel Destination Address (DST)	
0010h	0001h		Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)
0000h	FFFFh		BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h		Destination CCNT Index (DSTCIDX)	Source CCNT Index (SRCCIDX)
0000h	0004h		Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1
- EDMA_TPCC_OPT_n[23] ITCCHEN = 0x1

16.2.5.4 Peripheral Servicing Example

The EDMA channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register EDMA_TPCC_EER. When programming an EDMA channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

16.2.5.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA channel configuration is the same.

The McASP transmit and receive data streams are treated independently by the EDMA. The transmit and receive data streams can have completely different counts, data sizes, and formats.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA issue the transfer request for each element individually. Figure 16-40 shows the parameters for this transfer. The source address of the EDMA channel is set to the data port address (DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 0x2 (increment).

Based on the premise that serial data is typically a high priority, the EDMA channel should be programmed to be on queue 0.

Figure 16-39 shows servicing incoming McASP data.

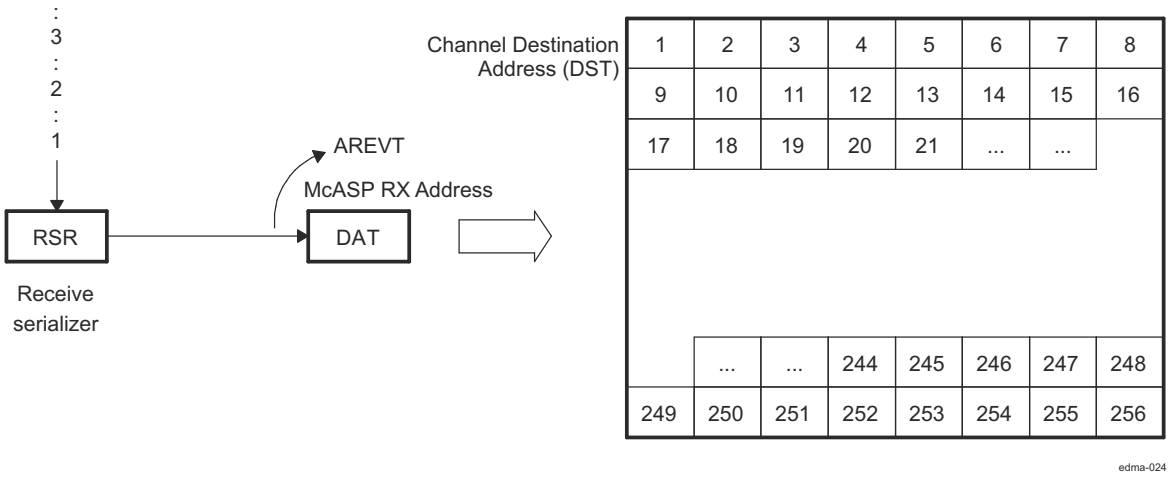

Figure 16-39. Servicing Incoming McASP Data Example

Figure 16-40. Servicing Incoming McASP Data Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents			Parameter	
0010 0000h			Channel Options Parameter (OPT)	
McASP RX Address			Channel Source Address (SRC)	
0100h	0001h		Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)			Channel Destination Address (DST)	
0001h	0000h		Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh		BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h		Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0004h		Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

16.2.5.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the DSP one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT*n* , channel *n* must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 16-42 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the EDMA_TPCC_BDIX_n[15:0] SBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the EDMA_TPCC_BIDX_n[31:16] DBIDX is set to pixel size, 2 bytes. EDMA_TPCC_ABCNT_n[15:0] ANCT is equal to the pixel size, 2 bytes. EDMA_TPCC_ABCNT_n[31:16] BCNT is set to the number of pixels in an array, 640. EDMA_TPCC_CCNT_n[15:0] CCNT is equal to the total number of arrays in the block, 480. EDMA_TPCC_CIDX_n[15:0] SCIDX is 0 because the source address undergoes no increment. The EDMA_TPCC_CIDX_n[31:16] DCIDX is equal to the difference between the starting addresses of each array. Because one pixel is 16 bits (2 bytes), EDMA_TPCC_CIDX_n[31:16] DCIDX is equal to 640 × 2.

Figure 16-41 shows Bursting Peripherals Transfer.

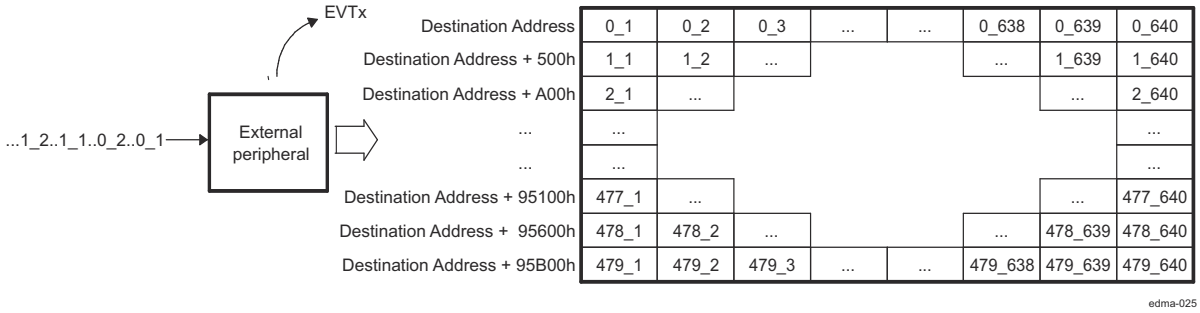

Figure 16-41. Servicing Peripheral Burst Example

Figure 16-42. Servicing Peripheral Burst Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents			Parameter	
0010 0004h			Channel Options Parameter (OPT)	
Channel Source Address			Channel Source Address (SRC)

0002h	0000h		Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)
0000h	FFFFh		BCNT Reload (BCNTRLD)	Link Address (LINK)
0500h	0000h		Destination CCNT Index (DSTCIDX)	Source CCNT Index (SRCCIDX)
0000h	01E0h		Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

16.2.5.4.3 Continuous Operation

Configuring an EDMA channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown in Figure 16-43.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, them DMA channels associated with the McASP must be setup for 1D-to-1D transfers with A-synchronization.

Figure 16-44 shows the parameter entries for the channel for these transfers. To service the McASP continuously throughout DSP operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA channels reload and continue.

Figure 16-45 shows the reload parameters for the channel.

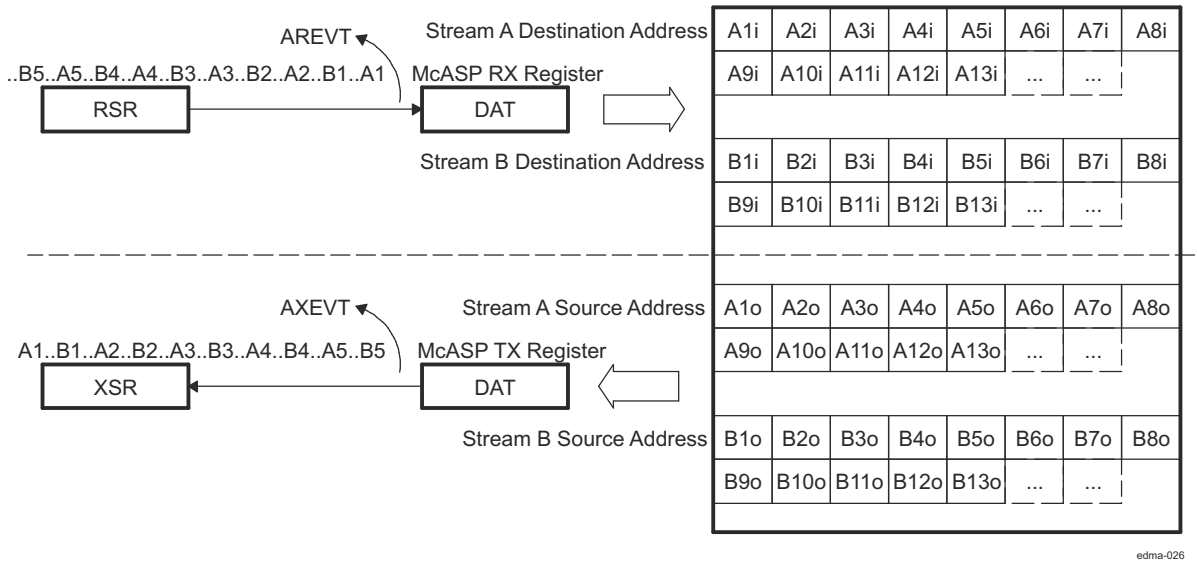

Figure 16-43. Servicing Continuous McASP Data Example

16.2.5.4.3.1 Receive Channel

EDMA channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

16.2.5.4.3.2 Transmit Channel

EDMA channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA channel, with duplicate PaRAM set entries at PaRAM set 65.

16.2.5.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA very closely to process the data. The EDMA receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA activity completes, they switch. The EDMA then writes over the old input data and transfers the new output data. Figure 16-46 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. Figure 16-47 shows the EDMA channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA channel is initially loaded with the ping parameters (Figure 16-47). The link address for the ping set is set to the PaRAM offset of the pong parameter set (Figure 16-48). The link address for the pong set is set to the PaRAM offset of the ping parameter set (Figure 16-49). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

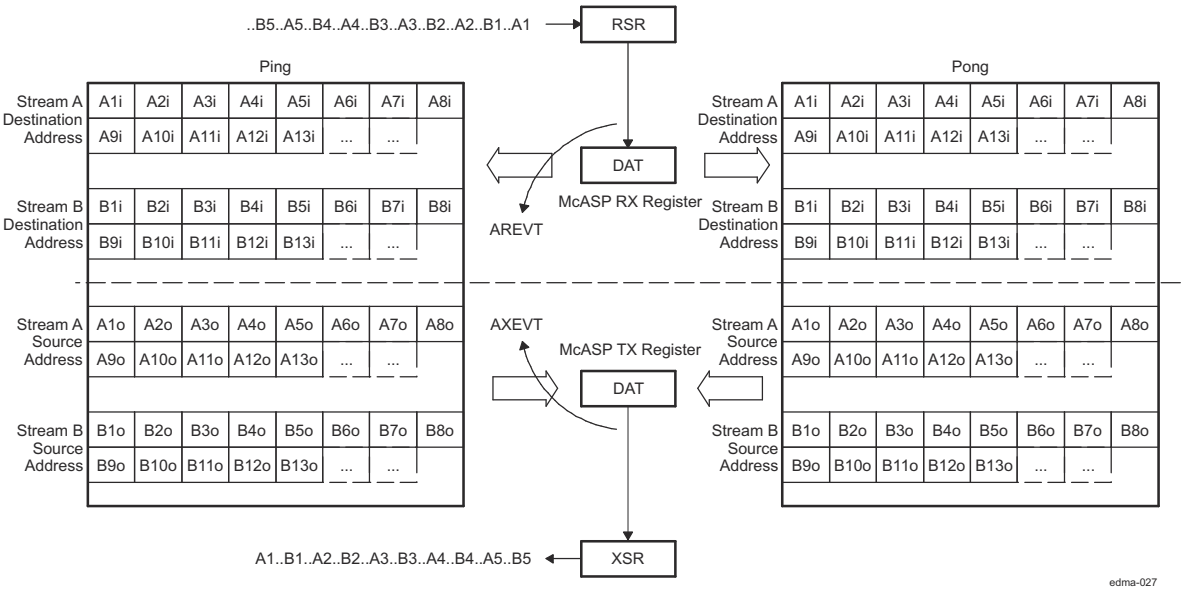

Figure 16-46. Ping-Pong Buffering for McASP Data Example

16.2.5.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the EDMA_TPCC_OPT_n[20] TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register EDMA_TPCC_IPR is set; when channel 12 empties an output buffer, the E12 bit in EDMA_TPCC_IPR is set. The CPU must manually clear

these bits. With the channel parameters set, the CPU polls EDMA_TPCC_IPR to determine when to switch. The EDMA and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA to complete.

Figure 16-47. Ping-Pong Buffering for McASP Example PaRAM Configuration

16.2.5.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

16.2.5.4.5.1 Servicing Input/Output FIFOs with a Single Event

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event.

For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). Figure 16-50 shows the EDMA setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register EDMA_TPCC_CER and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in EDMA_TPCC_CER (specified by EDMA_TPCC_OPT_n[11] TCCMODE: TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by EDMA_TPCC_OPT_n[11] TCCMODE: TCC) in the interrupt pending register EDMA_TPCC_IPR, which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register EDMA_TPCC_IER is set.

Figure 16-50 shows the Intermediate Transfer Completion Chaining Example.

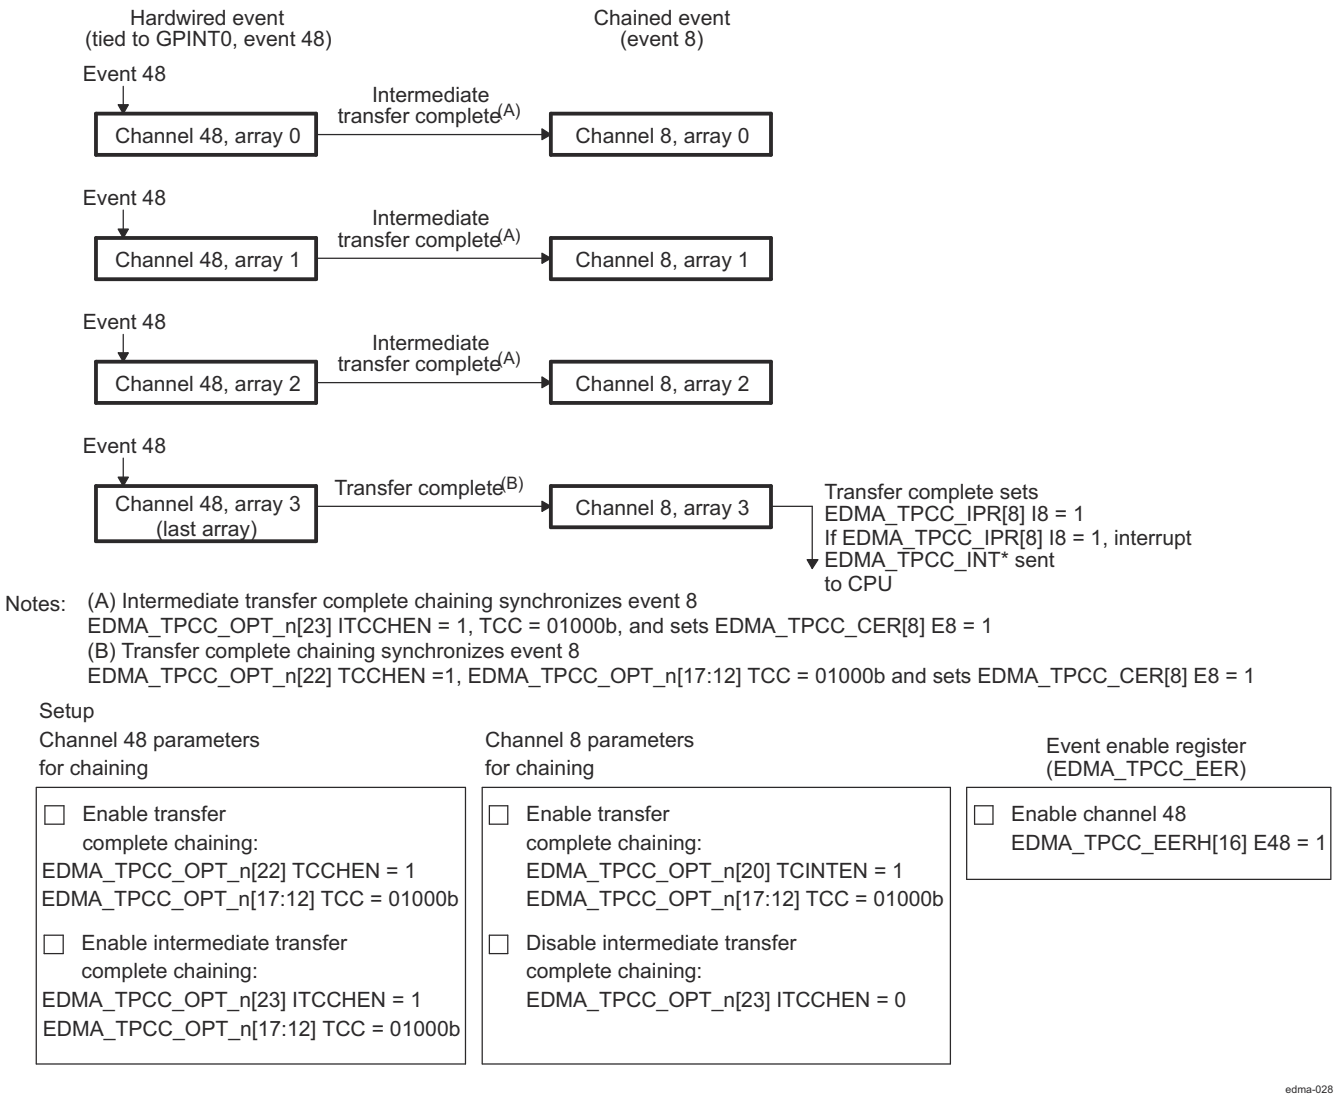

Figure 16-50. Intermediate Transfer Completion Chaining Example

16.2.5.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

Another feature of intermediate transfer chaining EDMA_TPCC_OPT_n[23] ITCCHEN is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 16-51 shows the EDMA setup and illustration of an example single large block transfer.

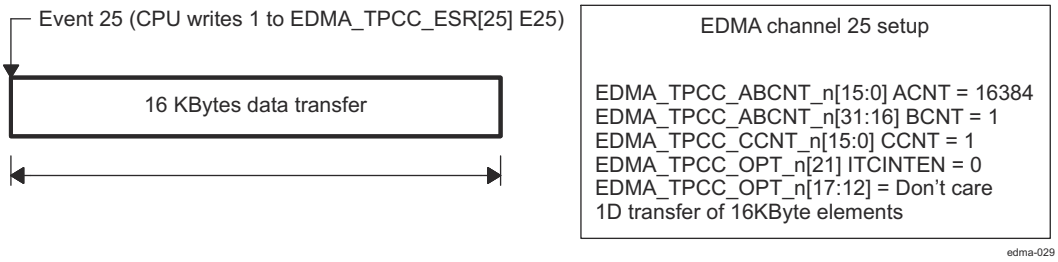

Figure 16-51. Single Large Block Transfer Example

The intermediate transfer chaining enable EDMA_TPCC_OPT_n[23] ITCCHEN provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The EDMA_TPCC_OPT_n[17:12] TCC field in the channel options parameter (OPT) is set to the same value as the channel number and EDMA_TPCC_OPT_n[23] ITCCHEN are set. In this example, EDMA channel 25 is used and EDMA_TPCC_OPT_n[17:12] TCC is also set to 25. The EDMA_TPCC_OPT_n[20] TCINTEN may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA transfer by writing to the appropriate bit of the event set register EDMA_TPCC_ESR[25] E25. The EDMA transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the EDMA_TPCC_OPT_n[17:12] TCC field. This intermediate transfer completion chaining event causes EDMA channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. Figure 16-52 shows the EDMA setup and illustration of the broken up smaller packet transfers.

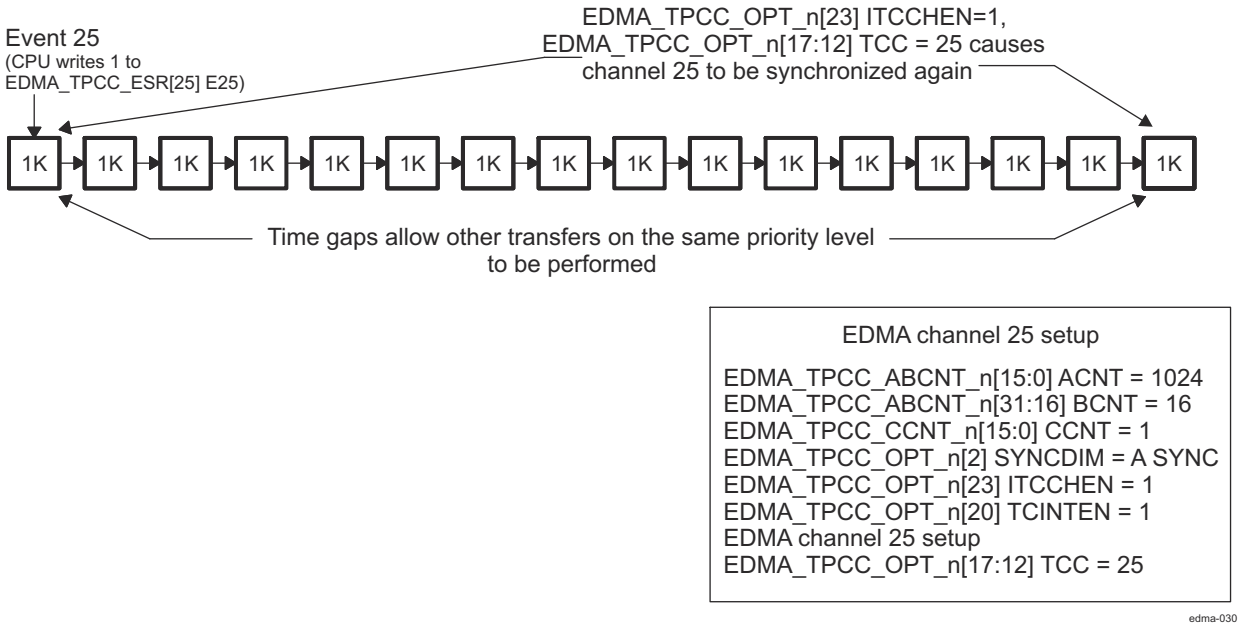

Figure 16-52. Smaller Packet Data Transfers Example

16.2.5.5 Setting Up an EDMA Transfer

16.2.5.5.1

The following list provides a quick guide for the typical steps involved in setting up a transfer.

1. Initiating a DMA/QDMA channel
   a. Determine the type of channel (QDMA or DMA) to be used.
   b. Channel mapping
      i. If using a QDMA channel, program the EDMA_TPCC_QCHMAPN_j with the parameter set number to which the channel maps and the trigger word.
      ii. If using a DMA channel, program the EDMA_TPCC_DCHMAPN_m with the parameter set number to which the channel maps.
   c. If the channel is being used in the context of a shadow region, ensure the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in Section 16.2.4.7.1.)
   d. Determine the type of triggering used.
      i. If external events are used for triggering (DMA channels), enable the respective event in EDMA_TPCC_EER / EDMA_TPCC_EERH by writing into EDMA_TPCC_EESR / EDMA_TPCC_EESRH.
      ii. If QDMA Channel is used, enable the channel in EDMA_TPCC_QEER by writing into EDMA_TPCC_QEESR.
   e. Queue setup
      i. If a QDMA channel is used, set up the EDMA_TPCC_QDMAQNUM to map the channel to the respective event queue.
      ii. If a DMA channel is used, set up the EDMA_TPCC_DMAQNUMN_k to map the event to the respective event queue.
2. Parameter set setup
   a. Program the PaRAM set number associated with the channel. Note that

Note

If it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.

3. Interrupt setup
   a. Enable the interrupt in the EDMA_TPCC_IER / EDMA_TPCC_IERH by writing into EDMA_TPCC_IESR / EDMA_TPCC_IESRH.
   b. Ensure that the EDMA_TPCC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
   c. Ensure the EDMA_TPCC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
   d. Set up the interrupt controller properly to receive the expected EDMA interrupt.
4. Initiate transfer
   a. This step is highly dependent on the event trigger source:
      i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the EDMA_TPCC_ER transfer.
      ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
      iii. Manually triggered transfers will be initiated by writes to the Event Set Registers EDMA_TPCC_ESR / EDMA_TPCC_ESRH.
      iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.
5. Wait for completion
   a. If the interrupts are enabled as mentioned in step 3 above, then the EDMA_TPCC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits

in the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH. The set bits must be cleared in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH by writing to corresponding bit in EDMA_TPCC_ICR / EDMA_TPCC_ICRH.

b. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH. Again, the set bits in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH must be manually cleared via EDMA_TPCC_ICR / EDMA_TPCC_ICRH before the next set of transfers is performed for the same transfer completion code values.

16.2.6 EDMA Debug Checklist and Programming Tips

This section lists some tips to keep in mind while debugging applications using the EDMA controller.

16.2.6.1 EDMA Debug Checklist

Table 16-76 provides some common issues and their probable causes and resolutions.

Table 16-76. Debug Checklist

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	The EDMA_TPCC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following: 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers EDMA_TPCC_ER / EDMA_TPCC_ERH, check that the event is enabled in the Event Enable Registers EDMA_TPCC_EER / EDMA_TPCC_EERH. Similarly, for QDMA channels, check that QDMA events are appropriately enabled in the QDMA Event Enable Register EDMA_TPCC_QEER. 2) Verify that the DMA or QDMA Secondary Event Register EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER bits corresponding to the particular event or channel are not set.
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases: 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., EDMA_TPCC_OPT_n[3] STATIC = 0x0, EDMA_TPCC_LNK_n[15:0] LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the EDMA_TPCC_QEMR and EDMA_TPCC_QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the EDMA_TPCC_SER[31:0] E*n* and EDMA_TPCC_EMR[31:0] E*n* set, preventing further event prioritization. Check the number of events received is limited to the expected number of events for which the parameter set is programmed, or check the bits corresponding to particular channel or event are not set in the Secondary event registers (EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER) and Event Missed Registers (EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR) before trying to perform subsequent transfers for the event/channel.

Table 16-76. Debug Checklist (continued)

Issue	Description/Solution
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	Check the following: 1) The interrupt generation is enabled in the EDMA_TPCC_OPT_n of the associated PaRAM set (EDMA_TPCC_OPT_n[20] TCINTEN = 0x1 and/or EDMA_TPCC_OPT_n[20] ITCINTEN = 0x1). 2) The interrupts are enabled in the EDMA Channel Controller, via the Interrupt Enable Registers (EDMA_TPCC_IER / EDMA_TPCC_IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 16.2.4.9.1.2 *Clearing Transfer Complerion Interrupts* for details on writing EDMA ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) are set up properly, because the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers act as secondary enables for shadow region completion interrupts, along with the EDMA_TPCC_IER / EDMA_TPCC_IERH registers. If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value are also enabled in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 EDMA_TPCC_OPT_n[17:12] TCC = 63, ensure that EDMA_TPCC_DRAEHM_k[31] E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be EDMA_TPCC_IPRH[31] I63 (not EDMA_TPCC_IPR[0] I0).

16.2.6.2 EDMA Programming Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (EDMA_TPCC_ER / EDMA_TPCC_ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (EDMA_TPCC_ECR / EDMA_TPCC_ECRH). Similarly, the Event Enable Register (EDMA_TPCC_EER / EDMA_TPCC_EERH) bits can only be set with writing of 0x1 to the Event Enable Set Registers (EDMA_TPCC_EESR / EDMA_TPCC_EESRH) and cleared with writing of 0x1 to the corresponding bits in the Event Enable Clear Register (EDMA_TPCC_EECR / EDMA_TPCC_EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k / EDMA_TPCC_QRAEN_k). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts.
   For example, if EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0 and EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0 are both set, then on completion of a transfer that returns a TCC = 0x0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the EDMA_TPCC_CCNT_n[15:0] CCNT is not left to zero.
5. Enable the EDMA_TPCC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, it can want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, it chooses to use the early chaining option to reduce the time between the sets of transfers and increase the throughput.
   However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA_TPCC internally signals completion when the TR is submitted to the EDMA_TPTC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

16.2.7 EDMA Register Manual

16.2.7.1 EDMA Instance Summary

Table 16-77shows the L3_MAIN base address and address space for the EDMA module instances.

Table 16-77. EDMA Instance Summary

Module Name	Base Address (L3_MAIN Access)	Size
SYS_EDMA_TPCC	0x4330 0000	1 MB
SYS_EDMA_TPTC0	0x4340 0000	1 MB
SYS_EDMA_TPTC1	0x4350 0000	1 MB
DSP1_EDMA_TPCC	0x40D1 0000	32 KB
DSP1_EDMA_TPTC0	0x40D0 5000	4 KB
DSP1_EDMA_TPTC1	0x40D0 6000	4 KB

Table 16-78 lists the base addresses for DSP internal (private) access to its embedded TPCC / TPTC modules.

Table 16-78. DSP Private Access EDMA Instance Summary

Module Name	Base Address	Size
DSP_EDMA_TPCC	0x01D1 0000	32 KB
DSP_EDMA_TPTC0	0x01D0 5000	4 KB
DSP_EDMA_TPTC1	0x01D0 6000	4 KB

Table 16-79 lists the base addresses for EVE internal (private) access to its embedded TPCC / TPTC modules.

Table 16-79. EVE EDMA Instance Summary (Private Access)

Module Name	Base Address (EVE Private Access)	Size
EVE_EDMA_TPCC	0x400A 0000	32 KB
EVE_EDMA_TPTC0	0x4008 6000	4 KB
EVE_EDMA_TPTC1	0x4008 7000	4 KB

16.2.7.2 EDMA Registers

16.2.7.2.1 EDMA Register Summary

Table 16-80 through summarize the EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1 registers.

Note

All EDMA modules in the SoC are functionally identical. Note that some of the configuration parameters may be different for the various EDMA instances (see Section 16.2.1.3, *EDMA Controllers Configuration*).

Table 16-80. System EDMA_TPCC Registers Mapping Summary

(1) i = 0 to 1 for DSP_EDMA_TPCC
(2) j = 0 to 7 for DSP_EDMA_TPCC
(3) k = 0 to 7 for DSP_EDMA_TPCC
(4) p = 0 to 15 for DSP_EDMA_TPCC
(5) m = 0 to 63 for DSP_EDMA_TPCC
(6) n = 0 to 127 for DSP_EDMA_TPCC

Note

The value for "n" is from 0 to 1 in the Table 16-83. It corresponds of the Transfer Controller (EDMA_TPTC0 and EDMA_TPTC1) instances in the device.

Table 16-121. EDMA_TPCC_ER

Address Offset	0x0000 1000		
Physical Address	0x4330 1000 0x40D1 1000 0x01D1 1000	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP_EDMA_TPCC
Description	Event Register: If EDMA_TPCC_ER.En bit is set and the EDMA_TPCC_EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EDMA_TPCC_EER.En bit. EDMA_TPCC_ER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EDMA_TPCC_EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the EDMA_TPCC_ECR pseudo-register.

Table 16-127. EDMA_TPCC_CER

Address Offset	0x0000 1018		
Physical Address	0x4330 1018 0x40D1 1018 0x01D1 1018	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP_EDMA_TPCC
Description	Chained Event Register: If EDMA_TPCC_CER.En bit is set (regardless of state of EDMA_TPCC_EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface, or is generated internally via Early Completion path. EDMA_TPCC_CER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. EDMA_TPCC_CER.En cannot be set or cleared via software.

Table 16-129. EDMA_TPCC_EER

Address Offset	0x0000 1020		
Physical Address	0x4330 1020 0x40D1 1020 0x01D1 1020	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP_EDMA_TPCC
Description	Event Enable Register: Enables DMA transfers for EDMA_TPCC_ER.En pending events. EDMA_TPCC_ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (EDMA_TPCC_CER) or Event Set Register (EDMA_TPCC_ESR). Note that if a bit is set in EDMA_TPCC_ER.En while EDMA_TPCC_EER.En is disabled, no action is taken. If EDMA_TPCC_EER.En is enabled at a later point (and EDMA_TPCC_ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EDMA_TPCC_EER.En is not directly writeable. Events can be enabled via writes to EDMA_TPCC_EESR and can be disabled via writes to EDMA_TPCC_EECR register. EDMA_TPCC_EER.En = 0: EDMA_TPCC_ER.En is not enabled to trigger DMA transfers. EDMA_TPCC_EER.En = 1: EDMA_TPCC_ER.En is enabled to trigger DMA transfers.

RESERVED																														SET	EVAL

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved	R	0x0
1	SET	Interrupt Set: CPU write of '1' to the SETn bit causes the tpcc_intN output signal to be pulsed egardless of state of interrupts enable (IERn) and status (EDMA_TPCC_IPRn). CPU write of '0' has no effect.	W	0x0
0	EVAL	Interrupt Evaluate: CPU write of '1' to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (EDMA_TPCC_IPRn). CPU write of '0' has no effect.	W	0x0

Table 16-150. EDMA_TPCC_QER

Address Offset	0x0000 1080		
Physical Address	0x4330 1080 0x40D1 1080 0x01D1 1080	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP_EDMA_TPCC
Description	QDMA Event Register: If EDMA_TPCC_QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. EDMA_TPCC_QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. EDMA_TPCC_QER.En bit is cleared when the corresponding event is prioritized and serviced. EDMA_TPCC_QER.En is also cleared when user writes a '1' to the EDMA_TPCC_QSECR.En bit. If the EDMA_TPCC_QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and EDMA_TPCC_QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

Table 16-162. EDMA_TPCC_CER_RN_k

Address Offset	0x0000 2018 + (0x200 * k)		
Physical Address	0x4330 2018 + (0x200 * k) 0x40D1 2018 + (0x200 * k) 0x01D1 2018 + (0x200 * k)	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP_EDMA_TPCC
Description	Chained Event Register If EDMA_TPCC_CER.En bit is set (regardless of state of EDMA_TPCC_EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface, or is generated internally via Early Completion path. EDMA_TPCC_CER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. EDMA_TPCC_CER.En cannot be set or cleared via software.

Instance SYS_EDMA_TPCC | DSP1_EDMA_TPCC | DSP_EDMA_TPCC

Description

Event Enable Register

Enables DMA transfers for EDMA_TPCC_ER.En pending events. EDMA_TPCC_ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (EDMA_TPCC_CER) or Event Set Register (EDMA_TPCC_ESR).

NOTE: If a bit is set in EDMA_TPCC_ER.En while EDMA_TPCC_EER.En is disabled, no action is taken.

If EDMA_TPCC_EER.En is enabled at a later point (and EDMA_TPCC_ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync' EDMA_TPCC_EER.En is not directly writeable. Events can be enabled via writes to EDMA_TPCC_EESR and can be disabled via writes to EDMA_TPCC_EECR register. EDMA_TPCC_EER.En = 0: EDMA_TPCC_ER.En is not enabled to trigger DMA transfers. EDMA_TPCC_EER.En = 1: EDMA_TPCC_ER.En is enabled to trigger DMA transfers.

Table 16-180. EDMA_TPCC_IPR_RN_k

Address Offset 0x0000 2068 + (0x200 * k)

Physical Address 0x4330 2068 + (0x200 * k) — **Instance** SYS_EDMA_TPCC
0x40D1 2068 + (0x200 * k) — DSP1_EDMA_TPCC
0x01D1 2068 + (0x200 * k) — DSP_EDMA_TPCC

Description Interrupt Pending Register
EDMA_TPCC_IPR.In bit is set when a interrupt completion code with TCC of N is detected.
EDMA_TPCC_IPR.In bit is cleared via software by writing a '1' to EDMA_TPCC_ICR.In bit.

Type R

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved	R	0x0
1	SET	Interrupt Set CPU writes 0x0 has no effect. CPU writes 0x1 to the SETn bit causes the tpcc_intN output signal to be pulsed egardless of state of interrupts enable (IERn) and status (EDMA_TPCC_IPRn).	W	0x0
0	EVAL	Interrupt Evaluate CPU writes 0x0 has no effect. CPU writes 0x1 to the EVALn bit causes the tpcc_intN output signal to be pulsed if any enabled interrupts (IERn) are still pending (EDMA_TPCC_IPRn).	W	0x0

Table 16-185. EDMA_TPCC_QER_RN_k

Address Offset	0x0000 2080 + (0x200 * k)		
Physical Address	0x4330 2080 + (0x200 * k) 0x40D1 2080 + (0x200 * k) 0x01D1 2080 + (0x200 * k)	**Instance**	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP_EDMA_TPCC
Description	QDMA Event Register If EDMA_TPCC_QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. EDMA_TPCC_QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. EDMA_TPCC_QER.En bit is cleared when the corresponding event is prioritized and serviced. EDMA_TPCC_QER.En is also cleared when user writes a '1' to the EDMA_TPCC_QSECR.En bit. If the EDMA_TPCC_QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and EDMA_TPCC_QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

Description QDMA Event Enable Register
Enabled/disabled QDMA address comparator for QDMA Channel N. EDMA_TPCC_QEER.En is not directly writeable.
The corresponding QDMA channel comparator is enabled and Events will be recognized and latched in EDMA_TPCC_QER.En. EDMA_TPCC_QEER.En = 0, The corresponding QDMA channel comparator is disabled. Events will not be recognized/latched in EDMA_TPCC_QER.En.
QDMA channels can be enabled via writes to EDMA_TPCC_QEESR and can be disabled via writes to EDMA_TPCC_QEECR register. EDMA_TPCC_QEER.En = 1,

Description	QDMA Secondary Event Clear Register CPU write of '0' has no effect. The secondary event clear register is used to clear the status of the EDMA_TPCC_QSER and EDMA_TPCC_QER register (note that this is slightly different than the EDMA_TPCC_SER operation, which does not clear the EDMA_TPCC_ER.En register). CPU write of '1' to the EDMA_TPCC_QSECR.En bit clears the EDMA_TPCC_QSER.En and EDMA_TPCC_QER.En register fields.

Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	BCNT: Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame. In normal mode, a BCNT of '0' is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the EDMA_TPCC_OPT_n.WIMODE bit is set, then the programmed BCNT value will be incremented by '1' before submission to TC. I.e., 0 means 1, 1 means 2, 2 means 3, ..., 0xFFFE means 0xFFFF. A value of 0xFFFF is an illegal value that will be treated as a Null TR.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	ACNT	ACNT: number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to '1' for a TR to be submitted to TC. An ACNT of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the EDMA_TPCC_OPT_n.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are reserved and should always be written as 'b00 by the user. If user writes a value other than 0, it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition, the ACNT definition will disregard the 2 msbits. I.e., a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer, resulting in null or dummy operation dependent on the state of BCNT and CCNT.	RW	0x0

Description	Link and Reload parameters		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															

Bits	Field Name	Description	Type	Reset
31:16	BCNTRLD	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Sync'ed transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not thus BCNTRLD is a don't care field.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	LINK	Link Address: The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e., after count fields are decremented to '0') with a new PaRAM Entry. This is called 'linking'. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the 'literal' byte address of the LINK parameter or the 'PaRAM base-relative' address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as 'b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (i.e., don't have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (i.e., do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Linkand all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e., a value of 0x3FFE is a non-NULL PaRAM link field.	RW	0x0

The privilege ID is issued on the VBusM read and write command bus such that the target endpoints can perform mMemory protection checks based on the privid of the external host that sets up the DMA transaction.	R	0x0

Chapter 17

Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

17.1 Interrupt Controllers Overview

The device has a large number of interrupts to service the needs of its many peripherals and subsystems. The MPU, DSP, IPU (x2), and PRU-ICSS (x2) subsystems are capable of servicing these interrupts via their integrated interrupt controllers. In addition, each processor's interrupt controller is preceded by an Interrupt Controller Crossbar (IRQ_CROSSBAR) that provides flexibility in mapping the device interrupts to processor interrupt inputs. For more information about IRQ crossbar, see *Control Module*.

Cortex®-A15 MPU Subsystem Interrupt Controller (MPU_INTC)

The MPU_INTC module (also called Generalized Interrupt Controller [GIC]) is a single functional unit that is integrated in the Arm ® Cortex-A15 multiprocessor core (MPCore) alongside Cortex-A15 processor. It provides:

- 160 hardware interrupt inputs
- Generation of interrupts by software
- Prioritization of interrupts
- Masking of any interrupts
- Distribution of the interrupts to the target Cortex-A15 processor(s)
- Tracking the status of interrupts

The Cortex-A15 processor supports three main groups of interrupt sources, with each interrupt source having a unique ID:

- *Software Generated Interrupts (SGIs):* SGIs are generated by writing to the Cortex-A15 Software Generated Interrupt Register (GICD_SGIR). A maximum of 16 SGIs (ID0–ID15) can be generated for the CPU interface. An SGI has edge-triggered properties. The software triggering of the interrupt is equivalent to the edge transition of the interrupt signal on a peripheral input.
- *Private Peripheral Interrupts (PPIs):* A PPI is an interrupt generated by a peripheral that is specific to the processor. Although interrupts ID16–ID31 are dedicated to PPIs in general, only seven PPIs are actually used for the CPU interface (ID25–ID31). Interrupts ID16–ID24 are reserved (not used).
- *Shared Peripheral Interrupts (SPIs):* SPIs are triggered by events generated on associated interrupt input lines. In this device, the GIC is configured to support 160 SPIs corresponding to its external IRQS[159:0] signals. SPIs start at ID32 and their mapping is presented in Section 17.3.1.

For detailed information about this module and description of SGIs and PPIs, see the Arm *Cortex-A15 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

C66x DSP Subsystem Interrupt Controller (DSP1_INTC)

The DSP1 subsystem integrates an interrupt controller - DSP1_INTC, which interfaces the system events to the C66x core interrupt and exceptions inputs. It combines up to 128 interrupts into 12 prioritized interrupts presented to the C66x CPU.

For detailed information about this module, see Chapter 5, *DSP Subsystem*.

Dual Cortex-M4 IPU Subsystem Interrupt Controller (IPUx_Cx_INTC, where x = 1, 2)

There are two Image Processing Unit (IPU) subsystems in the device - IPU1, and IPU2. Each IPU subsystem integrates two Arm Cortex-M4 cores.

A Nested Vectored Interrupt Controller (NVIC) is integrated within each Cortex-M4. The interrupt mapping is the same (per IPU) for the two cores to facilitate parallel processing. The NVIC supports:

- 64 external interrupts (in addition to 16 Cortex-M4 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
- Low-latency exception and interrupt handling
- Prioritization and handling of exceptions
- Control of the local power management
- Debug accesses to the processor core

For detailed information about this module, refer to Arm *Cortex-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

Note

IPUx_Cx_INTC is a unified name for the following interrupt controllers:

- IPU1_C0_INTC - NVIC in first Cortex-M4 core of IPU1
- IPU1_C1_INTC - NVIC in second Cortex-M4 core of IPU1
- IPU2_C0_INTC - NVIC in first Cortex-M4 core of IPU2
- IPU2_C1_INTC - NVIC in second Cortex-M4 core of IPU2

PRU-ICSS Interrupt Controller (PRUSSx_INTC, where x = 1 to 2)

The PRUSSx_INTC is an interface between interrupts coming from different parts of the system (referred to as system events) and the PRU-ICSS interrupt interface.

The PRUSSx_INTC has the following features:

- Capturing up to 64 System Events
- Supports up to 10 interrupt channels
- Generation of 10 Host Interrupts:
  - 2 Host Interrupts for the PRUs
  - 8 Host Interrupts exported from the PRU-ICSS for signaling the Arm interrupt controllers
- Each system event can be enabled and disabled
- Each host event can be enabled and disabled
- Hardware prioritization of events

For detailed information about this module, see Chapter 30, *Programmable Real-Time Unit and Industrial Communication Subsystems*.

Figure 17-1 shows the top-level block diagram of the interrupt controllers in this device.

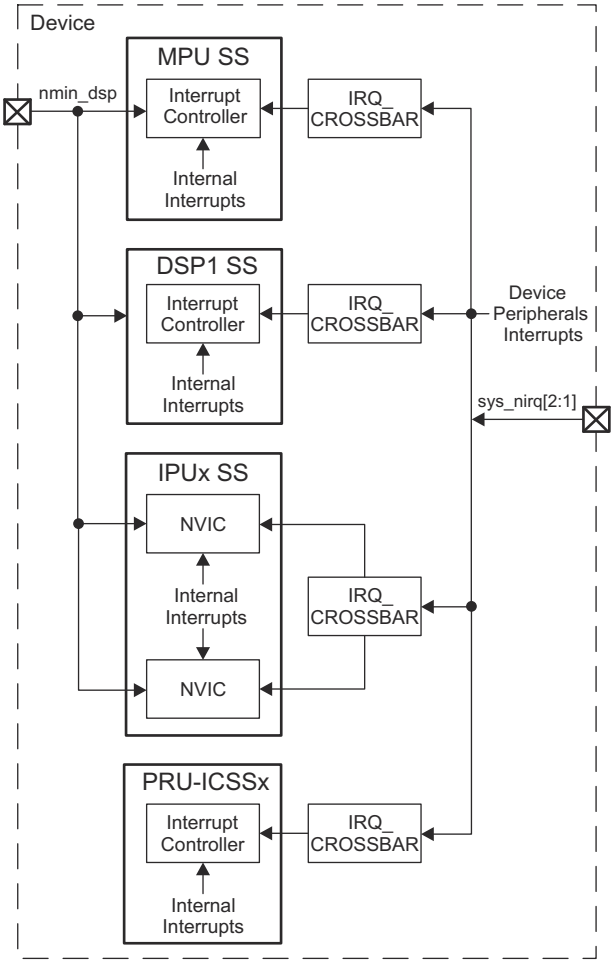

Figure 17-1. Interrupt Controllers in the Device

17.2 Interrupt Controllers Environment

Figure 17-2 shows the relationship between the device INTCs and external interrupts.

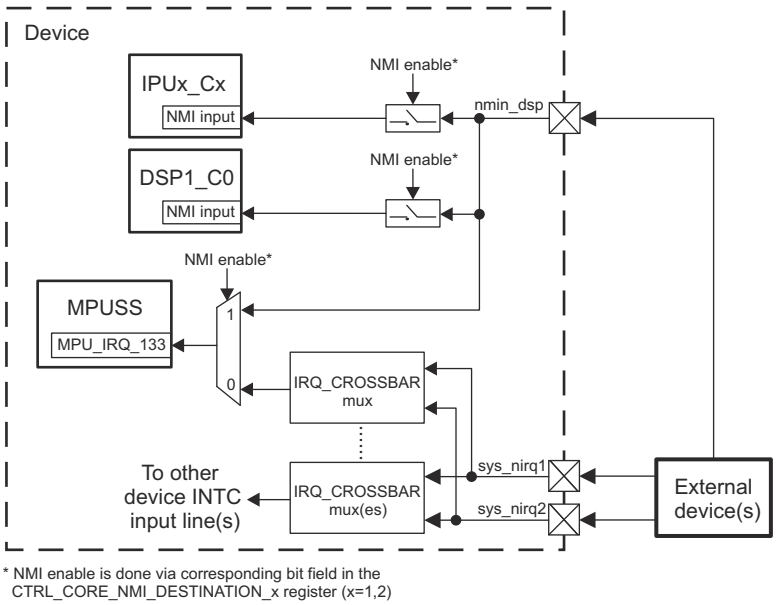

Figure 17-2. Interrupts From External Devices

Table 17-1 describes the signals that can be used by external devices to generate interrupts to the device INTCs.

Table 17-1. Interrupts From External Devices

Device Pin	I/O[1]	Description
sys_nirq1	I	External devices can use these pins to generate a system wake-up interrupt event to any device INTC. The user must take care to configure the corresponding IRQ_CROSSBAR properly (via Control Module).
sys_nirq2	I	

Table 17-1. Interrupts From External Devices (continued)

Device Pin	I/O[1]	Description
nmin_dsp	I	External device can use this pin to generate a non-maskable interrupt (NMI) event to the following device processors: - IPU1_C0, IPU1_C1. Upon enable (via Control Module), the NMI is routed directly to the NMI input of Cortex M4 core. Note that NMI can be enabled separately for IPU1_C0 and IPU1_C1. - IPU2_C0, IPU2_C1. Upon enable (via Control Module), the NMI is routed directly to the NMI input of Cortex M4 core. Note that NMI can be enabled separately for IPU2_C0 and IPU2_C1. - DSP1. Upon enable (via Control Module), the NMI is routed directly to the NMI input of C66x CPU. The signal from the **nmin_dsp** pin can also be mapped to the MPU_INTC (MPU_IRQ_133 input) but it would be treated by Cortex-A15 as a general interrupt and not as a non-maskable interrupt. The Cortex-A15 processor does not provide NMI input. The Control Module registers CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 are used to route the NMI signal to the corresponding device processor subsystems, as follows: • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_1 [23:16] IPU2_C1 enables NMI mapping to IPU2_C1; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_1 [15:8] IPU2_C0 enables NMI mapping to IPU2_C0; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_1 [7:0] IPU1_C1 enables NMI mapping to IPU1_C1; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2 [31:24] IPU1_C0 enables NMI mapping to IPU1_C0; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2 [15:8] DSP1 enables NMI mapping to DSP1; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2 [7:0] MPU enables NMI mapping to MPU_IRQ_133 interrupt line of MPU_INTC; writing 0x0 to this bit field disables the NMI mapping and IRQ_CROSSBAR mux is mapped to MPU_IRQ_133 instead. Refer to Chapter 18, *Control Module*, for more information about CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 registers.

(1) I = Input, O = Output

Note

External devices can also use the GPIO modules to generate an interrupt to the device INTCs. For more information, see Chapter 27, *General-Purpose Interface*.

17.3 Interrupt Controllers Integration

The following sections present the default interrupt mapping of the device INTCs. The mapping of device interrupts to IRQ_CROSSBAR inputs is presented in Table 17-8.

Note

All device interrupts (external to the MPU, DSP, IPU [x2], and PRU-ICSS [x2] subsystems) are active-high, level-sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs. With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

17.3.1 Interrupt Requests to MPU_INTC

Table 17-2 lists the default interrupt sources for the MPU_INTC. In addition, interrupts MPU_IRQ_4, MPU_IRQ_[130:7], MPU_IRQ_[138:133], and MPU_IRQ_[159:141] can alternatively be sourced through the MPU's IRQ_CROSSBAR from one of the 420 multiplexed device interrupts listed in Table 17-8. The CTRL_CORE_MPU_IRQ_y_z registers (where *y* and *z* are indexes of INTC input lines) in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Note

The interrupts listed in Table 17-2 are also called Shared Peripheral Interrupts (SPIs) in Arm Cortex-A15 terminology. That is, the MPU_IRQ_[159:0] interrupt inputs correspond to the **IRQS[N:0]** GIC signals (N = 159 for this device), described in the Arm *Cortex-A15 MPCore Processor Technical Reference Manual*.

The association between the Shared Peripheral Interrupts (MPU_IRQ_0 – MPU_IRQ_159) and the GIC inputs (ID32 – ID191) is shown in the first column of this table.

Table 17-2. MPU_INTC Default Interrupt Mapping

IRQ Input Line (GIC ID Number) (1)	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
MPU_IRQ_0 (ID32)	N/A	N/A	N/A	MPU_CLUSTER_IRQ_INTERR	Illegal writes to interrupt controller memory map region
MPU_IRQ_1 (ID33)	N/A	N/A	N/A	CS_CTI_MPU_C0_IRQ	TRIGOUT[6] of Cross Trigger Interface 0 (CTI0)
MPU_IRQ_2 (ID34)	N/A	N/A	N/A	CS_CTI_MPU_C1_IRQ	TRIGOUT[6] of Cross Trigger Interface 1 (CTI1)
MPU_IRQ_3 (ID35)	N/A	N/A	N/A	MPU_CLUSTER_IRQ_AXIERR	Error indication for AXI write transactions with a BRESP error condition
MPU_IRQ_4 (ID36)	1	CTRL_CORE_MPU_IRQ_4_7[8:0]	1	ELM_IRQ	Error location process completion interrupt
MPU_IRQ_5 (ID37)	N/A	N/A	N/A	WD_TIMER_MPU_C0_IRQ_WARN	MPU_WD_TIMER channel 0 warning interrupt
MPU_IRQ_6 (ID38)	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_7 (ID39)	2	CTRL_CORE_MPU_IRQ_4_7[24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin

Table 17-2. MPU_INTC Default Interrupt Mapping (continued)

IRQ Input Line (GIC ID Number) (1)	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
MPU_IRQ_8 (ID40)	3	CTRL_CORE_MPU_IRQ_8_9[8:0]	3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	Combined firewall error interrupt. For more information, see *Firewall Error Status Registers*.
MPU_IRQ_9 (ID41)	4	CTRL_CORE_MPU_IRQ_8_9[24:16]	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error
MPU_IRQ_10 (ID42)	5	CTRL_CORE_MPU_IRQ_10_11[8:0] (not functional)	5	L3_MAIN_IRQ_APP_ERR	L3_MAIN application or non-attributable error(2)
MPU_IRQ_11 (ID43)	6	CTRL_CORE_MPU_IRQ_10_11[24:16]	6	PRM_IRQ_MPU	PRCM interrupt to MPU
MPU_IRQ_12 (ID44)	7	CTRL_CORE_MPU_IRQ_12_13[8:0]	7	DMA_SYSTEM_IRQ_0	System DMA interrupt 0
MPU_IRQ_13 (ID45)	8	CTRL_CORE_MPU_IRQ_12_13[24:16]	8	DMA_SYSTEM_IRQ_1	System DMA interrupt 1
MPU_IRQ_14 (ID46)	9	CTRL_CORE_MPU_IRQ_14_15[8:0]	9	DMA_SYSTEM_IRQ_2	System DMA interrupt 2
MPU_IRQ_15 (ID47)	10	CTRL_CORE_MPU_IRQ_14_15[24:16]	10	DMA_SYSTEM_IRQ_3	System DMA interrupt 3
MPU_IRQ_16 (ID48)	11	CTRL_CORE_MPU_IRQ_16_17[8:0]	11	L3_MAIN_IRQ_STAT_ALARM	L3_MAIN statistic collector alarm interrupt
MPU_IRQ_17 (ID49)	12	CTRL_CORE_MPU_IRQ_16_17[24:16]	12	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_18 (ID50)	13	CTRL_CORE_MPU_IRQ_18_19[8:0]	13	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_19 (ID51)	14	CTRL_CORE_MPU_IRQ_18_19[24:16]	14	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_20 (ID52)	15	CTRL_CORE_MPU_IRQ_20_21[8:0]	15	GPMC_IRQ	GPMC interrupt
MPU_IRQ_21 (ID53)	16	CTRL_CORE_MPU_IRQ_20_21[24:16]	16	GPU_IRQ	GPU interrupt
MPU_IRQ_22 (ID54)	17	CTRL_CORE_MPU_IRQ_22_23[8:0]	17	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_23 (ID55)	18	CTRL_CORE_MPU_IRQ_22_23[24:16]	18	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_24 (ID56)	19	CTRL_CORE_MPU_IRQ_24_25[8:0]	19	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_25 (ID57)	20	CTRL_CORE_MPU_IRQ_24_25[24:16]	20	DISPC_IRQ	Display controller interrupt
MPU_IRQ_26 (ID58)	21	CTRL_CORE_MPU_IRQ_26_27[8:0]	21	MAILBOX1_IRQ_USER0	Mailbox 1 user 0 interrupt
MPU_IRQ_27 (ID59)	22	CTRL_CORE_MPU_IRQ_26_27[24:16]	22	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_28 (ID60)	23	CTRL_CORE_MPU_IRQ_28_29[8:0]	23	DSP1_IRQ_MMU0	DSP1 MMU0 interrupt

Table 17-2. MPU_INTC Default Interrupt Mapping (continued)

IRQ Input Line (GIC ID Number) (1)	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
MPU_IRQ_29 (ID61)	24	CTRL_CORE_MPU_IRQ_28_29[24:16]	24	GPIO1_IRQ_1	GPIO1 interrupt 1
MPU_IRQ_30 (ID62)	25	CTRL_CORE_MPU_IRQ_30_31[8:0]	25	GPIO2_IRQ_1	GPIO2 interrupt 1
MPU_IRQ_31 (ID63)	26	CTRL_CORE_MPU_IRQ_30_31[24:16]	26	GPIO3_IRQ_1	GPIO3 interrupt 1

MPU_IRQ_114 (ID146)	109	CTRL_CORE_MPU_IRQ_114_115[8:0]	109	Reserved	Reserved by default but can be remapped to a valid interrupt source

Table 17-2. MPU_INTC Default Interrupt Mapping (continued)

IRQ Input Line (GIC ID Number) (1)	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
MPU_IRQ_115 (ID147)	110	CTRL_CORE_MPU_IRQ_114_115[24:16]	110	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_116 (ID148)	111	CTRL_CORE_MPU_IRQ_116_117[8:0]	111	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_117 (ID149)	112	CTRL_CORE_MPU_IRQ_116_117[24:16]	112	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_118 (ID150)	113	CTRL_CORE_MPU_IRQ_118_119[8:0]	113	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_119 (ID151)	114	CTRL_CORE_MPU_IRQ_118_119[24:16]	114	EXT_SYS_IRQ_2	External interrupt (active low) via sys_nirq2 pin
MPU_IRQ_120 (ID152)	115	CTRL_CORE_MPU_IRQ_120_121[8:0]	115	KBD_IRQ	Keyboard controller interrupt
MPU_IRQ_121 (ID153)	116	CTRL_CORE_MPU_IRQ_120_121[24:16]	116	GPIO8_IRQ_1	GPIO8 interrupt 1
MPU_IRQ_122 (ID154)	117	CTRL_CORE_MPU_IRQ_122_123[8:0]	117	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_123 (ID155)	118	CTRL_CORE_MPU_IRQ_122_123[24:16]	118	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_124 (ID156)	119	CTRL_CORE_MPU_IRQ_124_125[8:0]	119	CAL_IRQ	CAL (CSI2) interrupt
MPU_IRQ_125 (ID157)	120	CTRL_CORE_MPU_IRQ_124_125[24:16]	120	BB2D_IRQ	BB2D interrupt
MPU_IRQ_126 (ID158)	121	CTRL_CORE_MPU_IRQ_126_127[8:0]	121	CTRL_MODULE_CORE_IRQ_THERMAL_ALERT	CTRL_MODULE thermal alert interrupt
MPU_IRQ_127 (ID159)	122	CTRL_CORE_MPU_IRQ_126_127[24:16]	122	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_128 (ID160)	123	CTRL_CORE_MPU_IRQ_128_129[8:0]	123	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_129 (ID161)	124	CTRL_CORE_MPU_IRQ_128_129[24:16]	124	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_130 (ID162)	125	CTRL_CORE_MPU_IRQ_130_133[8:0]	125	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_131 (ID163)	N/A	N/A	N/A	MPU_CLUSTER_IRQ_PMU_C0	MPU core 0 PMU interrupt
MPU_IRQ_132 (ID164)	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source

Table 17-2. MPU_INTC Default Interrupt Mapping (continued)

IRQ Input Line (GIC ID Number) (1)	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
MPU_IRQ_133 (ID165)	126	CTRL_CORE_MPU_IRQ_130_133[24:16]	0	Reserved	Reserved by default but can be remapped to: • a valid interrupt source (through CTRL_CORE_MPU_IRQ_130_133[24:16]) • the nmin_dsp pin (through CTRL_CORE_NMI_DESTINATION_2[7:0] MPU). See *Interrupt Controllers Environment* for details.
MPU_IRQ_134 (ID166)	127	CTRL_CORE_MPU_IRQ_134_135[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_135 (ID167)	128	CTRL_CORE_MPU_IRQ_134_135[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_136 (ID168)	129	CTRL_CORE_MPU_IRQ_136_137[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_137 (ID169)	130	CTRL_CORE_MPU_IRQ_136_137[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_138 (ID170)	131	CTRL_CORE_MPU_IRQ_138_139[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_139 (ID171)	N/A	N/A	N/A	WD_TIMER_MPU_C0_IRQ	MPU_WD_TIMER channel 0 timeout interrupt (watchdog reset)
MPU_IRQ_140 (ID172)	N/A	N/A	N/A	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_141 (ID173)	134	CTRL_CORE_MPU_IRQ_140_141[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_142 (ID174)	135	CTRL_CORE_MPU_IRQ_142_143[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_143 (ID175)	136	CTRL_CORE_MPU_IRQ_142_143[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_144 (ID176)	137	CTRL_CORE_MPU_IRQ_144_145[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_145 (ID177)	138	CTRL_CORE_MPU_IRQ_144_145[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_146 (ID178)	139	CTRL_CORE_MPU_IRQ_146_147[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source

Table 17-2. MPU_INTC Default Interrupt Mapping (continued)

IRQ Input Line (GIC ID Number) (1)	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
MPU_IRQ_147 (ID179)	140	CTRL_CORE_MPU_IRQ_146_147[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_148 (ID180)	141	CTRL_CORE_MPU_IRQ_148_149[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_149 (ID181)	142	CTRL_CORE_MPU_IRQ_148_149[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_150 (ID182)	143	CTRL_CORE_MPU_IRQ_150_151[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_151 (ID183)	144	CTRL_CORE_MPU_IRQ_150_151[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_152 (ID184)	145	CTRL_CORE_MPU_IRQ_152_153[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_153 (ID185)	146	CTRL_CORE_MPU_IRQ_152_153[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_154 (ID186)	147	CTRL_CORE_MPU_IRQ_154_155[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_155 (ID187)	148	CTRL_CORE_MPU_IRQ_154_155[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_156 (ID188)	149	CTRL_CORE_MPU_IRQ_156_157[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_157 (ID189)	150	CTRL_CORE_MPU_IRQ_156_157[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_158 (ID190)	151	CTRL_CORE_MPU_IRQ_158_159[8:0]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source
MPU_IRQ_159 (ID191)	152	CTRL_CORE_MPU_IRQ_158_159[24:16]	0	Reserved	Reserved by default but can be remapped to a valid interrupt source

(1) This column shows the association between the Shared Peripheral Interrupts (MPU_IRQ_0 – MPU_IRQ_159) and the GIC inputs (ID32 – ID191).
(2) The L3_MAIN_IRQ_APP_ERR interrupt is directly mapped to the MPU_IRQ_10 line, bypassing the crossbar instance dedicated to this line. No other interrupt source can be mapped to MPU_IRQ_10.
(3) USB3 (ULPI) is not supported on the AM571x / AM570x family of devices.
(4) SATA is NOT supported on the AM570x family of devices.

Note

The "**IRQ_CROSSBAR Default Input Index**" column of Table 17-2 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding MPU_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_MPU_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to MPU_INTC inputs. For example, the MPU_IRQ_4_7[8:0] bit field is used to configure which device interrupt would be mapped to the MPU_IRQ_4 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to MPU_IRQ_4 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the MPU subsystem. There is no IRQ_CROSSBAR dedicated to the associated MPU_INTC input line and therefore, the user cannot change its default mapping.

17.3.2 Interrupt Requests to DSP1_INTC

Table 17-3 lists the default interrupt sources for the DSP1_INTC. In addition, interrupts DSP1_IRQ_32 through DSP1_IRQ_95 can alternatively be sourced through the DSP1's IRQ_CROSSBAR from one of the 420 multiplexed device interrupts listed in Table 17-8. The DSP1_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 17-3. DSP1_INTC Default Interrupt Mapping

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_0	N/A	N/A	N/A	CGEM_IRQ_0	CGEM Internal Interrupt
DSP1_IRQ_1	N/A	N/A	N/A	CGEM_IRQ_1	CGEM Internal Interrupt
DSP1_IRQ_2	N/A	N/A	N/A	CGEM_IRQ_2	CGEM Internal Interrupt
DSP1_IRQ_3	N/A	N/A	N/A	CGEM_IRQ_3	CGEM Internal Interrupt
DSP1_IRQ_4	N/A	N/A	N/A	CGEM_IRQ_4	CGEM Internal Interrupt
DSP1_IRQ_5	N/A	N/A	N/A	CGEM_IRQ_5	CGEM Internal Interrupt
DSP1_IRQ_6	N/A	N/A	N/A	CGEM_IRQ_6	CGEM Internal Interrupt
DSP1_IRQ_7	N/A	N/A	N/A	CGEM_IRQ_7	CGEM Internal Interrupt
DSP1_IRQ_8	N/A	N/A	N/A	CGEM_IRQ_8	CGEM Internal Interrupt
DSP1_IRQ_9	N/A	N/A	N/A	CGEM_IRQ_9	CGEM Internal Interrupt
DSP1_IRQ_10	N/A	N/A	N/A	CGEM_IRQ_10	CGEM Internal Interrupt
DSP1_IRQ_11	N/A	N/A	N/A	CGEM_IRQ_11	CGEM Internal Interrupt
DSP1_IRQ_12	N/A	N/A	N/A	CGEM_IRQ_12	CGEM Internal Interrupt
DSP1_IRQ_13	N/A	N/A	N/A	CGEM_IRQ_13	CGEM Internal Interrupt

Table 17-3. DSP1_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_14	N/A	N/A	N/A	CGEM_IRQ_14	CGEM Internal Interrupt
DSP1_IRQ_15	N/A	N/A	N/A	CGEM_IRQ_15	CGEM Internal Interrupt
DSP1_IRQ_16	N/A	N/A	N/A	TPCC_INTG	EDMA CC global interrupt
DSP1_IRQ_17	N/A	N/A	N/A	TPCC_INT0	EDMA CC region0 interrupt
DSP1_IRQ_18	N/A	N/A	N/A	TPCC_INT1	EDMA CC region1 interrupt
DSP1_IRQ_19	N/A	N/A	N/A	TPCC_INT2	EDMA CC region2 interrupt
DSP1_IRQ_20	N/A	N/A	N/A	TPCC_INT3	EDMA CC region3 interrupt
DSP1_IRQ_21	N/A	N/A	N/A	FW0_FUNC_ERROR	Firewall0 func access error
DSP1_IRQ_22	N/A	N/A	N/A	FW0_DEBUG_ERROR	Firewall0 debug access error
DSP1_IRQ_23	N/A	N/A	N/A	FW1_FUNC_ERROR	Firewall1 func access error
DSP1_IRQ_24	N/A	N/A	N/A	FW1_DEBUG_ERROR	Firewall1 debug access error
DSP1_IRQ_25	N/A	N/A	N/A	MMU0_INT	DSP MMU0 Interrupt
DSP1_IRQ_26	N/A	N/A	N/A	MMU1_INT	DSP MMU1 Interrupt
DSP1_IRQ_27	N/A	N/A	N/A	TPCC_ERRINT	EDMA CC error interrupt
DSP1_IRQ_28	N/A	N/A	N/A	TPTC_ERRINT0	EDMA TC0 error interrupt
DSP1_IRQ_29	N/A	N/A	N/A	TPTC_ERRINT1	EDMA TC1 error interrupt
DSP1_IRQ_30	N/A	N/A	N/A	NOC_ERRINT	Interconnect error interrupt
DSP1_IRQ_31	NA	N/A	N/A	EDMA_WAKE_INT	EDMA wakeup interrupt
DSP1_IRQ_32	1	CTRL_CORE_DSP1_IRQ_32_33[8:0]	1	ELM_IRQ	Error location process completion interrupt
DSP1_IRQ_33	2	CTRL_CORE_DSP1_IRQ_32_33[24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin
DSP1_IRQ_34	3	CTRL_CORE_DSP1_IRQ_34_35[8:0]	3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	Combined firewall error interrupt. For more information, see *Firewall Error Status Registers*.
DSP1_IRQ_35	4	CTRL_CORE_DSP1_IRQ_34_35[24:16]	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error
DSP1_IRQ_36	5	CTRL_CORE_DSP1_IRQ_36_37[8:0]	5	L3_MAIN_IRQ_APP_ERR	L3_MAIN application or non-attributable error
DSP1_IRQ_37	6	CTRL_CORE_DSP1_IRQ_36_37[24:16]	6	PRM_IRQ_MPU	PRCM interrupt to MPU

Table 17-3. DSP1_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_38	7	CTRL_CORE_DSP1_IRQ_38_39[8:0]	7	DMA_SYSTEM_IRQ_0	System DMA interrupt 0
DSP1_IRQ_39	8	CTRL_CORE_DSP1_IRQ_38_39[24:16]	8	DMA_SYSTEM_IRQ_1	System DMA interrupt 1
DSP1_IRQ_40	9	CTRL_CORE_DSP1_IRQ_40_41[8:0]	9	DMA_SYSTEM_IRQ_2	System DMA interrupt 2
DSP1_IRQ_41	10	CTRL_CORE_DSP1_IRQ_40_41[24:16]	10	DMA_SYSTEM_IRQ_3	System DMA interrupt 3
DSP1_IRQ_42	11	CTRL_CORE_DSP1_IRQ_42_43[8:0]	11	L3_MAIN_IRQ_STAT_ALARM	L3_MAIN statistic collector alarm interrupt
DSP1_IRQ_43	12	CTRL_CORE_DSP1_IRQ_42_43[24:16]	12	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_44	13	CTRL_CORE_DSP1_IRQ_44_45[8:0]	13	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_45	14	CTRL_CORE_DSP1_IRQ_44_45[24:16]	14	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_46	15	CTRL_CORE_DSP1_IRQ_46_47[8:0]	15	GPMC_IRQ	GPMC interrupt
DSP1_IRQ_47	16	CTRL_CORE_DSP1_IRQ_46_47[24:16]	16	GPU_IRQ	GPU interrupt
DSP1_IRQ_48	17	CTRL_CORE_DSP1_IRQ_48_49[8:0]	17	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_49	18	CTRL_CORE_DSP1_IRQ_48_49[24:16]	18	Reserved	Reserved by default but can be remapped to a valid interrupt source

DSP1_IRQ_126	N/A	N/A	N/A	CGEM_IRQ_46	CGEM Internal Interrupt
DSP1_IRQ_127	N/A	N/A	N/A	CGEM_IRQ_47	CGEM Internal Interrupt

Note

The "**IRQ_CROSSBAR Default Input Index**" column of Table 17-3 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding DSP1_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_DSP1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to DSP1_INTC inputs. For example, the DSP1_IRQ_32_33[8:0] bit field is used to configure which device interrupt would be mapped to the DSP1_IRQ_32 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to DSP1_IRQ_32 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the DSP1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated DSP1_INTC input line and therefore, the user cannot change its default mapping.

17.3.3 Interrupt Requests to IPU1_Cx_INTC

Table 17-4 lists the default interrupt sources for the IPU1_Cx_INTC. In addition, device interrupts IPU1_IRQ_23 through IPU1_IRQ_79 can alternatively be sourced through the IPU1's IRQ_CROSSBAR from one of the 420 multiplexed device interrupts listed in Table 17-8. The CTRL_CORE_IPU1_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 17-4. IPU1_Cx_INTC Default Interrupt Mapping

IRQ Input Line[1]	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU1_IRQ_0	N/A	N/A	N/A	Reserved	MSP initial value in exception vector table
IPU1_IRQ_1	N/A	N/A	N/A	RESET_IRQ	Reset
IPU1_IRQ_2	N/A	N/A	N/A	NMI_IRQ	External NMI inputs
IPU1_IRQ_3	N/A	N/A	N/A	HARD_FAULT_IRQ	All fault conditions, if the fault handle is not enabled
IPU1_IRQ_4	N/A	N/A	N/A	MEM_MANAGE_FAULT_IRQ	Memory management fault; access to illegal locations
IPU1_IRQ_5	N/A	N/A	N/A	BUS_FAULT_IRQ	Bus error (on AHB intf)
IPU1_IRQ_6	N/A	N/A	N/A	USAGE_FAULT_IRQ	Program error
IPU1_IRQ_7	N/A	N/A	N/A	Reserved	Reserved
IPU1_IRQ_8	N/A	N/A	N/A	Reserved	Reserved
IPU1_IRQ_9	NA	N/A	N/A	Reserved	Reserved
IPU1_IRQ_10	N/A	N/A	N/A	Reserved	Reserved
IPU1_IRQ_11	N/A	N/A	N/A	SV_CALL_IRQ	Service system Call
IPU1_IRQ_12	N/A	N/A	N/A	DEBUG_MON_IRQ	BP, WP or external debug req.
IPU1_IRQ_13	N/A	N/A	N/A	Reserved	Reserved

Table 17-4. IPU1_Cx_INTC Default Interrupt Mapping (continued)

IRQ Input Line[1]	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description

IPU1_IRQ_77	55	CTRL_CORE_IPU1_IRQ_77_78[8:0]	88	USB3_IRQ_INTR0(2)	USB3 interrupt 0
IPU1_IRQ_78	56	CTRL_CORE_IPU1_IRQ_77_78[24:16]	62	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU1_IRQ_79	57	CTRL_CORE_IPU1_IRQ_79_80[8:0]	63	Reserved	Reserved by default but can be remapped to a valid interrupt source

(1) This column shows the number of the corresponding exception type.
(2) USB3 (ULPI) is not supported on the AM571x / AM570x family of devices.

Note

Exceptions/interrupts IPU1_IRQ_[15:0] are all internal to the Cortex-M4 core.

Exceptions/interrupts IPU1_IRQ_[79:16] are all external to the Cortex-M4 core – that is, the first Cortex-M4 external interrupt is mapped to IPU1_IRQ_16 (exception #16), and the last (sixty-fourth) Cortex-M4 external interrupt is mapped to IPU1_IRQ_79 (exception #79).

For more information about Cortex-M4 exception types, refer to Arm *Cortex™-M4 Devices Generic User Guide* (available at http://infocenter.arm.com/help/index.jsp).

Note

The "**IRQ_CROSSBAR Default Input Index**" column of Table 17-4 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding IPU1_Cx_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_IPU1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to IPU1_Cx_INTC inputs. For example, the IPU1_IRQ_23_24[8:0] bit field is used to configure which device interrupt would be mapped to the IPU1_IRQ_23 line. The reset value of this bit field is 0x14, meaning that DISPC_IRQ would be mapped to IPU1_IRQ_23 by default because it is connected to the IRQ_CROSSBAR_20 input.

'N/A' in this column means that the corresponding interrupt is internal to the IPU1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated IPU1_Cx_INTC input line and therefore, the user cannot change its default mapping.

The CTRL_CORE_IPU1_IRQ_y_z registers control the IRQ_CROSSBAR settings for both NVICs in the IPU1 subsystem. That is, it is not possible to map different interrupts to the same interrupt input of the NVICs in IPU1.

17.3.4 Interrupt Requests to IPU2_Cx_INTC

Table 17-5 lists the default interrupt sources for the IPU2_Cx_INTC. In addition, device interrupts IPU2_IRQ_23 through IPU2_IRQ_79 can alternatively be sourced through the IPU2's IRQ_CROSSBAR from one of the 420 multiplexed device interrupts listed in Table 17-8. The CTRL_CORE_IPU2_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 17-5. IPU2_Cx_INTC Default Interrupt Mapping

IRQ Input Line(1)	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU2_IRQ_0	N/A	N/A	N/A	Reserved	MSP initial value in exception vector table
IPU2_IRQ_1	N/A	N/A	N/A	RESET_IRQ	Reset
IPU2_IRQ_2	N/A	N/A	N/A	NMI_IRQ	External NMI inputs
IPU2_IRQ_3	N/A	N/A	N/A	HARD_FAULT_IRQ	All fault conditions, if the fault handle is not enabled
IPU2_IRQ_4	N/A	N/A	N/A	MEM_MANAGE_FAULT_IRQ	Memory management fault; access to illegal locations
IPU2_IRQ_5	N/A	N/A	N/A	BUS_FAULT_IRQ	Bus error (on AHB intf)
IPU2_IRQ_6	N/A	N/A	N/A	USAGE_FAULT_IRQ	Program error
IPU2_IRQ_7	N/A	N/A	N/A	Reserved	Reserved

IPU2_IRQ_74	52	CTRL_CORE_IPU2_IRQ_73_74[24:16]	73	USB2_IRQ_INTR0	USB2 interrupt 0
IPU2_IRQ_75	53	CTRL_CORE_IPU2_IRQ_75_76[8:0]	117	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU2_IRQ_76	54	CTRL_CORE_IPU2_IRQ_75_76[24:16]	87	USB2_IRQ_INTR1	USB2 interrupt 1
IPU2_IRQ_77	55	CTRL_CORE_IPU2_IRQ_77_78[8:0]	88	USB3_IRQ_INTR0[2]	USB3 interrupt 0
IPU2_IRQ_78	56	CTRL_CORE_IPU2_IRQ_77_78[24:16]	62	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU2_IRQ_79	57	CTRL_CORE_IPU2_IRQ_79_80[8:0]	63	Reserved	Reserved by default but can be remapped to a valid interrupt source

(1) This column shows the number of the corresponding exception type.
(2) USB3 (ULPI) is not supported on the AM571x / AM570x family of devices.

Note

Exceptions/interrupts IPU2_IRQ_[15:0] are all internal to the Cortex-M4 core.

Exceptions/interrupts IPU2_IRQ_[79:16] are all external to the Cortex-M4 core – that is, the first Cortex-M4 external interrupt is mapped to IPU2_IRQ_16 (exception #16), and the last (sixty-fourth) Cortex-M4 external interrupt is mapped to IPU2_IRQ_79 (exception #79).

For more information about Cortex-M4 exception types, refer to Arm *Cortex™-M4 Devices Generic User Guide* (available at http://infocenter.arm.com/help/index.jsp).

Note

The "**IRQ_CROSSBAR Default Input Index**" column of Table 17-5 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding IPU2_Cx_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_IPU2_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to IPU2_Cx_INTC inputs. For example, the IPU2_IRQ_23_24[8:0] bit field is used to configure which device interrupt would be mapped to the IPU2_IRQ_23 line. The reset value of this bit field is 0x14, meaning that DISPC_IRQ would be mapped to IPU2_IRQ_23 by default because it is connected to the IRQ_CROSSBAR_20 input.

'N/A' in this column means that the corresponding interrupt is internal to the IPU2 subsystem. There is no IRQ_CROSSBAR dedicated to the associated IPU2_Cx_INTC input line and therefore, the user cannot change its default mapping.

The CTRL_CORE_IPU2_IRQ_y_z registers control the IRQ_CROSSBAR settings for both NVICs in the IPU2 subsystem. That is, it is not possible to map different interrupts to the same interrupt input of the NVICs in IPU2.

17.3.5 Interrupt Requests to PRUSS1_INTC

Table 17-6 lists the default interrupt sources for the PRUSS1_INTC. In addition, device interrupts PRUSS1_IRQ_32 through PRUSS1_IRQ_63 can alternatively be sourced through the PRU-ICSS1's IRQ_CROSSBAR from one of the 420 multiplexed device interrupts listed in Table 17-8. The CTRL_CORE_PRUSS1_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 17-6. PRUSS1_INTC Default Interrupt Mapping

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
PRUSS1_IRQ_0	N/A	N/A	N/A	PRUSS1_INTERNAL_IRQ_0	PRU-ICSS1 Internal Interrupt

PRUSS1_IRQ_59	28	CTRL_CORE_PRUSS1_IRQ_58_59[24:16]	28	GPIO5_IRQ_1	GPIO5 interrupt 1

Table 17-6. PRUSS1_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
PRUSS1_IRQ_60	29	CTRL_CORE_PRUSS1_IRQ_60_61[8:0]	29	GPIO6_IRQ_1	GPIO6 interrupt 1
PRUSS1_IRQ_61	30	CTRL_CORE_PRUSS1_IRQ_60_61[24:16]	30	GPIO7_IRQ_1	GPIO7 interrupt 1
PRUSS1_IRQ_62	31	CTRL_CORE_PRUSS1_IRQ_62_63[8:0]	31	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS1_IRQ_63	32	CTRL_CORE_PRUSS1_IRQ_62_63[24:16]	32	TIMER1_IRQ	TIMER1 interrupt

Note

The "**IRQ_CROSSBAR Default Input Index**" column of Table 17-6 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding PRUSS1_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_PRUSS1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to PRUSS1_INTC inputs. For example, the PRUSS1_IRQ_32_33[8:0] bit field is used to configure which device interrupt would be mapped to the PRUSS1_IRQ_32 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to PRUSS1_IRQ_32 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the PRU-ICSS1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated PRUSS1_INTC input line and therefore, the user cannot change its default mapping.

17.3.6 Interrupt Requests to PRUSS2_INTC

Table 17-7 lists the default interrupt sources for the PRUSS2_INTC. In addition, device interrupts PRUSS2_IRQ_32 through PRUSS2_IRQ_63 can alternatively be sourced through the PRU-ICSS1's IRQ_CROSSBAR from one of the 420 multiplexed device interrupts listed in Table 17-8. The CTRL_CORE_PRUSS2_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 17-7. PRUSS2_INTC Default Interrupt Mapping

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
PRUSS2_IRQ_0	N/A	N/A	N/A	PRUSS2_INTERNAL_IRQ_0	PRU-ICSS1 Internal Interrupt
PRUSS2_IRQ_1	N/A	N/A	N/A	PRUSS2_INTERNAL_IRQ_1	PRU-ICSS1 Internal Interrupt
PRUSS2_IRQ_2	N/A	N/A	N/A	PRUSS2_INTERNAL_IRQ_2	PRU-ICSS1 Internal Interrupt

PRUSS2_IRQ_38	7	CTRL_CORE_PRUSS2_IRQ_38_39[8:0]	7	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_39	8	CTRL_CORE_PRUSS2_IRQ_38_39[24:16]	8	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_40	9	CTRL_CORE_PRUSS2_IRQ_40_41[8:0]	9	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_41	10	CTRL_CORE_PRUSS2_IRQ_40_41[24:16]	10	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_42	11	CTRL_CORE_PRUSS2_IRQ_42_43[8:0]	11	L3_MAIN_IRQ_STAT_ALARM	L3_MAIN statistic collector alarm interrupt
PRUSS2_IRQ_43	12	CTRL_CORE_PRUSS2_IRQ_42_43[24:16]	12	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_44	13	CTRL_CORE_PRUSS2_IRQ_44_45[8:0]	13	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_45	14	CTRL_CORE_PRUSS2_IRQ_44_45[24:16]	14	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_46	15	CTRL_CORE_PRUSS2_IRQ_46_47[8:0]	15	GPMC_IRQ	GPMC interrupt
PRUSS2_IRQ_47	16	CTRL_CORE_PRUSS2_IRQ_46_47[24:16]	16	GPU_IRQ	GPU interrupt
PRUSS2_IRQ_48	17	CTRL_CORE_PRUSS2_IRQ_48_49[8:0]	17	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_49	18	CTRL_CORE_PRUSS2_IRQ_48_49[24:16]	18	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_50	19	CTRL_CORE_PRUSS2_IRQ_50_51[8:0]	19	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_51	20	CTRL_CORE_PRUSS2_IRQ_50_51[24:16]	20	DISPC_IRQ	Display controller interrupt
PRUSS2_IRQ_52	21	CTRL_CORE_PRUSS2_IRQ_52_53[8:0]	21	MAILBOX1_IRQ_USER0	Mailbox 1 user 0 interrupt
PRUSS2_IRQ_53	22	CTRL_CORE_PRUSS2_IRQ_52_53[24:16]	22	Reserved	Reserved by default but can be remapped to a valid interrupt source

Table 17-7. PRUSS2_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
PRUSS2_IRQ_54	23	CTRL_CORE_PRUSS2_IRQ_54_55[8:0]	23	DSP1_IRQ_MMU0	DSP1 MMU0 interrupt
PRUSS2_IRQ_55	24	CTRL_CORE_PRUSS2_IRQ_54_55[24:16]	24	GPIO1_IRQ_1	GPIO1 interrupt 1
PRUSS2_IRQ_56	25	CTRL_CORE_PRUSS2_IRQ_56_57[8:0]	25	GPIO2_IRQ_1	GPIO2 interrupt 1
PRUSS2_IRQ_57	26	CTRL_CORE_PRUSS2_IRQ_56_57[24:16]	26	GPIO3_IRQ_1	GPIO3 interrupt 1
PRUSS2_IRQ_58	27	CTRL_CORE_PRUSS2_IRQ_58_59[8:0]	27	GPIO4_IRQ_1	GPIO4 interrupt 1
PRUSS2_IRQ_59	28	CTRL_CORE_PRUSS2_IRQ_58_59[24:16]	28	GPIO5_IRQ_1	GPIO5 interrupt 1
PRUSS2_IRQ_60	29	CTRL_CORE_PRUSS2_IRQ_60_61[8:0]	29	GPIO6_IRQ_1	GPIO6 interrupt 1
PRUSS2_IRQ_61	30	CTRL_CORE_PRUSS2_IRQ_60_61[24:16]	30	GPIO7_IRQ_1	GPIO7 interrupt 1
PRUSS2_IRQ_62	31	CTRL_CORE_PRUSS2_IRQ_62_63[8:0]	31	Reserved	Reserved by default but can be remapped to a valid interrupt source
PRUSS2_IRQ_63	32	CTRL_CORE_PRUSS2_IRQ_62_63[24:16]	32	TIMER1_IRQ	TIMER1 interrupt

Note

The "**IRQ_CROSSBAR Default Input Index**" column of Table 17-7 shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding PRUSS2_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_PRUSS2_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to PRUSS2_INTC inputs. For example, the PRUSS2_IRQ_32_33[8:0] bit field is used to configure which device interrupt would be mapped to the PRUSS2_IRQ_32 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to PRUSS2_IRQ_32 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the PRU-ICSS2 subsystem. There is no IRQ_CROSSBAR dedicated to the associated PRUSS2_INTC input line and therefore, the user cannot change its default mapping.

17.3.7 Mapping of Device Interrupts to IRQ_CROSSBAR Inputs

Table 17-8 shows the individual connection between all module IRQs and all IRQ_CROSSBAR inputs.

Table 17-8. Connection of Device IRQs to IRQ_CROSSBAR Inputs

IRQ_CROSSBAR Input	Interrupt Name	Interrupt Source	Description
IRQ_CROSSBAR_0	Reserved	Reserved	Reserved
IRQ_CROSSBAR_1	ELM_IRQ	ELM	Error location process completion interrupt
IRQ_CROSSBAR_2	EXT_SYS_IRQ_1	External system	External interrupt (active low) via sys_nirq1 pin
IRQ_CROSSBAR_3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	CTRL_MODULE_CORE	Combined firewall error interrupt. For more information, see *Firewall Error Status Registers*
IRQ_CROSSBAR_4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN	L3_MAIN debug error

Table 17-8. Connection of Device IRQs to IRQ_CROSSBAR Inputs (continued)

IRQ_CROSSBAR Input	Interrupt Name	Interrupt Source	Description
IRQ_CROSSBAR_5	L3_MAIN_IRQ_APP_ERR	L3_MAIN	L3_MAIN application or non-attributable error
IRQ_CROSSBAR_6	PRM_IRQ_MPU	PRM	PRCM interrupt to MPU
IRQ_CROSSBAR_7	DMA_SYSTEM_IRQ_0	DMA_SYSTEM	System DMA interrupt 0
IRQ_CROSSBAR_8	DMA_SYSTEM_IRQ_1	DMA_SYSTEM	System DMA interrupt 1
IRQ_CROSSBAR_9	DMA_SYSTEM_IRQ_2	DMA_SYSTEM	System DMA interrupt 2
IRQ_CROSSBAR_10	DMA_SYSTEM_IRQ_3	DMA_SYSTEM	System DMA interrupt 3
IRQ_CROSSBAR_11	L3_MAIN_IRQ_STAT_ALARM	L3_MAIN	L3_MAIN statistic collector alarm interrupt
IRQ_CROSSBAR_12	Reserved	Reserved	Reserved
IRQ_CROSSBAR_13	Reserved	Reserved	Reserved
IRQ_CROSSBAR_14	Reserved	Reserved	Reserved
IRQ_CROSSBAR_15	GPMC_IRQ	GPMC	GPMC interrupt
IRQ_CROSSBAR_16	GPU_IRQ	GPU	GPU interrupt
IRQ_CROSSBAR_17	Reserved	Reserved	Reserved
IRQ_CROSSBAR_18	Reserved	Reserved	Reserved
IRQ_CROSSBAR_19	Reserved	Reserved	Reserved
IRQ_CROSSBAR_20	DISPC_IRQ	DISPC	Display controller interrupt
IRQ_CROSSBAR_21	MAILBOX1_IRQ_USER0	MAILBOX1	Mailbox 1 user 0 interrupt
IRQ_CROSSBAR_22	Reserved	Reserved	Reserved
IRQ_CROSSBAR_23	DSP1_IRQ_MMU0	DSP1	DSP1 MMU0 interrupt
IRQ_CROSSBAR_24	GPIO1_IRQ_1	GPIO1	GPIO1 interrupt 1
IRQ_CROSSBAR_25	GPIO2_IRQ_1	GPIO2	GPIO2 interrupt 1
IRQ_CROSSBAR_26	GPIO3_IRQ_1	GPIO3	GPIO3 interrupt 1
IRQ_CROSSBAR_27	GPIO4_IRQ_1	GPIO4	GPIO4 interrupt 1
IRQ_CROSSBAR_28	GPIO5_IRQ_1	GPIO5	GPIO5 interrupt 1
IRQ_CROSSBAR_29	GPIO6_IRQ_1	GPIO6	GPIO6 interrupt 1
IRQ_CROSSBAR_30	GPIO7_IRQ_1	GPIO7	GPIO7 interrupt 1
IRQ_CROSSBAR_31	Reserved	Reserved	Reserved
IRQ_CROSSBAR_32	TIMER1_IRQ	TIMER1	TIMER1 interrupt
IRQ_CROSSBAR_33	TIMER2_IRQ	TIMER2	TIMER2 interrupt
IRQ_CROSSBAR_34	TIMER3_IRQ	TIMER3	TIMER3 interrupt
IRQ_CROSSBAR_35	TIMER4_IRQ	TIMER4	TIMER4 interrupt
IRQ_CROSSBAR_36	TIMER5_IRQ	TIMER5	TIMER5 interrupt
IRQ_CROSSBAR_37	TIMER6_IRQ	TIMER6	TIMER6 interrupt
IRQ_CROSSBAR_38	TIMER7_IRQ	TIMER7	TIMER7 interrupt
IRQ_CROSSBAR_39	TIMER8_IRQ	TIMER8	TIMER8 interrupt
IRQ_CROSSBAR_40	TIMER9_IRQ	TIMER9	TIMER9 interrupt
IRQ_CROSSBAR_41	TIMER10_IRQ	TIMER10	TIMER10 interrupt
IRQ_CROSSBAR_42	TIMER11_IRQ	TIMER11	TIMER11 interrupt
IRQ_CROSSBAR_43	MCSPI4_IRQ	MCSPI4	McSPI4 interrupt
IRQ_CROSSBAR_44	Reserved	Reserved	Reserved
IRQ_CROSSBAR_45	Reserved	Reserved	Reserved
IRQ_CROSSBAR_46	Reserved	Reserved	Reserved
IRQ_CROSSBAR_47	Reserved	Reserved	Reserved
IRQ_CROSSBAR_48	Reserved	Reserved	Reserved

Table 17-8. Connection of Device IRQs to IRQ_CROSSBAR Inputs (continued)

IRQ_CROSSBAR Input	Interrupt Name	Interrupt Source	Description
IRQ_CROSSBAR_49	SATA_IRQ(2)	SATA	SATA interrupt
IRQ_CROSSBAR_50	Reserved	Reserved	Reserved
IRQ_CROSSBAR_51	I2C1_IRQ	I2C1	I2C1 interrupt
IRQ_CROSSBAR_52	I2C2_IRQ	I2C2	I2C2 interrupt
IRQ_CROSSBAR_53	HDQ1W_IRQ	HDQ1W	HDQ1W interrupt
IRQ_CROSSBAR_54	Reserved	Reserved	Reserved
IRQ_CROSSBAR_55	I2C5_IRQ	I2C5	I2C5 interrupt
IRQ_CROSSBAR_56	I2C3_IRQ	I2C3	I2C3 interrupt
IRQ_CROSSBAR_57	I2C4_IRQ	I2C4	I2C4 interrupt
IRQ_CROSSBAR_58	Reserved	Reserved	Reserved
IRQ_CROSSBAR_59	Reserved	Reserved	Reserved
IRQ_CROSSBAR_60	MCSPI1_IRQ	MCSPI1	McSPI1 interrupt
IRQ_CROSSBAR_61	MCSPI2_IRQ	MCSPI2	McSPI2 interrupt
IRQ_CROSSBAR_62	Reserved	Reserved	Reserved
IRQ_CROSSBAR_63	Reserved	Reserved	Reserved
IRQ_CROSSBAR_64	Reserved	Reserved	Reserved
IRQ_CROSSBAR_65	UART4_IRQ	UART4	UART4 interrupt
IRQ_CROSSBAR_66	Reserved	Reserved	Reserved
IRQ_CROSSBAR_67	UART1_IRQ	UART1	UART1 interrupt
IRQ_CROSSBAR_68	UART2_IRQ	UART2	UART2 interrupt
IRQ_CROSSBAR_69	UART3_IRQ	UART3	UART3 interrupt
IRQ_CROSSBAR_70	PBIAS_IRQ	MMC1 PBIAS Cell	MMC1 PBIAS interrupt (controlled via device Control Module)
IRQ_CROSSBAR_71	USB1_IRQ_INTR0	USB1	USB1 interrupt 0
IRQ_CROSSBAR_72	USB1_IRQ_INTR1	USB1	USB1 interrupt 1
IRQ_CROSSBAR_73	USB2_IRQ_INTR0	USB2	USB2 interrupt 0
IRQ_CROSSBAR_74	Reserved	Reserved	Reserved
IRQ_CROSSBAR_75	WD_TIMER2_IRQ	WD_TIMER2	WD_TIMER2 interrupt
IRQ_CROSSBAR_76	Reserved	Reserved	Reserved
IRQ_CROSSBAR_77	Reserved	Reserved	Reserved
IRQ_CROSSBAR_78	MMC1_IRQ	MMC1	MMC1 interrupt
IRQ_CROSSBAR_79	Reserved	Reserved	Reserved
IRQ_CROSSBAR_80	Reserved	Reserved	Reserved
IRQ_CROSSBAR_81	MMC2_IRQ	MMC2	MMC2 interrupt
IRQ_CROSSBAR_82	Reserved	Reserved	Reserved
IRQ_CROSSBAR_83	Reserved	Reserved	Reserved
IRQ_CROSSBAR_84	Reserved	Reserved	Reserved
IRQ_CROSSBAR_85	DEBUGSS_IRQ_CT_UART	DEBUGSS	CT_UART interrupt generated when data ready on RX or when TX empty
IRQ_CROSSBAR_86	MCSPI3_IRQ	MCSPI3	McSPI3 interrupt
IRQ_CROSSBAR_87	USB2_IRQ_INTR1	USB2	USB2 interrupt 1
IRQ_CROSSBAR_88	USB3_IRQ_INTR0(1)	USB3	USB3 interrupt 0
IRQ_CROSSBAR_89	MMC3_IRQ	MMC3	MMC3 interrupt
IRQ_CROSSBAR_90	TIMER12_IRQ	TIMER12	TIMER12 interrupt
IRQ_CROSSBAR_91	MMC4_IRQ	MMC4	MMC4 interrupt

Table 17-8. Connection of Device IRQs to IRQ_CROSSBAR Inputs (continued)

IRQ_CROSSBAR Input	Interrupt Name	Interrupt Source	Description

(1) VCP1, VCP2, MLB, USB3 (ULPI) and I2C6 are not supported on the AM571x / AM570x family of devices.
(2) RTC and SATA are not supported on the AM570x family of devices.
(3) PRUSSn_IRQ_HOST[2:9] correspond to PRU-ICSSn HOST_INT[0:7] or PRU-ICSSn EVTOUT[0:7] in other TI Sitara devices' SoC-level interrupt controller.

17.4 Interrupt Controllers Functional Description

For detailed information about each device INTC (including functional description and registers descriptions), see the TRM chapters and Arm documents referenced in Section 17.1, *Interrupt Controllers Overview*.

Chapter 18

Control Module

This chapter describes the system control module for the device.

18.1 Control Module Overview

The control module allows software control of the various operation modes supported by the device. It is composed of two submodules. The CTRL_MODULE_CORE submodule which resides in the COREAON power domain and the CTRL_MODULE_WKUP submodule which resides in the WKUPAON power domain. These two submodules represent a set of registers which are used to control the device I/O ports and also various kinds of settings related to the different device operation modes and also to its internal modules.

The CTRL_MODULE_CORE submodule has registers for the following features:

- Pad configuration with following controls:
  - Pad I/O multiplexing
  - Pad pullup and pulldown configuration
  - Pad wake-up detection enabling
  - Pad wake-up event status
  - Pad input buffer enable
  - Pad slew rate control
- Device thermal management control and status registers
- PBIAS cell and MMC1 I/O cells control
- IRQ_CROSSBAR and DMA_CROSSBAR control
- Control the priority of initiator accesses to the external SDRAM
- Control the priority of initiators connected to L3_MAIN interconnect
- Memory region lock registers
- Mapping of the device non-maskable interrupt (NMI) to respective cores
- Controls for the DDR3 I/O Cells
- Controls for the DDR3 associated vref-generation cells
- AVS Class 0 associated registers
- ABB associated registers
- PCIe related registers
- Standard eFuse logic
- Other miscellaneous functions:
  - Status of the system boot settings
  - DSP1 reset vector address
  - Settings assoaciated with USB, SATA and HDMI PHYs
    Note: SATA is NOT supported on the AM570x family of devices
  - DSS PLLs multiplexing and enabling
  - Force MPU write nonposted transactions
  - Firewalls error status
  - Settings related to different peripheral modules
  - Others

The CTRL_MODULE_WKUP submodule has registers for the following features:

- Basic EMIF configuration settings
- XTAL Oscilator control
- Efuse I/O compensation
- Other functions

Figure 18-1 represents an overview block diagram of the control module.

Note

ATL, VCP1, VCP2, MLB and USB3 (ULPI) are not supported on the AM571x / AM570x family of devices.

SATA and RTC are not supported on the AM570x family of devices.

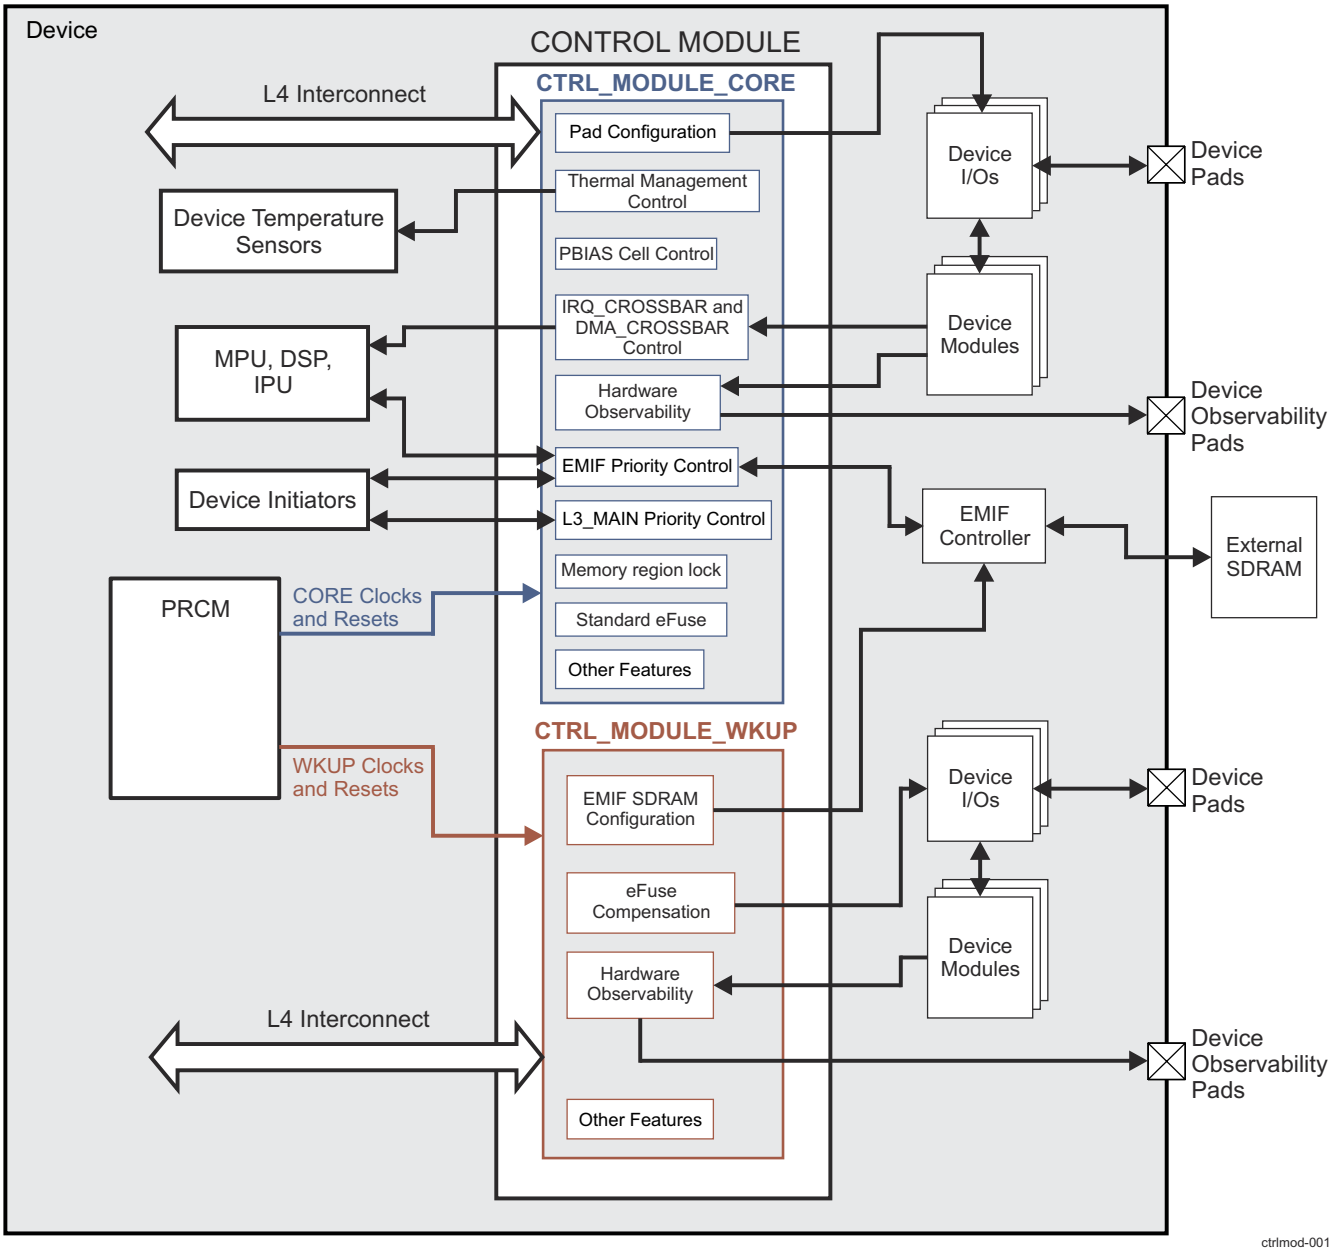

Figure 18-1. Control Module Overview Block Diagram

18.2 Control Module Environment

One of the control module functions is to control the multiplexing of certain signals from the device internal modules. Using the correct pad configuration settings, the control module maps these observability lines to the device boundary and a set of user selected internal module signals are available to be observed on the device pads. In addition, there are also two lines intended for observation of any of the device interrupt requests connected to the inputs of the IRQ_CROSSBAR module and two lines intended for observation of any of the DMA requests connected to the inputs of the DMA_CROSSBAR module. For more information, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description* and Section 18.4.6.5, *DMA_CROSSBAR Module Functional Description*.

An external non-maskable interrupt signal is also present. Using the appropriate registers the NMI can be mapped to different device cores. For more information, see Section 18.4.6.9, *NMI Mapping to respective cores*.

Figure 18-2 is an overview of the control module environment.

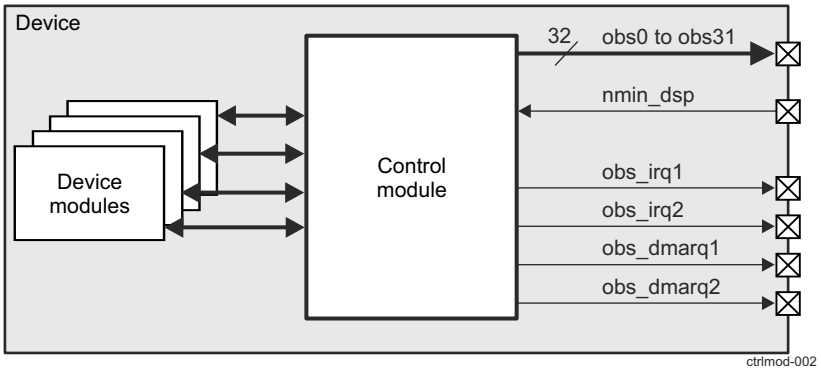

Figure 18-2. Control Module Environment

Table 18-1 shows the NMI input signal and observability outputs used to observe different signals of the device modules.

Table 18-1. Control Module I/O Description

Signal	I/O(1)	Description
obs[31:0]	O	32 internal hardware observability signals
nmin_dsp	I	External non-maskable interrupt signal
obs_irq1	O	Two signals intended for IRQ observation
obs_irq2	O	
obs_dmarq1	O	Two signals intended for DREQ observation
obs_dmarq2	O	

(1) I = Input; O = Output; I/O = Bidirectional

18.3 Control Module Integration

Figure 18-3 shows the integration of the control module in the device.

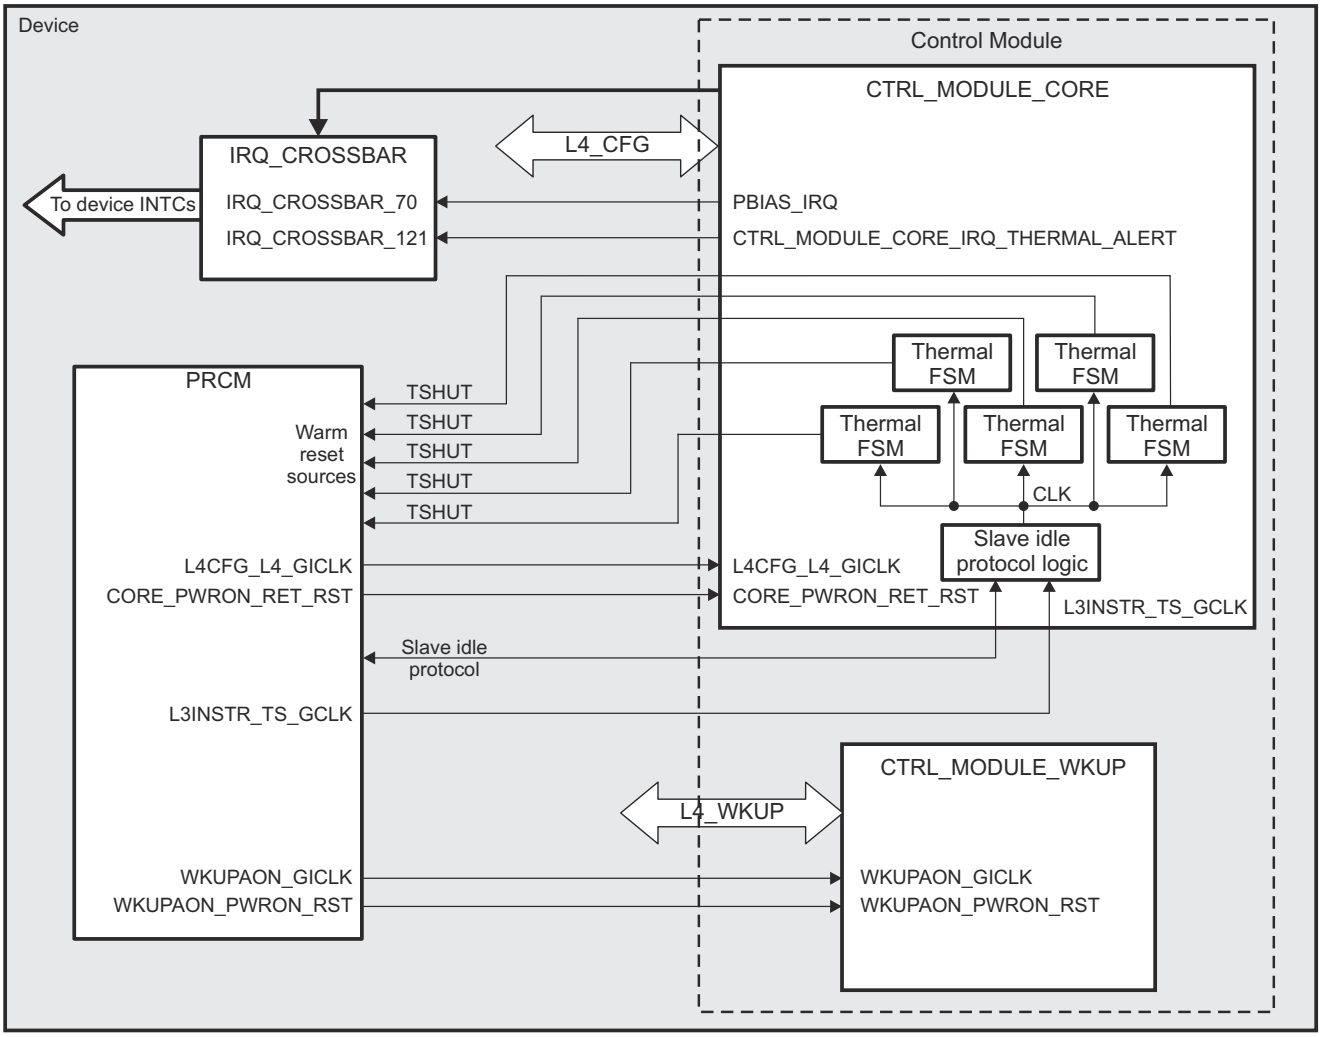

Figure 18-3. Control Module Integration

Table 18-2 through Table 18-4 summarize the integration of the Control Module in the device.

Table 18-2. Control Module Integration Attributes

Submodule	Attributes	
	Power Domain	Interconnect
CTRL_MODULE_CORE	PD_COREAON	L4_CFG
CTRL_MODULE_WKUP	PD_WKUPAON	L4_WKUP

Table 18-3. Control Module Clocks and Resets

Clocks				
Submodule	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**

Table 18-3. Control Module Clocks and Resets (continued)

CTRL_MODULE_CORE	L4CFG_L4_GICLK	L4CFG_L4_GICLK	PRCM	Interface clock to the CTRL_MODULE_CORE submodule
	L3INSTR_TS_GCLK	L3INSTR_TS_GCLK	PRCM	Common functional clock for the five thermal FSMs instantiated in the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP	WKUPAON_GICLK	WKUPAON_GICLK	PRCM	Interface clock to the CTRL_MODULE_WKUP submodule
		Resets		
CTRL_MODULE_CORE	CORE_PWRON_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal power-on reset (POR) affecting the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP	WKUPAON_PWRON_RST	WKUPAON_PWRON_RST	PRCM	Internal POR affecting the CTRL_MODULE_WKUP submodule

Table 18-4. Control Module Hardware Requests

Interrupt Requests				
Submodule	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
CTRL_MODULE_CORE	PBIAS_IRQ	IRQ_CROSSBAR_70	MPU_IRQ_75	Interrupt signal generated by the PBIAS cell when the MMC1 I/Os supply voltage is not equal to the bias voltage generated by the PBIAS cell
	CTRL_MODULE_CORE_IRQ_THERMAL_ALERT	IRQ_CROSSBAR_121	MPU_IRQ_126	Thermal alert interrupt signal generated when one of the five thermal sensors goes over the tepmerature threshold value

Note

The "**Default Mapping**" column in Table 18-4 *Control Module Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*.
For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

The integration of the control module is the following:

- No wake-up request generation
- No DMA request generation
- No master standby protocol with the PRCM
- Slave idle protocol, between the CTRL_MODULE_CORE submodule and the PRCM, related only to the L3INSTR_TS_GCLK
- One interrupt request to the IRQ_CROSSBAR module
- Five (thermal shutdown) TSHUT signals used as PRCM warm reset sources
- Two clocks and one reset signal to the CTRL_MODULE_CORE submodule
- One clock and one reset signal to the CTRL_MODULE_WKUP submodule

18.4 Control Module Functional Description

18.4.1 Control Module Clock Configuration

There is no software control over the L4CFG_L4_GICLK and WKUPAON_GICLK clocks neither in the control module nor in the PRCM module. The L4CFG_L4_GICLK clock is automatically gated when there is no access to the CTRL_MODULE_CORE registers and the WKUPAON_GICLK is automatically gated when there is no access to the CTRL_MODULE_WKUP registers. There are clock activity status bits for these two clocks in the PRCM module.

The L3INSTR_TS_GCLK is controlled by the CTRL_CORE_BANDGAP_MASK_1[31:30] SIDLEMODE bit field. For more information, see Section 18.4.6.2.5.

The L3INSTR_TS_GCLK has also the following software controls located in the PRCM module:

- Status: see Chapter 3, *Power, Reset, and Clock Management*
- Divider ratio: see Chapter 3, *Power, Reset, and Clock Management*

18.4.2 Control Module Resets

The control module is not sensitive to software reset. It does not respond to global warm reset too. The control module is reset only by the internal POR (global cold reset).

Despite the previously stated that control module is not sensitive to global warm reset all CTRL_CORE_PAD_x registers are exception of this rule and are sensitive to global warm reset. All other control module registers are sensitive only to global cold reset.

The PRCM provides the CORE_PWRON_RET_RST POR signal to the CTRL_MODULE_CORE and the WKUPAON_PWRON_RST POR signal to the CTRL_MODULE_WKUP. For more information, see Section 3.5.5, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

18.4.3 Control Module Power Management

18.4.3.1 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support master standby or slave idle protocols for handshaking with the PRCM. Only the five thermal FSMs support slave idle protocol used to control their common functional clock, that is the L3INSTR_TS_GCLK clock.

18.4.4 Hardware Requests

The control module does not generate DMA and wake-up requests. The CTRL_MODULE_CORE submodule generates only two IRQs to the IRQ_CROSSBAR module. The first one is the PBIAS_IRQ and the second one is the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT. For more information, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*.

18.4.5 Control Module Initialization

The control module responds to the internal POR. During device initialization, only modules used at boot time are associated with the pads. Other module inputs are internally tied and output buffers are turned off. After POR, software must set the pad configuration registers to appropriate values according to the desired device configuration.

The CTRL_CORE_BOOTSTRAP[15:0] bit field reflects the state of the sysboot[15:0] pads captured at POR in the PRCM module.

18.4.6 Functional Description Of The Various Register Types In CTRL_MODULE_CORE Submodule

The following sections describe in detail the purpose of the various kinds of registers and register groups which reside in the CTRL_MODULE_CORE submodule.

18.4.6.1 Pad Configuration

18.4.6.1.1 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register is assotiated only with one pad. The name of each register is formed by the corresponding pad name and the prefix "CTRL_CORE_PAD_". Almost all pad configuration registers have same bits. In some of these registers certain bits cannot be present. Figure 18-4 shows the general case in which all the pad configuration register bits are present. Table 18-5 describes these bits.

After POR, software must set the pad configuration registers to appropriate values depending on the desired device configuration. Configuration of the pad configuration registers is normally done as part of the IO delay recalibration sequence described in Section 18.4.6.1.8, *IO Delay Recalibration*.

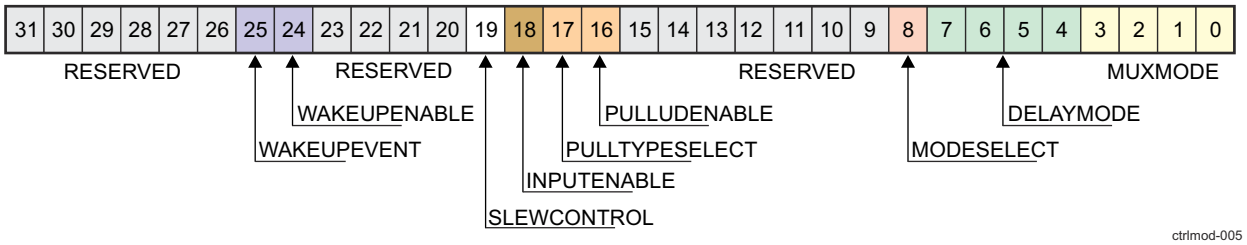

Figure 18-4. Pad Configuration Register Bits

Table 18-5. Description Of The Pad Configuration Register Bits

Bit/Bit Field	Bit Meaning		Description
	0b0	0b1	
WAKEUPEVENT	Wake-up event is not detected	Wake-up event is detected	Wake-up event status for a given pad. Indicates whenever the pad state is changed (0->1 or 1->0). In addition, when a wake-up event from a given I/O cell is received, the PRCM will wake up the MPU by switching-on its power domain and clocks and then generating an interrupt.
WAKEUPENABLE	Disable I/O wake-up function	Enable I/O wake-up function	Enables wake-up detection on input
SLEWCONTROL	Fast slew is selected	Slow slew is selected	Selects the slew rate for a given pad. The slew rate should be set to the value specified in the device Data Manual for a given mode of operation.
INPUTENABLE(1)	Receive mode is disabled. The pad is configured in output mode only.	Receive mode is enabled. The pad is configured in bidirectional mode.	Enables the input buffer of a given I/O
PULLTYPESELECT	Weak pull-down resistor is selected	Weak pull-up resistor is selected	Weak pull-up or weak pull-down resistor selection for a given pad
PULLUDENABLE	Weak pull-up/pull-down resistor is enabled	Weak pull-up/pull-down resistor is disabled	Enables weak pull-up/pull-down feature of a given pad
MODESELECT	Default IO Timing Mode is used	A Virtual or Manual IO Timing Mode is used.	Selects between the Default IO Timing Mode and a Virtual or Manual IO Timing Mode. Refer to the device Data Manual for definition of the required settings for a given mode of operation. When this bit is 0b1, a Virtual IO Timing Mode can be selected via the DELAYMODE field of this register, as described in Section 18.4.6.1.5, *Virtual IO Timing Modes*. Manual IO Timing Modes are selected via the procedure described in Section 18.4.6.1.6, *Manual IO Timing Modes*.

Table 18-5. Description Of The Pad Configuration Register Bits (continued)

Bit/Bit Field	Bit Meaning		Description
	0b0	0b1	
DELAYMODE	This bit field selects the Virtual Timing Mode used when the MODESELECT bit is set to 0b1. See Section 18.4.6.1.5, *Virtual IO Timing Modes* for details.		
MUXMODE	This bit field selects the desired Multiplexing Mode for the pad. See section "*Multiplexing Characteristics*" of the Data Manual for a list of available functions for each pad.		

(1) To enable/disable the input buffers of the mmc1_* pads the ACTIVE bits of the corresponding CTRL_CORE_PAD_x registers are used. These registers have ACTIVE bits instead of INPUTENABLE bits.

Note

The default SLEWCONTROL settings in each pad configuration register must be used to guarantee timings, unless specific instructions otherwise are given in the individual timing sub-sections of the device Data Manual. The only exception is when the MUXMODE is configured to select a vout*_* signal. In this case the corresponding SLEWCONTROL bit must be configured to slow slew instead of the default fast slew.

Note

It must be taken into account that when an external pull resistor is desired, the internal pull resistors must be disabled by software because they are enabled by default.

Note

GPIO pins can directly snoop device pads even if those are configured in the other modes. For GPIO output user needs to set pad mux.

The following signals require CTRL_CORE_PAD_x to be programmed with INPUTENABLE=1 for retiming purposes:

- mmc2_clk, mmc3_clk, and mmc4_clk
- gpmc_clk
- i2cj_scl where j=1-6
- spim_sclk where m=1-4
- mcaspi_aclkx, mcaspi_ahclkx and mcaspi_aclkr signals where i=1-8

Aside from the pad configuration registers, there are also two additional registers related to signal multiplexing. These are the CTRL_CORE_VIP_MUX_SELECT and CTRL_CORE_ALT_SELECT_MUX registers. The CTRL_CORE_VIP_MUX_SELECT register has bits for remapping the VIP1 signals to several device pads. Table 18-6 shows the VIP1 signals and the corresponding device pads to which these signals can be mapped.

Using the CTRL_CORE_VIP_MUX_SELECT register the signals of the CAL video port (described in Section 8.3.2 *CAL Integration - Video Port*) can also be mapped to VIP1.

For example, the vin1a_clk0 signal can be mapped to the gpmc_cs3 pad when CTRL_CORE_PAD_GPMC_CS3[3:0] GPMC_CS3_MUXMODE = 0x2 or to the vout1_fld pad when CTRL_CORE_PAD_VOUT1_FLD[3:0] VOUT1_FLD_MUXMODE = 0x4 only if the CTRL_CORE_VIP_MUX_SELECT[6:4] VIP_SEL_1A bit field is set to 0x0 (GROUP3A pads). If the CTRL_CORE_VIP_MUX_SELECT[6:4] VIP_SEL_1A bit field is set to 0x1 (GROUP5A pads) the vin1a_clk0 signal can be mapped to the gpio6_10 device pad after the CTRL_CORE_PAD_GPIO6_10[3:0] GPIO6_10_MUXMODE bit field has been set to 0x9.

The vin1a_clk0 signal can also be mapped to the xref_clk1 pad when the CTRL_CORE_VIP_MUX_SELECT[6:4] VIP_SEL_1A bit field is set to 0x2 (GROUP6A pads) and the

CTRL_CORE_PAD_XREF_CLK1[3:0] XREF_CLK1_MUXMODE bit field is set to 0x7. The same logic applies to the other VIP1 signals listed in Table 18-6.

It must be taken into account that some VIP1 signals may be available on the device pads in one combination of MUXMODE values and values in certain bit field of the CTRL_CORE_VIP_MUX_SELECT register but in another combination of values the same signals may not be available on another device pads. For example, the vin2a_d[23:0] set of signals are available on the vin2a_d[23:0] device pads when the corresponding MUXMODE bit fields are set to 0x0 and the CTRL_CORE_VIP_MUX_SELECT[2:1] VIP_SEL_2A bit field is set to 0x0 (GROUP2A pads). But the signals vin2a_d[23:12] are not available on another device pads when CTRL_CORE_VIP_MUX_SELECT[2:1] VIP_SEL_2A = 0x0 (GROUP2A pads).

Table 18-6. Additional Multiplexing of the VIP1 Signals

Pad Group (1)	Device Pads	VIP1 Signals	The signal in column "VIP1 Signals" is available on the pad in column "Device Pads" when:
GROUP2A	vin2a_clk0	vin2a_clk0	the MUXMODE bit field of the corresponding pad configuration registers is set to 0x0 and the CTRL_CORE_VIP_MUX_SELECT[2:1] VIP_SEL_2A bit is set to 0x0.
	vin2a_de0	vin2a_de0	
	vin2a_fld0	vin2a_fld0	
	vin2a_hsync0	vin2a_hsync0	
	vin2a_vsync0	vin2a_vsync0	
	vin2a_d[23:0]	vin2a_d[23:0]	
	mdio_mclk	vin2a_clk0	the MUXMODE bit field of the corresponding pad configuration registers is set to 0x4 and the CTRL_CORE_VIP_MUX_SELECT[2:1] VIP_SEL_2A bit is set to 0x0.
	mdio_d	vin2a_d0	
	RMII_MHZ_50_CLK	vin2a_d11	
	uart3_rxd	vin2a_d1	
	uart3_txd	vin2a_d2	
	rgmii0_txc	vin2a_d3	
	rgmii0_txctl	vin2a_d4	
	rgmii0_txd3	vin2a_de0	
	rgmii0_txd2	vin2a_hsync0	
	rgmii0_txd1	vin2a_vsync0	
	rgmii0_txd0	vin2a_d10	
	rgmii0_rxc	vin2a_d5	
	rgmii0_rxctl	vin2a_d6	
	rgmii0_rxd[3:1]	vin2a_d[7:9]	
	rgmii0_rxd0	vin2a_fld0	
	vin2a_de0	vin2a_fld0	the MUXMODE bit field of the corresponding pad configuration register is set to 0x1 and the CTRL_CORE_VIP_MUX_SELECT[2:1] VIP_SEL_2A bit is set to 0x0.

Table 18-6. Additional Multiplexing of the VIP1 Signals (continued)

Pad Group (1)	Device Pads	VIP1 Signals	The signal in column "VIP1 Signals" is available on the pad in column "Device Pads" when:
GROUP2B	vin2a_de0	vin2b_fld1	the MUXMODE bit field of the corresponding pad configuration registers is set to 0x2 and the CTRL_CORE_VIP_MUX_SELECT[0] VIP_SEL_2B bit is set to 0x0.

	rgmii0_rxd0	usb3_ulpi_d7	

Note

USB3 (ULPI) is not supported on the AM571x / AM570x family of devices.

Aside from the maximum 16 possible combinations through the MUXMODE bit fields using the CTRL_CORE_ALT_SELECT_MUX[5:0] bits, an additional signal can be mapped to several device pads. These pads are listed in Table 18-8. In other words, for these pads there are up to 17 possible signal combinations, although not all of them are really implemented.

Table 18-8. Pads Having Capability for Additional Signal Mapping

Figure 18-5 shows the multiplexing scheme of pads from GROUP1 to GROUP4.

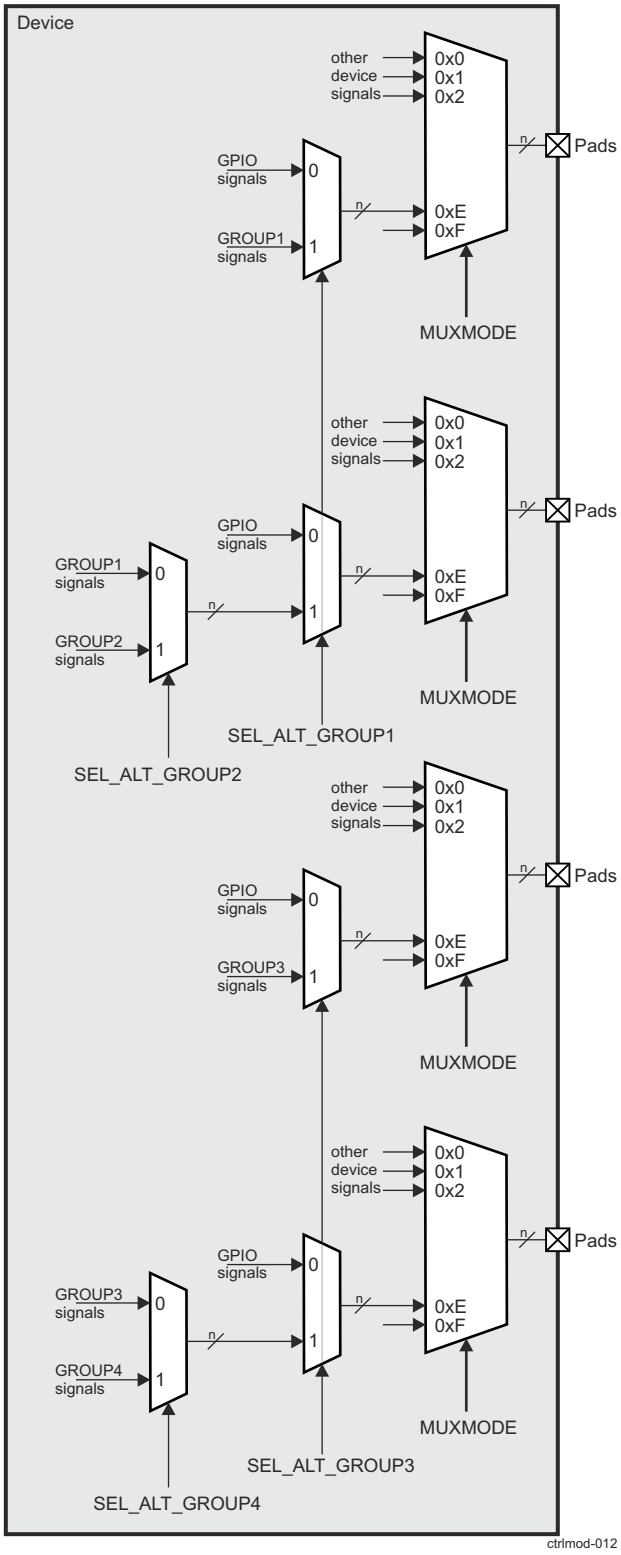

Figure 18-5. Multiplexing Scheme of the Pads Having Capability for Additional Signal Mapping

18.4.6.1.1.1 Permanent PU/PD disabling (SR 2.x only)

This section applies only to SR2.x.

The internal pull resistors of pads gpmc_a[27:24, 22:19] can be permanently disabled by pulling sysboot15 low during power-on-reset deassertion. When sysboot15 = 0, the corresponding PULLUDENABLE bit does not apply anymore. In this case it is a don't care bit whatever value set. This functionality is intended to be used when mmc2_dat* signals are configured on the gpmc_a[27:24, 22:19] pads. In this case, if sysboot15 = 0, external pull-up resistors with values as per JEDEC eMMC specification (JESD84-B451) must be connected to these pads. If gpmc_a[27:24, 22:19] are connected to non-multiplexed NOR flash used for booting and sysboot15 = 0, external pull-down resistors are mandatory on these pads otherwise boot is not possible. During NOR flash run-time accesses the external pull-down resistors are not needed.

18.4.6.1.2 Pull Selection

There is no automatic gating control to ensure that internal weak pull-up or pull-down resistors on a pad are disconnected whenever pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it to avoid unnecessary consumption.

Table 18-9 describes the software controls available for pad internal pull-up and pull-down resistors in the control module pad configuration registers.

Table 18-9. Pull Selection

PULL		Pad Behavior
PULLTYPESELECT	PULLUDENABLE	
0	1	Pull-down selected but not activated
0	0	Pull-down selected and activated
1	1	Pull-up selected but not activated
1	0	Pull-up selected and activated

18.4.6.1.3 Pad multiplexing

Many of the Device pads support pad multiplexing. This means that their function can be independently chosen from two or more options. The selection of functions available on each pad is enumerated in the "*Multiplexing Characteristics*" section of the Data Manual. The desired function is selected via the MUXMODE field of the associated pad configuration register.

By default, the MUXMODE field of most device pads is set to 0xF, which means the pads are in Hi-Z. Only MUXMODE values which correspond to defined functions should be used.

Note

When setting the MUXMODE of any mmc1_* pad, the following register fields should also be programmed:

- CTRL_CORE_CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ = 1
- CTRL_CORE_CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ = 1
- If MUXMODE=0 is not selected, configure CTRL_CORE_CONTROL_PBIAS[21] SDCARD_BIAS_VMODE
  - Clear to 0 if vddshv8 = 1.8V
  - Set to 1 if vddshv8 = 3.3V

18.4.6.1.4 IOSETs

An IO signal may have multiplexing options across two or more device pads. In many cases, the user is allowed to select any combination of IO signal multiplexing options to use for an interface. But in some cases, specific combinations of multiplexing options must be selected to guarantee the Timing and Switching Characteristics in the *Data Manual*. These specific combinations are called IOSETs, and they generally represent layout-friendly groups of pads that are pinned-out in close proximity to each other. IOSETs are defined in the Data Manual for interfaces that require them.

18.4.6.1.5 Virtual IO Timing Modes

When operating a pad in certain modes, a Virtual IO Timing Mode must be selected to ensure that IO timings are met. The modes requiring Virtual IO Timing Modes are described in *Virtual Functions Mapping* tables within the "*Timing Requirements and Switching Characteristics*" section of the Data Manual. These tables list each pad associated with a specific Virtual IO Timing Mode, along with the DELAYMODE setting required for that pad.

To select a Virtual IO Timing Mode, both the MODESELECT field of each associated pad configuration register must be set to 0b1 and DELAYMODE field of each associated pad configuration register must be set to match the *Virtual Function Mapping* tables in the Data Manual.

Selection of all Virtual IO Timings Modes should be done as part of the IO Delay Recalibration Sequence described in Section 18.4.6.1.8, *IO Delay Recalibration*.

18.4.6.1.6 Manual IO Timing Modes

When operating a pad in certain modes, a Manual IO Timing Mode must be configured to ensure that IO timings are met. The modes requiring Manual IO Timing Modes are described in *Manual Functions Mapping* tables within the "*Timing Requirements and Switching Characteristics*" section of the Data Manual. These tables list each pad associated with a specific Manual IO Timing Mode, along with the required A_DELAY and G_DELAY values that should be used to calculate the correct values to be set in the CFG_x_IN, CFG_x_OEN, and CFG_x_OUT registers associated with that pad. For more information regarding these registers, see Section 18.7, *IODELAYCONFIG Module Register Manual*

To select a Manual IO Timing Mode, the MODESELECT field of each associated pad configuration register must be set to 0b1 and the associated CFG_x_IN, CFG_x_OEN, and CFG_x_OUT registers should be set via the following sequence:

1. Compute CDPE and FPDE based on the following equations using values from the IODELAYCONFIG module registers (the register values must be converted to decimal before calculating):

$$CDPE = \frac{10*(CONFIG\_REG\_3[15:0]\ COARSE\_REF\_COUNT*CONFIG\_REG\_2[15:0]\ REFCLK\_PERIOD)}{(2*(CONFIG\_REG\_3[31:16]\ COARSE\_DELAY\_COUNT*88))}$$

$$FDPE = \frac{10*(CONFIG\_REG\_4[15:0]\ FINE\_REF\_COUNT*CONFIG\_REG\_2[15:0]\ REFCLK\_PERIOD)}{(2*(CONFIG\_REG\_4[31:16]\ FINE\_DELAY\_COUNT*264))}$$

ctrlmod-014

2. For each pad that requires a Manual IO Timing Mode, perform the following setups to calculate the values required to be programmed into each of the associated CFG_x_IN, CFG_x_OEN, and CFG_x_OUT IODELAYCONFIG module registers:
   a. Calculate the Coarse Values and Fine Values corresponding to the A_DELAY and G_DELAY values listed in the Data Manual for the associated Manual IO Timing Mode as follows:

$$G\_DELAY\_COARSE = floor(\frac{G\_DELAY}{920})$$

$$G\_DELAY\_FINE = \frac{floor(G\_DELAY\ mod\ 920)*10}{60}$$

$$A\_DELAY\_COARSE = floor(\frac{A\_DELAY}{CDPE})$$

$$A\_DELAY\_FINE = \frac{floor(A\_DELAY\ mod\ CDPE)*10}{FDPE}$$

ctrlmod-015

   b. Calculate the required number of Coarse Elements and Fine Elements:

$$COARSE\_ELEMENTS = G\_DELAY\_COARSE + A\_DELAY\_COARSE$$

$$FINE\_ELEMENTS = \frac{G\_DELAY\_FINE + A\_DELAY\_FINE}{10}$$

ctrlmod-016

c. If FINE_ELEMENTS > 22, recalculate COARSE_ELEMENTS and FINE_ELEMENTS as follows:

$$\text{COARSE\_ELEMENTS} = \frac{\text{TOTAL\_DELAY}}{\text{CDPE}}$$

$$\text{FINE\_ELEMENTS} = \frac{\text{TOTAL\_DELAY mod CDPE}}{\text{FDPE}}$$

Where TOTAL_DELAY = (Original COARSE_ELEMENTS * CDPE) + (Original FINE_ELEMENTS * FDPE)

ctrlmod-017

d. Convert COARSE_ELEMENTS and FINE_ELEMENTS to 5-bit binary values COARSE_ELEMENTS_5b and FINE_ELEMENETS_5b
e. Write associated CFG_x register with 0x29400 + COARSE_ELEMENTS_5b<<5 + FINE_ELEMENETs_5b

Selection of all Manual IO Timing Modes should be done as part of the IO Delay Recalibration Sequence described in Section 18.4.6.1.8, *IO Delay Recalibration*.

18.4.6.1.7 Isolation Requirements

When reprogramming the MUXMODE, DELAYMODE, and MODESELECT fields of a pad configuration register or the CFG_x_IN, CFG_x_OEN, and CFG_x_OUT registers in the IODELAYCONFIG Module, there is potential for a glitch on the corresponding IO. Therefore, the device IOs should be isolated when writing to any of these fields. Isolating the IOs forces them to tri-state output with internal pulls holding their previous levels. De-isolating the IOs returns their control to the selected peripheral modules.

Note

While the IOs are Isolated, code must execute only from internal RAM and the isolated IO interfaces should not be actively used.

Isolation is a global event that affects all LVCMOS IOs except for the following:

- JTAG IOs
- on_off
- rstoutn

Isolation/De-isolation of the device IOs is accomplished via the following sequences:

Isolation Sequence:

1. Ensure that the CTRL_CORE_CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ and CTRL_CORE_CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ bits are set to 1
2. Write 1 to the PRM_IO_PMCTRL[0] ISOCLK_OVERRIDE bit
3. Poll the PRM_IO_PMCTRL[1] ISOCLK_STATUS bit until it reads 1
4. Write 1 to the CTRL_CORE_SMA_SW_0[2] ISO_CTRL_IO bit
5. Read the CTRL_CORE_SMA_SW_0[2] ISO_CTRL_IO bit for timing purposes only
6. Write the PRM_IO_PMCTRL[0] ISOCLK_OVERRIDE bit to 0
7. Poll the PRM_IO_PMCTRL[1] ISOCLK_STATUS bit until it reads 0

De-isolation Sequence:

1. Write 1 to the PRM_IO_PMCTRL[0] ISOCLK_OVERRIDE bit
2. Poll the PRM_IO_PMCTRL[1] ISOCLK_STATUS bit until it reads 1
3. Write 0 to the CTRL_CORE_SMA_SW_0[2] ISO_CTRL_IO bit
4. Read the CTRL_CORE_SMA_SW_0[2] ISO_CTRL_IO bit for timing purposes only
5. Write the PRM_IO_PMCTRL[0] ISOCLK_OVERRIDE bit to 0
6. Poll the PRM_IO_PMCTRL[1] ISOCLK_STATUS bit until it reads 0

Configuration of the pad configuration registers is normally done as part of the IO Delay Recalibration Sequence described in Section 18.4.6.1.8, *IO Delay Recalibration*, which references the above Isolation/De-isolation sequences.

18.4.6.1.8 IO Delay Recalibration

After adjusting the AVS voltage for VDD_CORE_L voltage domain, an IO Delay Recalibration Sequence must be followed to ensure device IO timings are met. The IO Delay Recalibration Sequence is as follows:

IO Delay Recalibration Sequence:

1. Complete the AVS voltage change on the VDD_CORE_L voltage domain and ensure voltage has stabilized to the new AVS target voltage
2. Unlock the registers used by this sequence as follows:
   a. Write 0x2FF1AC2B to register CTRL_CORE_MMR_LOCK_1 of the Control Module
   b. Write 0x6F361E05 to register CTRL_CORE_MMR_LOCK_5 of the Control Module
   c. Write 0x0000AAAA to register CONFIG_REG_8 of the IODELAYCONFIG Module
3. Perform IO Delay Calibration
   a. Write register field CONFIG_REG_2[15:0] REFCLK_PERIOD of the IODELAYCONFIG Module with the L4_ICLK clock period in ps divided by 10 (or, equivalently, L3_ICLK clock period in ps divided by 5), then rounded down to the closest integer.
      i. L4_ICLK = 133MHz requires a value of 0x2EF
   b. Write 1 to register field CONFIG_REG_0[0] CALIBRATION_START of the IODELAYCONFIG module to initiate the calibration.
   c. Poll register field CONFIG_REG_0[0] CALIBRATION_START for 0, indicating calibration is complete.
4. Isolate the device IOs via the Isolation Sequence described in Section 18.4.6.1.7 *Isolation Requirements*
5. Update the delay mechanism for each IO with new calibrated values:
   a. Write 1 to register field CONFIG_REG_0[1] ROM_READ of the IODELAYCONFIG module to initiate a reload of calibrated delay values for all IOs.
   b. Poll register field CONFIG_REG_0[1] ROM_READ for 0, indicating reload is complete.
6. Configure the pad configuration register (CTRL_CORE_PAD_x) for each IO with the desired MUXMODE, DELAYMODE, and MODESELECT settings.
7. Configure all required Manual IO Timing Modes as described in Section 18.4.6.1.6, *Manual IO Timing Modes*
8. De-isolate the device IOs via the de-isolation sequence described in Section 18.4.6.1.7 *Isolation Requirements*
9. Relock the registers used by this sequence:
   a. Write 0x1A1C8144 to register CTRL_CORE_MMR_LOCK_1
   b. Write 0x143F832C to register CTRL_CORE_MMR_LOCK_5
   c. Write 0x0000AAAB to register CONFIG_REG_8

18.4.6.2 Thermal Management Related Registers

There are five temperature sensors on the device die. Each sensor is associated only with one voltage domain and is also a part of a VBGAPTS cell. This cell has a 10-bit ADC. The ADC converts the temperature values into digital output values proportional to the temperature measured. Each VBGAPTS cell is controlled by a dedicated FSM referred to as thermal FSM. The registers associated with each FSM reside in the CTRL_MODULE_CORE submodule. All FSMs are clocked by the L3INSTR_TS_GCLK clock. The PRCM module controlls this clock through the slave idle protocol.

The device thermal management related registers can be split into the following classes:

- Temperature sensors control registers
- Registers for the thermal alert comparators
- Temperature timestamp registers
- Other registers used for:
  – controlling the FIFOs
  – controlling the clock provided to the five FSMs

Figure 18-6 shows the block diagram of the device thermal management.

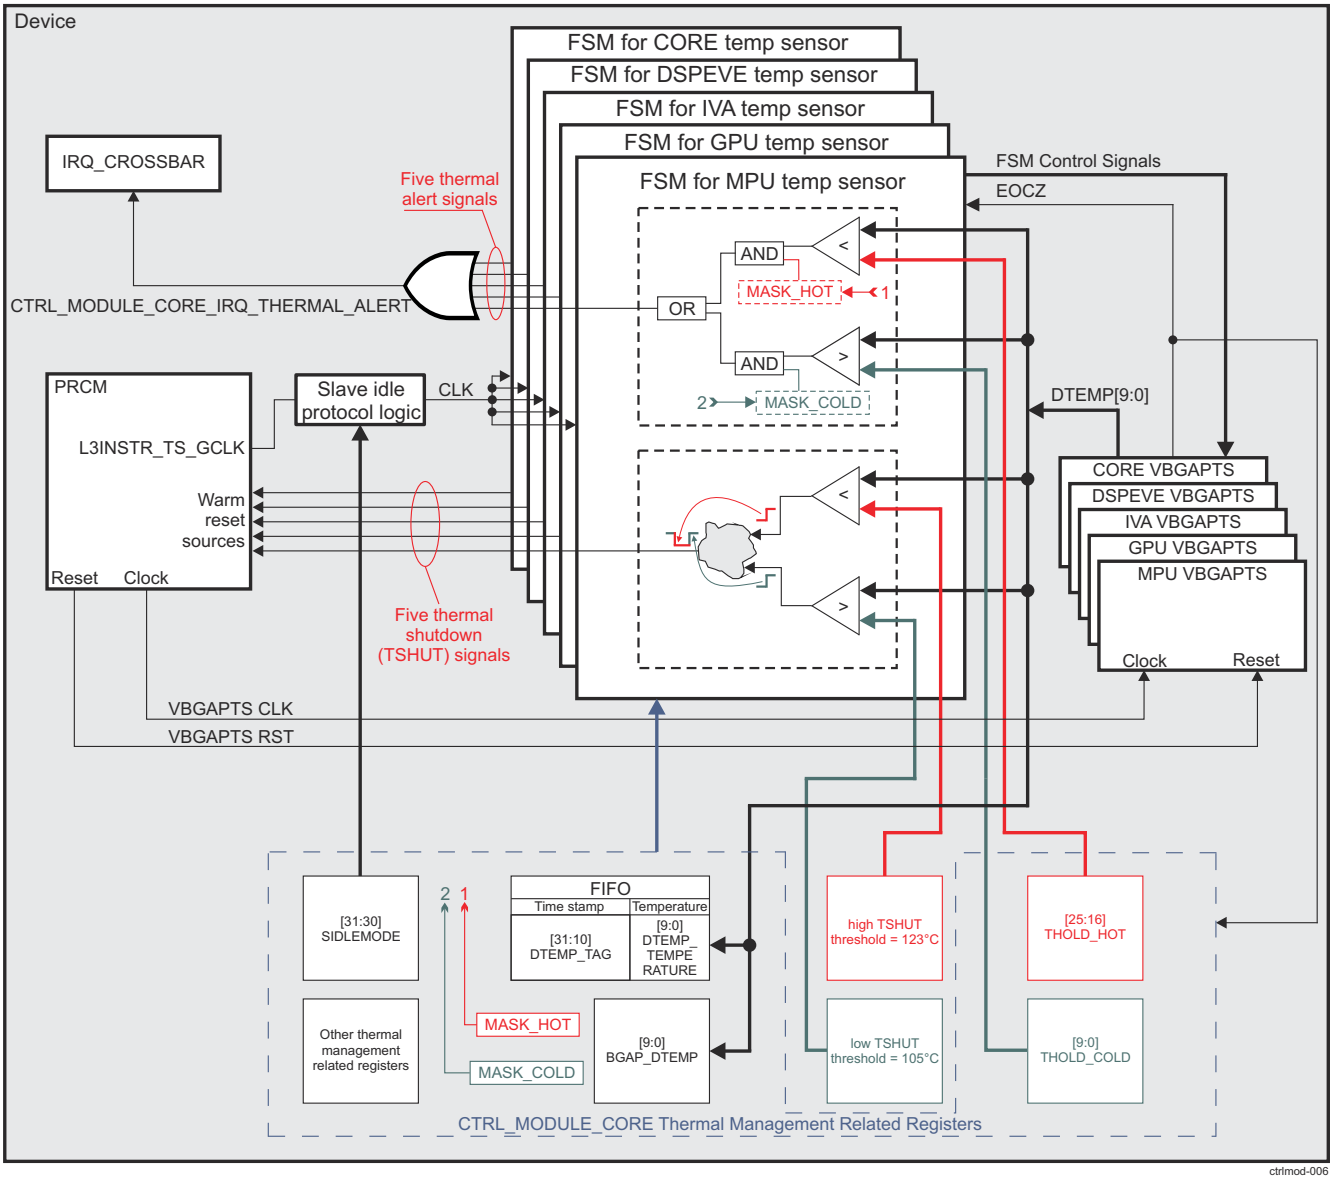

Figure 18-6. Thermal Management Functional Block Diagram

Table 18-10 describes the signals related to the device thermal management logic.

Table 18-10. Thermal Management Signals Description

Signal	I/O[1]	Description
EOCZ	O	End of conversion signal. When low, this signal indicates that the value of DTEMP[9:0] is valid.
DTEMP[9:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
VBGAPTS CLK	I	Functional clock from the WKUPAON power domain used by the temperature sensor during temperature conversion.
THERMAL ALERT	O	The five thermal alert outputs from each thermal FSM are ORed and then mapped as an interrupt request to the IRQ_CROSSBAR module. Software uses this interrupt to implement the device thermal management policy.

Table 18-10. Thermal Management Signals Description (continued)

Signal	I/O(1)	Description
TSHUT	O	Each of the five thermal shutdown signals is mapped to the PRCM and is used as a warm reset signal. These overheat protection signals are high during normal operation and go low during thermal shutdown event.

(1) I = Input; O = Output

The ADC values which correspond to the current temperature are listed in Table 18-13.

18.4.6.2.1 Temperature Sensors Control Registers

Each VBGAPTS cell works in continuous conversion mode controlled by the corresponding FSM. This means that the temperature is measured at regular time intervals. The start of temperature measurement is initiated automatically by each FSM after it goes out of reset state. To control the main delay between two measurements the CTRL_CORE_BANDGAP_MASK_1[29:27] COUNTER_DELAY bit field is used. After this delay expires the five FSMs automatically start a temperature conversion.

The conversion is complete when the CTRL_CORE_TEMP_SENSOR_x[10] BGAP_EOCZ_x status bits are set to 0x0. After this the valid temperature is written automatically by each FSM in the CTRL_CORE_TEMP_SENSOR_x[9:0] BGAP_DTEMP_x bit fields, and then software is able to read it from the corresponding register. After writing the valid temperature values the five FSMs wait one clock cycle and start another conversion cycle.

For details regarding the CTRL_CORE_TEMP_SENSOR_x registers, see Table 18-12.

18.4.6.2.2 Registers For The Thermal Alert Comparators

There is a comparator block responsible for the thermal alert function of the CTRL_MODULE_CORE thermal management logic. This comparator block is composed of two comparators. One dedicated to low temperature threshold and the other one to high temperature threshold. Because of the five temperature sensors there are also five comparator blocks. Software can configure the low temperature threshold through the CTRL_CORE_BANDGAP_THRESHOLD_x[9:0] THOLD_COLD_x bit fields and high temperature threshold through the CTRL_CORE_BANDGAP_THRESHOLD_x[25:16] THOLD_HOT_x bit fields. The values which have to be loaded in these bit fields are the same as those listed in Table 18-13. For example, to set the high temperature threshold value to 120°C, the THOLD_HOT filed must be loaded with value of 931 (0x3A3).

The thermal alert logic provides also a capability to mask the outputs of the comparators associated with low and high temperature thresholds. The low temperature threshold comparator outputs are masked by setting to 0x0 the corresponding MASK_COLD_x bits in the CTRL_CORE_BANDGAP_MASK_1 and CTRL_CORE_BANDGAP_MASK_2 registers. The high temperature threshold comparator outputs are masked by setting to 0x0 the corresponding MASK_HOT_x bits in CTRL_CORE_BANDGAP_MASK_1 and CTRL_CORE_BANDGAP_MASK_2 registers.

The masked low and high temperature threshold outputs are ORed once and as a result a single thermal alert signal is produced. As there are five temperature sensors there are also five thermal alert output signals produced. These five signals are then ORed (see Figure 18-6) in the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal, which delivers an interrupt to the IRQ_CROSSBAR_121 input line of the IRQ_CROSSBAR module. Software can use this interrupt to implement the device thermal management policy. The CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal is also routed to the CTRL_CORE_BANDGAP_STATUS_1[31] ALERT bit. Value of 0x1 indicates that the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal is asserted.

The non masked (raw) comparator outputs are available for reading through the corresponding bits in the CTRL_CORE_BANDGAP_STATUS_1 and CTRL_CORE_BANDGAP_STATUS_2 registers. The low temperature threshold comparator outputs are read through the COLD_x bits and the high temperature threshold comparator outputs through the HOT_x bits.

Figure 18-7 shows the behavior of the thermal alert logic.

For details regarding the CTRL_CORE_BANDGAP_THRESHOLD_x registers, see Table 18-12.

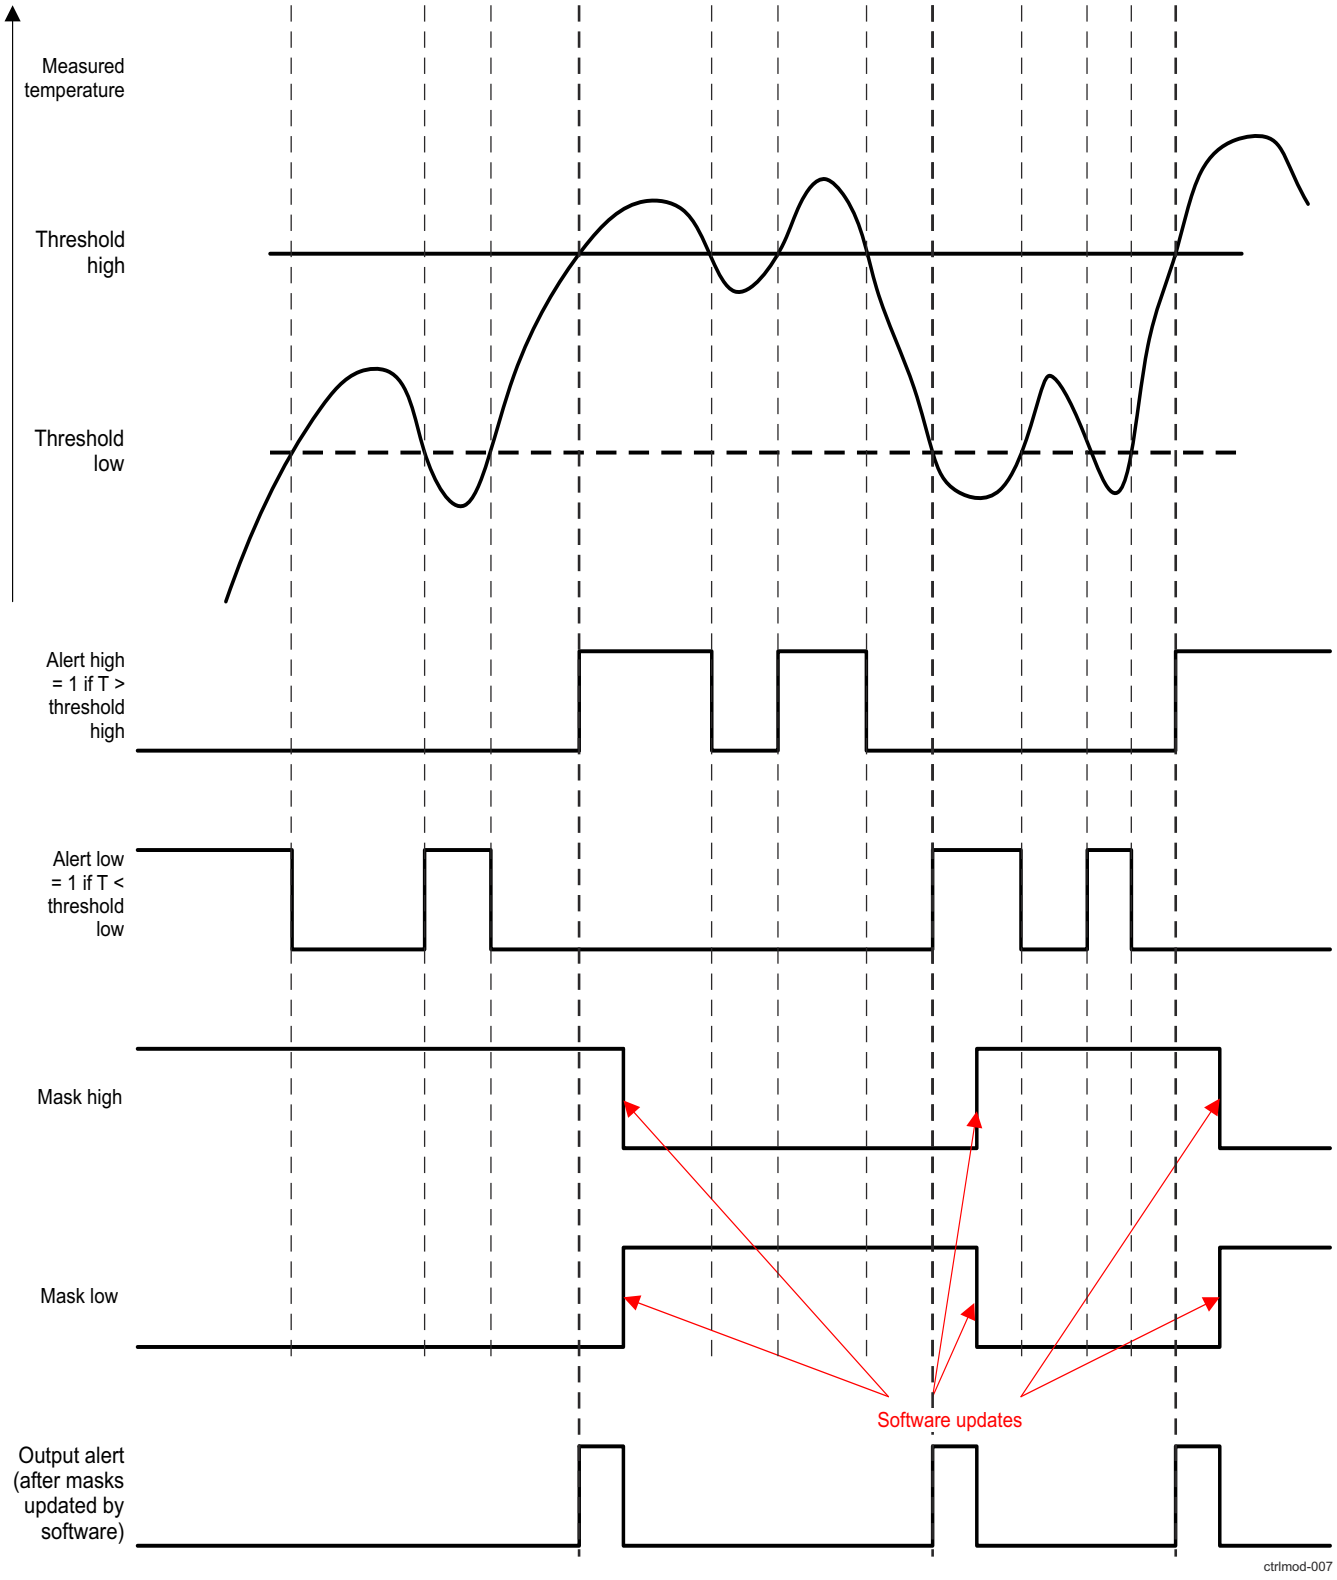

Figure 18-7. Behavior Of The Thermal Alert Logic

18.4.6.2.3 Thermal Shutdown Comparators

There is also a comparator block responsible for the thermal shutdown (TSHUT) function of the CTRL_MODULE_CORE thermal management logic. This comparator block is also composed of two comparators. One dedicated to low TSHUT threshold and the other one to high TSHUT threshold. Because of the five temperature sensors there are also five comparator blocks. The comparator outputs for the low and high TSHUT thresholds of each comparator block are connected to a logic which then generates a single TSHUT signal. All five TSHUT signals are tied to the PRCM and used as warm reset sources. For details, see Figure 18-6.

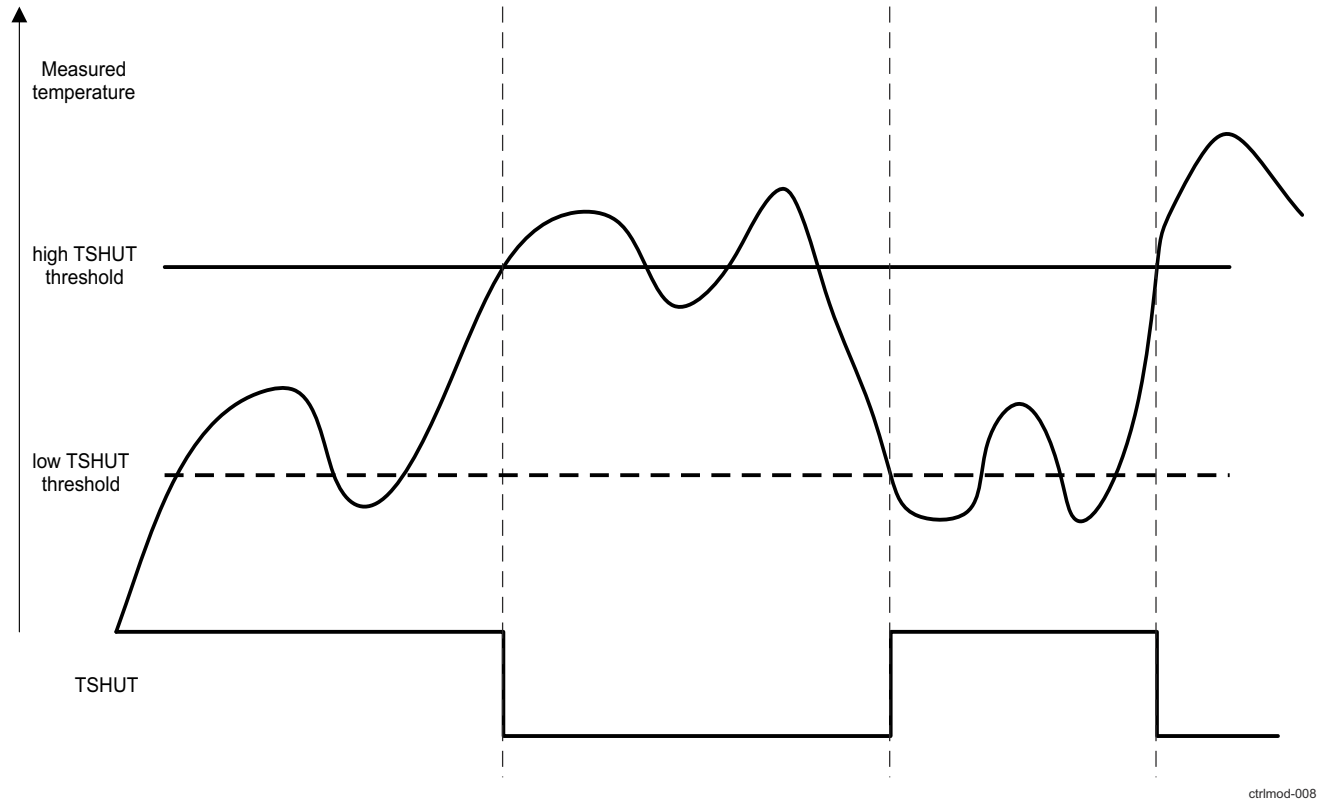
The values of the five low and high TSHUT thresholds are fixed and can be neither overridden nor read by software. The value for the high TSHUT threshold is 123°C (assuming ±2°C temperature sensor accuracy), and the low TSHUT threshold is 105°C.

When the high TSHUT threshold is reached, a the TSHUT output is activated. To deactivate each TSHUT output, the temperature must go below the value of each low TSHUT threshold.

Each of the five TSHUT signals is used as an overheat protection.

Figure 18-8 shows the behavior of the TSHUT logic.

Figure 18-8. Behavior Of The Thermal Shutdown Logic



18.4.6.2.4 Temperature Timestamp Registers

Each time one of the CTRL_CORE_TEMP_SENSOR_x[9:0] BGAP_DTEMP_x bit fields is updated with new temperature value, this value is also automatically stored into a 5-level deep FIFO and a timestamp is registered too. There are five FIFOs used to store a brief history for the last few temperature measurements and are also dedicated to temperature timestamping feature. Each FIFO has two fields. The first one is 10 bits wide, 5 levels deep, and is intended to store the temperature values for the last five measurements. The second field is 22 bits wide, 5 levels deep, and acts like a counter for the number of temperature measurements. Each FIFO is composed of the following registers:

- CTRL_CORE_DTEMP_x_0
- CTRL_CORE_DTEMP_x_1
- CTRL_CORE_DTEMP_x_2
- CTRL_CORE_DTEMP_x_3
- CTRL_CORE_DTEMP_x_4

Table 18-11 shows a generic description of the five FIFOs.

For details regarding the five CTRL_CORE_DTEMP_x registers, see Table 18-12.

Table 18-11. FIFOs Generic Description

FIFO Levels	Second FIFO Field (22 Bits) – Timestamp	Description	First FIFO field (10 Bits) – Temperature	Description
	Bits [31:10]		Bits [9:0]	
Level 1	DTEMP_TAG_x_0	Indicates the number of temperature measurements	DTEMP_TEMPERATURE_x_0	Indicates the last measured temperature value (the most recent sample)
Level 2	DTEMP_TAG_x_1	Indicates the number of temperature measurements minus one (DTEMP_TEMPERATURE_x_0 – 1)	DTEMP_TEMPERATURE_x_1	Indicates the penultimate measured temperature value
Level 3	DTEMP_TAG_x_2	Indicates the number of temperature measurements minus two (DTEMP_TEMPERATURE_x_0 – 2)	DTEMP_TEMPERATURE_x_2	Indicates temperature value measured before DTEMP_TEMPERATURE_x_1
Level 4	DTEMP_TAG_x_3	Indicates the number of temperature measurements minus three (DTEMP_TEMPERATURE_x_0 – 3)	DTEMP_TEMPERATURE_x_3	Indicates temperature value measured before DTEMP_TEMPERATURE_x_2
Level 5	DTEMP_TAG_x_4	Indicates the number of temperature measurements minus four (DTEMP_TEMPERATURE_x_0 – 4)	DTEMP_TEMPERATURE_x_4	Indicates temperature value measured before DTEMP_TEMPERATURE_x_3 (the oldest sample)

Note

DTEMP_TAG_x_4 increments its value with one after each fifth temperature measurement.

DTEMP_TAG_x_3 increments its value with one after each fourth temperature measurement.

DTEMP_TAG_x_2 increments its value with one after each third temperature measurement.

DTEMP_TAG_x_1 increments its value with one after each second temperature measurement.

DTEMP_TAG_x_0 increments its value with one after each temperature measurement.

18.4.6.2.5 Other Thermal Management Related Registers

- **Controlling the FIFOs:**

  Software can stop a certain FIFO to update with new temperature and timestamp values when setting to 0x1 one of the FREEZE_x bits in the CTRL_CORE_BANDGAP_MASK_1 and CTRL_CORE_BANDGAP_MASK_2 registers. These 5 bits are automatically cleared by hardware after the FIFOs are cleared.

Each FIFO is cleared by setting to 0x1 one of the CLEAR_x bits in the CTRL_CORE_BANDGAP_MASK_1 and CTRL_CORE_BANDGAP_MASK_2 registers. These 5 bits are also automatically set by hardware to 0x0 after the FIFOs clearing procedure completes.

- **Controlling the clock provided to the five FSMs:**

  The five FSMs comply with the PRCM slave idle protocol. They share common functional clock (L3INSTR_TS_GCLK), which is automatically gated by PRCM depending on the value of the CTRL_CORE_BANDGAP_MASK_1[31:30] SIDLEMODE bit field. L3INSTR_TS_GCLK clock is also enabled automatically by the PRCM module.

18.4.6.2.6 Summary Of The Thermal Management Related Registers

Table 18-12 summarizes all the thermal management related registers.

Table 18-12. Summary Of The Thermal Management Related Registers

Register Name	Description	Access
CTRL_CORE_TEMP_SENSOR_MPU	Temperature sensor control registers	RW

CTRL_CORE_BANDGAP_MASK_1 CTRL_CORE_BANDGAP_MASK_2	Registers used to mask the comparator outputs for the low and high thermal alert thresholds. These registers are also used to control the FIFOs and the clock provided to the five FSMs.	RW

18.4.6.2.7 ADC Values Versus Temperature

Table 18-13 provides all the valid ADC values which correspond to the temperature measured which is read from the CTRL_CORE_TEMP_SENSOR_x[9:0] BGAP_DTEMP_x bit fields. Table 18-13 also provides the values for the low and high temperature thresholds which are configurable through the CTRL_CORE_BANDGAP_THRESHOLD_x[9:0] THOLD_COLD_x and CTRL_CORE_BANDGAP_THRESHOLD_x[25:16] THOLD_HOT_x bit fields.

Table 18-13. ADC Values Versus Temperature

ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature	
	From	To		From	To		From	To		From	To

18.4.6.3 PBIAS Cell And MMC1 I/O Cells Control Registers

The PBIAS cell is associated with device MMC1 interface and used together with the MMC1 I/O cells. Its purpose is to provide bias voltage to the MMC1 I/O cells. Without this bias voltage these I/O cells can not function properly.

The PBIAS cell is controlled by software using the CTRL_CORE_CONTROL_PBIAS register. The CTRL_CORE_CONTROL_HYST_1 register is used for hysteresis and drive strength control of the MMC1 I/O cells.

Figure 18-9 shows the PBIAS cell with the control bits and connections between it, the control module and the MMC1 I/O cells.

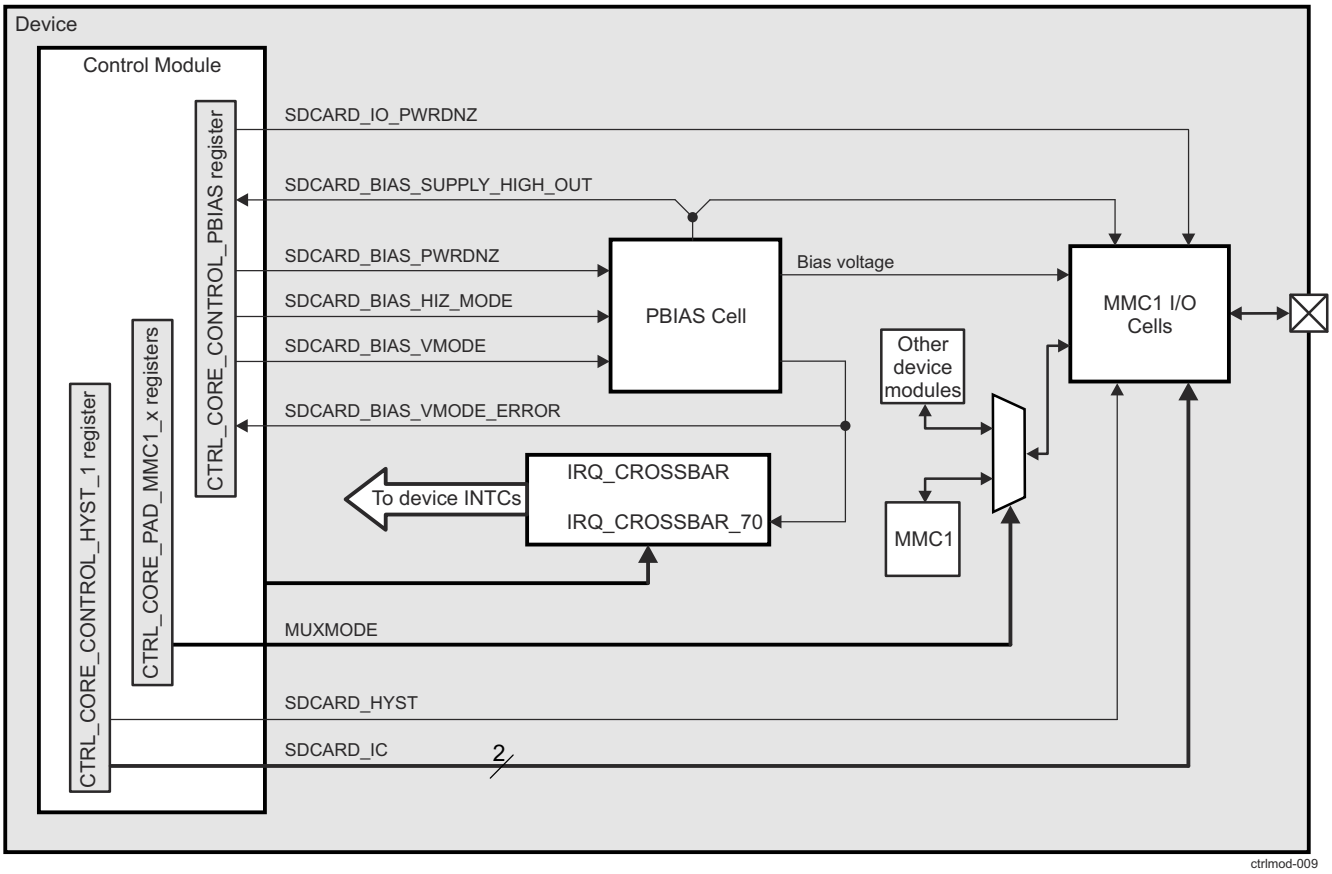

Figure 18-9. PBIAS Cell And Its Connections

Table 18-14 describes PBIAS cell and MMC1 I/O cells control bits.

Table 18-14. Control Bits For the PBIAS and MMC1 I/O Cells

Control bits for PBIAS cell and MMC1 I/O cells	Reset Value	Description
CTRL_CORE_CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ	0x0	This bit turns ON and OFF the PBIAS cell. Software must keep it to 0x0 whenever the PBIAS cell supply voltage is ramping up/down or changing. Thus the PBIAS cell is protected. This bit should be set to 0x1 only after the PBIAS cell supply voltage is stable. This action power up the PBIAS cell.
CTRL_CORE_CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ	0x0	This bit turns ON and OFF the MMC1 I/O cells. Software must keep it to 0x0 whenever the MMC1 IOs supply voltage is ramping up/down or changing. Thus the MMC1 I/O cells are protected. When this bit is set to 0x0, the MMC1 pads are floating. This bit should be set to 0x1 only after the MMC1 IOs supply voltage is stable. This action powers up the MMC1 I/O cells.
CTRL_CORE_CONTROL_PBIAS[25] SDCARD_BIAS_HIZ_MODE	0x0	When this bit is set to 0x1, the PBIAS cell output is in high impedance state and the SDCARD_BIAS_VMODE_ERROR bit sets automatically to 0x1. When SDCARD_BIAS_HIZ_MODE is set to 0x0, the PBIAS cell is in normal operation mode.
CTRL_CORE_CONTROL_PBIAS[24] SDCARD_BIAS_SUPPLY_HI_OUT	0x0	This is status bit indicating whether the MMC1 I/O cells supply voltage is equal to 1,8V or 3,3V.

Table 18-14. Control Bits For the PBIAS and MMC1 I/O Cells (continued)

Control bits for PBIAS cell and MMC1 I/O cells	Reset Value	Description
CTRL_CORE_CONTROL_PBIAS[23] SDCARD_BIAS_VMODE_ERROR	0x0	Status bit wich indicates, during PBIAS cell normal operation mode, whether the voltage defined by the SDCARD_BIAS_VMODE bit is equal to the MMC1 I/Os supply voltage or not. If not, this bit is automatically set to 0x1 4µs after the voltage detection. It is also mapped to the IRQ_CROSSBAR_70 input line and is used as an interrupt source. If both voltage values are not equal an interrupt is generated.
CTRL_CORE_CONTROL_PBIAS[21] SDCARD_BIAS_VMODE	0x1	By controlling this bit software tells the PBIAS cell whether the MMC1 I/O cells supply voltage is equal to 1,8V or 3,3V. Its reset value indicates that the MMC1 I/Os voltage level is 3,3V.
CTRL_CORE_CONTROL_HYST_1[31] SDCARD_HYST	0x1	Hysteresis enabling/disabling for the MMC1 I/Os input buffer.
CTRL_CORE_CONTROL_HYST_1[30:29] SDCARD_IC	0x0	Impedance control (drive strength) for the MMC1 I/Os output buffer.

When the MMC1 signals are not used, that is MUXMODE different than 0x0 selected, the PBIAS cell must also be configured for proper work of the other interface signals multiplexed on the MMC1 I/O cells. For example, if MUXMODE = 0xE (gpio6_21 to gpio6_26 signals selected) the PBIAS cell and MMC1 I/O cells must be configured. This means that both the cells must be powerd and the appropriate PBAIS cell control bits must also be configured.

The MMC1 interface pads are the following:

- mmc1_clk
- mmc1_cmd
- mmc1_dat[3:0]
- mmc1_sdcd
- mmc1_sdwp

All of these pads except the mmc1_sdcd and mmc1_sdwp pads are associated with the PBIAS cell and the CTRL_CORE_CONTROL_PBIAS register and are also controlled by the CTRL_CORE_CONTROL_HYST_1 register.

The PBIAS cell and the MMC1 I/O cells are powered externally through the vddshv8 ball.

The PBIAS cell must be programmed according to the MMC1 I/O cells supply voltage. For details, see Table 18-15.

Table 18-15. PBIAS Cell Voltage Configuration

CTRL_CORE_CONTROL_PBIAS[21] SDCARD_BIAS_VMODE Bit Configuration	PBIAS Cell and MMC1 I/O Cells Supply Voltage	Type of Operation
1.8V (0x0)	1.8V	Normal 1.8V operation
1.8V (0x0)	3.3V	Damaging configuration(2)
3.3V (0x1)	1.8V	Damaging configuration(2)
3.3V (0x1)	3.3V	Normal 3.3V operation

(1) For damaging configuration, hardware system protection is provided to prevent deterioration of the associated MMC1 I/Os.
(2) These modes must not be used.

Table 18-16 summarizes the generation of the CTRL_CORE_CONTROL_PBIAS[23] SDCARD_BIAS_VMODE_ERROR status flag, which depends on the various combinations of bits in the CTRL_CORE_CONTROL_PBIAS register. When this flag sets to 0x1, it is recommended the MMC1 I/O cells to be powered down by setting to 0x0 the CTRL_CORE_CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ bit.

Table 18-16. PBIAS Cell Error Signal Truth Table

Programmed Voltage Level (SDCARD_BIAS_VMODE)	SDCARD_BIAS_SUPPLY_HI_OUT	SDCARD_BIAS_HIZ_MODE	PWRDNZ Bits	SDCARD_BIAS_VMODE_ERROR
0	0	X	0	0
0	0	0	1	0
0	1	0	1	1
X	X	1	1	1
1	0	X	0	0
1	0	0	1	1
1	1	0	1	0

SDCARD_BIAS_VMODE_ERROR = 0x1 shows that the programmed voltage level is not the same as the voltage indicated by the SDCARD_BIAS_SUPPLY_HI_OUT bit or high impedance mode is selected.

SDCARD_BIAS_VMODE_ERROR = 0x0 shows that the programmed voltage level is the same as the voltage indicated by the SDCARD_BIAS_SUPPLY_HI_OUT bit or it is not considered because SDCARD_PWRDNZ = 0x0.

18.4.6.4 IRQ_CROSSBAR Module Functional Description

There is an IRQ_CROSSBAR module in the device, which is controlled by registers in the CTRL_MODULE_CORE submodule. The IRQ_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device interrupt sources. The IRQs from all the device modules are connected to the IRQ_CROSSBAR inputs. Each module IRQ is connected only to one cross-bar input. Each output of the IRQ_CROSSBAR module is connected only to one interrupt line of certain interrupt controller (INTC). Thus, the device IRQs are mapped to the device INTCs through the IRQ_CROSSBAR. Some of these IRQs are mapped by default to certain interrupt lines of one of the device INTCs, but there are IRQs which are not mapped by default to any interrupt line of any device INTC. All IRQs, connected to the IRQ_CROSSBAR inputs, can be remapped to other interrupt lines of the different device INTCs through the CTRL_CORE_X_IRQ_B_A registers. Each of these registers has a structure described in Table 18-17.

Table 18-17. Generic Description of the CTRL_CORE_X_IRQ_B_A IRQ_CROSSBAR Control Registers

Bits	Field Name	Description	Type	Note
31:25	RESERVED		R	
24:16	X_IRQ_A	Selects an interrupt source signal for the X_IRQ_A INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_A INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_A INTC line 0x-: ..... 0x64: Maps IRQ_CROSSBAR input 100 to X_IRQ_A INTC line 0x-: ..... 0x190 to 0x1FF: Reserved	RW	X is summarization. It is equal to: • MPU • DSP1 • IPU1 • IPU2 • PRU-ICSS1 • PRU-ICSS2 X shows the module name to which interrupt controller all inputs of the IRQ_CROSSBAR module can be mapped. A is also summarization. It shows the number of the line for the corresponding INTC. A is equal to 0, 1, 2, ..., and so on, depending on the count of the INTC lines controlled by the IRQ_CROSSBAR module. For more details, see Table 18-18.
15:9	RESERVED		R	

Table 18-17. Generic Description of the CTRL_CORE_X_IRQ_B_A IRQ_CROSSBAR Control Registers (continued)

Bits	Field Name	Description	Type	Note
8:0	X_IRQ_B	Selects an interrupt source signal for the X_IRQ_B INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_B INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_B INTC line 0x-: ..... 0x64: Maps IRQ_CROSSBAR input 100 to X_IRQ_B INTC line 0x-: ..... 0x190 to 0x1FF: Reserved	RW	B is summarization. It shows the number of the line for the corresponding INTC. B is equal to 0, 1, 2, ..., and so on, depending on the count of the INTC lines controlled by the IRQ_CROSSBAR module.

Figure 18-10 represents the way in which the IRQ_CROSSBAR module works. It shows the device modules and their IRQs connected to the IRQ_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device INTCs.

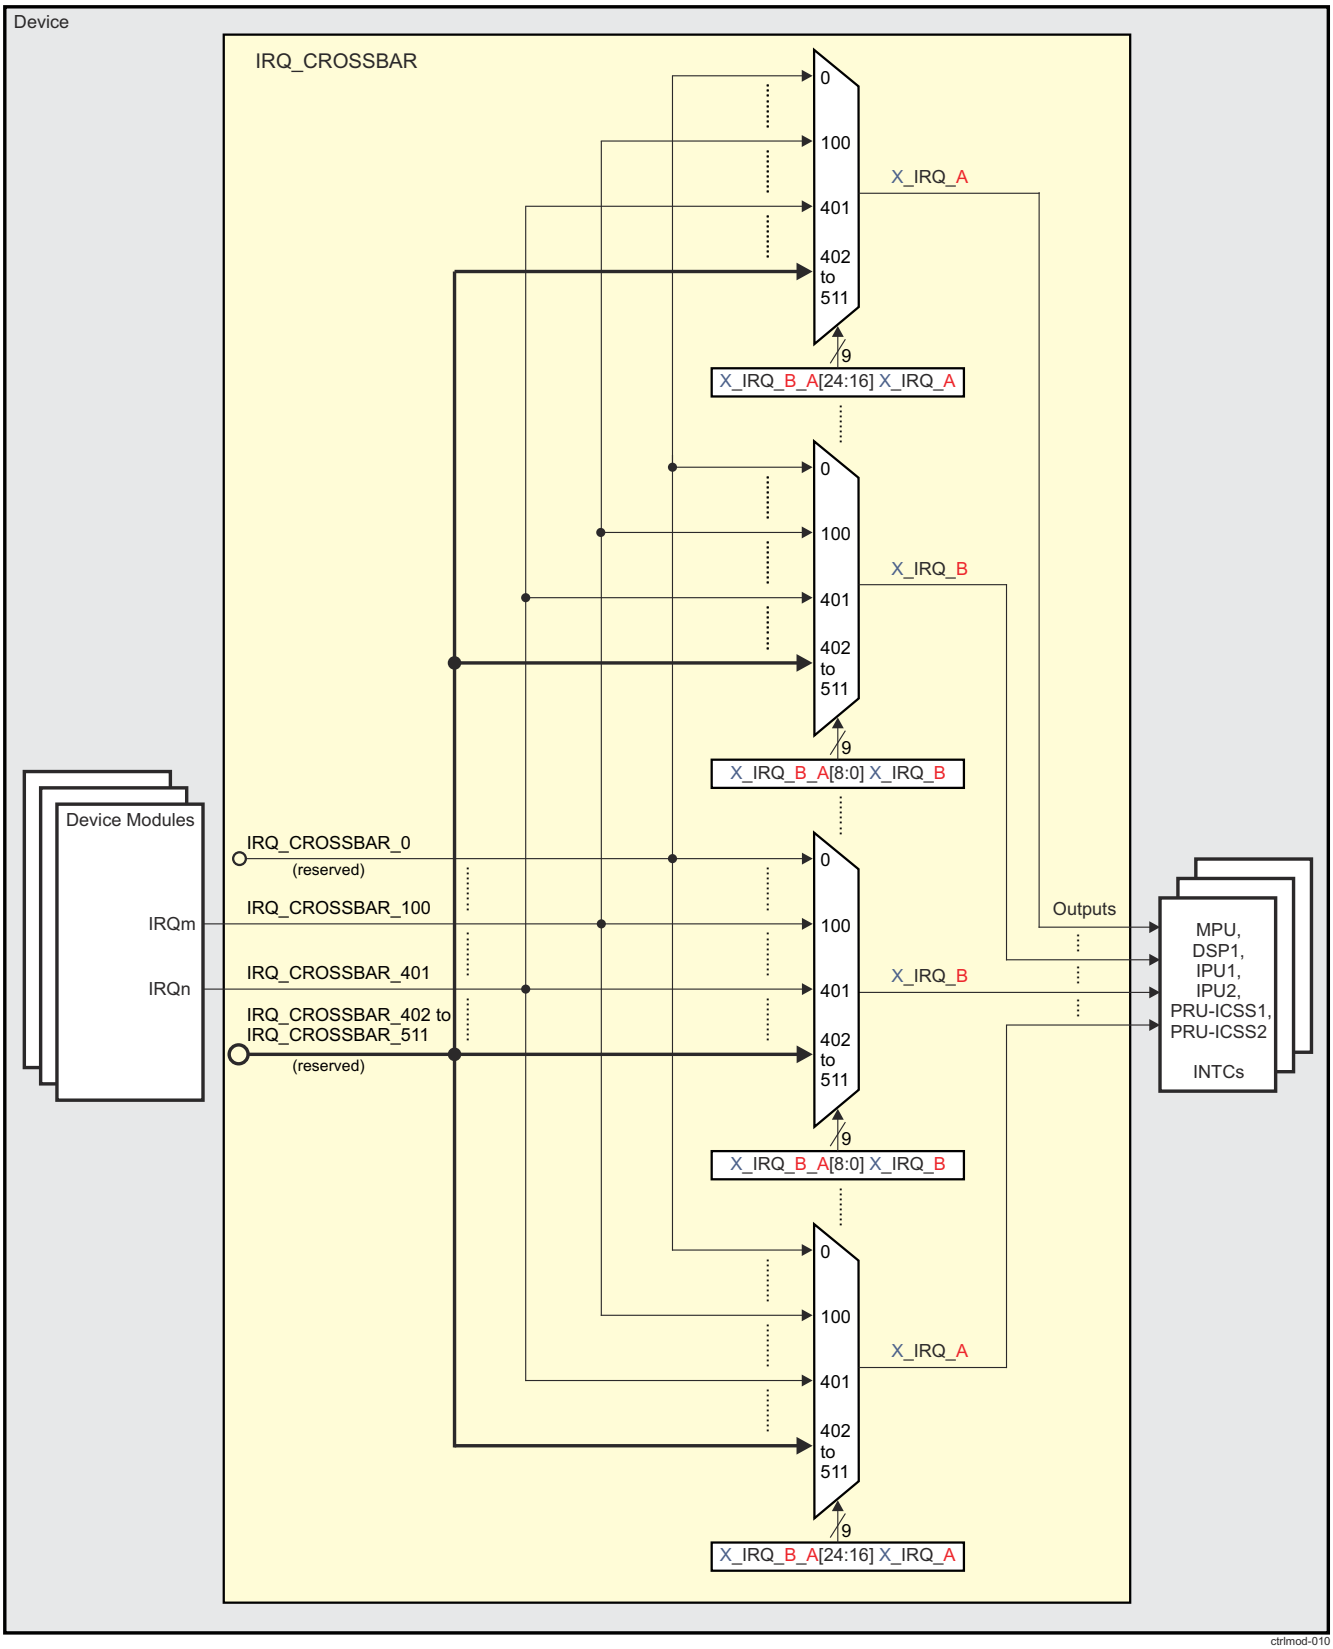

Figure 18-10. IRQ_CROSSBAR Module Functional Diagram

Each IRQ_CROSSBAR control register has two 9-bit fields. Each 9-bit field is associated only with one interrupt line. Through this 9-bit field any of the IRQs connected to the IRQ_CROSSBAR inputs can be mapped to the INTC line associated with this 9-bit field. For example, the register CTRL_CORE_MPU_IRQ_74_75 is associated with MPU_IRQ_74 and MPU_IRQ_75. The 9-bit field CTRL_CORE_MPU_IRQ_74_75[24:16] MPU_IRQ_75 is associated only with MPU_IRQ_75 interrupt line of the MPU INTC. Setting this bit field to any other value different than its reset value will map another module IRQ to the MPU_IRQ_75 interrupt line. The default (reset) value of this bit field is 0x46 which corresponds to the IRQ_CROSSBAR_70 input. The PBIAS_IRQ is connected to this cross-bar input. Setting another register to 0x46 will cause the PBIAS_IRQ to be mapped to another INTC line. For example, if the CTRL_CORE_DSP1_IRQ_40_41[8:0] DSP1_IRQ_40 is set to 0x46 the PBIAS_IRQ will be mapped to the DSP1_IRQ_40 interrupt line. The same logic also applies to the other interrupt lines of the device INTCs.

In addition, not all of the interrupt lines of a given INTC are controlled by the IRQ_CROSSBAR registers. This means, that there are interrupt lines which are not connected to any IRQ_CROSSBAR output and thus only one IRQ is connected to these interrupt lines. In the most common case these lines are used by interrupt sources internal or specific for the corresponding module, which has an INTC.

Table 18-18 shows which lines of each INTC are associated with the IRQ_CROSSBAR control registers. The rest of the INTC lines (not listed in the table) cannot be controlled by the cross-bar registers.

Table 18-18. Interrupt Lines Associated With The IRQ_CROSSBAR Control Registers

MPU INTC Lines	DSP INTC Lines	IPU INTC Lines	PRU-ICSS INTC Lines
MPU_IRQ_4, MPU_IRQ_7 to MPU_IRQ_130, MPU_IRQ_133 to MPU_IRQ_159	DSP1_IRQ_32 to DSP1_IRQ_95	IPU1_IRQ_23 to IPU1_IRQ_79, IPU2_IRQ_23 to IPU2_IRQ_79	PRUSS1_IRQ_32 to PRUSS1_IRQ_63, PRUSS2_IRQ_32 to PRUSS2_IRQ_63

The individual connection between all module IRQs and all IRQ_CROSSBAR inputs is shown in Section 17.3.7, *Mapping of Device Interrupts to IRQ_CROSSBAR Inputs* of Chapter 17, *Interrupt Controllers*.

In addition, the CTRL_CORE_OVS_IRQ_IO_MUX register is used to select for observation on two external pads any IRQ connected to the IRQ_CROSSBAR inputs. Using the CTRL_CORE_OVS_IRQ_IO_MUX[17:9] OVS_IRQ_IO_MUX_2 bit field all IRQs can be mapped to the obs_irq2 signal. The CTRL_CORE_OVS_IRQ_IO_MUX[8:0] OVS_IRQ_IO_MUX_1 bit field maps all IRQs to the obs_irq1 signal. For example, setting the CTRL_CORE_OVS_IRQ_IO_MUX[8:0] OVS_IRQ_IO_MUX_1 to 0x18 maps the GPIO1_IRQ_1 to the obs_irq1 line and thus this IRQ can be observed.

18.4.6.5 DMA_CROSSBAR Module Functional Description

There is a DMA_CROSSBAR module in the device, which is controlled by registers in the CTRL_MODULE_CORE submodule. The DMA_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device DMA request source signals. The DREQs from all the device modules are connected to the DMA_CROSSBAR inputs. Each DREQ signal is connected only to one DMA cross-bar input. Each output of the DMA_CROSSBAR module is connected only to one input line of the device DMA modules. The DMAs associated with the DMA_CROSSBAR are the following:

- DMA_SYSTEM
- DMA_EDMA
- DMA_DSP1_EDMA

All DREQs, connected to the DMA_CROSSBAR inputs, can be remapped to other lines of the these DMA modules through the CTRL_CORE_DMA_X_DREQ_B_A registers. Each of these registers has a structure described in Table 18-19.

Table 18-19. Generic Description of the CTRL_CORE_DMA_X_DREQ_B_A DMA_CROSSBAR Control Registers

Bits	Field Name	Description	Type	Note
31:24	RESERVED		R	

Table 18-19. Generic Description of the CTRL_CORE_DMA_X_DREQ_B_A DMA_CROSSBAR Control Registers (continued)

Bits	Field Name	Description	Type	Note
23:16	DMA_X_DREQ_A_IRQ_A	Selects a DMA request source signal for the DMA_X_DREQ_A_IRQ_A DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_A_IRQ_A DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: ..... 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: ..... 0xCC to 0xFF: Reserved	RW	X is summarization. It is equal to: • SYSTEM • EDMA • DSP1_EDMA X shows to which DMA all inputs of the DMA_CROSSBAR module can be mapped. A is also summarization. It shows the number of the DREQ line for the corresponding DMA module. A is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see Table 18-20.
15:8	RESERVED		R	
7:0	DMA_X_DREQ_B_IRQ_B	Selects a DMA request source signal for the DMA_X_DREQ_B_IRQ_B DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_B_IRQ_B DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: ..... 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: ..... 0xCC to 0xFF: Reserved	RW	B is also summarization. It shows the number of the DREQ line for the corresponding DMA module. B is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see Table 18-20.

Figure 18-11 represents the way in which the DMA_CROSSBAR module works. It shows the device modules and their DREQs connected to the DMA_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device DMA modules.

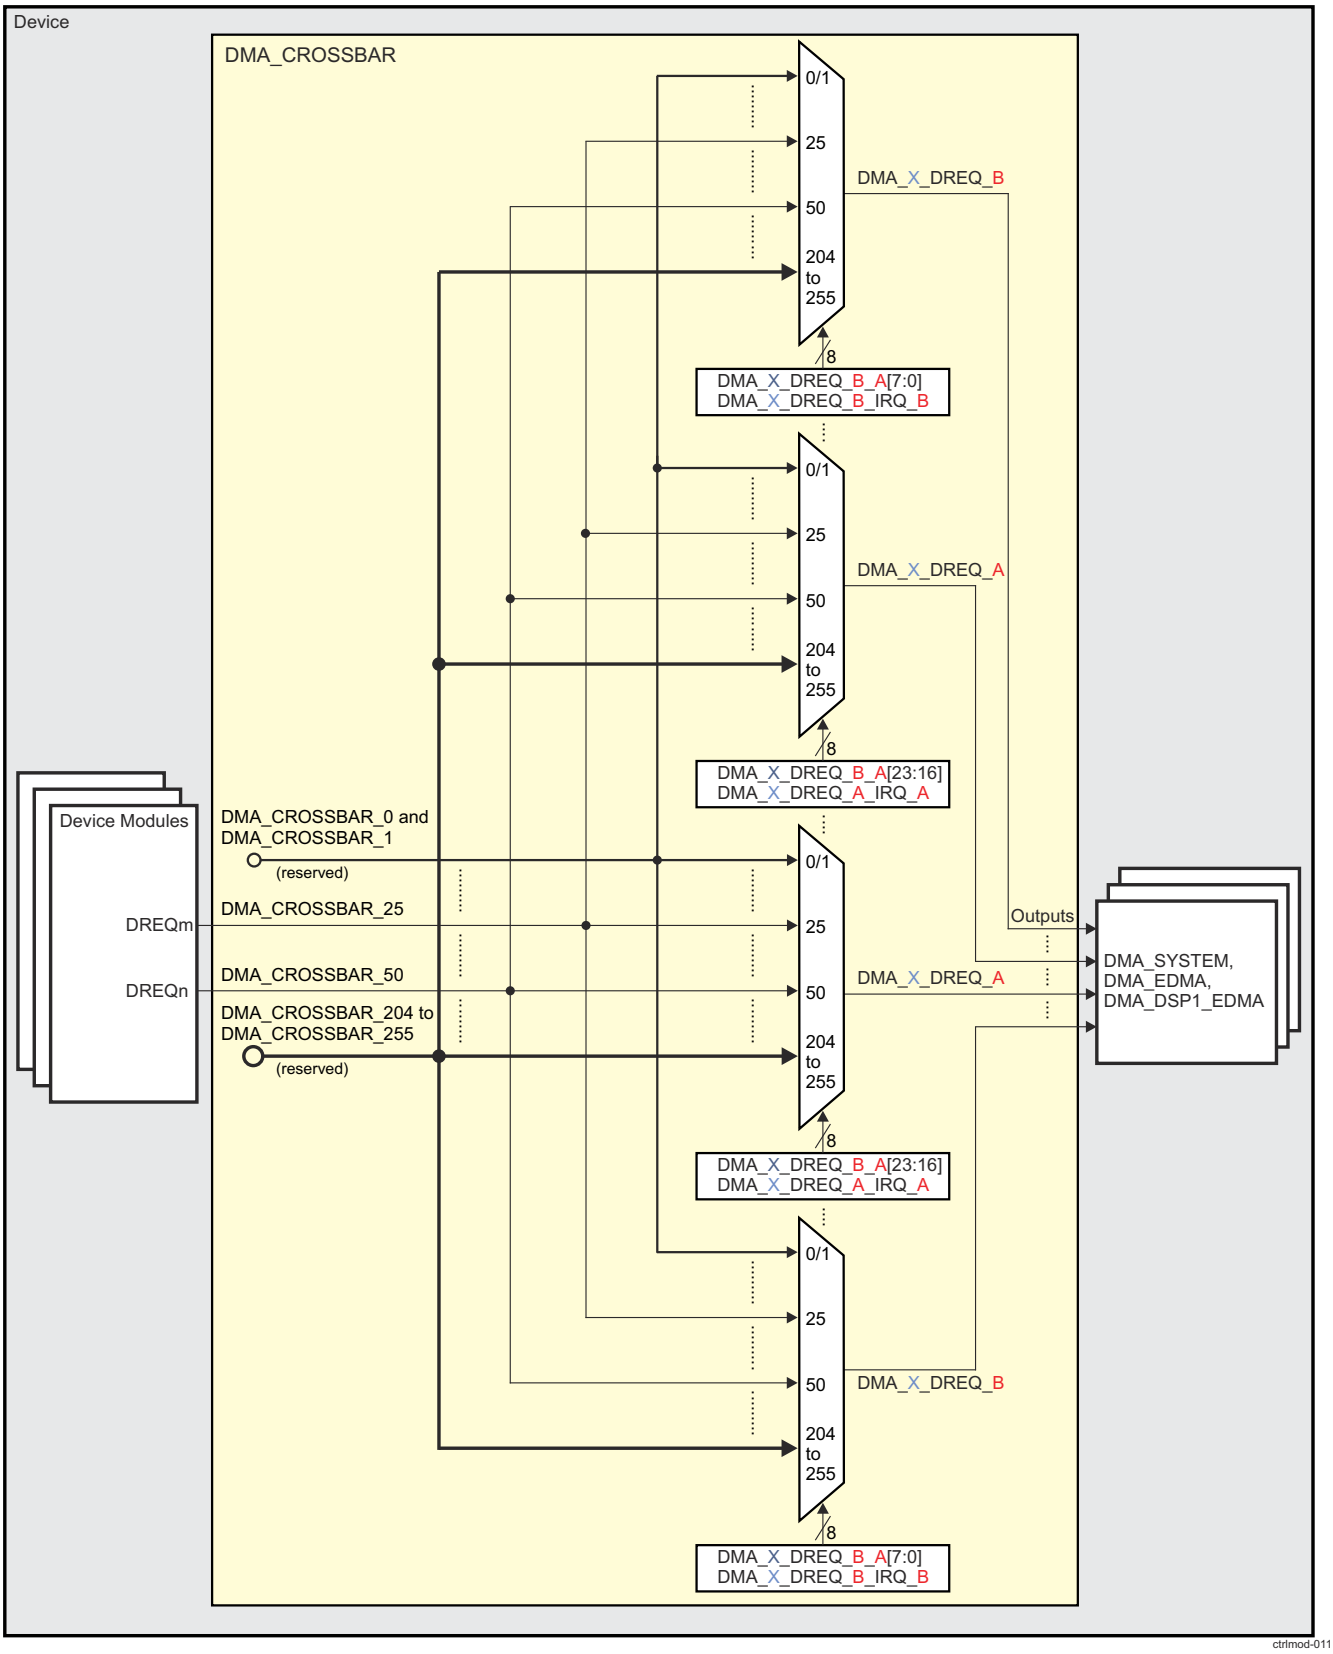

Figure 18-11. DMA_CROSSBAR Module Functional Diagram

Each DMA_CROSSBAR control register has two 8-bit fields. Each 8-bit field is associated only with one line of certain DMA module. Through this 8-bit field any of the DREQs connected to the DMA_CROSSBAR inputs can be mapped to the DMA line associated with this 8-bit field. For example, the register CTRL_CORE_DMA_EDMA_DREQ_62_63 is associated with DMA_EDMA_DREQ_62 and DMA_EDMA_DREQ_63 lines. The 8-bit field CTRL_CORE_DMA_EDMA_DREQ_62_63[7:0] DMA_EDMA_DREQ_62_IRQ_62 is associated only with DMA_EDMA_DREQ_62 line of the DMA_EDMA module. Setting this bit field to any other value different than its reset value will map another DREQ from the device modules to the DMA_EDMA_DREQ_62 line. The default (reset) value of this bit field is 0x3F which corresponds to the DMA_CROSSBAR_63 input. The UART5_DREQ_TX is connected to this cross-bar input. Setting another register to 0x3F will cause the UART5_DREQ_TX to be mapped to another DMA line. For example, if the CTRL_CORE_DMA_EDMA_DREQ_30_31[23:16] DMA_EDMA_DREQ_31_IRQ_31 is set to 0x3F the UART5_DREQ_TX will be mapped to the DMA_EDMA_DREQ_31 line. The same logic also applies to the other lines of the device DMAs.

Table 18-20 shows which lines of each DMA are associated with the DMA_CROSSBAR control registers. The rest of the lines (not listed in the table) cannot be controlled by the cross-bar registers.

Table 18-20. DREQ Lines Associated With The DMA_CROSSBAR Control Registers

DMA_SYSTEM DREQ Lines	DMA_EDMA DREQ Lines	DMA_DSP1_EDMA DREQ Lines
DMA_SYSTEM_DREQ_0 to DMA_SYSTEM_DREQ_126	DMA_EDMA_DREQ_0 to DMA_EDMA_DREQ_63	DMA_DSP1_DREQ_0 to DMA_DSP1_DREQ_19

The individual connection between all module DREQs and all DMA_CROSSBAR inputs is shown in Section 16.1.3.2, *Mapping of DMA Requests to DMA_CROSSBAR Inputs* of Section 16.1, *System DMA*.

In addition, the CTRL_CORE_OVS_DMARQ_IO_MUX register is used to select for observation on two external pads any DREQ connected to the DMA_CROSSBAR inputs. Using the CTRL_CORE_OVS_DMARQ_IO_MUX[15:8] OVS_DMARQ_IO_MUX_2 bit field all DREQs can be mapped to the obs_dmarq2 signal. The CTRL_CORE_OVS_DMARQ_IO_MUX[7:0] OVS_DMARQ_IO_MUX_1 bit field maps all DREQs to the obs_dmarq1 signal. For example, setting the CTRL_CORE_OVS_DMARQ_IO_MUX[7:0] OVS_DMARQ_IO_MUX_1 to 0x6 maps the DISPC_DREQ to the obs_dmarq1 line and thus this DREQ can be observed.

18.4.6.6 SDRAM Initiator Priority Registers

The CTRL_CORE_EMIF_INITIATOR_PRIORITY_1 to CTRL_CORE_EMIF_INITIATOR_PRIORITY_6 registers are intended to control the priority of each initiator accessing the EMIF controller. Each 3-bit field in these registers is associated only with one initiator. Setting this bit field to 0x0 means that the corresponding initiator has a highest priority over the others and setting it to 0x7 is for lowest priority. This feature is useful in case of concurrent access to the external SDRAM from several initiators.

Note

The priorities configured through the CTRL_CORE_EMIF_INITIATOR_PRIORITY_1 to CTRL_CORE_EMIF_INITIATOR_PRIORITY_6 registers have affect only at the L3 switch levels and are always overridden at DMM level by the priorities configured thorough the DMM_PEG_PRIO_k registers.

18.4.6.7 L3_MAIN Initiator Priority Registers

The CTRL_CORE_L3_INITIATOR_PRESSURE_1 to CTRL_CORE_L3_INITIATOR_PRESSURE_6 registers are used for controlling the priority of certain initiators on the L3_MAIN. Each 2-bit field in these registers is associated only with one initiator. Setting this bit field to 0x3 means that the traffic of this initiator has highest proiroty over the other traffics. A value of 0x0 is for lowest priority. These registers provide a dynamic priority escalation for the following L3_MAIN initiators:

- MPU

- DSP1
- IPU1
- IPU2
- GPU P1
- GPU P2
- PRU-ICSS1
- PRU-ICSS2
- SATA
- MMC1
- MMC2
- USB1
- USB2
- USB3

Note

USB3 (ULPI) is not supported on the AM571x / AM570x family of devices.

SATA is not supported on the AM570x family of devices.

18.4.6.8 Memory Region Lock Registers

There are five registers used to lock different memory regions of CTRL_MODULE_CORE memory mapped space. A memory region is locked, means that all wite accesses to this region are ignored. Writing a value unique for each register will lock certain memory region and writing another unique value results in unlocking of the same region. These five registers can lock the entire memory space of the CTRL_MODULE_CORE submodule. Table 18-21 gives more details.

Table 18-21. Memory Region Lock Registers

Register	Memory Space to Lock	Groups of Registers Associated With This Memory Region	Lock/Unlock (register reset value)
CTRL_CORE_MMR_LOCK_1	Region from 0x0000 0100 to 0x0000 079F	Thermal management related registers, EMIF initiator priority, L3_MAIN initiator pressure (priority), standard eFuse and other registers	locked
CTRL_CORE_MMR_LOCK_2	Region from 0x0000 07A0 to 0x0000 0D9F	IRQ_CROSSBAR and DMA_CROSSBAR registers	locked
CTRL_CORE_MMR_LOCK_3	Region from 0x0000 0DA0 to 0x0000 0FFF	A few registers associated with device I/Os	locked
CTRL_CORE_MMR_LOCK_4	Region from 0x0000 1000 to 0x0000 13FF	Reserved range	locked
CTRL_CORE_MMR_LOCK_5	Region from 0x0000 1400 to 0x0000 1FFF	Mainly pad configuration registers	locked

Note

By default the entire CTRL_MODULE_CORE memory space is locked but the ROM code unlocks it by writing corresponding unlock values to all CTRL_CORE_MMR_LOCK_x registers.

18.4.6.9 NMI Mapping To Respective Cores

Two registers CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 are intended to map the external non-maskable interrupt (NMI) to certain of the device host processors. Writing 0x1 into a bit field of these registers enables the NMI to be mapped to the corresponding processor associated with this bit field. Writing 0x0 disables the NMI mapping to this processor.

18.4.6.10 Software Controls for the DDR3 I/O Cells

There are two types of I/O cells associated with the DDR3 interface. These are single-ended and differential I/O cells.

These I/O cells have the following software controls which reside in registers of the CTRL_MODULE_CORE:

- Output impedance controls - I[2:0]
- Slew rate controls - SR[2:0]
- Weak driver controls - WD[1:0]

The I and SR controls apply when the I/Os operate as outputs. The WD controls apply when the I/Os operate as both inputs or outputs.

The bits I[2:0] are used for programming the desired impedance value of the output buffer. Table 18-22 describes the I[2:0] controls which are valid for pull-up and pull-down outputs.

Table 18-22. Output Impedance Controls - I[2:0]

I[2]	I[1]	I[0]	Drive Setting Name	Output Impedance
0	0	0	Imp80	80 Ohms
0	0	1	Imp60	60 Ohms
0	1	0	Imp48	48 Ohms
0	1	1	Imp40	40 Ohms
1	0	0	Imp34	34 Ohms
1	0	1	Reserved	Reserved
1	1	0	Reserved	Reserved
1	1	1	Reserved	Reserved

To achieve optimal noise/speed trade-off the slew rate of the output signal can also be programmed using the slew rate control bits SR[2:0] shown in Table 18-23. These SR settings do not affect the DC drive strength of the output buffer. They only control its turn-on time.

Table 18-23. Slew Rate Controls - SR[2:0]

SR[2]	SR[1]	SR[0]	Turn-On Time Level	Note
0	0	0	fastest	All 8 values are valid.
...	...	...		
...	...	...		
1	1	1	slowest	

Weak pull-up, pull-down or keeper option for device DDR3 pads is enabled through the WD[1:0] bits. The weak pull-up or pull-down option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value when nothing is driving the pad. Table 18-24 describes the WD controls. They are used for avoiding floating pads on the DDR3 interface.

Table 18-24. Weak Driver Controls - WD[1:0]

WD[1]	WD[0]	Single-Ended Operation	Differential Pair Operation	
			padp	padn
0	0	Pull logic disabled	Pull logic disabled	Pull logic disabled
0	1	Weak pullup enabled	Weak pullup enabled	Weak pulldown enabled
1	0	Weak pulldown enabled	Weak pulldown enabled	Weak pullup enabled
1	1	Weak keeper enabled	Weak keeper enabled	Weak keeper enabled

Note

To avoid unnecessary power consumption, software must overwrite the Weak Driver (WD) reset values by setting them to 0x0.

It must be taken into account that the I, SR and WD software controls apply for several pads combined in groups, and not for a single pad. For example, writing 0x1 to the CTRL_CORE_CONTROL_DDRCACH1_0[17:16] DDR3CH1_PART5A_WD bit field enables the weak pull-up resistors for all 16 pads in the PART5A group. These are the ddr1_a[15:0] pads. Table 18-25 shows the I, SR and WD controls for the different DDR3 pad groups.

Table 18-25. Software Group Controls for the DDR3 Pads

DDR3 Interface I/O Group Controls	Group Name	Pads in a Group
EMIF1 Pads		
CTRL_CORE_CONTROL_DDRCACH1_0[31:29] DDR3CH1_PART0_I CTRL_CORE_CONTROL_DDRCACH1_0[28:26] DDR3CH1_PART0_SR CTRL_CORE_CONTROL_DDRCACH1_0[25:24] DDR3CH1_PART0_WD	PART0	ddr1_casn, ddr1_rasn, ddr1_rst, ddr1_wen, ddr1_csn[0], ddr1_cke, ddr1_odt[0]

18.4.6.11 Reference Voltage for the Device DDR3 Receivers

The device DDR3 input buffers work in so-called Vref-based receiver mode. In this mode, the buffers act like differential comparators with positive terminal connected to a device pad which receives signals from DDR3 memory and negative terminal connected to a source of reference voltage.

To work properly, a reference voltage must be provided to the device DDR3 input buffers. There are two Vref-generation cells in the device intended to supply this internal reference voltage.

Figure 18-12 shows the Vref-generation cells in the device.

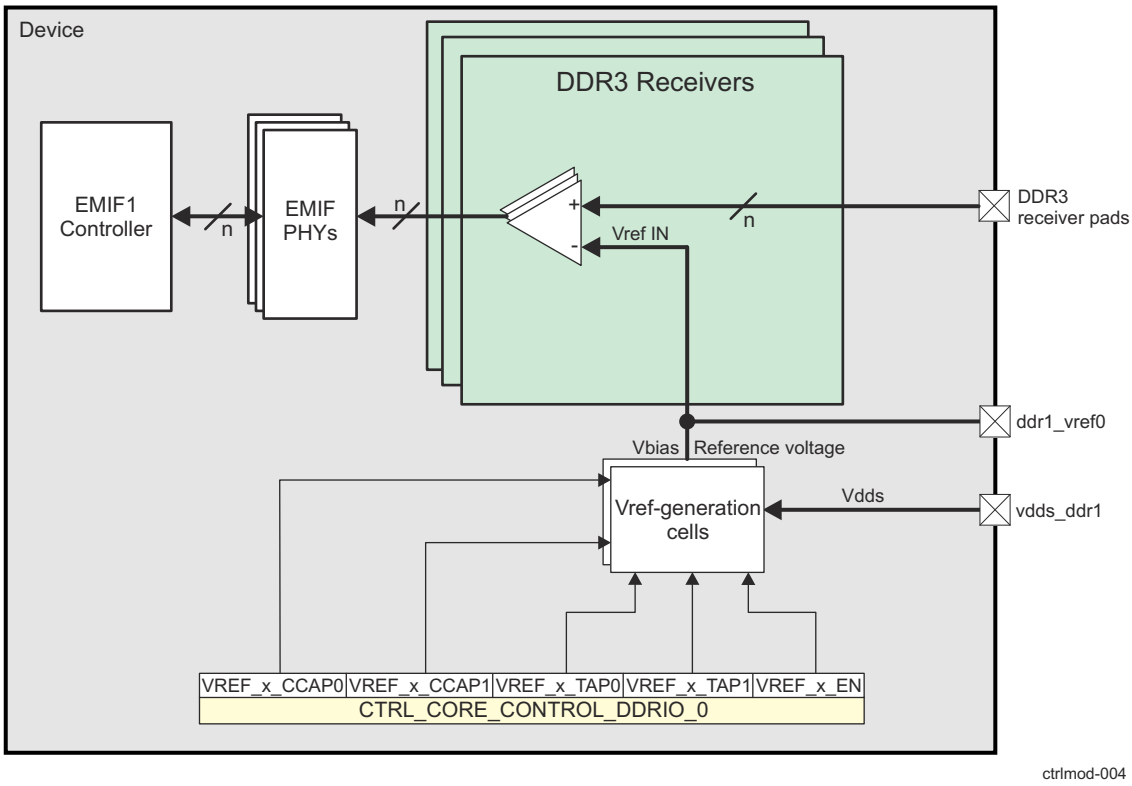

Figure 18-12. Vref-Generation Cells and Their Controls

Both the Vref-generation cells associated with EMIF1 are powerd through the vdds_ddr1 ball. For more information, see the device data manual.

The control bits for the Vref-generation cells reside in the CTRL_CORE_CONTROL_DDRIO_0 register. There are VREF_x_TAP[1:0] control bits which set the output drive capability of the Vref cells. Table 18-26 lists the possible options for selection of load current sourced from the output of each Vref-generation cell.

Table 18-26. Vref Cell Load Current Selection

VREF_x_TAP1	VREF_x_TAP0	Description
0	0	2-µA load current
0	1	4-µA load current
1	0	8-µA load current
1	1	32-µA load current

According to the noise environment, the user can choose to filter the supplied reference voltage. Two coupling capacitors internal to each Vref-generation cell are available and configurable through the VREF_x_CCAP[1:0] control bits in the CTRL_CORE_CONTROL_DDRIO_0 register, as specified in Table 18-27.

Table 18-27. Vref Cell Coupling Capacitor Selection

VREF_x_CCAP1	VREF_x_CCAP0	Capacitor
0	0	No capacitor connected.
0	1	One capacitor connected between Vbias and ground.(1)
1	0	One capacitor connected between Vbias and Vdds.(2)

Table 18-27. Vref Cell Coupling Capacitor Selection (continued)

VREF_x_CCAP1	VREF_x_CCAP0	Capacitor
1	1	One capacitor connected between Vbias and ground and one capacitor connected between Vbias and Vdds.

(1) Vbias is the output of the Vref-generation cell which provides the reference voltage.
(2) Vdds is the power supply voltage of the Vref-generation cell.

The Vref-gereration cells can be enabled by setting to 0x1 the VREF_x_EN bits in the CTRL_CORE_CONTROL_DDRIO_0 register. These cells can be disabled (for leakage improvement and when not in use) by clearing the same VREF_x_EN bits.

Table 18-28 shows the Vref-generation cells control bits and the DDR3 pads used as receivers to which the corresponding Vref cell supplies reference voltage.

Table 18-28. Controls for the Vref-Generation Cells Versus DDR3 Receiver Pads

Vref-generation Cell Control Bits	DDR3 Vref Cell Associated Pads Used as Receivers
CTRL_CORE_CONTROL_DDRIO_0[19] DDRCH1_VREF_DQ0_INT_CCAP0	ddr1_d[7:0], ddr1_d[15:8]

CTRL_CORE_CONTROL_DDRIO_0[13] DDRCH1_VREF_DQ1_INT_CCAP1	
CTRL_CORE_CONTROL_DDRIO_0[12] DDRCH1_VREF_DQ1_INT_TAP0	
CTRL_CORE_CONTROL_DDRIO_0[11] DDRCH1_VREF_DQ1_INT_TAP1	
CTRL_CORE_CONTROL_DDRIO_0[10] DDRCH1_VREF_DQ1_INT_EN	

18.4.6.12 AVS Class 0 Associated Registers

AVS Class 0 attempts to normalize the power consumption across all devices by lowering the operating voltage of certain voltage rails. This procedure of lowering the voltage should be performed in the boot loader after ROM code. The new voltage to be set for each AVS Class 0 supported voltage rail should be read from the eFuse using dedicated registers. Then the power supply output voltage is adjusted to this new voltage value.

The following voltage rails support AVS Class 0:

- vdd_iva
- vdd_dsp
- vdd
- vdd_gpu
- vdd_mpu

Note

For descriptions of the voltage rails previously listed see the *"Power Supply Signal Descriptions"* table in the device Data Manual.

Table 18-29 shows all registers associated with AVS Class 0. The corresponding AVS Class 0 voltage value can be read from the 12 LSbits of each of the listed registers. They contain the voltage value in hex format. To find the actual value in mV a conversion from hex to decimal value is needed. For example, if the value read from CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_2[11:0] STD_FUSE_OPP_VMIN_MPU_2 is 0x041F, then this corresponds to 1055 mV.

Table 18-29. Registers Associated With AVS Class 0 Voltage

Physical Address	Bit Field Containing the AVS Class 0 Voltage Value	Voltage Rail	Supported OPP
0x4A00 25CC	CTRL_CORE_STD_FUSE_OPP_VMIN_IVA_2[11:0] STD_FUSE_OPP_VMIN_IVA_2	vdd_iva	OPP_NOM
0x4A00 25D0	CTRL_CORE_STD_FUSE_OPP_VMIN_IVA_3[11:0] STD_FUSE_OPP_VMIN_IVA_3		OPP_OD
0x4A00 25D4	CTRL_CORE_STD_FUSE_OPP_VMIN_IVA_4[11:0] STD_FUSE_OPP_VMIN_IVA_4		OPP_HIGH

0x4A00 25D8	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_5[11:0] STD_FUSE_OPP_VMIN_DSPEVE_5		OPP_PLUS
0x4A00 25F4	CTRL_CORE_STD_FUSE_OPP_VMIN_CORE_2[11:0] STD_FUSE_OPP_VMIN_CORE_2	vdd	OPP_NOM
0x4A00 3B08	CTRL_CORE_STD_FUSE_OPP_VMIN_GPU_2[11:0] STD_FUSE_OPP_VMIN_GPU_2	vdd_gpu	OPP_NOM
0x4A00 3B0C	CTRL_CORE_STD_FUSE_OPP_VMIN_GPU_3[11:0] STD_FUSE_OPP_VMIN_GPU_3		OPP_OD
0x4A00 3B10	CTRL_CORE_STD_FUSE_OPP_VMIN_GPU_4[11:0] STD_FUSE_OPP_VMIN_GPU_4		OPP_HIGH
0x4A00 3B14	CTRL_CORE_STD_FUSE_OPP_VMIN_GPU_5[11:0] STD_FUSE_OPP_VMIN_GPU_5		OPP_PLUS
0x4A00 3B1C	CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_1[11:0] STD_FUSE_OPP_VMIN_MPU_1	vdd_mpu	OPP_LOW
0x4A00 3B20	CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_2[11:0] STD_FUSE_OPP_VMIN_MPU_2		OPP_NOM
0x4A00 3B24	CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_3[11:0] STD_FUSE_OPP_VMIN_MPU_3		OPP_OD
0x4A00 3B28	CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_4[11:0] STD_FUSE_OPP_VMIN_MPU_4		OPP_HIGH
0x4A00 3B2C	CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_5[11:0] STD_FUSE_OPP_VMIN_MPU_5		OPP_PLUS

Some of the OPPs listed in Table 18-29 may not be supported for some devices. In these cases the voltage values in the corresponding AVS Class 0 registers can be disregarded.

Note

For more information about the supported OPPs, see the "*Operating Performance Points*" section of the device Data Manual.

In some cases, the AVS Class 0 voltage that is read from the CTRL_CORE_STD_FUSE_OPP_VMIN_xxx_y registers has a value between two incremental voltage steps of the power supply. If such a case occurs, the higher voltage value should be selected.

If several AVS Class 0 supported voltage rails are combined with each other, then all corresponding registers should be read and the highest value should be selected. The power supply of the combined rails should be changed to this highest voltage value.

Note

For a list of the supported voltage rail combinations, see the device Data Manual.

Figure 18-13 shows a general example of how AVS Class 0 should be performed.

Figure 18-13. AVS Class 0 Procedure

18.4.6.13 ABB Associated Registers

When ABB is needed the following registers should be used:

- CTRL_CORE_LDOVBB_DSPEVE_VOLTAGE_CTRL
- CTRL_CORE_LDOVBB_IVA_VOLTAGE_CTRL
- CTRL_WKUP_LDOVBB_GPU_VOLTAGE_CTRL
- CTRL_WKUP_LDOVBB_MPU_VOLTAGE_CTRL
- The CTRL_CORE_STD_FUSE_OPP_VMIN_xxx_y registers depending on the OPP. There are different values for each OPP stored in each one of these registers.

The ABB LDO target value can be read from CTRL_CORE_STD_FUSE_OPP_VMIN_xxx_y[24:20] VSETABB bits, if CTRL_CORE_STD_FUSE_OPP_VMIN_xxx_y[25] ABBEN is set to 0x1. Then this value should be written to bits FBB_VSET_OUT (bits [4:0]) of registers CTRL_CORE/WKUP_LDOVBB_x_VOLTAGE_CTRL. The ABB LDO target value applies when CTRL_CORE/WKUP_LDOVBB_x_VOLTAGE_CTRL[10] FBB_ MUX_CTRL is set to 0x1, that is, FBB_VSET_OUT is used as a target bias voltage. When ABB is bypassed (not used) the FBB_VSET_OUT bits should be loaded with 0x0 and FBB_ MUX_CTRL should be set to 0x0.

It must be taken into account that the ABB LDO target value depends on the OPP. For example, concerning the MPU voltage domain:

- in case of OPP_NOM the value from CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_2[24:20] VSETABB should be used.
- in case of OPP_OD the value from CTRL_CORE_STD_FUSE_OPP_VMIN_MPU_3[24:20] VSETABB should be used.

Note

Before enabling the ABB LDO in FBB mode the FBB_VSET_OUT and FBB_ MUX_CTRL bits must be programmed. The FBB_VSET_OUT bits must be loaded with a value which corresponds to the relevant OPP.

For more details regarding ABB see Section 3.8.3.4 *ABB LDO Programming sequence*.

18.4.6.14 Registers For Other Miscellaneous Functions

18.4.6.14.1 System Boot Status Settings

The CTRL_CORE_BOOTSTRAP register is a status register which indicates the state of the sysboot0 to sysboot15 input signals. Their purpose is to select the boot interface, the device source clock configuration and also other boot related settings.

Note

For proper device operation, sysboot14 must be tied to vss. For SR1.0, sysboot15 must be tied to vdd, but for SR2.x it is configurable. For more information, see Section 18.4.6.1.1.1, *Permanent PU/PD disabling (SR 2.x only)* in Chapter 18, *Control Module*.

SR1.0 information is valid only for the AM571x family of devices.

18.4.6.14.2 Force MPU Write Nonposted Transactions

The control module provides a way for software to force all writes from the MPU subsystem to the L3_MAIN to be nonposted regardless of the attributes of the transactions coming from the MPU. This is done by setting to 0x1 the CTRL_CORE_MPU_FORCEWRNP[0] MPU_FORCEWRNP bit. This bit must not be changed until the transfer completes.

18.4.6.14.3 Firewall Error Status Registers

There are four status registers which show when there is a firewall error. The CTRL_CORE_SEC_ERR_STATUS_FUNC_1 and CTRL_CORE_SEC_ERR_STATUS_FUNC_2 registers are used in device normal operation mode. The x_FW_ERROR bits from these two registers are combined

into a single interrupt signal sent to the IRQ_CROSSBAR module as shown in Figure 18-14. The CTRL_CORE_SEC_ERR_STATUS_DEBUG_1 and CTRL_CORE_SEC_ERR_STATUS_DEBUG_2 registers are used when the device is in debug mode. These two registers have bits same as in the CTRL_CORE_SEC_ERR_STATUS_FUNC_1 and CTRL_CORE_SEC_ERR_STATUS_FUNC_2 registers.

All bits in these registers are cleared when the ERROR_LOG_k and L4_IA_ERROR_LOG_L registers are cleared.

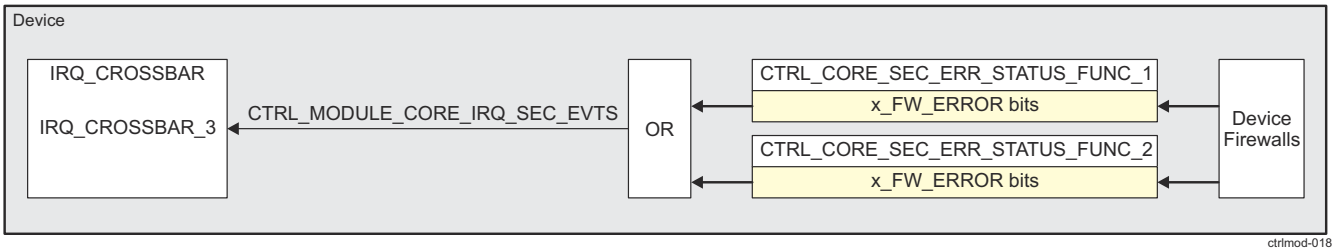

Figure 18-14. Combined Firewall Error Interrupt

18.4.6.14.4 Settings Related To Different Peripheral Modules

The CTRL_CORE_CONTROL_IO_1 and CTRL_CORE_CONTROL_IO_2 registers have controls for specific settings of several device peripheral modules.

18.4.7 Functional Description Of The Various Register Types In CTRL_MODULE_WKUP Submodule

The following sections describe in detail the purpose of the various kinds of registers and register groups which reside in the CTRL_MODULE_WKUP submodule.

18.4.7.1 Registers For Basic EMIF configuration

The CTRL_WKUP_SECURE_EMIF1_SDRAM_CONFIG register has bits which determine the basic settings of the EMIF controller. These are, for example, settings like CAS write latency, SDRAM drive strength, SDRAM termination resistor values, SDRAM type and others.

The CTRL_WKUP_SECURE_EMIF1_SDRAM_CONFIG bit field values are exported upon POR to the EMIF1.EMIF_SDRAM_CONFIG register.

The CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT register is associated with DDR PHY controls, ODT values for device DDR I/Os, some leveling related parameters and others.

18.5 Control Module Register Manual

18.5.1 Control Module Instance Summary

Note

ATL, VCP1, VCP2, MLB and USB3 (ULPI) are not supported on the AM571x / AM570x family of devices.

SATA and RTC are not supported on the AM570x family of devices.

Note

MreqDomain is supported only on SR2.1.

15:9	RESERVED		R	0x0
8	GPIO6_16_MODESELECT	Selects between the Default IO Timing Mode and a Virtual or Manual IO Timing Mode. Refer to the device Data Manual for definition of the required settings for a given mode of operation. When this bit is 0b1, a Virtual IO Timing Mode can be selected via the DELAYMODE field of this register, as described in Section 18.4.6.1.5, Virtual IO Timing Modes. Manual IO Timing Modes are selected via the procedure described in Section 18.4.6.1.6, Manual IO Timing Modes. 0x0: Default IO Timing Mode is used 0x1: A Virtual or Manual IO Timing Mode is used	RW	0x0
7:4	GPIO6_16_DELAYMODE	This bit field selects the Virtual Timing Mode used when the MODESELECT bit is set to 0b1. See Section 18.4.6.1.5, Virtual IO Timing Modes for details.	RW	0x0
3:0	GPIO6_16_MUXMODE	0x0: gpio6_16 0x1: mcasp1_axr10 0x6: vout2_fld 0x8: vin2a_fld0 vin1a_fld0 0x9: clkout1 0xA: timer3 0xE: gpio6_16 0xF: Driver off	RW	0xF
