In these sequences, some soft variables are used:

- write_count = 0
- read_count = 0
- channel_enable = FALSE
- last_transfer = FALSE
- last_request = FALSE

They are initialized before starting the channel.

24.4.5.2.1.3 Transmit-and-Receive (Master and Slave)

If the requests are configured in DMA, write_count and read_count are assigned with 'N' when the DMA handlers have completed their 'N' OCP accesses.

Table 24-215. Transmit-and-Receive (Master and Slave) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPI_CHxCTRL[0] EN	1
Wait for write_count = N **AND** read_count = N		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

Read the receiver register	MCSPI_RXx	0x-
Increment read_count +1		
ENDIF		

24.4.5.2.1.8 Transfer Procedures With FIFO

These flows describe the transfer with FIFO.

The McSPI module allows the transfer of one or several words, according to different modes:

- MASTER Normal, MASTER Turbo, SLAVE
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see Section 24.4.4.6, *FIFO Buffer Management*.

Table 24-231. FIFO Mode Common Sequence (Master) (Main Process)

Step	Register/Bit Field/Programming Model	Value
Write MCSPI_IRQSTATUS to reset channel status bits	MCSPI_IRQSTATUS	1
Write MCSPI_IRQENABLE to enable interrupts	MCSPI_IRQENABLE	1
Write MCSPI_CHxCONF to configure the channel	MCSPI_CHxCONF	0x-
Write MCSPI_XFERLEVEL	MCSPI_XFERLEVEL	0x-
Start the channel	MCSPI_CHxCTRL[0] EN	1
IF: Receive only		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	MCSPI_TXx	0x-
ENDIF		
Wait for the host event for end of transfer		
Stop the channel	MCSPI_CHxCTRL[0] EN	0

24.4.5.2.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in Section 24.4.5.2.1.8, *Transfer Procedures With FIFO*.

In multi-channel, only one channel can use the FIFO.

Before enabling the FIFO for a channel (MCSPI_CHxCONF[28] FFER and MCSPI_CHxCONF[27] FFEW bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Slave mode, the channel 0 only can be activated. The correct SPIEN line is chosen in MCSPI_CHxCONF[22:21] SPIENSLV bits (where x = 0).

The McSPI module can start the transfer only when the first write request has been released by writing the MCSPI_TXx register, even in receive-only mode (only one write request occurs in this case).

24.4.5.2.1.8.2 End of Transfer Sequences in FIFO Mode

Table 24-232 summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

Table 24-232. End of Transfer Sequences in FIFO Mode

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See Figure 24-96	See Figure 24-98	See Figure 24-99
No	See Figure 24-97	See Figure 24-98	See Figure 24-100

The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write_count = N
- read_count = N
- last_request = FALSE

They are initialized before starting the channel.

24.4.5.2.1.8.3 Transmit-and-Receive With Word Count

Figure 24-96 shows the flow of a transfer in transmit-and-receive mode, with word count.

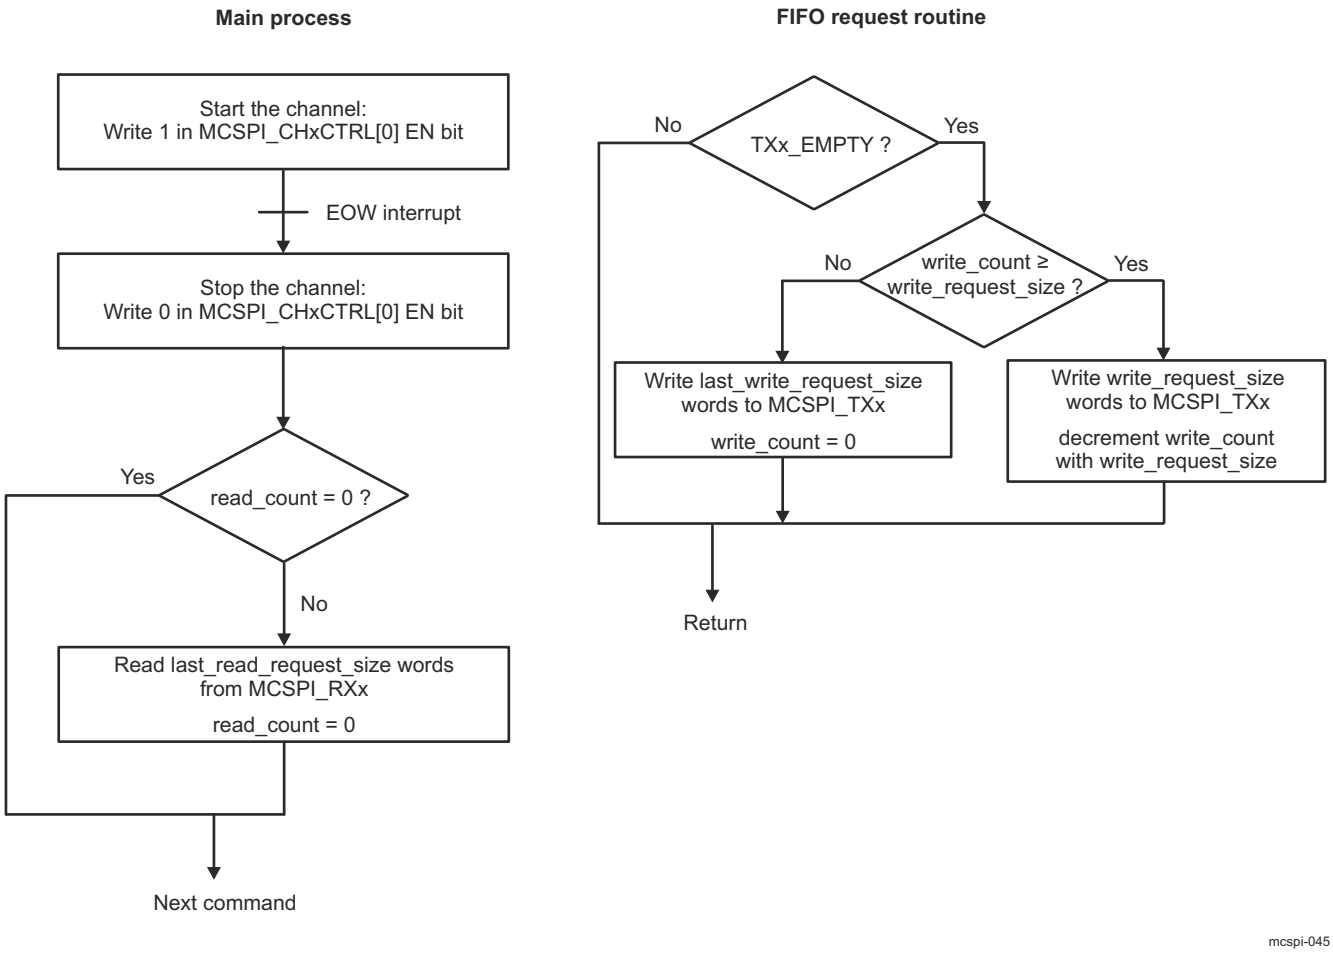

Figure 24-96. FIFO Mode Transmit-and-Receive With Word Count (Master)

24.4.5.2.1.8.4 Transmit-and-Receive Without Word Count

Figure 24-97 shows the flow of a transfer in transmit-and-receive mode, without word count.

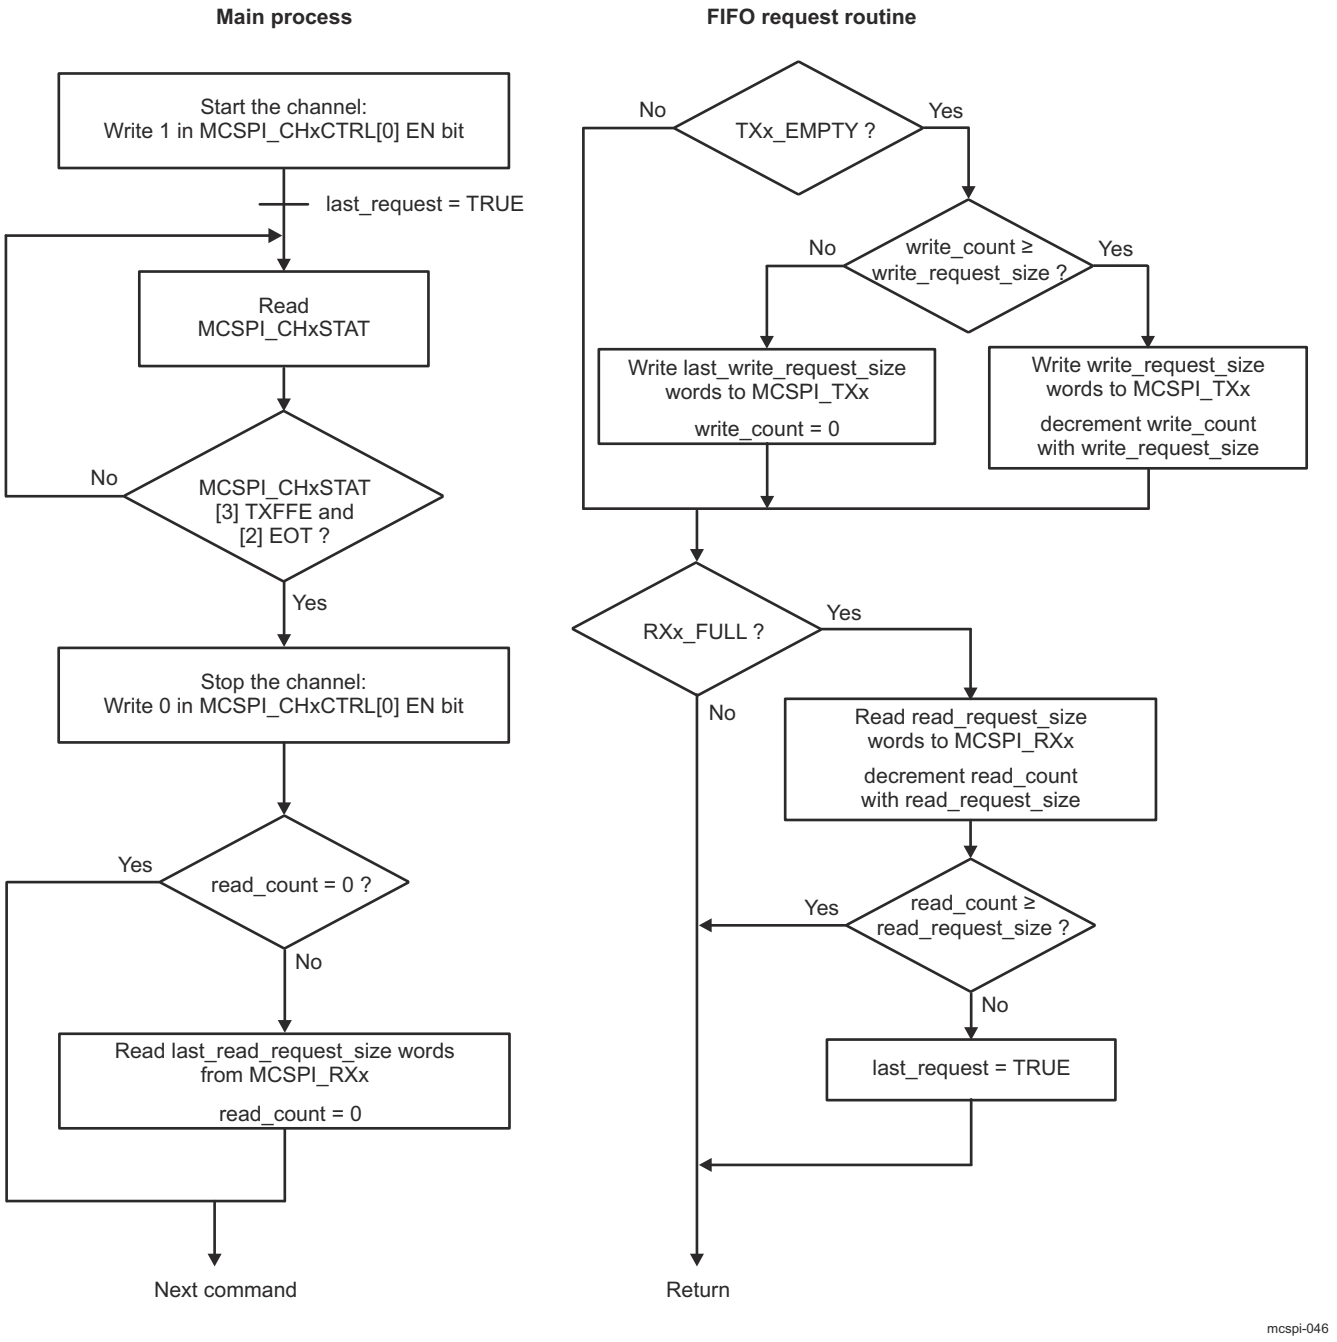

Figure 24-97. FIFO Mode Transmit-and-Receive Without Word Count (Master)

24.4.5.2.1.8.5 Transmit-Only

Figure 24-98 shows the flow of a transfer in transmit-only mode, with or without word count. The difference between word count enabled or not is just on the condition after starting the channel:

- word count enable: wait for EOW interrupt
- word count disable: wait for write_count = 0

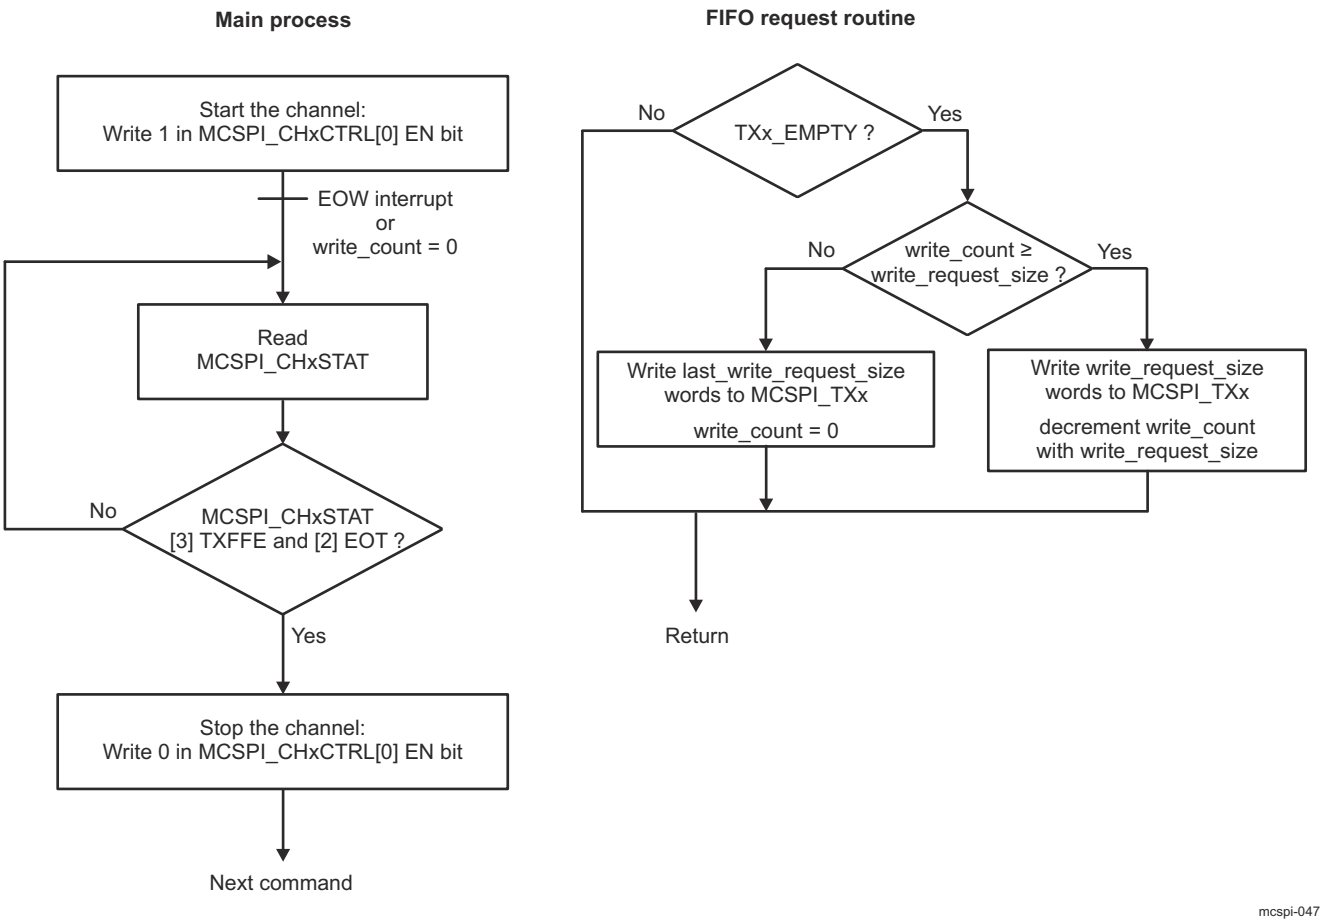

Figure 24-98. FIFO Mode Transmit-Only (Master)

24.4.5.2.1.8.6 Receive-Only With Word Count

Figure 24-99 shows the flow of a transfer in receive-only mode, with word count.

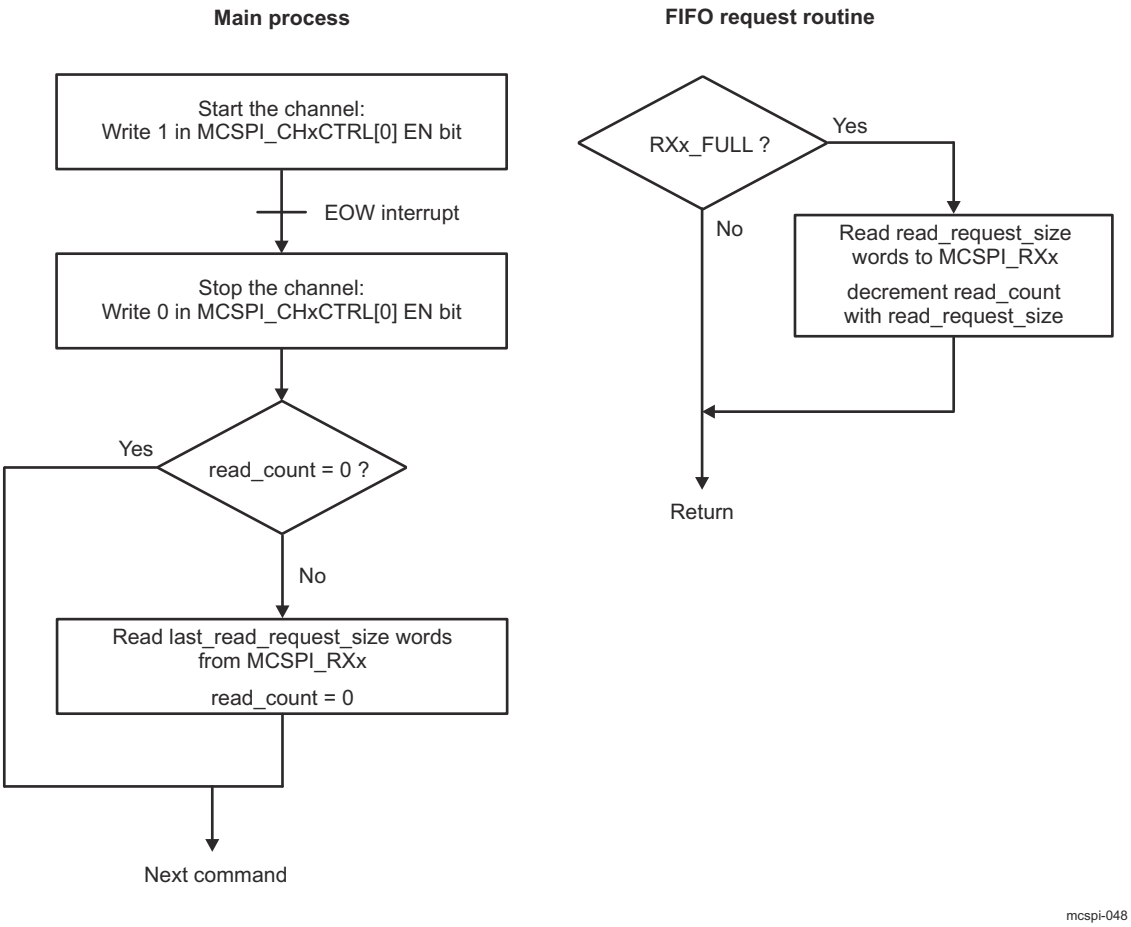

Figure 24-99. FIFO Mode Receive-Only With Word Count (Master)

24.4.5.2.1.8.7 Receive-Only Without Word Count

Figure 24-100 shows the flow of a transfer in receive-only mode, without word count.

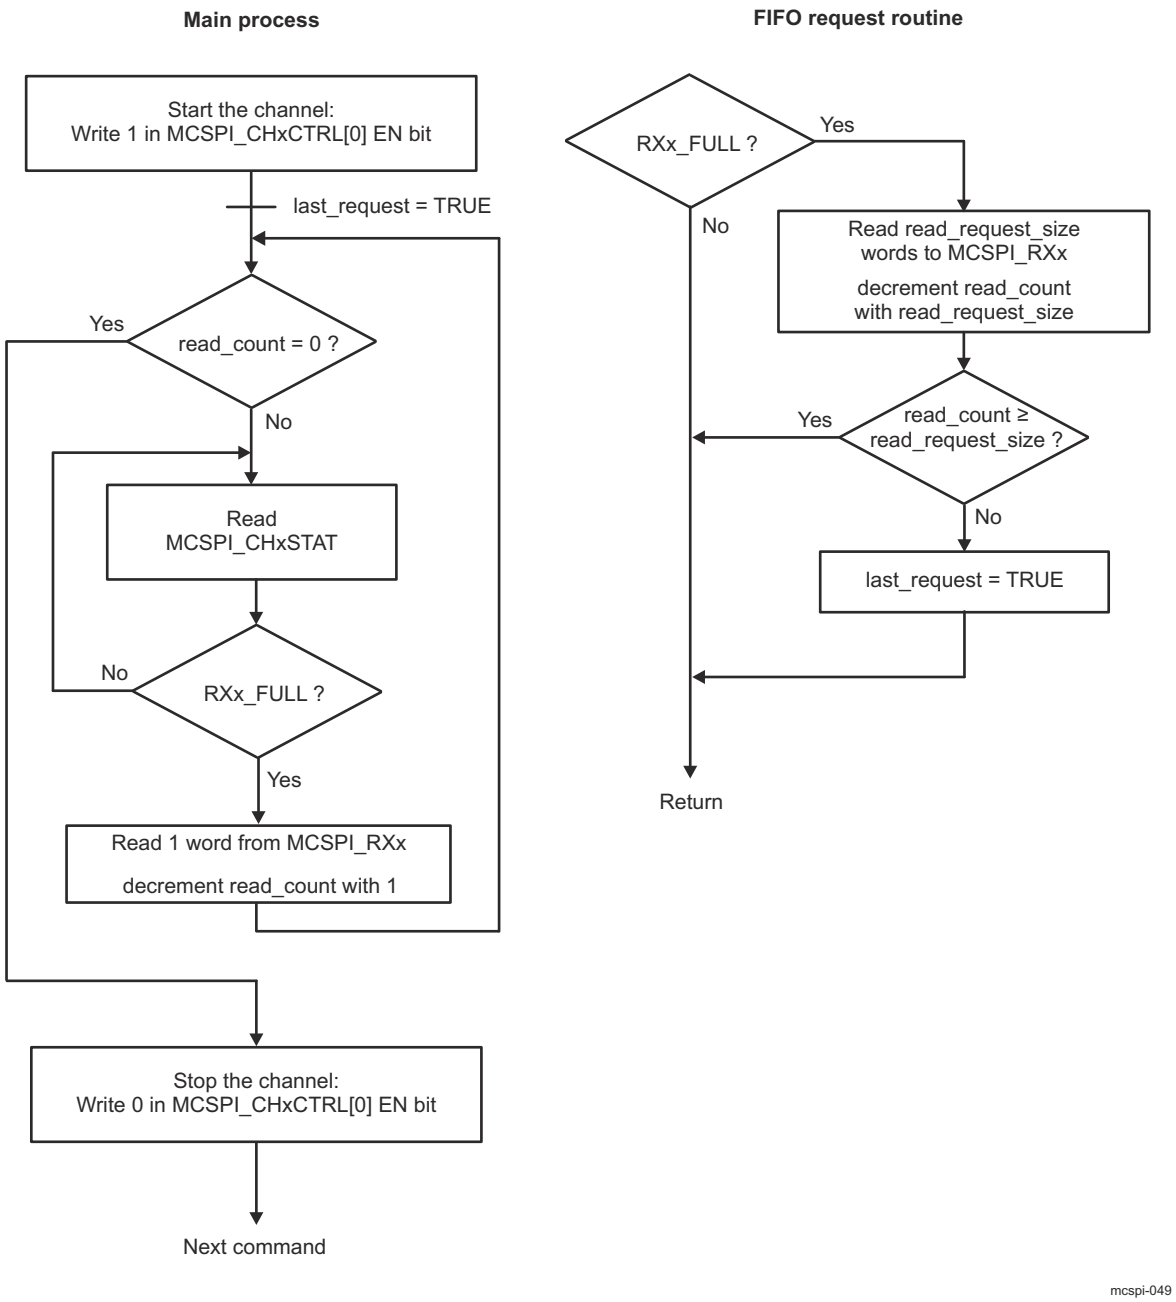

Figure 24-100. FIFO Mode Receive-Only Without Word Count (Master)

24.4.5.3 Common Transfer Procedures Without FIFO – Polling Method

24.4.5.3.1 Receive-Only Procedure – Polling Method

Table 24-233 lists the receive-only procedure using the polling method.

Table 24-233. Receive-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 24-210.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Wait for end-of-transfer.	MCSPI_CHxSTAT[2] EOT	=1
Read the receiver register.	MCSPI_RXx	0x-

Table 24-233. Receive-Only Procedure – Polling Method (continued)

Step	Register/Bit Field/Programming Model	Value
Stop the channel if no more data is expected.	MCSPI_CHxCTRL[0] EN	0

24.4.5.3.2 Receive-Only Procedure – Interrupt Method

Table 24-234 lists the receive-only procedure using the interrupt method.

Table 24-234. Receive-Only Procedure – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-210.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Enable the interrupt for the receiver register.	MCSPI_IRQENABLE[2] RX_FULL_ENABLE	1
Wait for interrupt.		
Read the status register.	MCSPI_IRQSTATUS[2] RX_FULL	1
Disable the interrupt if no more data is expected.	MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0
Stop the channel if no more data is expected.	MCSPI_CHxCTRL[0] EN	0
Read the receiver register.	MCSPI_RXx	0x-

24.4.5.3.3 Transmit-Only Procedure – Polling Method

Table 24-235 lists the transmit-only procedure using the polling method.

Table 24-235. Transmit-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-211	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Write the transmitter register with data.	MCSPI_TXx	0x-
Wait until end of transfer?	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0

24.4.5.3.4 Transmit-and-Receive Procedure – Polling Method

Table 24-235 lists the transmit-and-receive procedure using the polling method.

Table 24-236. Transmit-and-Receive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 24-212.	
Start the channel.	MCSPI_CHxCTRL[0] EN	1
Write the transmitter register with data.	MCSPI_TXx	0x-
Wait until transmit/receive word?	MCSPI_CHxSTAT[2] EOT	=1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0
Read the receiver register.	MCSPI_TXx	0x-

Table 24-246. Register Call Summary for Register MCSPI_REVISION

Multichannel Serial Peripheral Interface

- McSPI Register Summary: [0]

Table 24-247. MCSPI_SYSCONFIG

Address Offset	0x110		
Physical Address	0x4809 8110 0x4809 A110 0x480B 8110 0x480B A110	**Instance**	McSPI1 McSPI2 McSPI3 McSPI4
Description	This register allows controlling various parameters of the configuration interface and is not affected by software reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						CLOCKACTIVITY		RESERVED				SIDLEMODE		ENAWAKEUP		SOFTRESET		AUTOIDLE	

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reads return 0	RW	0x000000

Bits	Field Name	Description	Type	Reset
9:8	CLOCKACTIVITY	Clocks activity during wake-up mode period 0x0: Interface and functional clocks may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched off. 0x2: Functional clock is maintained. Interface clock may be switched off. 0x3: Interface and functional clocks are maintained.	RW	0x0
7:5	RESERVED	Reads returns 0	RW	0x0
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the McSPI acknowledges it unconditionally and goes in inactive mode. Interrupt, DMA requests and wake-up lines are unconditionally deasserted and the module wake-up capability is deactivated even if the [2] ENAWAKEUP bit is set. 0x1: If an IDLE request is detected, the request is ignored and the module does not switch to wake-up mode, and keeps on behaving normally. 0x2: If an IDLE request is detected, the module will switch to wake-up mode based on its internal activity, and the wake-up capability can be used if the bit [2] ENAWAKEUP is set. 0x3: Reserved - do not use.	RW	0x2
2	ENAWAKEUP	Wake-up feature control 0x0: Wake-up capability is disabled. 0x1: Wake-up capability is enabled.	RW	1
1	SOFTRESET	Software reset. During reads it always returns 0. 0x0: (write) Normal mode 0x1: (write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.	RW	0
0	AUTOIDLE	Internal interface clock-gating strategy 0x0: Interface clock is free-running. 0x1: Automatic interface clock gating strategy is applied, based on the interface activity.	RW	1

Description	This register is used to check the correctness of the system interconnect either internally to peripheral bus, or externally to device I/O pads, when the module is configured in system test (SYSTEST) mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED	SSB	SPIENDIR	SPIDATDIR1	SPIDATDIR0	WAKD	SPICLK	SPIDAT_1	SPIDAT_0	SPIEN_3	SPIEN_2	SPIEN_1	SPIEN_0

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reads returns 0.	RW	0x00000
11	SSB	Set status bit 0x0: No action. Writing 0 does not clear already set status bits. This bit must be cleared before trying to clear a status bit of the MCSPI_IRQSTATUS register. 0x1: Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits in the MCSPI_IRQSTATUS register.	RW	0
10	SPIENDIR	Set the direction of the SPIEN[3:0] lines and SPICLK line. 0x0: Output (as in master mode) 0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1]. 0x0: Output 0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0]. 0x0: Output 0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	SPICLK line (signal data value) If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If [10] SPIENDIR = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this bit.	RW	0
5	SPIDAT_1	SPIDAT[1] line (signal data value) If [9] SPIDATDIR1 = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this bit. If [9] SPIDATDIR1 = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.	RW	0
4	SPIDAT_0	SPIDAT[0] line (signal data value) If [8] SPIDATDIR0 = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this bit. If [8] SPIDATDIR0 = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.	RW	0

Bits	Field Name	Description	Type	Reset
3	SPIEN_3	SPIEN[3] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[3] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.	RW	0
2	SPIEN_2	SPIEN[2] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[2] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.	RW	0
1	SPIEN_1	SPIEN[1] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[1] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.	RW	0
0	SPIEN_0	SPIEN[0] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIENT[0] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.	RW	0

Table 24-259. MCSPI_MODULCTRL

Address Offset	0x128		
Physical Address	0x4809 8128 0x4809 A128 0x480B 8128 0x480B A128	**Instance**	McSPI1 McSPI2 McSPI3 McSPI4
Description	This register is dedicated to the configuration of the serial peripheral interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								FDAA	MOA	INITDLY					
																												SYSTEM_TEST	MS	PIN34	SINGLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reads returns 0.	RW	0x000000

Bits	Field Name	Description	Type	Reset
8	FDAA	FIFO DMA address 256-bit aligned This bit is used when a FIFO is managed by the module and DMA connected to the controller provides only 256-bit aligned address. If this bit is set the enabled channel which uses the FIFO has its data managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TXx and MCSPI_RXx registers. 0x0: FIFO data managed by MCSPI_TXx and MCSPI_RXx registers. 0x1: FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.	RW	0
7	MOA	Multiple word interface access: this bit can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit interface word access. This is possible for WL < 16. 0x0: Multiple word access disabled 0x1: Multiple word access enabled with FIFO	RW	0
6:4	INITDLY	Initial SPI delay for first transfer: this field is an option only available in SINGLE master mode. The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock. No clock output provided to the boundary and chip select is not active in 4-pin mode within this period. 0x0: No delay for first spi transfer. 0x1: The controller wait 4 SPI bus clock 0x2: The controller wait 8 SPI bus clock 0x3: The controller wait 16 SPI bus clock 0x4: The controller wait 32 SPI bus clock	RW	0x0
3	SYSTEM_TEST	Enables the system test mode 0x0: Functional mode 0x1: System test mode (SYSTEST)	RW	0
2	MS	Master/slave 0x0: Master - The module generates the SPICLK and SPIEN[3:0]. 0x1: Slave - The module receives the SPICLK and SPIEN[3:0].	RW	1
1	PIN34	Pin mode selection: This bit is used in master or slave mode to configure the SPI pin mode (3-pin or 4-pin). If asserted the controller only uses SIMO, SOMI, and SPICLK clock pin for SPI transfers. 0x0: SPIEN is used as a chip-select. 0x1: SPIEN is not used. In this mode all related options to chip-select have no meaning.	RW	0
0	SINGLE	Single channel/Multi Channel (master mode only) 0x0: More than one channel will be used in master mode. 0x1: Only one channel will be used in master mode. This bit must be set in Force SPIEN[x] mode.	RW	0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Read returns 0.	R	0x0
29	CLKG	Clock divider granularity this bit defines the granularity of channel clock divider: power of 2 or one clock cycle granularity. When this bit is set the register MCSPI_CHxCTRL[15:8] EXTCLK must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of [5:2] CLKD and MCSPI_CHxCTRL[15:8] EXTCLK values 0x0: Clock granularity of power of 2 0x1: One clock cycle granularity	RW	0
28	FFER	FIFO enabled for receive: Only one channel can have this bit field set. 0x0: The buffer is not used to receive data. 0x1: The buffer is used to receive data.	RW	0
27	FFEW	FIFO enabled for transmit: Only one channel can have this bit field set. 0x0: The buffer is not used to transmit data. 0x1: The buffer is used to transmit data.	RW	0
26:25	TCS0	Chip-select time control This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0

Bits	Field Name	Description	Type	Reset
24	SBPOL	Start-bit polarity 0x0: Start-bit polarity is held to 0 during SPI transfer. 0x1: Start-bit polarity is held to 1 during SPI transfer.	RW	0
23	SBE	Start-bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by bit [24] SBPOL	RW	0
22:21	SPIENSLV	Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits for other cases. 0x0: Detection enabled only on SPIEN[0] 0x1: Detection enabled only on SPIEN[1] 0x2: Detection enabled only on SPIEN[2] 0x3: Detection enabled only on SPIEN[3]	RW	0x0
20	FORCE	Manual SPIEN assertion to keep SPIEN active between SPI words (single channel master mode only). 0x0: Writing 0 into this bit drives low the SPIEN line when [6] EPOL=0, and drives it high when [6] EPOL=1. 0x1: Writing 1 into this bit drives high the SPIEN line when [6] EPOL=0, and drives it low when [6] EPOL=1.	RW	0
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer). 0x1: Turbo is activated to maximize the throughput for multiple SPI words transfer.	RW	0
18	IS	Input Select 0x0: Data line 0 (SPIDAT[0]) selected for reception 0x1: Data line 1 (SPIDAT[1]) selected for reception	RW	1
17	DPE1	Transmission enable for data line 1 0x0: Data line 1 (SPIDAT[1]) selected for transmission 0x1: No transmission on Data Line1 (SPIDAT[1])	RW	1
16	DPE0	Transmission Enable for data line 0 0x0: Data Line0 (SPIDAT[0]) selected for transmission 0x1: No transmission on data line 0 (SPIDAT[0])	RW	0
15	DMAR	DMA read request The DMA read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled	RW	0
14	DMAW	DMA write request. The DMA write request line is asserted when The channel is enabled and the transmitter register of the channel is empty. The DMA write request line is deasserted on load completion of the transmitter register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0

Bits	Field Name	Description	Type	Reset
5:2	CLKD	Frequency divider for SPICLK (only when the module is a Master SPI device). A programmable clock divider divides the SPI reference clock (FCLK) with a 4-bit value, and results in a new clock SPICLK available to shift-in and shift-out data. By default, the clock divider ratio has a power of 2 granularity when [29] CLKG is cleared. Otherwise, this field is the 4-LSB bit of a 12-bit register concatenated with clock divider extension MCSPI_CHxCTRL[15:8] EXTCLK register. The value description below defines the clock ratio when [29] CLKG is set to 0. 0x0: 1 0x1: 2 0x2: 4 0x3: 8 0x4: 16 0x5: 32 0x6: 64 0x7: 128 0x8: 256 0x9: 512 0xA: 1024 0xB: 2048 0xC: 4096 0xD: 8192 0xE: 16384 0xF: 32768	RW	0x0
1	POL	SPICLK polarity (see Section 24.4.2.3.1, *Transfer Format*) 0x0: SPICLK is held low during the INACTIVE state 0x1: SPICLK is held high during the INACTIVE state	RW	0
0	PHA	SPICLK phase (see Section 24.4.2.3.1, *Transfer Format*) 0x0: Data are latched on odd-numbered edges of SPICLK. 0x1: Data are latched on even-numbered edges of SPICLK.	RW	0

- McSPI Register Summary: [0]
- McSPI Register Description: [1] [2]

24.5 Quad Serial Peripheral Interface

24.5.1 Quad Serial Peripheral Interface Overview

The quad serial peripheral interface (QSPI) module is a kind of SPI module that allows single, dual, or quad read access to external SPI devices. This module has a memory mapped register interface, which provides a direct interface for accessing data from external SPI devices and thus simplifying software requirements. The QSPI works as a master only.

The one QSPI in the device is primarily intended for fast booting from quad-SPI flash memories. Figure 24-101 shows the QSPI module overview.

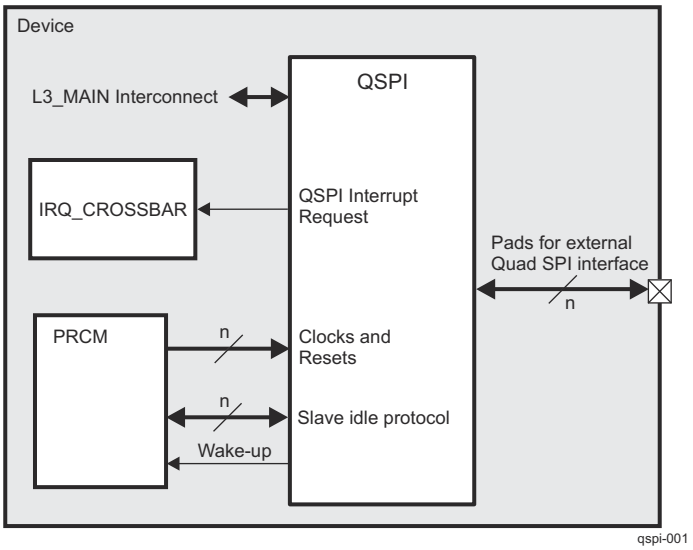

Figure 24-101. QSPI Overview

The QSPI supports the following features:

- General SPI features:
  - Programmable clock divider
  - Six pin interface
  - Programmable length (from 1 to 128 bits) of the words transferred
  - Programmable number (from 1 to 4096) of the words transferred
  - 4 external chip-select signals
  - Support for 3-, 4-, or 6-pin SPI interface
  - Optional interrupt generation on word or frame (number of words) completion
  - Programmable delay between chip select activation and output data from 0 to 3 QSPI clock cycles
  - Programmable signal polarities
  - Programmable active clock edge
  - Software-controllable interface allowing for any type of SPI transfer
  - Control through L3_MAIN configuration port
- Serial flash interface (SFI) features:
  - Serial flash read/write interface
  - Additional registers for defining read and write commands to the external serial flash device
  - 1 to 4 address bytes
  - Fast read support, where fast read requires dummy bytes after address bytes; 0 to 3 dummy bytes can be configured.
  - Dual read support
  - Quad read support
  - Little-endian support (only for memory mapped registers used to configure QSPI controller and not SPI content accesses)

– Linear increment addressing mode only

The QSPI supports only dual and quad reads. Dual or quad writes are not supported. In addition, there is no "pass through" mode supported where the data present on the QSPI input is sent to its output.

Note

The QSPI module does not support cache line wrap mode.

24.5.2 QSPI Environment

Figure 24-102 shows a typical connection of the QSPI module to the external quad-SPI flash memory.

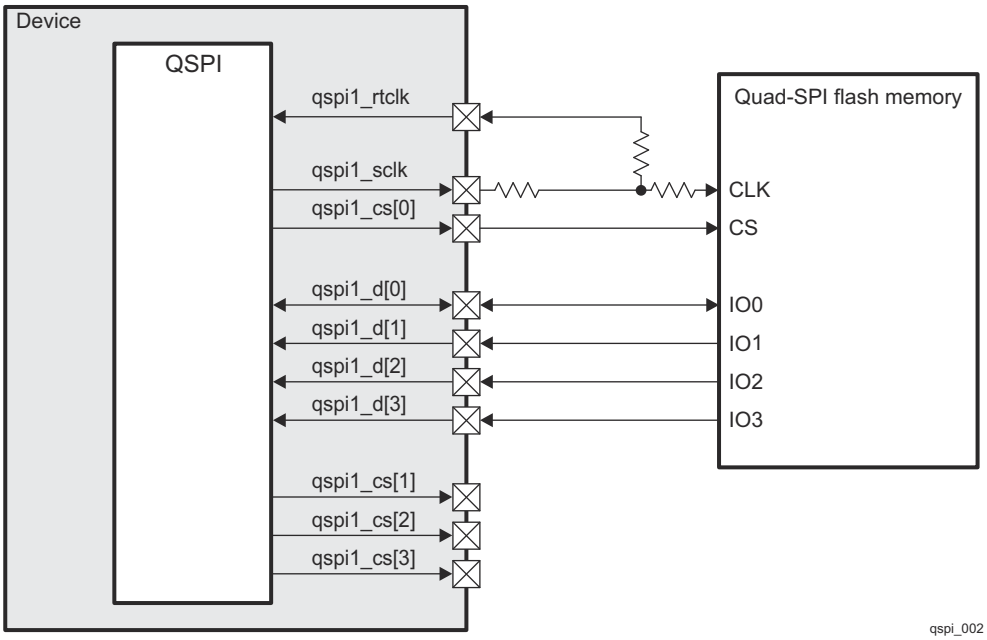

Figure 24-102. QSPI Connected to an External Quad-SPI Flash Memory

Table 24-277 lists and describes the QSPI I/O signals.

Table 24-277. QSPI I/O Signals

qspi1_rtclk	I	The qspi1_sclk output must be connected to the qspi1_rtclk input, and is used for controlling the timing of the read return data when the QSPI module operates in Mode 0. In case Mode 3 is used, there is no need to connect the qspi1_sclk to the qspi1_rtclk.					

(1) I = Input; O = Output
(2) This is the pin count at the SPI flash memory side. The pin count at the device side is increased by one because of the qspi1_rtclk signal. References to the pin count throughout this chapter consider the pin count at the SPI flash memory side.

Note

In order to ensure proper timing, precise layout and routing requirements must be followed. For layout and routing requirements for all QSPI signals, see section “PCB Guidelines” of the device Data Manual.

24.5.3 QSPI Integration

Figure 24-103 shows the integration of the QSPI module in the device.

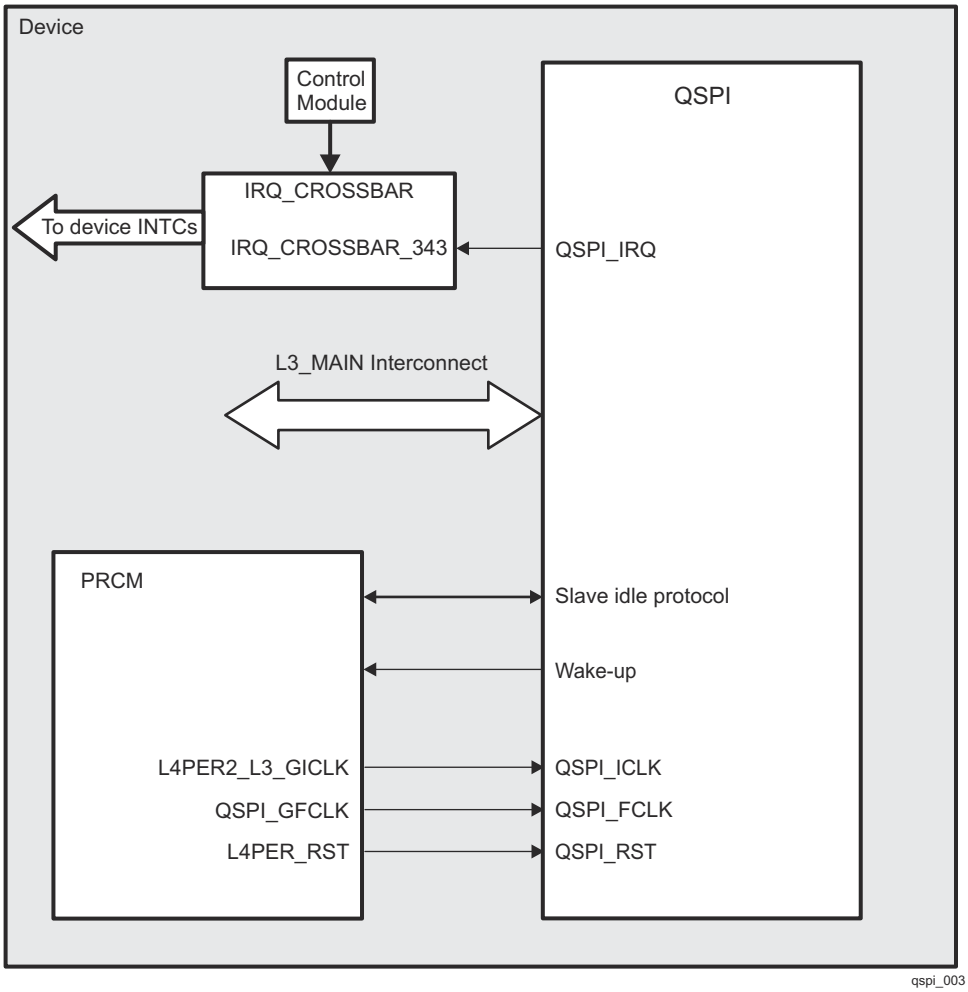

Figure 24-103. QSPI Integration

Table 24-278 through Table 24-280 summarize the integration of the QSPI in the device.

Note

The Default Mapping column in Table 24-280 shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device interrupt controller (INTC) through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device INTCs, see *Interrupt Controllers*.

Note

For the description of the interrupt source, see Section 24.5.4.3, *QSPI Interrupt Requests*.

24.5.4 QSPI Functional Description

24.5.4.1 QSPI Block Diagram

Iinitial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the qspi1_d[0] signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. Figure 24-104 shows the QSPI block diagram.

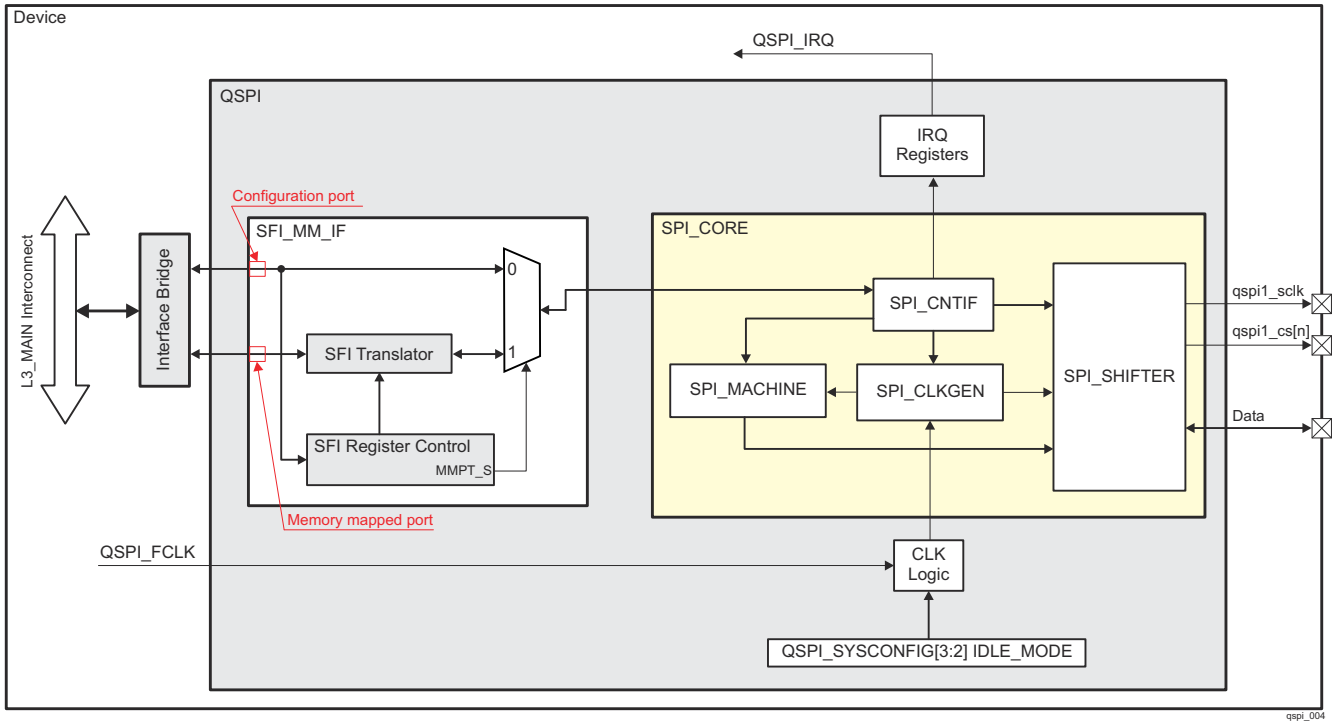

Figure 24-104. QSPI Block Diagram

The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI_MM_IF) and the second one is the SPI core (SPI_CORE). The SFI_MM_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI_MM_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI_CORE comprises the following four subblocks:

- SPI control interface (SPI_CNTIF)
- SPI clock generator (SPI_CLKGEN)
- SPI control state machine (SPI_MACHINE)
- SPI data shifter (SPI_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI_MM_IF block to the L3_MAIN interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI_MM_IF block because it is intended to ease the communication with serial flash devices. If the SPI_CORE is used to communicate

with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

Note

The SFI_MM_IF block only allows reading and writing to an externaly connected SPI flash device. The SFI_MM_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI_CORE block.

24.5.4.1.1 SFI Register Control

The SFI register control block consists of the following five configuration registers:

- QSPI_SPI_SETUP0_REG
- QSPI_SPI_SETUP1_REG
- QSPI_SPI_SETUP2_REG
- QSPI_SPI_SETUP3_REG
- QSPI_SPI_SWITCH_REG

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI_SPI_SETUPi_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI_SPI_SETUPi_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the QSPI_SPI_SETUPi_REG[9:8] NUM_A_BYTES bit field
- Number of “dummy bytes” that may be needed to support the fast read mode function of some serial flash devices. The QSPI_SPI_SETUPi_REG[11:10] NUM_D_BYTES bit field specifies the number of "dummy bits." In addition, the QSPI_SPI_SETUPi_REG[28:24] NUM_D_BITS bit field can also specify the number of "dummy bits."
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI_SPI_SETUPi_REG[13:12] READ_TYPE bit field. (i is equal to 0, 1, 2 and 3 and means that the QSPI_SPI_SETUPi_REG registers are associated with each of the four supported chip-selects [that is, four supported output SPI flash devices])

The QSPI_SPI_SWITCH_REG register acts as a static switch which allows the configuration port (shown in Figure 24-104) to connect directly to the SPI_CORE block, or allows the memory-mapped port (also shown in Figure 24-104) to connect to the SPI_CORE block. This is done using the QSPI_SPI_SWITCH_REG[0] MMPT_S bit.

In addition, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

24.5.4.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.

6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

24.5.4.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:

- The QSPI_PID register, which is read only and contains QSPI revision associated information
- The QSPI_SPI_CLOCK_CNTRL_REG register, which is used to control external SPI clock (qspi1_sclk)
- The QSPI_SPI_DC_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI_SPI_CMD_REG register used to control the operation of the SPI command. This register is also used to configure and transfer data.
- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
  - QSPI_SPI_DATA_REG
  - QSPI_SPI_DATA_REG_1
  - QSPI_SPI_DATA_REG_2
  - QSPI_SPI_DATA_REG_3

  These four registers compose a 128-bit shift register.
- The QSPI_SPI_STATUS_REG register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the QSPI_SPI_STATUS_REG[0] BUSY bit is 0x0. The QSPI becomes busy when a write to the QSPI_SPI_CMD_REG[18:16] CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1_sclk clock and clearing of the BUSY bit is synchronized to the QSPI_FCLK clock.

The register group QSPI_SPI_DATA_REG_3, QSPI_SPI_DATA_REG_2, QSPI_SPI_DATA_REG_1 and QSPI_SPI_DATA_REG is treated as a single 128-bit word for shifting data in and out. The QSPI_SPI_DATA_REG_3 register is used for the most significant bits and the QSPI_SPI_DATA_REG is used for the least significant bits.This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at QSPI_SPI_DATA_REG_3[31] position and the least significant bit, that is bit 0 of the data read, will be located at the QSPI_SPI_DATA_REG[0] position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The QSPI_SPI_CMD_REG[25:19] WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set

to 0x7 and the data byte should be written to the lower byte of the QSPI_SPI_DATA_REG register. By setting the word length to 0x7 the QSPI_SPI_DATA_REG register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the QSPI_SPI_DATA_REG and the rest 8 most significant bits of data should be written to the lower byte of the QSPI_SPI_DATA_REG_1 register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the QSPI_SPI_DATA_REG_2 register is also used and the previosly described logic applies. The QSPI_SPI_DATA_REG_3 register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the QSPI_SPI_CMD_REG[11:0] FLEN bit field.

Note

The QSPI module does not support a "pass through" mode where the data present on qspi1_d[1] is sent to qspi1_d[0], when 4-pin non-dual read mode is used. This means that setting the QSPI_SPI_CMD_REG[18:16] CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1_d[0] pad to be used as an output.

24.5.4.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI_FCLK clock as an input, and generates the qspi1_sclk, which is a divided version of the QSPI_FCLK clock. The divide ratio is a 16-bit value configured through the QSPI_SPI_CLOCK_CNTRL_REG[15:0] DCLK_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI_FCLK clock is divided by the DCLK_DIV value + 1 to provide the qspi1_sclk clock. When DCLK_DIV = 0x0 the QSPI_FCLK clock equals the DCLK clock. The value in the DCLK_DIV bit field applies only when the QSPI_SPI_CLOCK_CNTRL_REG[31] CLKEN bit is set to 0x1. Figure 24-105 shows the SPI_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the QSPI_SPI_CMD_REG[18:16] CMD bit field is not executed and the QSPI_SPI_STATUS_REG[0] BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

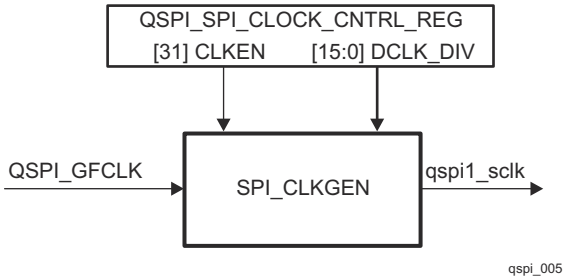

Figure 24-105. SPI_CLKGEN Block

24.5.4.1.5 SPI Control State-Machine

The SPI control state-machine (SPI_MACHINE) manages the operation of the SPI_CORE block. SPI_MACHINE takes control and configuration information from the registers in the SPI_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI_MACHINE also generates status information, which is sent back to the SPI_CNTIF block.

Writing a valid value to the QSPI_SPI_CMD_REG[18:16] CMD bit field sets immediately the QSPI_SPI_STATUS_REG[0] BUSY bit to 0x1, activates the corresponding qspi1_cs[n] (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when QSPI_SPI_CMD_REG[25:19] WLEN number

of bits are shifted in or out. If the value of the QSPI_SPI_STATUS_REG[27:16] WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this increments the value of the WDCNT bit field from 0x0 and starts shifting data in or out again. This is repeated until the WDCNT bit field reaches the frame length (QSPI_SPI_CMD_REG[11:0] FLEN), that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI_MACHINE is waiting for write to the CMD bit field the corresponding qspi1_cs[n] (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the QSPI_SPI_CMD_REG[25:19] WLEN bit field.

The SPI_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding qspi1_cs[n] (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

24.5.4.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI_MACHINE and SPI_CNTIF blocks, data is shifted in or out on falling or rising edge of qspi1_sclk clock depending on the SPI clock mode selected. Table 24-281 lists the four defined clock modes of operation for the QSPI.

Table 24-281. SPI Clock Modes Definition

Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock
1	0	1	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
2	1	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

Note

Mode 1 and Mode 2 are not supported and should not be used.

The CKPi and CKPHi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register control the clock modes. Each of these 4 bits corresponds to an output chip select.

Figure 24-106 shows all four clock modes. In addition, through the DDi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register the data can be delayed from one to three qspi1_sclk clock cycles after the corresponding qspi1_cs[n] (n = 0 to 3) goes active. The active state of each chip-select can also be controlled through the CSPi (i = 0 to 3) bits of the QSPI_SPI_DC_REG register.

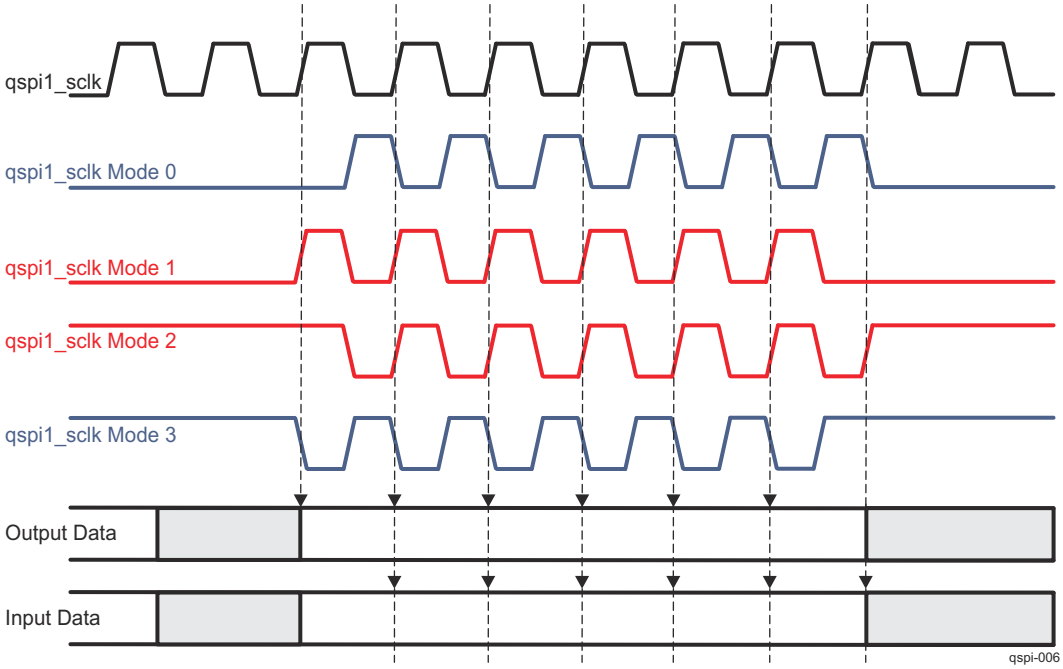

Figure 24-106. SPI Clock Modes

24.5.4.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI_FCLK clock is gated based on the values loaded in the QSPI_SYSCONFIG[3:2] IDLE_MODE bit field. Three modes are supported:

- Force-idle: The QSPI_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI_FCLK clock is gated by the QSPI, depending on its internal requirements.

24.5.4.3 QSPI Interrupt Requests

The QSPI generates one interrupt request which is connected to the IRQ_CROSSBAR module. This interrupt request, QSPI_IRQ, is connected to the IRQ_CROSSBAR_343 input. The QSPI_IRQ interrupt line can be activated by one of the interrupt events listed in Table 24-282.

Figure 24-107 shows a logical representation of the QSPI interrupt generation scheme.

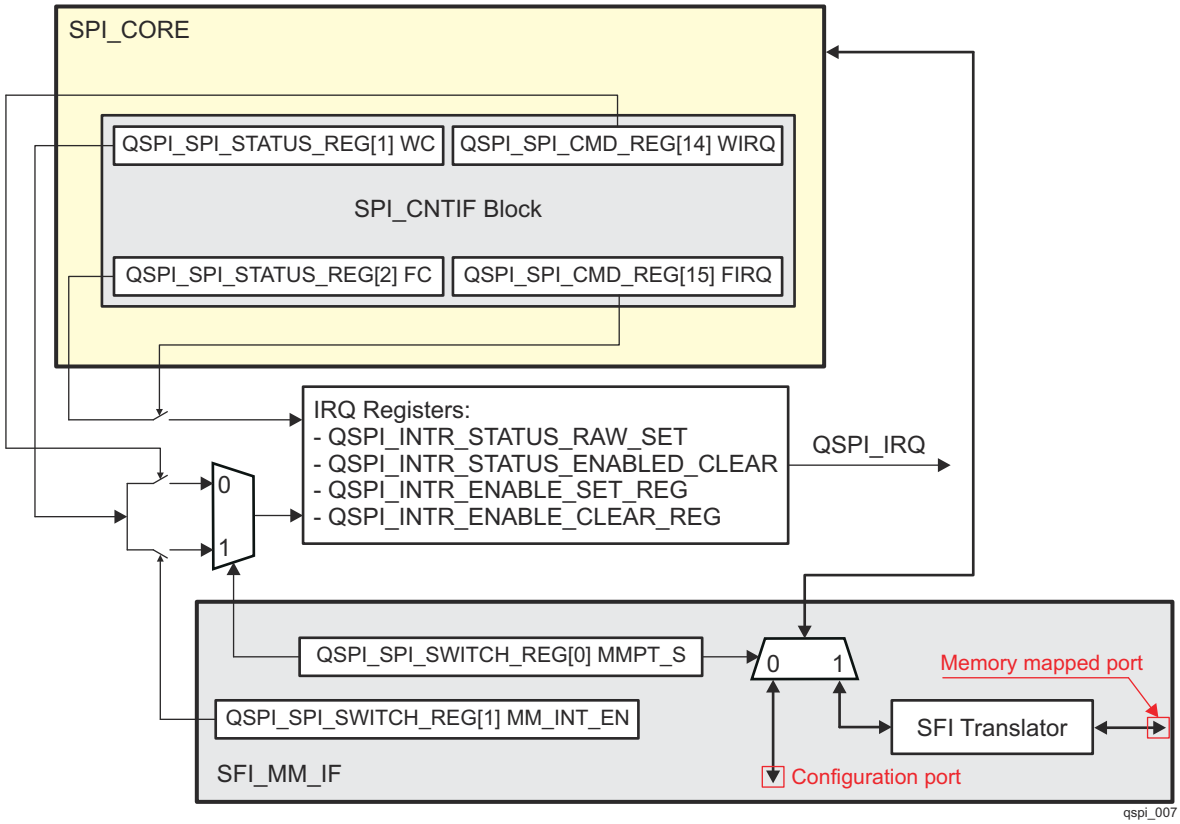

Figure 24-107. Logical Representation of the QSPI Interrupt Generation Scheme

QSPI_SPI_STATUS_REG[1] WC and QSPI_SPI_STATUS_REG[2] FC are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (WIRQ or FIRQ) in the QSPI_SPI_CMD_REG register allows these events (WC and FC) to generate an interrupt. The WC and FC bits are reset every time the user writes to the QSPI_SPI_CMD_REG register or reads the QSPI_SPI_STATUS_REG register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the QSPI_INTR_ENABLE_SET_REG register. These interrupts can be disabled by setting the corresponding bits in the QSPI_INTR_ENABLE_CLEAR_REG register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register to 0x1, which also clears the corresponding bit in the QSPI_INTR_STATUS_RAW_SET register. The status flags in the QSPI_INTR_STATUS_RAW_SET register are set even if the corresponding interrupt is disabled unlike those in the QSPI_INTR_STATUS_ENABLED_CLEAR register, which are set only if the corresponding interrupt is enabled.
- The QSPI also generates an interrupt if a certain bit in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the QSPI_INTR_ENABLE_SET_REG register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the QSPI_INTR_STATUS_RAW_SET register is set to 0x1 when an IRQ condition occurs.

- Even if interrupts are not enabled, a certain status bit in the QSPI_INTR_STATUS_RAW_SET register can also be cleared by setting to 0x1 the corresponding bit in the QSPI_INTR_STATUS_ENABLED_CLEAR register.

It must be considered that the previously described scenario applies if the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_SPI_CMD_REG[15] FIRQ bits are set to 0x1.

Note

The QSPI_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
  - during operations using the memory-mapped port by setting to 0x1 both the QSPI_SPI_SWITCH_REG[1] MM_INT_EN and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
  - during operations using the configuration port by setting to 0x1 both the QSPI_SPI_CMD_REG[14] WIRQ and QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the QSPI_SPI_CMD_REG[15] FIRQ and QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET bits.

The QSPI_IRQ interrupt line is also activated when both the conditions are met.

Table 24-282 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 24-282. QSPI Events

Event Flag	Event Mask	Description
QSPI_INTR_STATUS_RAW_SET[1] WIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[1] WIRQ_ENA QSPI_SPI_STATUS_REG[1] WC	QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[1] WIRQ_ENA_CLR QSPI_SPI_CMD_REG[14] WIRQ	Word complete interrupt event. Asserted each time after a word is transferred or received.
QSPI_INTR_STATUS_RAW_SET[0] FIRQ_RAW QSPI_INTR_STATUS_ENABLED_CLEAR[0] FIRQ_ENA QSPI_SPI_STATUS_REG[2] FC	QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET QSPI_INTR_ENABLE_CLEAR_REG[0] FIRQ_ENA_CLR QSPI_SPI_CMD_REG[15] FIRQ	Frame complete interrupt event. Asserted each time after a frame is transferred or received.

24.5.4.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the four supported external SPI devices. The L3_MAIN start address at which the configuration port is available is 0x4B30 0000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with one of the four supported external SPI devices. This memory region starts at 0x5C00 0000 and ends at 0x5FFF FFFF L3_MAIN address.

The CTRL_CORE_CONTROL_IO_2[10:8] QSPI_MEMMAPPED_CS bit field provides a functionality for remapping the previously described address space which starts at 0x5C00 0000 L3_MAIN address to one of the four supported chip selects or to the configuration registers. The CTRL_CORE_CONTROL_IO_2 register resides in the CTRL_MODULE_CORE.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in Table 24-284. These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory) the SPI_CORE module should be used and the data exchanged is available thorough these four data registers,

which can be accessed only through the configuration port. When a communication with an external SPI flash memory is desired, the memory-mapped port should be used.

In other words, to read from an external SPI flash memory, first configure the QSPI through the configuration port and then perform a read through the memory-mapped port.

24.6 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

24.6.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP module can operate in both transmit and receive modes. The McASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

Although intercomponent digital audio interface reception (DIR) mode (i.e. S/PDIF stream receiving) is not natively supported by the McASP module, a specific TDM mode implementation for the McASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

The device have integrated eight McASP modules with:

- McASP1 and McASP2 supporting up to 16 channels with independent TX/RX clock/sync domain
- McASP3 through McASP8 modules supporting up to 4 channels with independent TX/RX clock/sync domain

Figure 24-108 shows the McASP modules in the device.

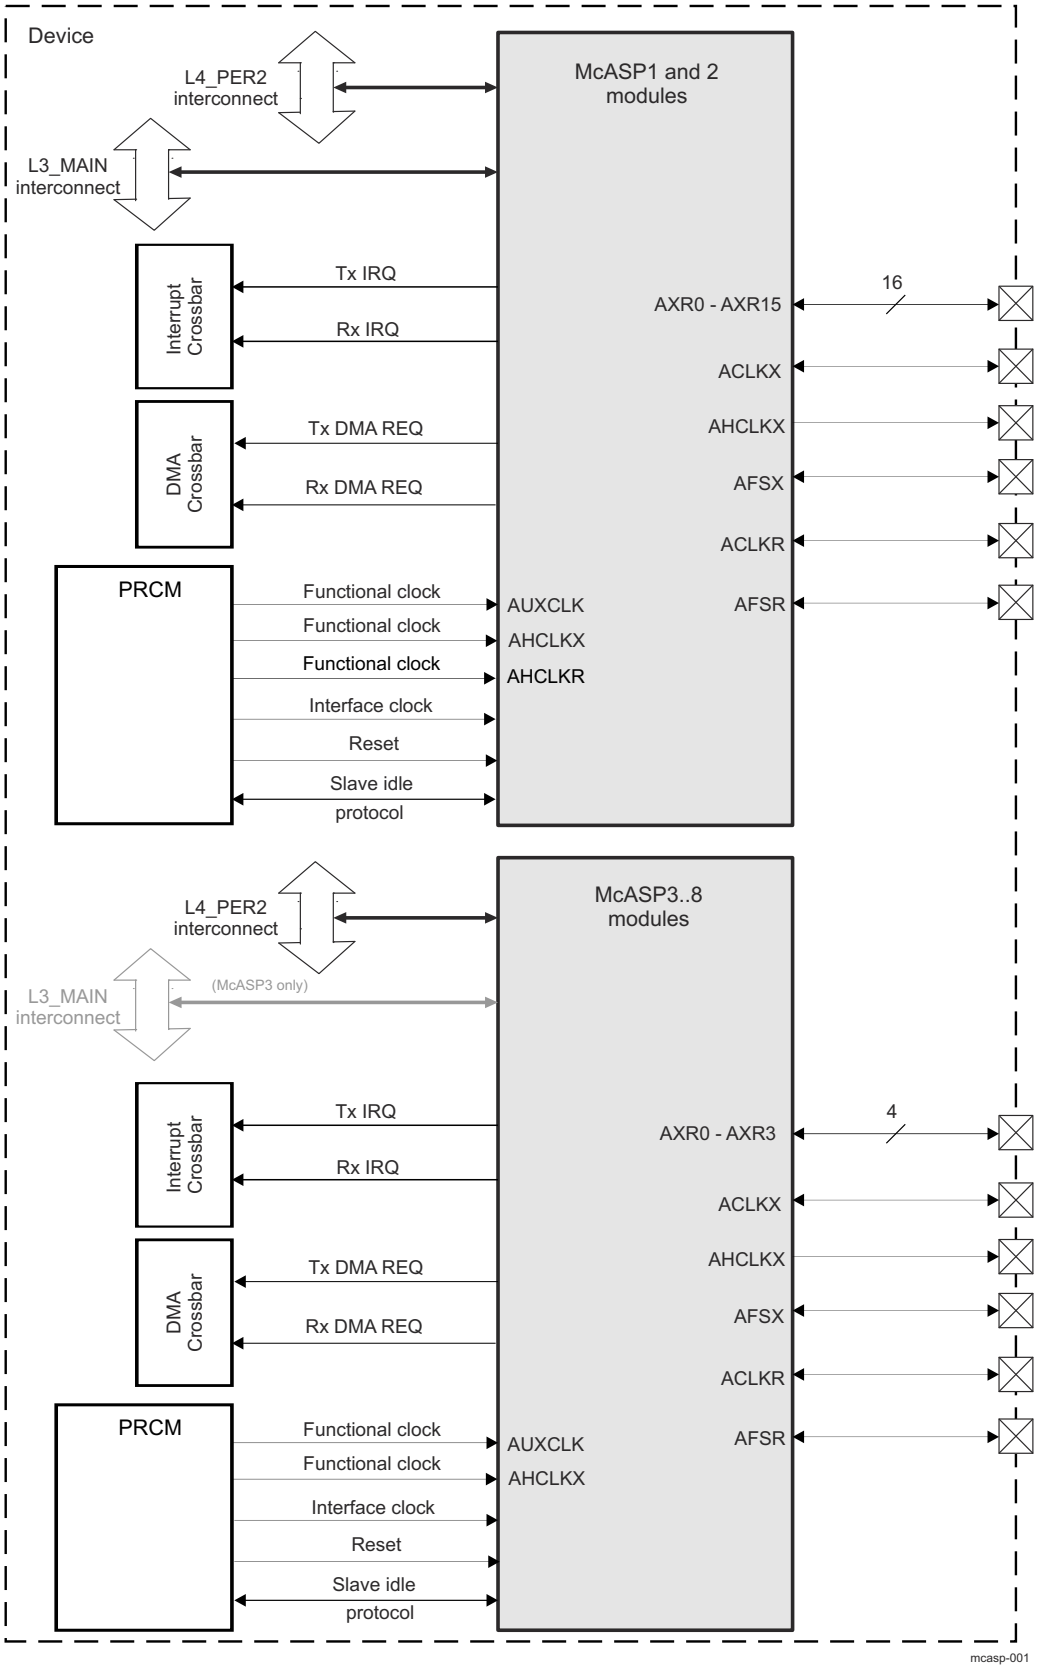

Figure 24-108. McASP Modules Overview

Note

The ACLKR and AFSR signals of McASP2 are not pinned out on the AM570x family of devices.

McASP module includes the following main features:

- Two modules (McASP1 and McASP2) supporting up to 16 channels each and independent TX/RX clock/sync domains.
- Six modules (McASP3, McASP4, McASP5, McASP6, McASP7, and McASP8) supporting up to 4 channels each and unified clock/sync domain.
- Independent serializer for each AXRx channel of each McASPx module.
- Idle request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- 2 x interconnect slave interface ports:
  - A configuration (CFG) port supplied with an internal L4-interconnect interface clock
  - A slave DMA data port synchronized with functional clock
- Two independent clock generator modules for transmit and receive.
  - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- McASP module functional clock can be generated:
  - internally (master mode)
  - supplied over McASP serial interface (slave mode)
  - has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator.
  - TDM streams from 2 to 32, and 384 time slots.
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
  - Data formatter for bit manipulation.
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT):
  - S/PDIF, IEC60958-1, AES-3 formats.
  - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Support for 2x DMA requests (one per direction):
  - 1 level-sensitive transmit direct memory access (DMA) request common for all of the McASP serializers
  - 1 level-sensitive receive direct memory access (DMA) request common for all of the McASP serializers
  - All transmit DMA requests are mapped to the device DMA crossbar
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupt Crossbar

Note

Because a serializer receive and transmit channels data is shared on the same McASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

24.6.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case. Figure 24-109 shows the McASP modules in their environment in the device.

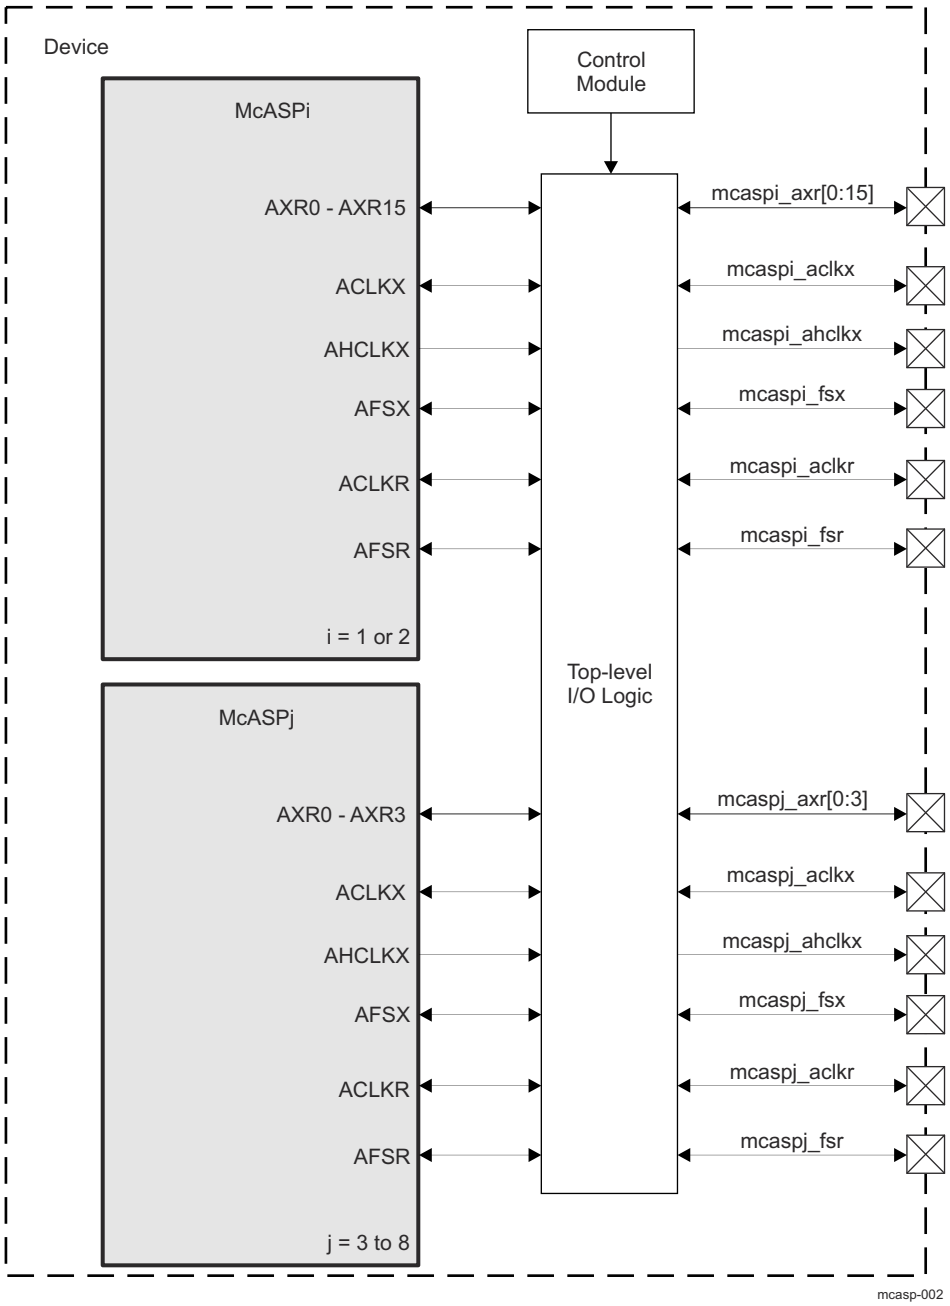

Figure 24-109. McASP Environment

Note

McASP8 module may have fewer number of serializers depending on device part number or device package type. Refer to the device Data Manual, for more information.

24.6.2.1 McASP Signals

Table 24-325 describes the McASP pins, their corresponding signal names at device level and specifies their links to functions.

Table 24-325. McASP I/O Signals

Module Pin Name	Device Level Signal Name	I/O[1]	Description	Module Pin Reset Value

AFSX	mcasp8_fsx	I/O	Transmit frame synchronization	HiZ
ACLKR	mcasp8_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcasp8_fsr	I/O	Receive frame synchronization	HiZ

(1) I = Input; O = Output; I/O = Bidirectional
(2) The ACLKR and AFSR pins of McASP2 are not pinned out on the AM570x family of devices.
(3) McASP8 module may have fewer number of serializers depending on device part number or device package type. Refer to the device Data Manual, for more information.

Note

For the mcaspx_aclkx, mcaspx_ahclkx and mcaspx_aclkr signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

Note

The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the *Pad Configuration Registers*, and *Control Module Register Manual*, in *Control Module*.

Note

A serializer AXR data pin is shared between the transmit and receive logic of that serializer. The direction of data is determined in the MCASP_PDIR and the function (Tx or Rx) is selected in the corresponding serializer control register MCASP_XRSRCTLn.

24.6.2.2 Protocols and Data Formats

24.6.2.2.1 Protocols Supported

The McASP supports a wide variety of protocols:

- Transmit section supports:
  - Wide variety of I2S and similar bit-stream formats.

  - TDM streams from 2 to 32 time slots.
  - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections of the module may be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
  - Automatically aligns data internally in either Q31 or integer formats.
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

Note

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode for McASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.
- Stereo Support Only (Mono means send data 2x via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

Note

The McASP does NOT natively support DIR-mode reception (i.e. receiving in the S/PDIF format). To allow this, the McASP can use a DIR-input to I2S-output converter implemented by an external device (i.e. external DIR component). To facilitate reception in this case, the TDM mode of McASP receivers logic is extended to support a non-standard 384-slot TDM stream.

Note

An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

24.6.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a McASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 24-110 shows two of the three basic components: the clock signal (ACLKX/ACLKR) and the data signals AXRn. Figure 24-110 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the McASP are configured to operate synchronously.

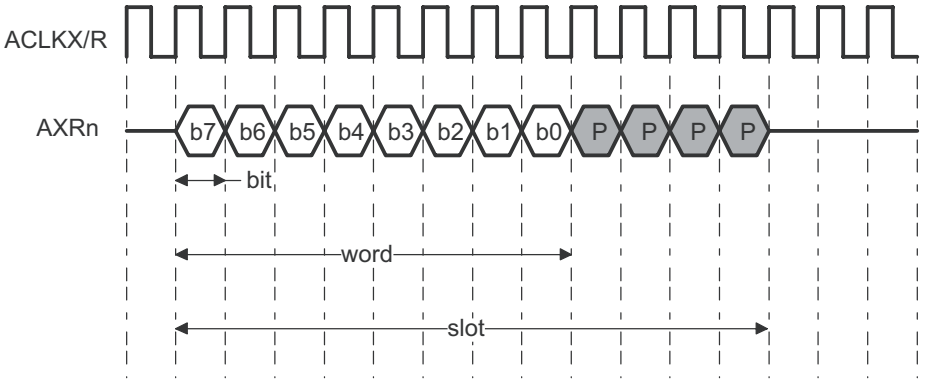
- Bit:

  A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.
- Word:

  A word is a group of bits that make up the data being transferred between the McASP and the external device. Figure 24-110 shows an 8-bit word.
- Slot:

  A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In Figure 24-110, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on an AXRn pin with either MSB or LSB first.

  When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, i.e. left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. Figure 24-111 shows these options.



(1) b7:b0 - bits. Bits b7 to b0 form a word.

(2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.

(3) In this example, the data is transmitted MSB first, left-aligned.

mcasp-003

Figure 24-110. Definition of Bit, Word, and Slot

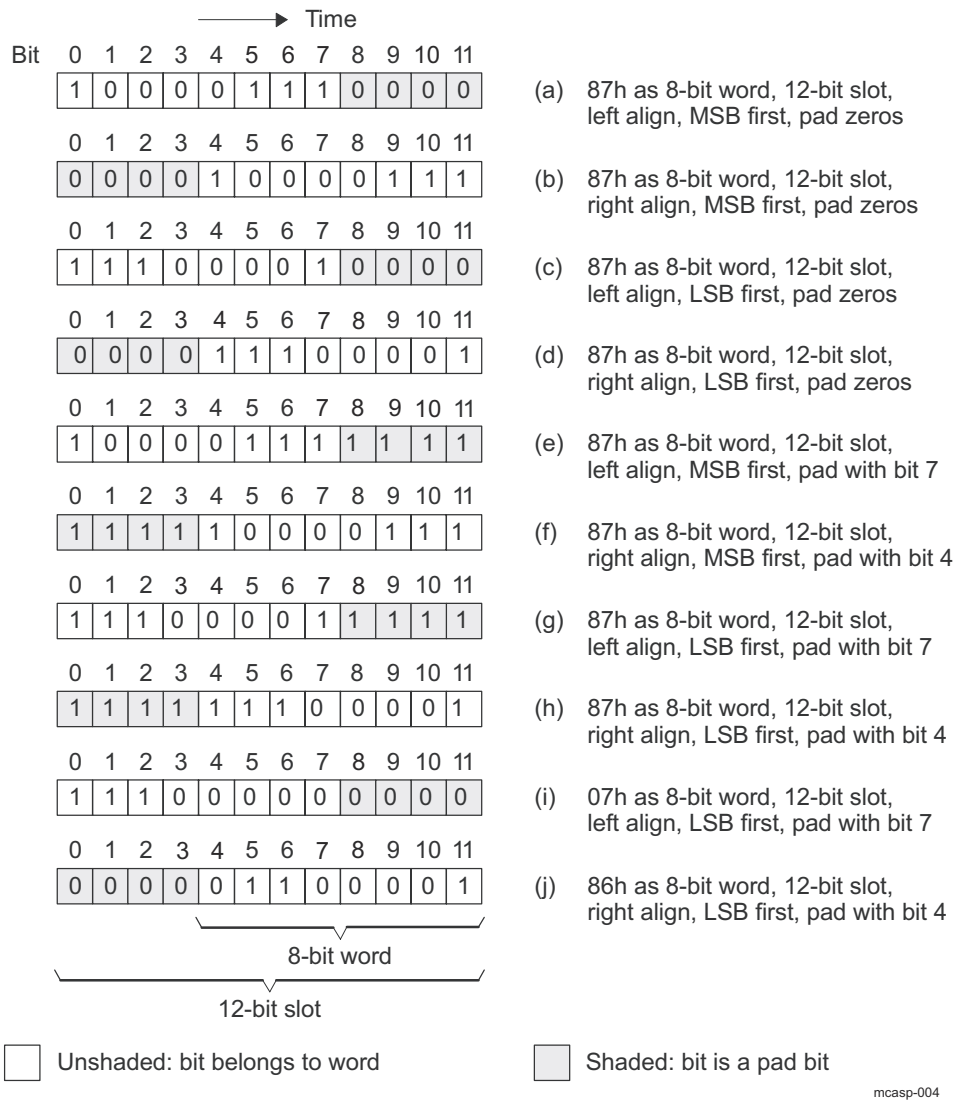


Figure 24-111. Bit Order and Word Alignment Within a Slot Examples

- Frame

  The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. Figure 24-112 shows an example frame of data and the frame definitions. In operation, the transmitter uses AFSX, and the receiver - AFSR signal. Figure 24-112 does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter/receiver uses AFSX/AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously. This example shows two slots in a frame (I2S format) and a frame-sync (FS) duration of a slot length.

  This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see Section 24.6.2.2.3, *TDM Format* and Section 24.6.2.2.5, *S/PDIF-Coding Format*.

Note

All of the McASP serializers share the same, device pad accessible, clock and frame signals, as follows:

– AHCLKX, ACLKX, and AFSX for the transmitting section
– ACLKR and AFSR for the receiving section

Note

The ACLKR and AFSR signals of McASP2 are not pinned out on the AM570x family of devices.

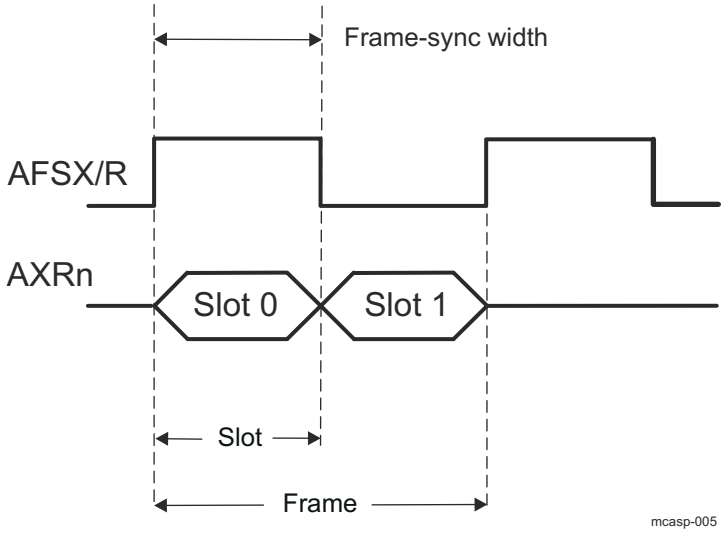

Figure 24-112. Definition of Frame and Frame-Sync Width

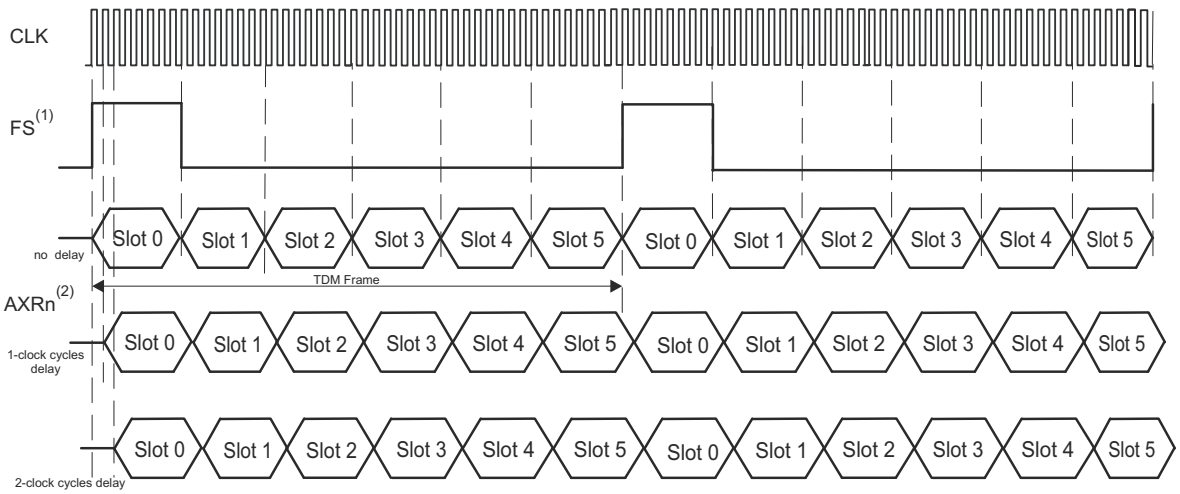
The following terms are used throughout this chapter:

- TDM: Time-division multiplexed. See Section 24.6.2.2.3 for details on the TDM protocol
- I2S: Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on each AXRn data pin.
- DIR: Digital audio interface receive. The McASP does NOT natively support receiving in S/PDIF format on AXRn data pins and requires an external DIR-to-TDM or DIR-to-I2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT/DIR format, a McASP time slot corresponds to a DIT/DIR subframe.

24.6.2.2.3 TDM Format

The TDM format is used to transfer data between the host CPU and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one McASP data pin - AXRn is illustrated on Figure 24-113.



(1) - Frame sync duration of 1 slot - length is shown. A single bit - duration of FS is also supported

(2) - Slot 0 of AXRn stream is being offset with 0-, 1-, and 2- clock cycle delay from the frame sync, respectively.

mcasp-006

Figure 24-113. TDM Format - 6 channel example

The TDM format uses three signals In a basic synchronous serial interface: data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also Section 24.6.2.2.2), the latter being also refered to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For McASP, there is an option to offset the first bit of the first slot with a 0-,1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does not determine the boundaries of a slot, there is a requirement for a connected transmitter and receiver to agree on the number of transferred bits per slot.

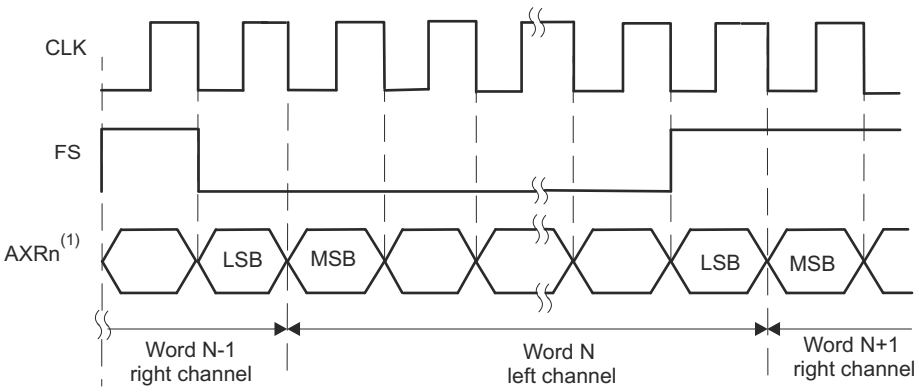
In a typical audio system involving McASP module, a single TDM data frame is transferred during each sample period Ts of a data converter. The user has following choices to implement multiple channels:

- Use more data slots (on a price of higher speed serial clock) per frame transmitted/received on just one of the available McASP data pins AXRn.
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the McASP pins AXRn.

24.6.2.2.4 I2S Format

The TDM transfer mode of the McASP supports the I2S format when frame is configured to have 2 slots. I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format equals size of a slot. The frame signal is also referred to as "word select" in the I2S format.

The I2S protocol is illustrated on Figure 24-114.



(1) - The example shows I2S data MSB-first transmission with 1-clock cycle delay between FS and data MSB

mcasp-036

Figure 24-114. I2S Format Overview

24.6.2.2.5 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphase-mark encoded output. The S/PDIF format is supported by the DIT- transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

Note

The DIR- reception of S/PDIF format frames is NOT natively supported from the device McASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the McASP TDM-only compatible receiver input.

24.6.2.2.5.1 Biphase-Mark Code

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). For each serializer transmitter n, the clock, frame, and data are embedded in only one signal - the data signal AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 24-115 and Table 24-326 show how data is encoded to the BMC format.

As shown in Figure 24-115, the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to 128 × f_s, where f_s is the sample rate (see Section 24.6.2.2.5.3, *Frame Format*, for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

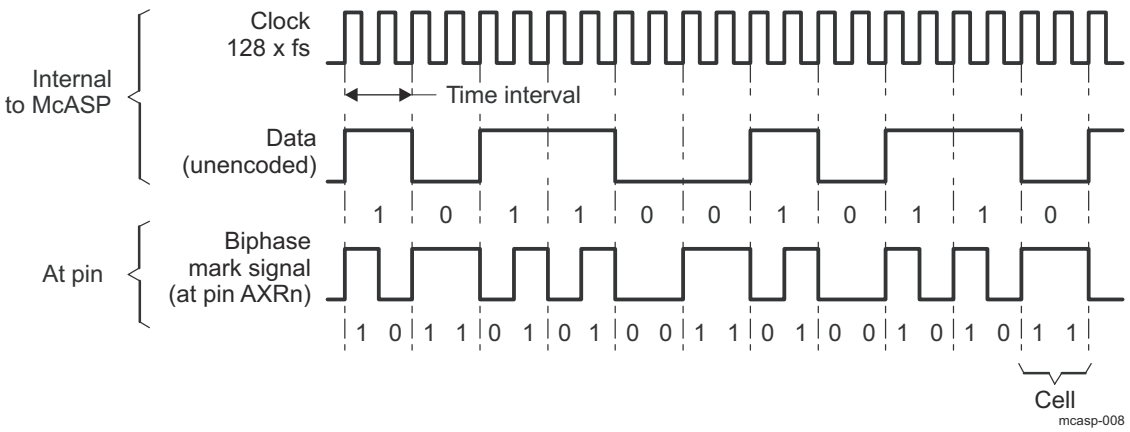


Figure 24-115. Biphase-Mark Code

Table 24-326. Biphase-Mark Encoder

Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at Pin AXRn
0	0	11
0	1	00
1	0	10
1	1	01

24.6.2.2.5.2 S/PDIF Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. Figure 24-116 shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 24-327.
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in Table 24-327, the preambles (time intervals 0–3) are also defined with even parity.

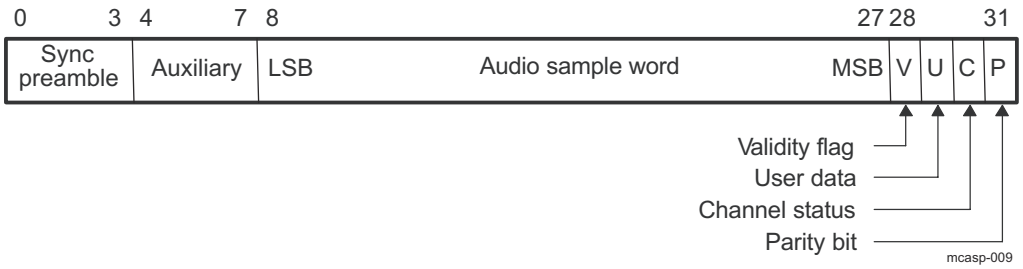

Figure 24-116. S/PDIF Subframe Format

As listed in Table 24-327, the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

Table 24-327. Preamble Codes

Preamble Code(1)	Previous Logical State	Logical States on pin AXRn(2)	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

(1) Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.
(2) The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

24.6.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see Figure 24-117). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s. The S/PDIF format clock rate is therefore 128 × f_s (128 = 32 cells per subframe × 2 clocks per cell × 2 subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is 128 × 192 kHz = 24.58 MHZ.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

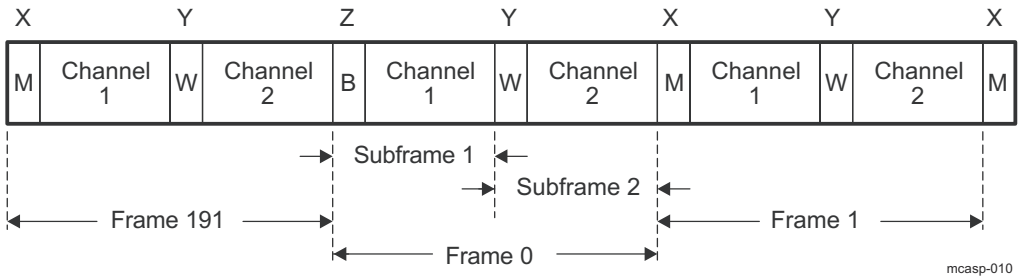

Figure 24-117. S/PDIF Frame Format

24.6.3 McASP Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

McASP module includes the following features:

- Slave idle protocol
- One DMA request for transmit event
- One DMA request for receive event
- One interrupt request (IRQ) for transmit
- One interrupt request (IRQ) for receive

Figure 24-118 shows McASP integration.

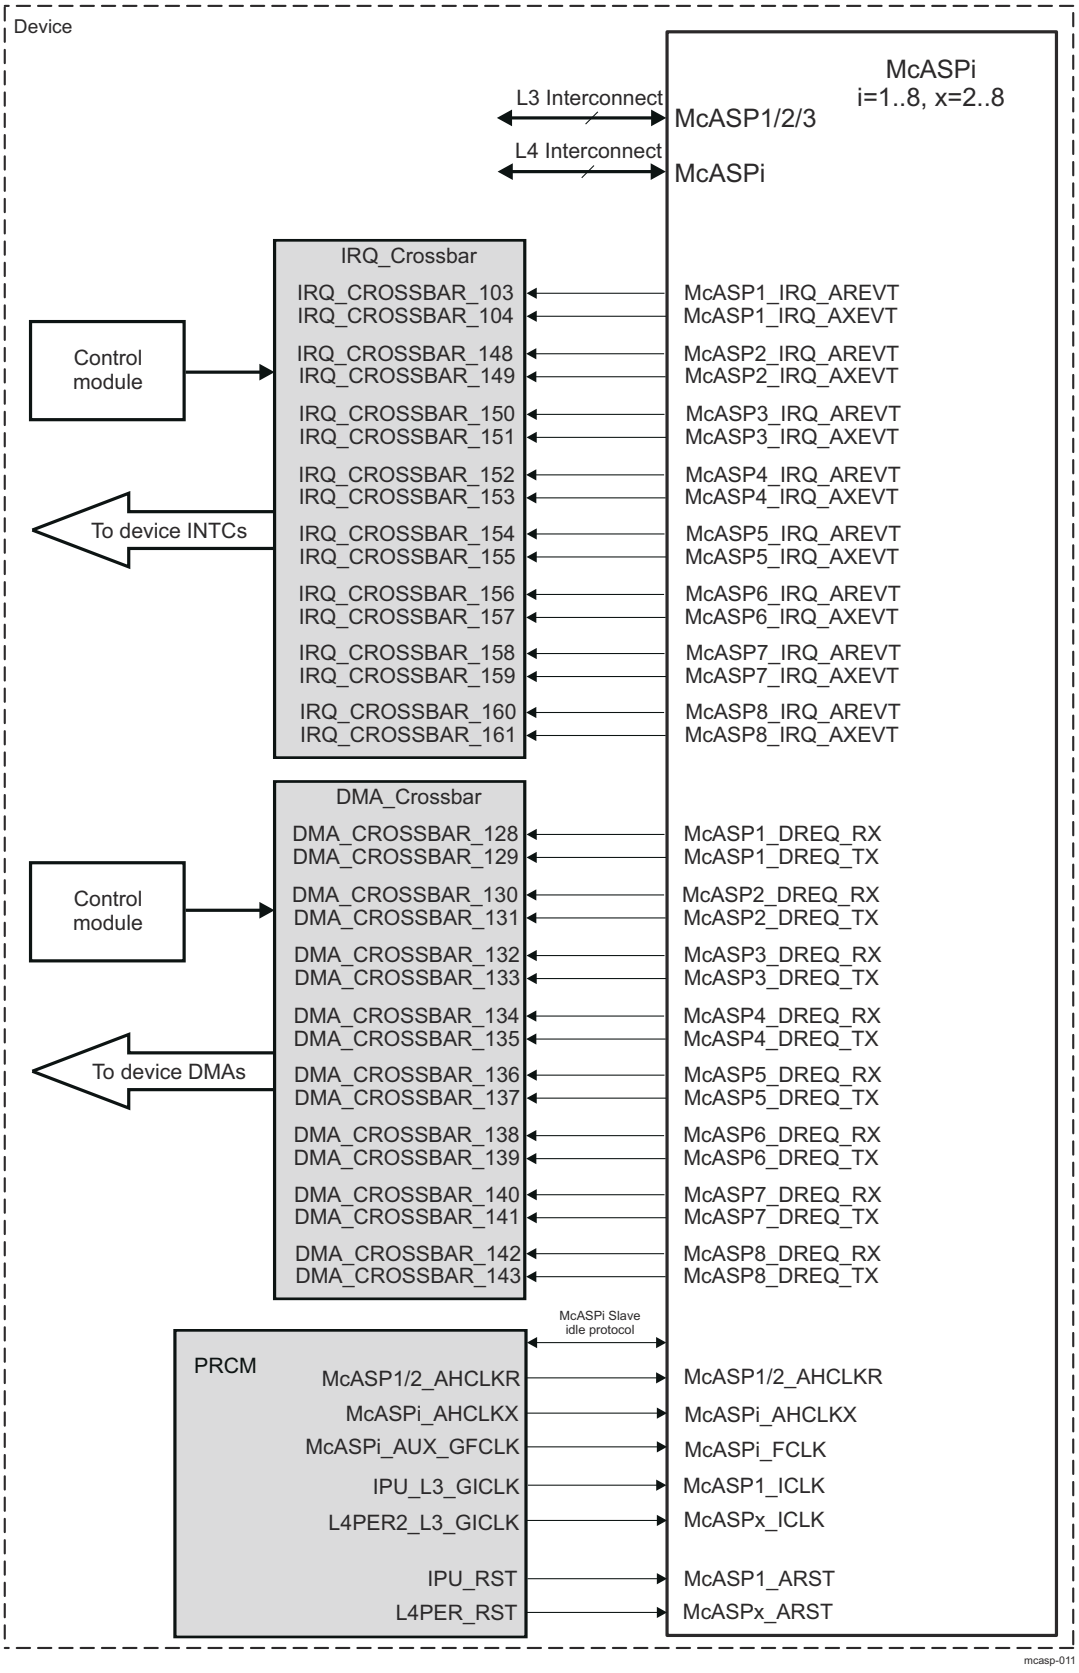

Figure 24-118. McASP Integration

Note

For more information about the slave idle protocol, see *Module Level Clock Management* of *Power, Reset, and Clock Management*.

Table 24-328 through Table 24-330 summarize McASP integration in the device.

Table 24-328. McASP Integration Attributes

Note

The **Default Mapping** column in Table 24-330 *McASP Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.
For more information about the device DSP1_EDMA , see *DSP Integrated EDMA Subsystem*.

Note

- For the description of the interrupt source, see Section 24.6.4.12, *McASP Events and Interrupt Requests*.
- For the description of the DMA source, see Section 24.6.4.13, *DMA Requests*.

24.6.4 McASP Functional Description

In the text throughout this section a single instance of McASP is described assuming that all modules are functionally identical. For module availability and integration differences, see Section 24.6.2, *McASP Environment*, and Section 24.6.3, *McASP Integration*

24.6.4.1 McASP Block Diagram

Figure 24-119 shows the major blocks of the McASP module. McASP1 and McASP2 have 16 serializers each, and McASPn (n = 3 to 8) have 4 serializers each. The serializers share a clock and frame-sync generator, format unit, and error-checking logic independently for the receive and transmit part.

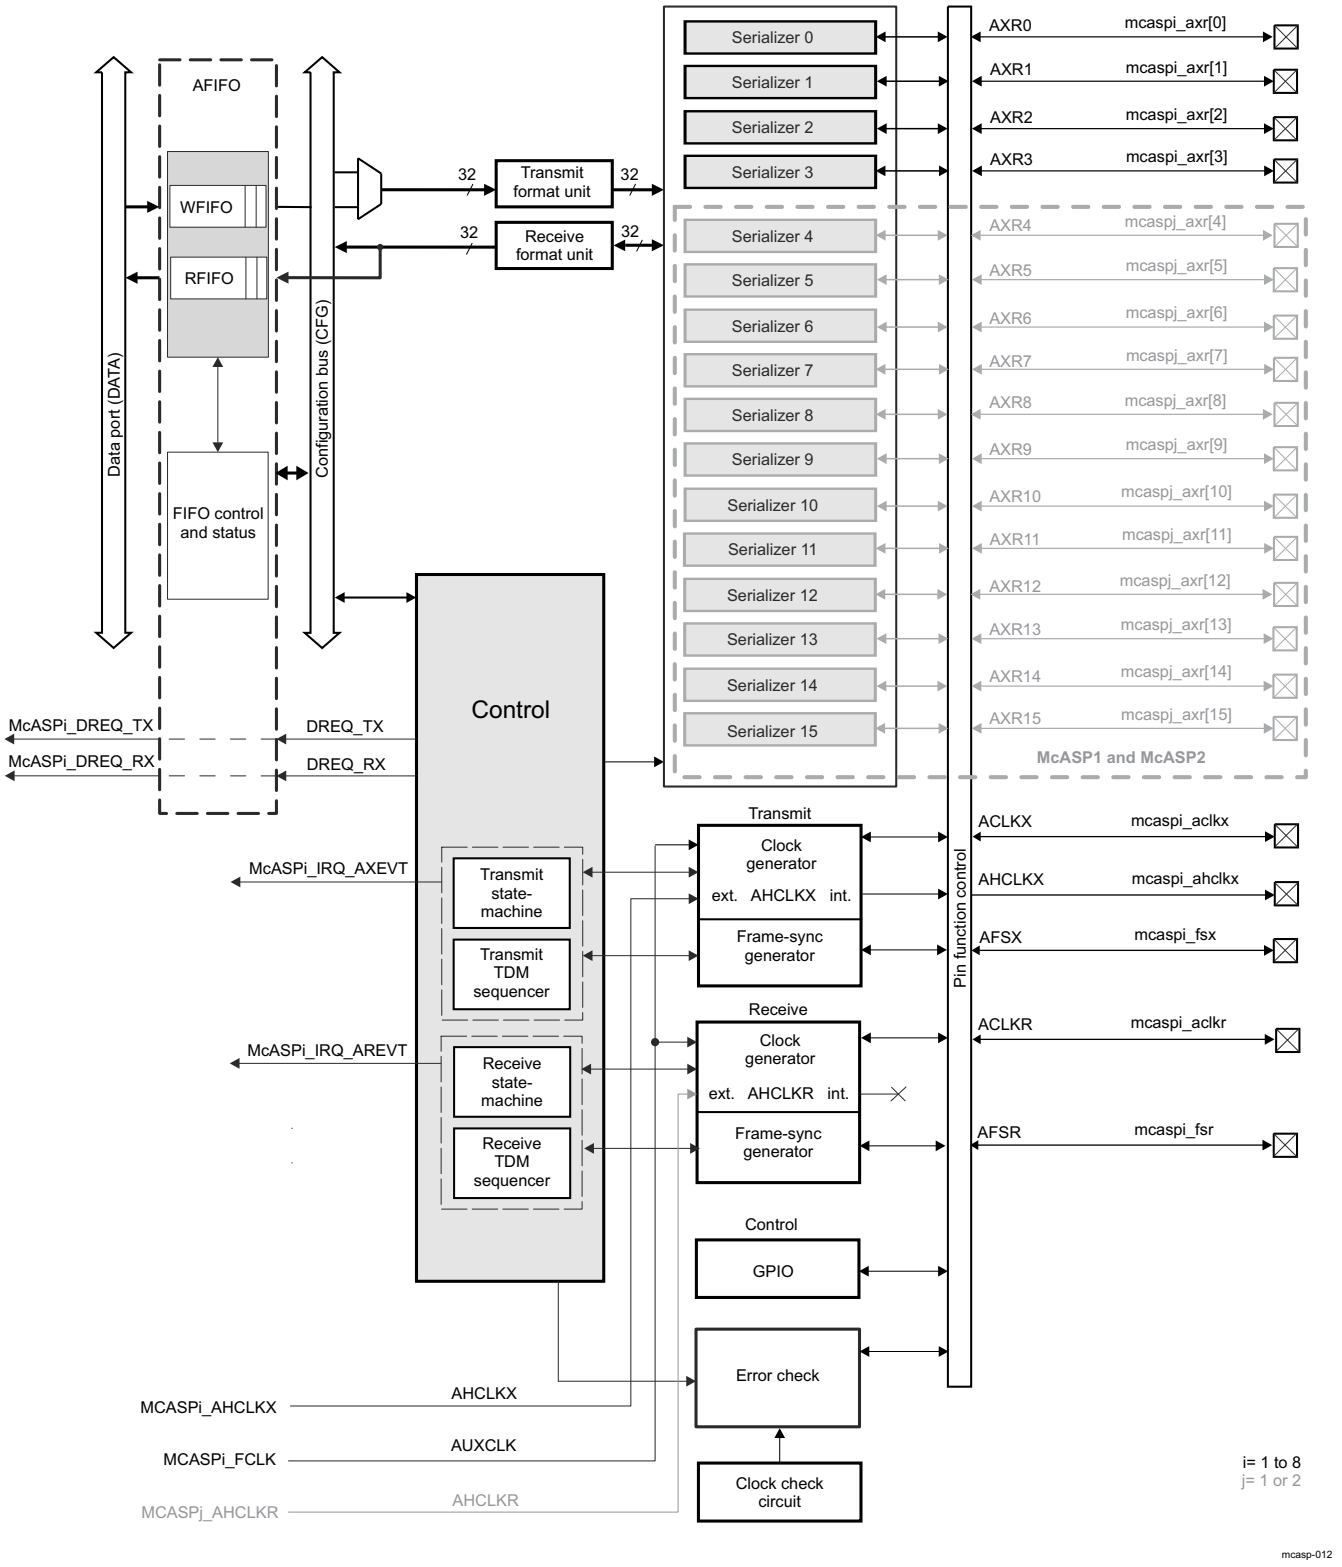

Figure 24-119. McASP Module Block Diagram

Note

The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

24.6.4.2 McASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the McASP serializers. The first three scenarios are identical between the Tx and Rx part of the McASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for McASP receivers - RCLK is derived from the bit rate clock of the McASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the McASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

24.6.4.2.1 McASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- MCASP_ACLKXCTL
- MCASP_AHCLKXCTL

In case, the transmit bit clock, ACLKX, is generated internally, the MCASP_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKXCTL[4:0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in Section 24.6.4.2, the MCASP_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKXCTL[11:0] HCLKXDIV bit field) from the McASP internal clock source AUXCLK.

Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see Figure 24-120). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If MCASP_ACLKXCTL[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If MCASP_ACLKXCTL[7] CLKXP = 1, the CLKX mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

It can be seen in Figure 24-120 that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between McASP transmitters and receivers. This is used for example in the McASP loopback mode.

Note

The polarity of ACLKX can be controlled in MCASP_ACLKXCTL[7] CLKXP, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the MCASP_AHCLKXCTL[14] HCLKXP bit.

Note

In a similar way, the polarity of AHCLKX clock can be controlled in MCASP_AHCLKXCTL[14] HCLKXP, regardless of the AHCLKX signal being internally or externally sourced.

Figure 24-120 is the block diagram of the transmit clock generator.

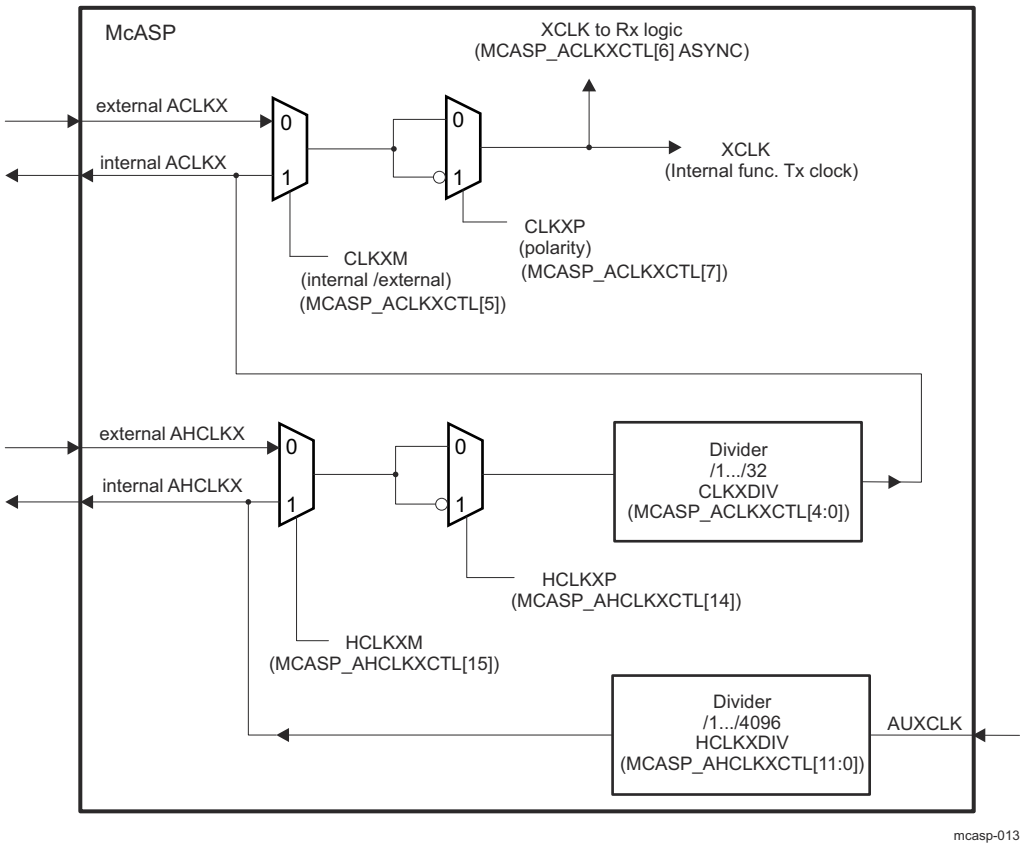

Figure 24-120. Transmit Clock Generator Block Diagram

Note

In this device:

- ACLKX is mapped on the device ball mcaspi_aclkx, where i = 1 to 8
- internal AHCLKX is mapped on the device ball mcaspi_ahclkx
- external AHCLKX is mapped on MCASPi_AHCLKX clock from the PRCM

For more on McASP integration, see Section 24.6.2, *McASP Environment*, and Section 24.6.3, *McASP Integration*.

24.6.4.2.2 McASP Receive Clock

The McASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- MCASP_ACLKRCTL
- MCASP_AHCLKRCTL

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the MCASP_ACLKRCTL[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKRCTL[4:0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in Section 24.6.4.2) and the MCASP_AHCLKRCTL[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKRCTL[11:0] HCLKRDIV bit field) from the McASP internal clock source AUXCLK.

Note

The polarity of ACLKR can be controlled in MCASP_ACLKRCTL[7] CLKRP, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in MCASP_AHCLKRCTL[14] HCLKRP, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the McASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see Figure 24-120 and Figure 24-121) becomes source of the receive clock (RCLK output), when the MCASP_ACLKXCTL[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to Section 24.6.4.2.4.

Figure 24-121 is the block diagram of the receive clock generator.

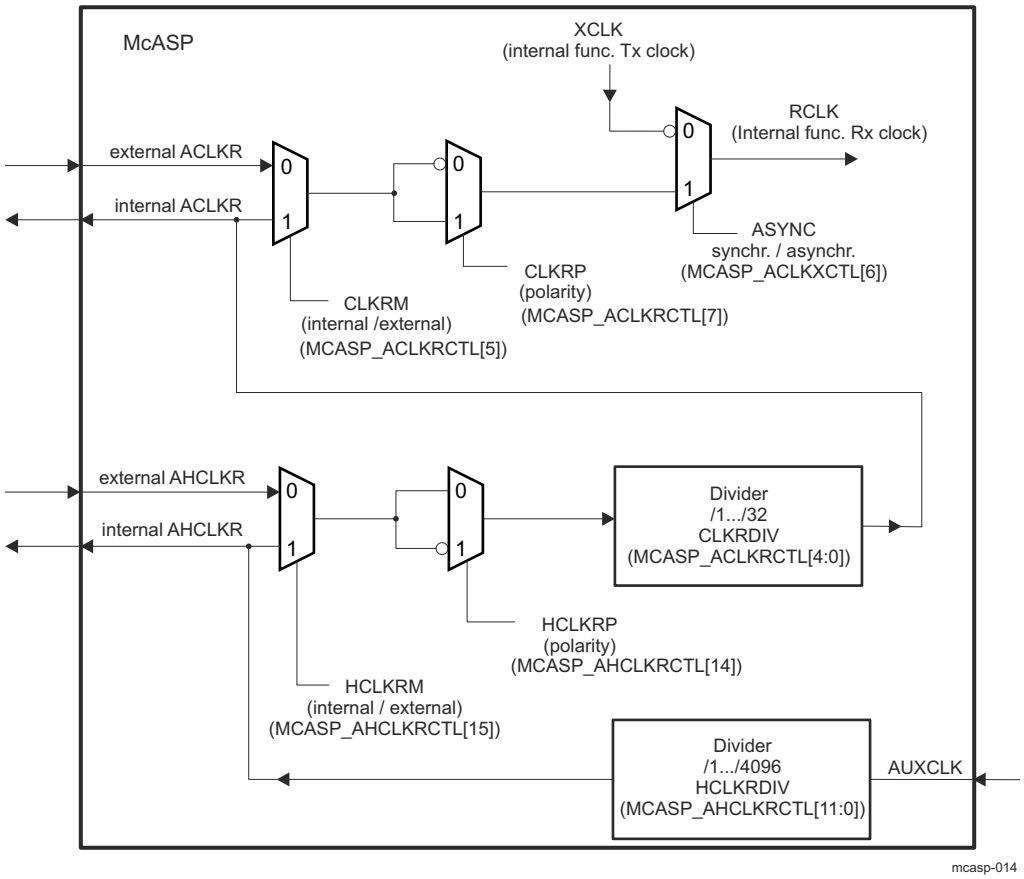

Figure 24-121. Receive Clock Generator Block Diagram

Note

In this device:

- ACLKR is mapped on the device ball mcaspi_aclkr, where i = 1 to 8
- internal AHCLKR is tied-off
- external AHCLKR is mapped on PRCM MCASPi_AHCLKR from PRCM for McASP1 and McASP2
- external AHCLKR is tied-off for McASP3 through McASP8
- the ACLKR and AFSR signals of McASP2 are not pinned out on the AM570x family of devices.

For more on McASP integration, see Section 24.6.2, *McASP Environment*, and Section 24.6.3, *McASP Integration*.

24.6.4.2.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The McASP frame sync generator logic is illustrated in Figure 24-122. I/O buffers are not part of the McASP module, and are not shown in the figure.

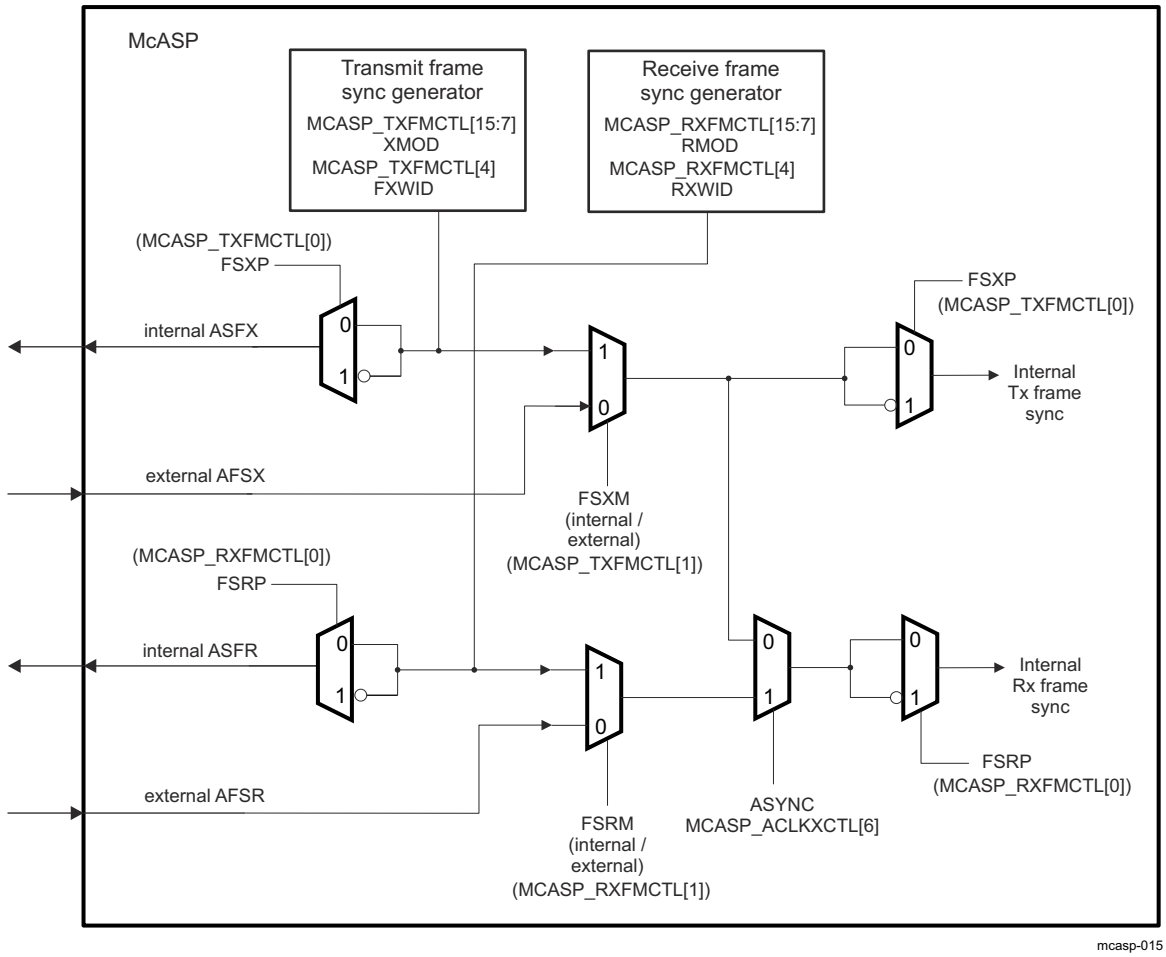

Figure 24-122. Frame Sync Generator Block Diagram

Note

For more on McASP integration, see Section 24.6.2, *McASP Environment*, and Section 24.6.3, *McASP Integration*.

For the transmit logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_TXFMCTL[1] FSXM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_TXFMCTL[0] FSXP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_TXFMCTL[4] FXWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_TXFMCTL[15:7] XMOD, as follows:
  - For DIT mode (384 slots) - MCASP_TXFMCTL[15:7] XMOD = 0x180
  - For I2S mode (2 TDM slots) - MCASP_TXFMCTL[15:7] XMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP_TXFMCTL[15:7] XMOD set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_TXFMT[17:16] XDATDLY

For the receive logic, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring bit MCASP_RXFMCTL[1] FSRM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_RXFMCTL[0] FSRP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_RXFMCTL[4] FRWID

- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_RXFMCTL[15:7] RMOD, as follows:
  - For I2S mode (2 TDM slots) - MCASP_RXFMCTL[15:7] RMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP_RXFMCTL[15:7] RMOD set in range 0x3 - 0x20
  - For the special 384-slot TDM mode - MCASP_RXFMCTL[15:7] RMOD=0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_RXFMT[17:16] RDATDLY
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to Section 24.6.4.2.4.

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

Note

Certain restrictions apply to the receive and transmit logic settings, when MCASP_ACLKXCTL[6] ASYNC is set to 0b0. They are described in Section 24.6.4.2.4.

24.6.4.2.4 Synchronous and Asynchronous Transmit and Receive Operations

Synchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the Figure 24-121, with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When MCASP_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP_TXDITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ * RMOD product value must equal XSSZ * XMOD product value)
- The settings in MCASP_ACLKRCTL are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

Asynchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

Note

Synchronous transmit and receive operations are allowed only in the McASP TDM (I2S) mode (i.e. when MCASP_TXDITCTL[0] DITEN=0b0).

24.6.4.3 Serializers

The McASP serializers shift serial data in (Rx) and out (Tx) of the McASP. A given serializer n consists of a shift register (XRSRn) with a single-entry data buffer XRBUFn used either for transmitting (write accessible in register MCASP_TXBUFn) or for receiving (read accessible in register MCASP_RXBUFn) data. In addition, each serializer has a dedicated control register (MCASP_XRSRCTLn) and a serial bidirectional data pin - AXRn. The register MCASP_XRSRCTLn allows n-th serializer to be configured as a transmitter, receiver, or as inactive.

There are transmit and receive data formatting units to support data alignment options of the McASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSRn shifter configured as a receiver in MCASP_XRSRCTLn, shifts in data through McASP corresponding device level bidirectional data pad AXRn. A given serializer XRSRn shifter configured as a transmitter in MCASP_XRSRCTLn, shifts out data on McASP corresponding device level bidirectional data pad AXRn.

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for McASP there are at most a couple of zones, one for transmit and one for receive.

Figure 24-123 is the serializer block diagram.

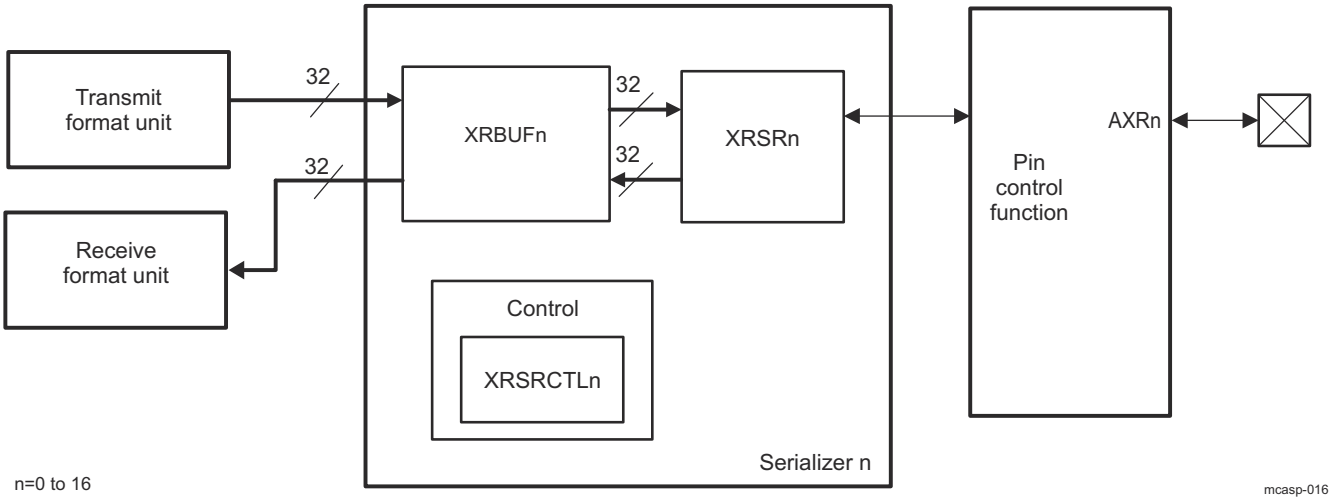

Figure 24-123. Individual Serializer and Connections Within McASP

Transmission on the n-th serializer is performed as follows:

The McASP is serviced by writing data into the register MCASP_TXBUFn, which is an alias of the serializer data buffer - XRBUFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFn register in the serializer. The data is then copied from the XRBUFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

Reception from the n-th serializer is performed as follows:

The data is shifted into the McASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFn,and can be accessed in the MCASP_RXBUFn register, which is an alias of the serializer data buffer - XRBUFn for receive function. When software reads the data from this register, the McASP passes the data through the receive format unit, hence it returns the formatted data.

Serializer controls:

A serializer n is configured as inactive via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x0.

For a transmitting serializer, the MCASP_XRSRCTLn[3:2] DISMOD bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x1.

Receive function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x2.

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see Section 24.6.2.2.5

24.6.4.4 Format Units

The McASP has one transmit data formatting unit and one receive data formatting unit, shared between the device McASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers.

Note

The McASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP_RXFMT/MCASP_TXFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the MCASP_RXFMT/MCASP_TXFMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in MCASP_RXFMT/MCASP_TXFMT means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

24.6.4.4.1 Transmit Format Unit

The McASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

Figure 24-124 shows the transmit formatting unit.

The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register - MCASP_TXFMT:

- XRVRS: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

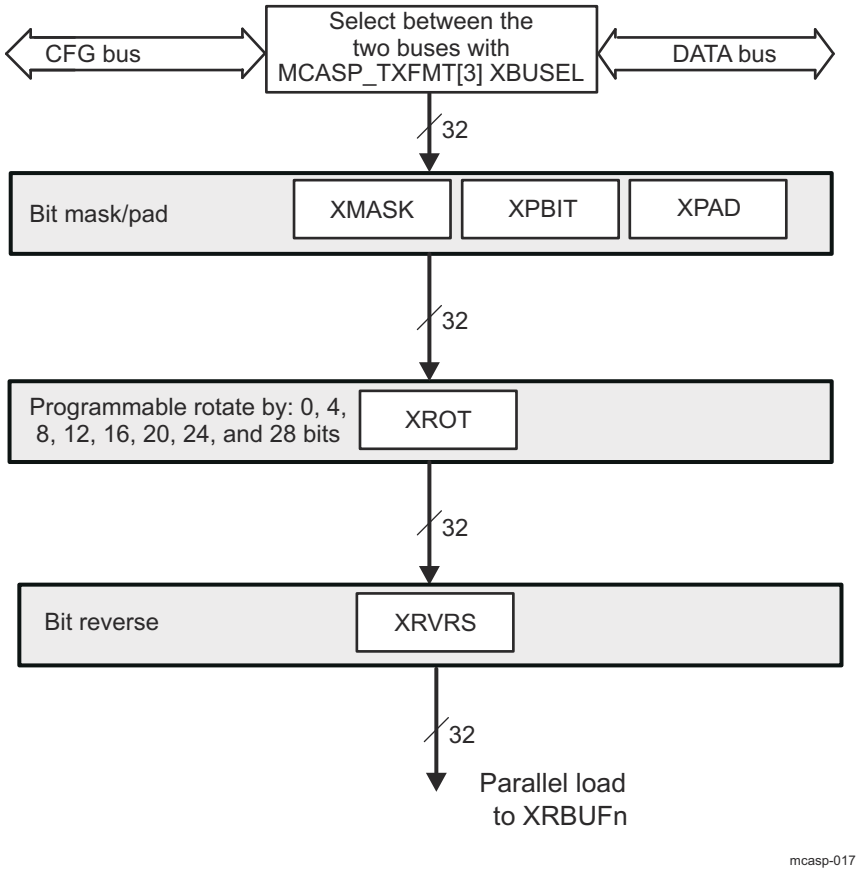

Figure 24-124. Transmit Format Unit

As shown in Figure 24-124, the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_TXFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the Section 24.6.4.10.1.3, *Transfers Through the DATA Port*, and Section 24.6.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP_TXMASK[31:0] XMASK contents. The masked data is then right-rotated to MCASP_TXFMT[2:0] XROT positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

24.6.4.4.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots.

XSSZ should always be programmed to match the slot size of the serial stream.

Note

Note that, TDM word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

The Table 24-331 show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The Table 24-331 assumes that all slot size (SLOT in Table 24-331) and word size (WORD in Table 24-331) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter by the MPU or DSP (typically Q31 or integer).

Table 24-331. McASP TFU TDM Mode Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_TXFMT bits	
			XROT(1)	XRVRS
MSB first(2)	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first(2)	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

24.6.4.4.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP_TXFMT[17:16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP_TXFMT[2:0] XROT =
  - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
  - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
  - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0xFFFFFF00 – 0xFFFF0000
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP_TXFMT[2:0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in Table 24-332 should be applied to McASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the McASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

Table 24-332. McASP TFU DIT-Mode Example Settings

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFFF000	0x3
LEFT	24	8	0xFFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated by MPU on the McASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the Table 24-332, the user must set XMASK=0xFFFFF000, and to select a right-rotation to 12 positions (XROT=0x3).

- After applying 0-s (XPAD=0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF.Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVRS = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the McASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table McASP TFU Example Settings, user is supposed to set XMASK=0x0000FFFF, and to select right-rotation to 0 positions (XROT=0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

24.6.4.4.2 Receive Format Unit

The McASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

Figure 24-125 shows the receive format unit (RFU).

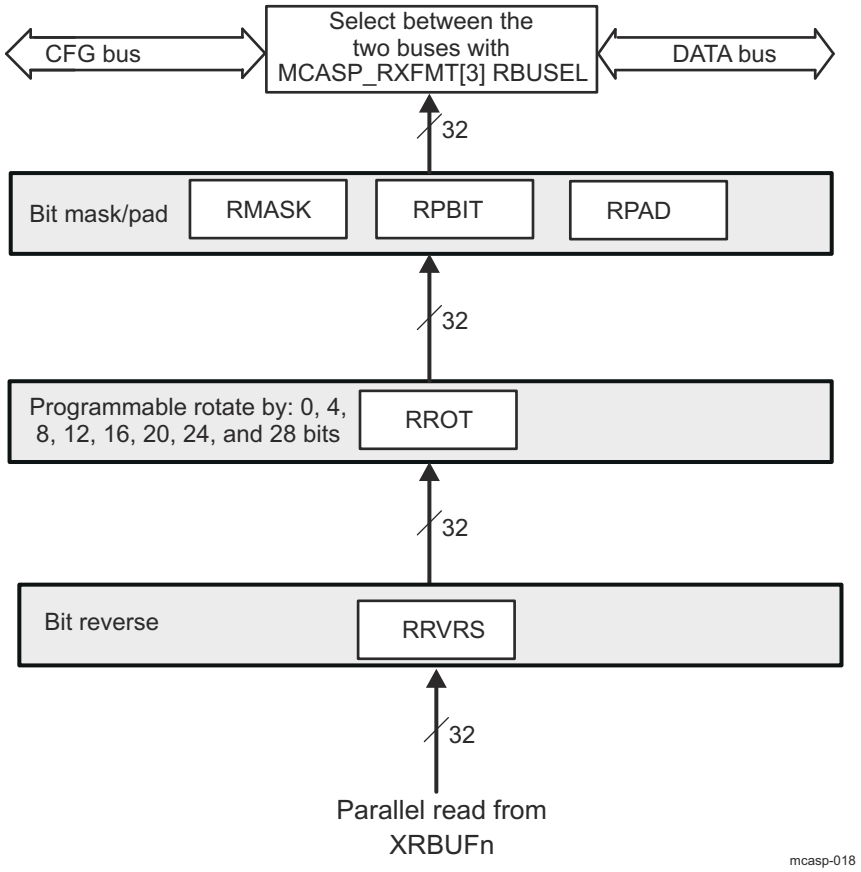

Figure 24-125. Receive Format Unit

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - MCASP_RXFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on Figure 24-125, the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_RXFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the Section 24.6.4.10.1.3, *Transfers Through the DATA Port*, and Section 24.6.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

24.6.4.4.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

Note

Note that the word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 24-333 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

Table 24-333. McASP RFU Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RXFMT bits	
			RROT(1)	RRVRS
MSB first(2)	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first(2)	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 24-333 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 24-125), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer).

24.6.4.5 State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the McASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP_TXFMT) and it reports the McASP status and error conditions in the transmitter status register (MCASP_TXSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP_RXFMT) and it reports the McASP status and error conditions in the receiver status register (MCASP_RXSTAT).

24.6.4.6 TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of MCASP_RXTDM/ MCASP_TXTDM and determines if the McASP should receive/transmit in that time slot.

There are two possibilities for a slot: The McASP either performs Rx/Tx operations during the time slot (transmit/ receive bit is active), or the McASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control register MCASP_XRSRCTLn[3:2] DISMOD. Refer also to Section 24.6.4.9.2.1, *TDM Time Slots Generation and Processing*, for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

In case of a DIT-transmission (S/PDIF transfers): the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP_TXBUFn register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the MCASP_TXTDM register and reports the current transmit slot to the MCASP_TXTDMSLOT[9:0] XSLOTCNT bit field.

24.6.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit and receive control register (MCASP_GBLCTL). A valid serial clock must be supplied to the McASP to assert the software reset bits in the MCASP_GBLCTL register.

24.6.4.8 McASP Power Management

Table 24-334 describes power-management features available to the McASP.

Table 24-334. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	PWRIDLESYSCONFIG[1:0] IDLE_MODE	Force-idle, no-idle, and smart-idle modes are available.

CAUTION

No wakeup schema is supported for the McASP. To ensure a correct behavior after enabling McASP at device PRCM level, the user software is strongly recommended to choose *No Idle* mode, setting PWRIDLESYSCONFIG[1:0] IDLE_MODE to 0x1. Before disabling McASP at device PRCM level, user software is strongly recommended to choose a *Smart-Idle* mode, setting PWRIDLESYSCONFIG[1:0] IDLE_MODE to 0x2.

24.6.4.9 Transfer Modes

24.6.4.9.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

When operating in burst frame sync mode (see Figure 24-126), as specified for transmit (MCASP_TXFMCTL[15:7] = 0) and receive (MCASP_RXFMCTL[15:7] RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (MCASP_RXFMCTL[4] FRWID = 0, MCASP_TXFMCTL[4] FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUFn (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUFn (for every serializer set to operate as a receiver) has been read.

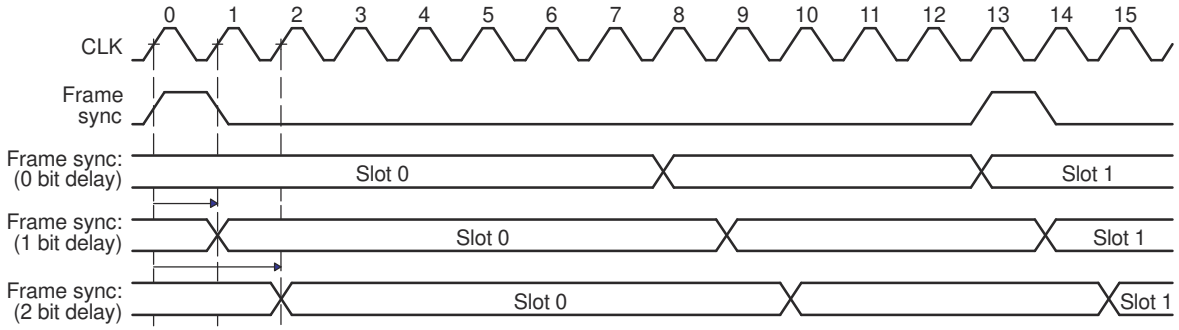

Figure 24-126. Burst Frame Sync Mode

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- MCASP_PFUNC: The clock, frame, data pins must be configured for McASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDSET, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_GBLCTL: Follow the initialization sequence in Section 24.6.5.1.2, *McASP Global Initialization*, to configure this register.
- MCASP_AMUTE: Not applicable. Leave at default.
- MCASP_LBCTL: If loopback mode is desired, configure this register according to Section 24.6.4.14 Loopback Modes, otherwise leave this register at default.
- MCASP_TXDITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- MCASP_RXMASK/MCASP_TXMASK: Mask desired bits according to Section 24.6.4.4, *Format Units*.
- MCASP_RXFMT/MCASP_TXFMT: Program all fields according to data format desired. See Section 24.6.4.4, *Format Units*.
- MCASP_RXFMT/MCASP_TXFMT: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. See Section 24.6.4.2, *McASP Clock and Frame-Sync Configurations*.
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 24.6.4.2, *McASP Clock and Frame-Sync Configurations*.
- MCASP_RXTDM/MCASP_TXTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- MCASP_EVTCTLR/MCASP_EVTCTLX: Program all fields according to interrupts desired.
- MCASP_RXCLKCHK/MCASP_TXCLKCHK: Not applicable. Leave at default.
- MCASP_XRSRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- MCASP_DITCSRAi, MCASP_DITCSRBi, MCASP_DITUDRAi, MCASP_DITUDRBi: Not applicable. Leave at default.

24.6.4.9.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in Section 24.6.2.2.3.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to transmit

For more details on McASP transmitting serializers clock and frame sync options, refer to the Section 24.6.4.2.1, *Transmit Clock*, and Section 24.6.4.2.3, *Frame-Sync Generator* .

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on McASP receiving serializers clock and frame sync options, refer to Section 24.6.4.2.2, *Receive Clock*, and Section 24.6.4.2.3, *Frame-Sync Generator* .

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- MCASP_PFUNC: The clock, frame, data pins must be configured for McASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDSET, MCASP_PDCLR: Not applicable. Leave at default.
- MCASP_GBLCTL: Follow the initialization sequence is described in the Section 24.6.5.2, *Operational Modes Configuration*.
- MCASP_AMUTE: Leave this register at default state.
- MCASP_LBCTL: If loopback mode is desired, configure this register according to Section 24.6.4.14, otherwise leave this register at default.
- MCASP_TXDITCTL: DITEN must be left at default 0 to select TDM mode (transmitters only).
- MCASP_RXMASK/MCASP_TXMASK: Mask desired bits according to Section 24.6.4.4, *Format Units*.
- MCASP_RXFMT/MCASP_TXFMT: Program all fields according to data format desired. See the Section 24.6.4.4, *Format Units*.
- MCASP_RXFMCTL/MCASP_TXFMCTL: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by McASP. Configure other fields as desired.
- MCASP_ACLKRCTL/MCASP_ACLKXCTL: Program all fields according to bit clock desired. For more inforamtion, refer to Section 24.6.4.2.
- MCASP_AHCLKRCTL/MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. For more details, refer to Section 24.6.4.2.
- MCASP_RXTDM/MCASP_TXTDM: Program all fields according to the time slot characteristics desired.
- MCASP_EVTCTLX: Program all fields according to transmit interrupts desired.
- MCASP_RXCLKCHK/MCASP_TXCLKCHK: Program all fields according to clock checking desired.
- MCASP_XRSRCTLn: Program all fields according to serializer operation desired.

Note

The MCASP_DITCSRAi, MCASP_DITCSRBi, MCASP_DITUDRAi, MCASP_DITUDRBi (i=0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

24.6.4.9.2.1 TDM Time Slots Generation and Processing

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring MCASP_TXTDM and/or MCASP_RXTDM registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either MCASP_TXTDM or MCASP_RXTDM to determine if the McASP transmits/receives in that time slot.

Note

If a MCASP_TXTDM/MCASP_RXTDM bit defines an active slot (number of slot matches the bit position), the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. McASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP_XRSRCTLn[3:2] DISMOD.

Figure 24-127 shows when the transmit DMA event - AXEVT is generated. See Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation* for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUFn to XRSRn generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

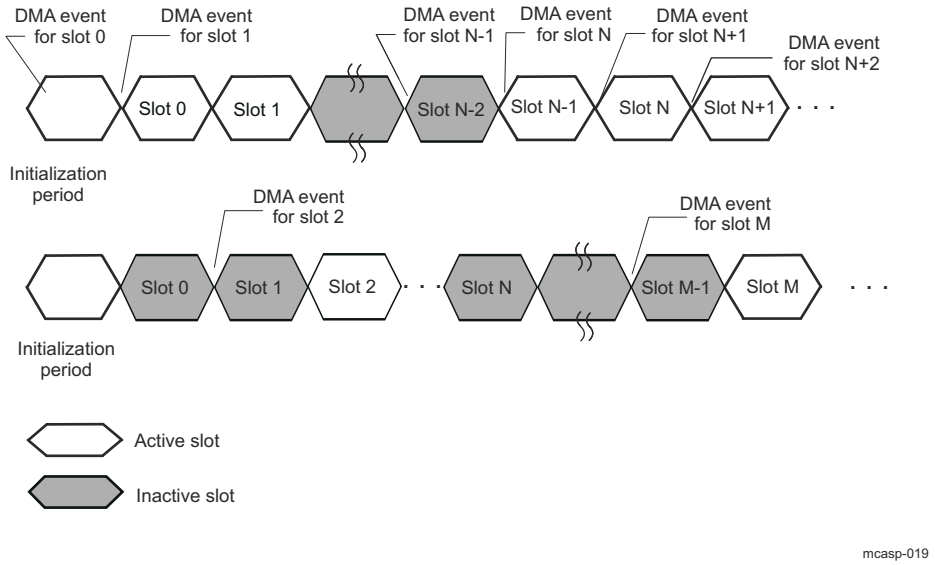

Figure 24-127. Transmit DMA Event (AXEVT) Generation in TDM Time Slots

24.6.4.9.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The receive TDM time slot register (MCASP_RXTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXRn, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in MCASP_RXFMCTL to 384 (0x180) to receive 384 time slots

24.6.4.9.3 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see Section 24.6.2.2.5, *S/PDIF Coding Format*.

24.6.4.9.3.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphase-mark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

Note

The transmit TDM time slot register (MCASP_TXTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see Section 24.6.4.4.1.2.

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

24.6.4.9.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP_TXFMCTL):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP_TXFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- MCASP_PFUNC: The data pin - AXRn must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- MCASP_PDIR: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- MCASP_GBLCTL: Global initialization
- MCASP_AMUTE: Leave this register at default state.
- MCASP_TXDITCTL: The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as desired.
- MCASP_TXMASK: Mask the desired bits, depending upon left-aligned or right-aligned internal data.

- MCASP_TXFMT: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the Section 24.6.4.4.1.2 .
- MCASP_TXFMCTL: Configure the bits according to former discussions.
- MCASP_ACLKXCTL: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- MCASP_AHCLKXCTL: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- MCASP_TXTDM: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP_EVTCTLX: Program all fields according to the interrupts desired.
- MCASP_TXCLKCHK: Program all fields according to the clock checking desired.
- MCASP_XRSRCTLn: Set SRMOD = 1 (transmitter) for the DIT pins.
- MCASP_DITCSRAi and MCASP_DITCSRBi: Program the channel status bits as desired.
- MCASP_DITUDRAi and MCASP_DITUDRBi: Program the user data bits as desired.

Note

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphase Mark Encoded Data - see Section 24.6.2.2.5.1).

24.6.4.9.3.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP_DITCSRAi and MCASP_DITCSRBi) and user data registers (MCASP_DITUDRAi and MCASP_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in Section 24.6.2.2.5.2, *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP_DITCSRA0 to MCASP_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP_DITCSRB0 to MCASP_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP_DITUDRA0 to MCASP_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP_DITUDRB0 to MCASP_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in Figure 24-117. There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in Table 24-335.

Table 24-335. Channel Status and User Data for Each DIT Block

24.6.4.10 Data Transmission and Reception

The McASP is serviced by writing data to the MCASP_TXBUFn registers for transmit operations, and by reading data from the MCASP_RXBUFn registers for receive operations. The McASP sets status flags and notifies the software whenever data is ready to be serviced. The Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation*, discusses data-ready status in details.

The McASP transmit/receive XRBUFn buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA initiated data transfers on the device for McASP transmit (Tx) purposes.
- Configuration bus (CFG): The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

Section 24.6.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 24.6.4.10.1.4, *Transfers Through the Configuration Bus (CFG),* discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in Section 24.6.4.10.1.5, *Using the device CPUs for McASP Servicing*, and Section 24.6.4.10.1.6, *Using the DMA for McASP Servicing*, respectively.

McASP DATA port allows DMAs to access the McASP transmit buffer more efficiently on the L3_MAIN-interconnect or L4_PER2 interconect, using burst transfers. The physical addresses to access these registers are listed in Section 24.6.6.2.5.

24.6.4.10.1 Data Ready Status and Event/Interrupt Generation

24.6.4.10.1.1 Transmit Data Ready

The transmit data ready flag - XDATA in the MCASP_TXSTAT register reflects the data ready status of XRBUFn buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUFn to its corresponding XRSRn shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUFn is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTLn[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP_TXBUFn is written to by the host, the MCASP_XRSRCTLn[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the McASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_TXBUFn register has to be currently written. Once all requested MCASP_TXBUFn are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP_TXSTAT[5] XDATA bit is written to 0b1, or once MCASP_TXBUFn registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the AXEVT event is automatically generated on MCASPi_DREQ_TX line (if enabled in the MCASP_XEVTCTL register) to notify the DMA of the MCASP_TXBUFn empty status. An interrupt - MCASPi_IRQ_AXEVT can be also generated if the XDATA interrupt is enabled in the MCASP_EVTCTLX register (for details, see Section 24.6.4.12.1, *Transmit Data Ready Interrupt*).

For DMA requests, the McASP does not require that MCASP_TXSTAT be read between DMA events. This means that, even if MCASP_TXSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

Figure 24-128 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP interface clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the CPU can begin servicing the McASP by writing word C into the MCASP_TXBUFn (service time). The CPU must write word C into the MCASP_TXBUFn within the setup time required by the McASP (setup time).

The maximum service time (see Figure 24-128) can be calculated as:

Service Time = Time Slot – AXEVT Latency –Setup Time

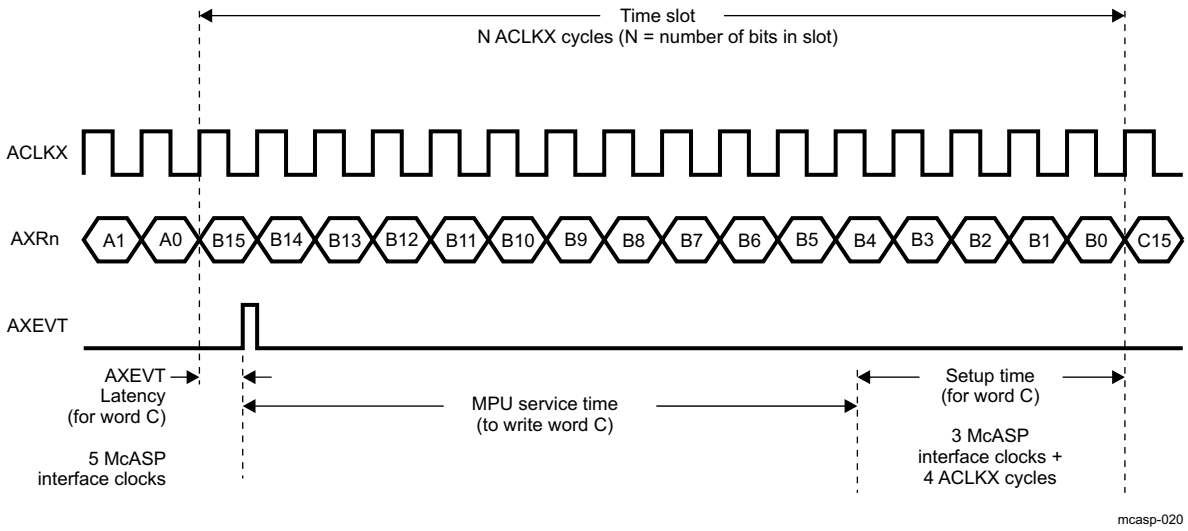

Figure 24-128. MPU Service Time Upon Transmit DMA Event (AXEVT)

24.6.4.10.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the MCASP_RXSTAT register reflects the data ready status of XRBUFn buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSRn to its corresponding XRBUFn data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer - RXBUFn already contains received data (i.e. a buffer is full) and is ready to transfer it to the host (MPU/DSP). The receive data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTLn [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP_RXBUFn is read from the host, the MCASP_XRSRCTLn [5] RRDY is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the McASP host (RDATA=0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_RXBUFn register has to be currently read. Once all requested MCASP_RXBUFn are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

The global RDATA flag can be cleared when the MCASP_RXSTAT[5] RDATA bit is written to 0b1, or once MCASP_RXBUFn registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA is set, the AREVT event is automatically generated on MCASPi_DREQ_RX line (if enabled in the MCASP_REVTCTL register) to notify the DMA of the MCASP_RXBUFn full status. An interrupt - MCASPi_IRQ_AREVT can be also generated if the RDATA interrupt is enabled in the MCASP_EVTCTLR register (for details, see Section 24.6.4.12.1, *Receive Data Ready Interrupt*).

Figure 24-129 shows the timing details of when AREVT event is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to five McASP interface clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the CPU can begin servicing the McASP by reading Word A from the MCASP_RXBUFn (service time). The CPU must read Word A from the MCASP_RXBUFn register no later than the setup time required by the McASP (Setup Time).

The maximum service time (see Figure 24-129) can be calculated as:
Service Time = Time Slot - AREVT Latency - Setup Time

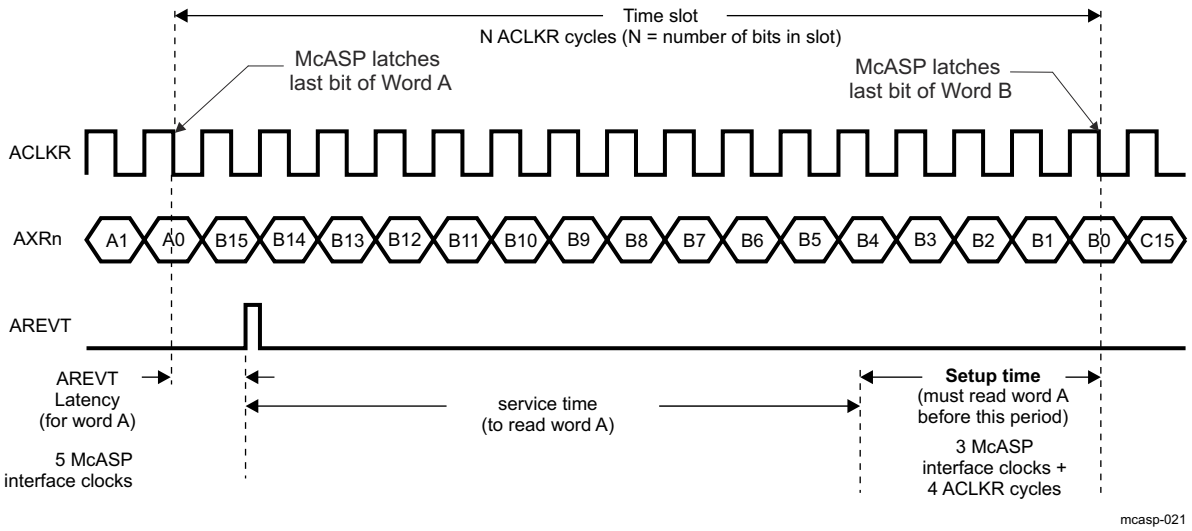

Figure 24-129. CPU Service Time Upon Receive Event (AREVT)

24.6.4.10.1.3 Transfers Through the Data Port (DATA)

CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the MCASP_TXFMT/MCASP_RXFMT register, respectively. Failure to do so may result in software malfunction.

Note

McASP1, McASP2, and McASP3, whose data ports are accessible directly via L3_MAIN, do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In a typical McASP transfer scenario, the DMA Controller write accesses the XRBUFn transmit buffer through the McASP data port (DATA) on L3_MAIN Interconect for McASP1/2/3 and on L4_PER2 Interconect for McASP4/5/6/7/8 . CPU hosts can access both XRBUFn transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the McASP Tx buffer through Interconect DATA port location. Refer to Section 24.6.6.2.5. Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in Section 24.6.4.11.

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in Section 24.6.6.2.5, the same physical DATA port address is used regardless of a read or write access is performed. The McASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

Note

DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the McASP configuration registers addressing their corresponding McASP DATA port.

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port adress) to service all of the active slot transmitting

serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See Section 24.6.6.2.5).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, the DMA/CPU should write to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

Note

For write transfers through McASP DATA port it is preferable to use DMA on corresponding Interconect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port adress) to service all of the active slot receiving serializers. Regardless of McASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See Section 24.6.6.2.5).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the MPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0,1 and 3 in this exact order, upon each receive data ready event.

Note

To service a serializer for a transmit or receive operation through the McASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to Section 24.6.6.2.5), respectively.

See Section 24.6.6.2.5, *McASP_DATA Register Summary*, for more details about XRBUFn buffer physical address corresponding to the McASP DATA port on:

- Main Interconect (L3_MAIN or L4_PER2)

Note

When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in MCASP_TXTDM) and *transmit* (Tx enabled in MCASP_XRSRCTLn) within each time slot. Failure to do so results in a buffer underrun condition (see Section 24.6.4.15.1, *Buffer Underrun Error - Transmitter*). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in MCASP_RXTDM) and *receive* (Rx enabled in MCASP_XRSRCTLn) within each time slot. Failure to do results in a buffer overrun condition (see Section 24.6.4.15.2, *Buffer Overrun Error - Receiver*).

24.6.4.10.1.4 Transfers Through the Configuration Bus (CFG)

CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the MCASP_TXFMT/MCASP_RXFMT registers, respectively. Failure to do so may result in software malfunction.

Note

McASP1, McASP2, and McASP3, whose data ports are accessible directly via L3_MAIN do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In this method, the DMA/CPU accesses the XRBUFn transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUFn transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of McASP CFG port actual for L4_PER2 accesses. The XRBUFn buffer of the n-th serializer configured as a transmitter is aliased - MCASP_TXBUFn in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the MCASP_TXBUF2 register. Similarly, the XRBUFn buffer of the n-th serializer configured as a receiver is aliased - MCASP_RXBUFn in the CFG port address space. For example, the XRBUF3 receive buffer is mapped as the MCASP_RXBUF3 register.

Accessing the XRBUF through the DATA port (see Section 24.6.4.10.1.3) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index , while accessing through the peripheral configuration port - CFG, the DMA/CPU must provide the exact MCASP_TXBUFn or MCASP_RXBUFn address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP_TXBUFn and MCASP_RXBUFn addresses corresponding to McASP CFG port, see Section 24.6.6.2.1, *MCASP_CFG Register Summary*.

24.6.4.10.1.5 Using a Device CPU for McASP Servicing

The device CPUs can be used to service the McASP transmit channels through interrupts (upon MCASPi_IRQ_AXEVT and MCASPi_IRQ_AREVT interrupts). Because these interrupt events are connected to device IRQ_CROSSBAR module, they could be software mapped to input IRQ lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP_TXSTAT register and RDATA bit in the MCASP_RXSTAT register can be performed by device CPUs, respectively. As discussed in Section 24.6.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 24.6.4.10.1.4, *Transfers Through the Configuration Bus (CFG)* , the device CPUs can access McASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the device CPUs to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective MCASP_EVTCTLX/MCASP_EVTCTLR registers, to generate interrupts MCASPi_IRQ_AXEVT/ MCASPi_IRQ_AREVT to the device CPUs upon data ready

24.6.4.10.1.6 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP transmit and receive logic through the DATA port, although the DMA can also service the McASP through the configuration bus (CFG). The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see Figure 24-119). The data transfer is managed by the AFIFO according to generated transmit and receive events in the McASP and data is fed to transmit buffers and fetched from receive buffers as described in Section 24.6.4.11. The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from McASP module, these events are collected in AFIFO and on specific AFIFO conditions described in Section 24.6.4.11 the requests (transmit or receive) are forwarded to a DMA controller via MCASPi_DREQ_TX and MCASPi_DREQ_RX outputs. If the AFIFO is disabled (default state) it is transperrant for the McASP module and all request are directly sent to the DMA controller.

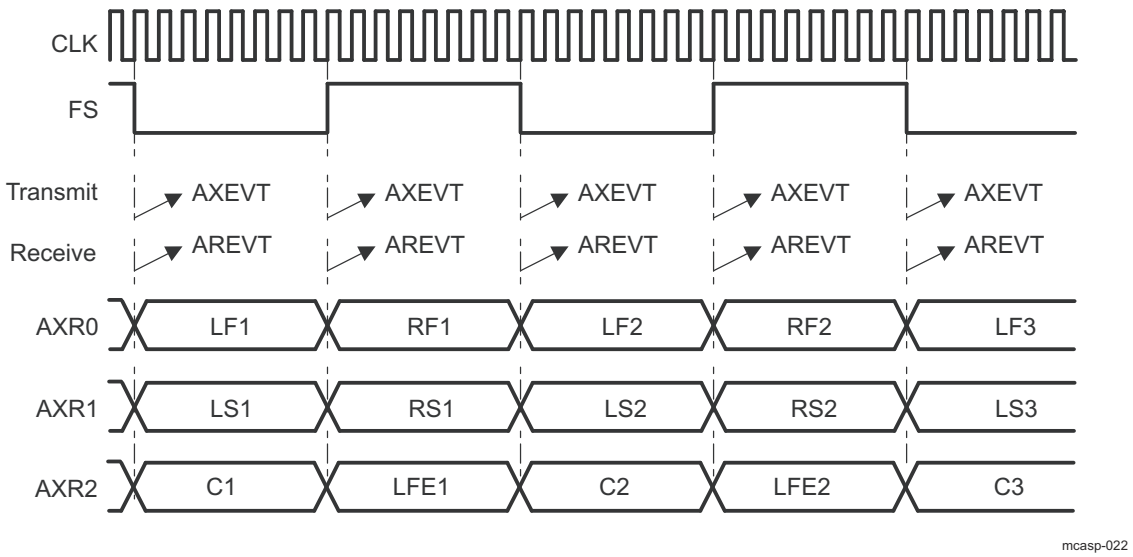

Figure 24-130. DMA Transmit and Receive Event in an Audio Example – One Event

In transmit mode, the DMA event - AXEVT (MCASPi_DREQ_TX output), which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP TXBUFn transmit buffers. In receive mode, the DMA event AREVT (MCASPi_DREQ_RX output) which is triggered upon each RDATA transition from 0 to 1, is used to service the McASP RXBUFn receive buffers.

Figure 24-130 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the McASP signals - AXR0, AXR1 and AXR2. It shows the points at which events AXEVT/AREVT are triggered.

In Figure 24-130, a Tx DMA event AXEVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP_XEVTCTL register. Similarly, Rx DMA event AREVT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP_REVTCTL register.

24.6.4.11 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 24-131 for a high-level block diagram of the AFIFO. The AFIFO may be enabled/disabled and configured via the WFIFOCTL and RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP.

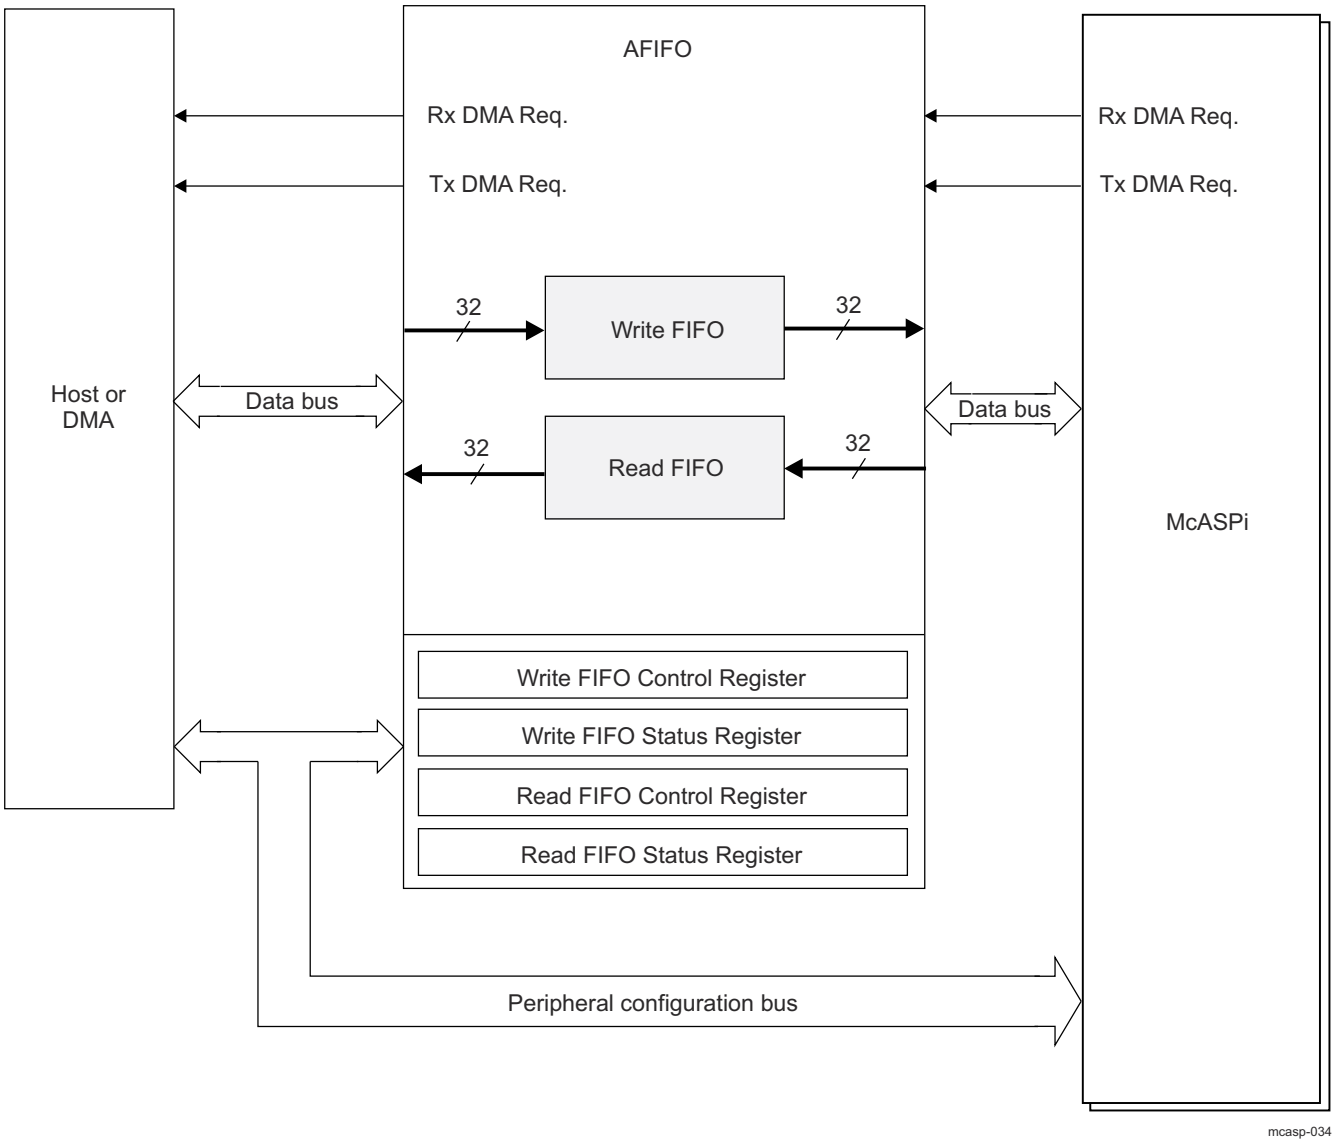

Figure 24-131. McASP Audio FIFO (AFIFO) Block Diagram

24.6.4.11.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes WNUMDMA 32-bit words to the McASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the McASP. (See description for WFIFOCTL[7:0] WNUMDMA.) If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

24.6.4.11.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the

host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, WFIFOCTL[15:8] WNUMEVT should be set to a non-zero integer multiple of the value in WFIFOCTL[7:0] WNUMDMA. If transmit DMA event pacing is not desired, then the value in WFIFOCTL[15:8] WNUMEVT should be set equal to the value in WFIFOCTL[7:0] WNUMDMA.

24.6.4.11.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP. When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the McASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the McASP. (See description for RFIFOCTL[7:0] RNUMDMA.) If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than RNUMEVT words, those words will be read correctly, emptying the FIFO.

24.6.4.11.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least RNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once RNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another RNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, RFIFOCTL[15:8] RNUMEVT should be set to a non-zero integer multiple of the value in RFIFOCTL[7:0] RNUMDMA. If receive DMA event pacing is not desired, then the value in RFIFOCTL[15:8] RNUMEVT should be set equal to the value in RFIFOCTL[7:0] RNUMDMA.

24.6.4.11.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

24.6.4.12 McASP Events and Interrupt Requests

Table 24-336 lists all the transmit event flags. Table 24-337 lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any McASPi serializer configured as transmitter or receiver respectivly.

Table 24-336. TX Events

Event Mask[2]	Event Flag	Map to [1]	Description
MCASP_EVTCTLX[0] XUNDRN	MCASP_TXSTAT[0] XUNDRN	MCASPi_IRQ_AXEVT	Transmit buffer underrun
MCASP_EVTCTLX[1] XSYNCERR	MCASP_TXSTAT[1] XSYNCERR	MCASPi_IRQ_AXEVT	Unexpected transmit frame sync
MCASP_EVTCTLX[2] XCKFAIL	MCASP_TXSTAT[2] XCKFAIL	MCASPi_IRQ_AXEVT	Transmit clock failure
MCASP_EVTCTLX[3] XDMAERR	MCASP_TXSTAT[7] XDMAERR	MCASPi_IRQ_AXEVT	DATA port transmit error
MCASP_EVTCTLX[4] XLAST	MCASP_TXSTAT[4] XLAST	MCASPi_IRQ_AXEVT	Transmit last slot interrupt
MCASP_EVTCTLX[5] XDATA	MCASP_TXSTAT[5] XDATA	MCASPi_IRQ_AXEVT	Transmit data-ready interrupt
MCASP_EVTCTLX[7] XSTAFRM	MCASP_TXSTAT[6] XSTAFRM	MCASPi_IRQ_AXEVT	Transmit start of frame interrupt

Table 24-336. TX Events (continued)

Event Mask(2)	Event Flag	Map to (1)	Description
n.a.	MCASP_TXSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR | XCKFAIL | XUNDRN | XSYNCERR). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_TXSTAT[3] XTDMSLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every McASPi module generates separate IRQ event.
(2) Global events for all transmitting serializers in a single McASPi module.

Table 24-337. RX Events

Event Mask(2)	Event Flag	Map to(1)	Description
MCASP_EVTCTLR[0] ROVRN	MCASP_RXSTAT[0] ROVRN	MCASPi_IRQ_AREVT	Receive buffer overrun
MCASP_EVTCTLR[1] RSYNCERR	MCASP_RXSTAT[1] RSYNCERR	MCASPi_IRQ_AREVT	Unexpected receive frame sync
MCASP_EVTCTLR[2] RCKFAIL	MCASP_RXSTAT[2] RCKFAIL	MCASPi_IRQ_AREVT	Receive clock failure
MCASP_EVTCTLR[3] RDMAERR	MCASP_RXSTAT[7] RDMAERR	MCASPi_IRQ_AREVT	DATA port receive error
MCASP_EVTCTLR[4] RLAST	MCASP_RXSTAT[4] RLAST	MCASPi_IRQ_AREVT	Receive last slot
MCASP_EVTCTLR[5] RDATA	MCASP_RXSTAT[5] RDATA	MCASPi_IRQ_AREVT	Receive data-ready
MCASP_EVTCTLR[7] RSTAFRM	MCASP_RXSTAT[6] RSTAFRM	MCASPi_IRQ_AREVT	Receive start of frame
n.a.	MCASP_RXSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR | RCKFAIL | ROVRN | RSYNCERR). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RXSTAT[3] RTDMSLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every McASP module generates separate IRQ event.
(2) Global events for all receiving serializers in a single McASPi module. These events and masks are available in same format for every McASPi module

Software has to read the MCASP_TXSTAT/MCASP_RXSTAT register to determine which event occurs at a global level for McASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the MCASP_XRSRCTLn registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASPi_IRQ_AXEVT) is asserted (active high) when one of the MCASP_TXSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_EVTCTLX bit. Similarly, a Rx interrupt line (MCASPi_IRQ_AREVT) is asserted (active high) when one of MCASP_RXSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_EVTCTLR bit. See also Section 24.6.4.12.4, *Multiple Interrupts* and the Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation*.

24.6.4.12.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the MCASP_TXSTAT register and XDATA is enabled in MCASP_EVTCTLX. The Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when XDATA is set in the MCASP_TXSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

24.6.4.12.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if RDATA is 1 in the MCASP_RXSTAT register and RDATA is enabled in MCASP_EVTCTLR. The Section 24.6.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when RDATA flag is set in the MCASP_RXSTAT register.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

24.6.4.12.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP_TXSTAT):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP_EVTCTLX). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_TXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP_RXSTAT) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (MCASP_EVTCTLR). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_RXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

24.6.4.12.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in MCASP_TXSTAT is set and the interrupt is enabled in MCASP_EVTCTLX.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP_TXSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in MCASP_TXSTAT/ MCASP_RXSTAT and the interrupt enabled in MCASP_EVTCTLX/MCASP_EVTCTLR generates a request on the McASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to MCASP_TXSTAT/MCASP_RXSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

24.6.4.13 DMA Requests

The McASP can generate one DMA request to the DMA_CROSSBAR to transmit (MCASPi_DREQ_TX) or receive (MCASPi_DREQ_RX) data. A DMA request to transmit data is generated if the XDATDMA bit in the

MCASP_XEVTCTL register is cleared. A DMA request to receive data is generated if the RDATDMA bit in the MCASP_REVTCTL register is cleared.

24.6.4.14 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between McASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

Figure 24-132shows the basic logical connection of the serializers in loopback mode.

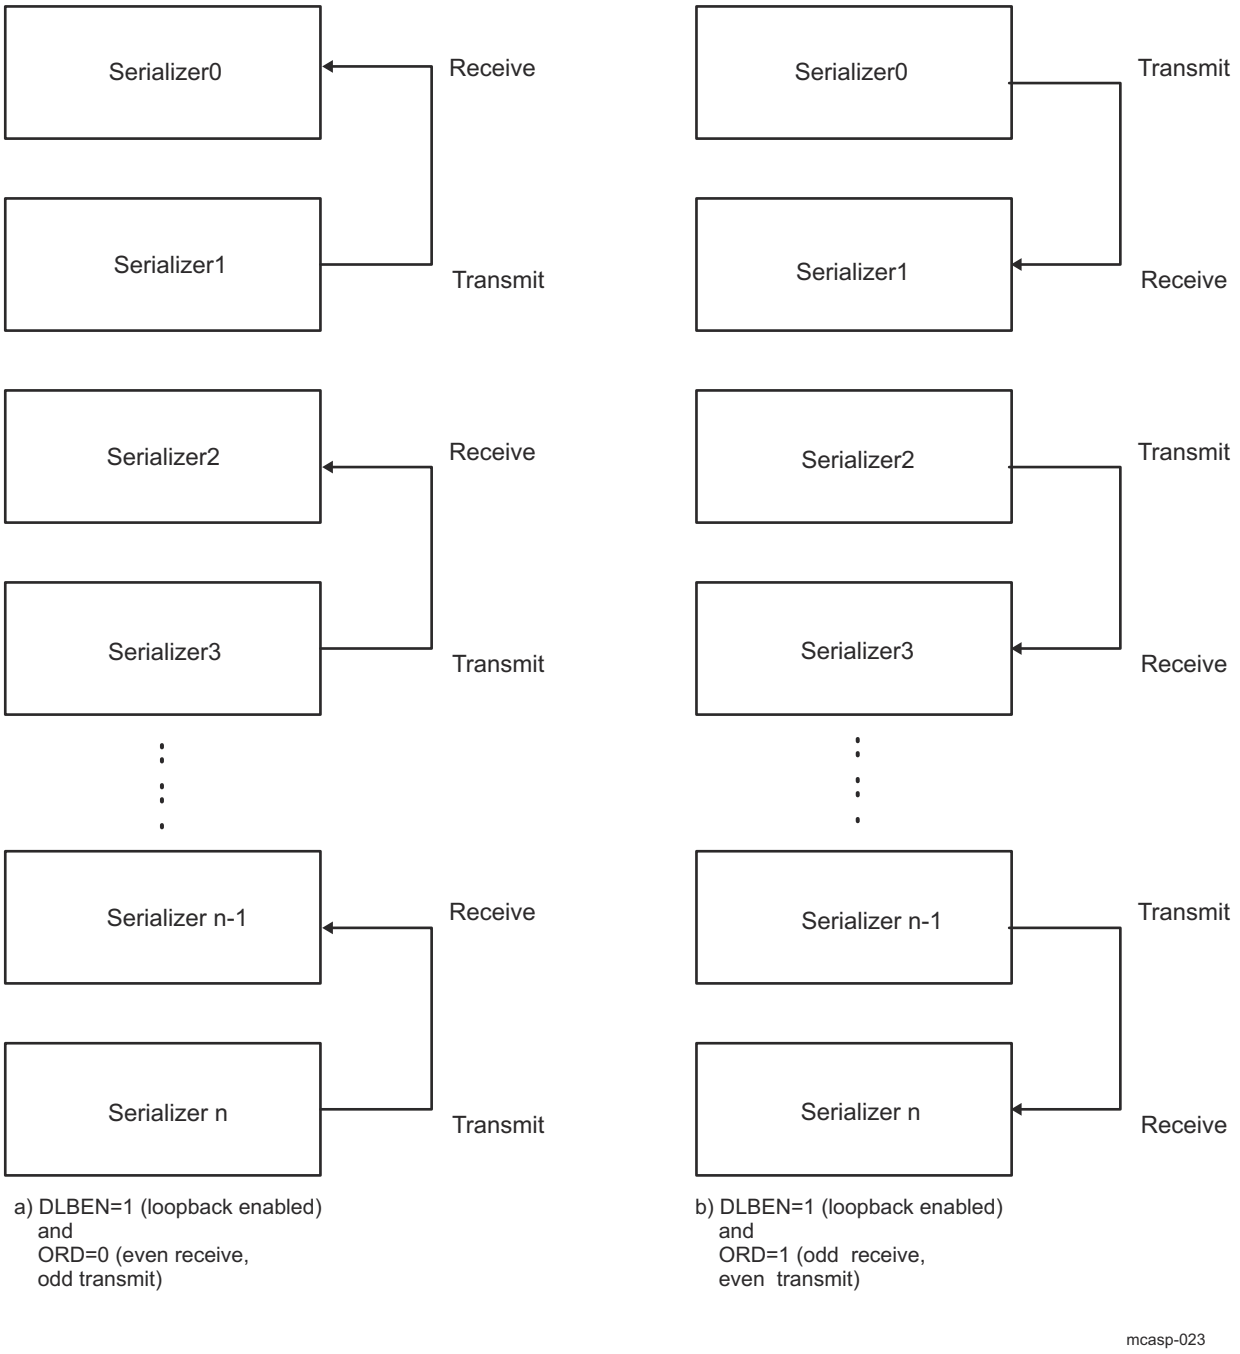

Figure 24-132. McASP Serializers Operation in Loopback Mode

Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - MCASP_LBCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (bit IOLBEN of the MCASP_LBCTL) between a McASP module internal loopback and a device I/O level loopback.

When a **McASP internal loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b0), it is NOT necessary to configure MCASP_PFUNC and MCASP_PDIR registers for McASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a McASP output pin by setting the corresponding MCASP_PFUNC bit to 0 (i.e. to function as McASP, not GPIO) and MCASP_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b1), the MCASP_PFUNC and MCASP_PDIR registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (i.e. reaching device I/O buffers).

Hence, the corresponding padconfiguration registers must be appropriately configured in the device Control Module - CTRL_MODULE_CORE_PAD. For more details, see *Pad Configuration Rregisters*, in *Control Module*.

When In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bitfield of the MCASP_LBCTL register to 0x1 and the ASYNC bit of the MCASP_ACLKXCTL register to 0b0.

24.6.4.14.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The MCASP_LBCTL[0] DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal McASP operation.
- The MCASP_LBCTL[4] IOLBEN bit must be set to select between internal (McASP local) loopback mode or device I/O level loopback mode.
- The MCASP_LBCTL[3:2] MODE bitfield must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP_LBCTL[1] ORD must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The bit - MCASP_ACLKXCTL[6] ASYNC must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The bitfields - MCASP_RXFMCTL[15:7] RMOD and MCASP_TXFMCTL[15:7] XMOD must be set within range (0x2- 0x20) to indicate TDM mode.

Note

Loopback mode does not apply to DIT or burst mode, because McASP receivers do NOT natively support DIR - reception.

24.6.4.15 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

24.6.4.15.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUFn buffer to XRSRn shift register, but the corresponding (MCASP_TXBUFn) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP_TXSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

24.6.4.15.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding MCASP_RXBUFn register has not yet been read since the last time the transfer occured. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The MCASP_RXSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

24.6.4.15.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the XDMAERR flag in the MCASP_TXSTAT register, occurs when the DMA or device CPU writes more words to the DATA port of the McASP than it should.

The MCASP_TXSTAT[7] XDMAERR=0b1 indicates that the DMA or device CPU wrote too many words to the McASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in MCASP_TXSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

24.6.4.15.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the RDMAERR flag in the MCASP_RXSTAT register, occurs when the DMA or device CPU reads more words from the DATA port of the McASP than it should.

The MCASP_RXSTAT[7] RDMAERR indicates that the DMA or device CPU read too many words from the McASP DATA port for a given receive AREVT event. Reading too few words results in a receiver overrun error setting ROVRN in MCASP_RXSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or device CPU. The McASP receiver and the DMA must be reinitialized to resynchronize them.

24.6.4.15.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
   - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
   - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

24.6.4.15.6 Clock Failure Detection

24.6.4.15.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP_TXCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP_TXSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
   a. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP_EVTCTLX)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP_RXCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP_RXSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
   a. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register (MCASP_EVTCTLR)

24.6.4.15.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see Figure 24-133) works off the internal McASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (MCASP_TXCLKCHK) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in MCASP_TXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the

external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in MCASP_TXSTAT is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in MCASP_EVTCTLX is set.

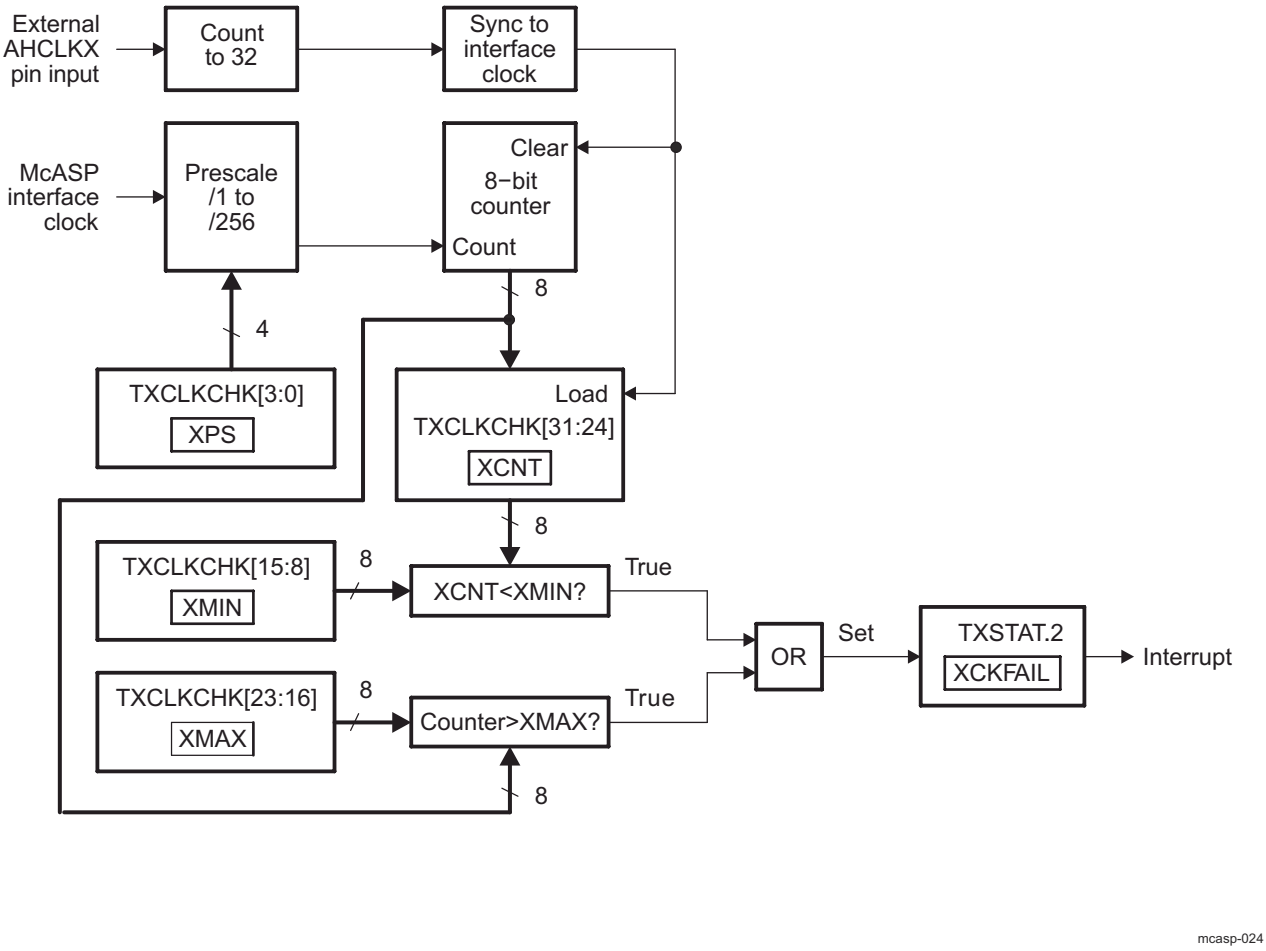

Figure 24-133. Transmit Clock Failure Detection Circuit Block Diagram

24.6.4.15.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (see Figure 24-134) works off both the internal McASP interface clock and the high-frequency serial clock (AHCLKR) coming from the device clock generator. It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP_RXCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (RCKFAIL in MCASP_RXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum

condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

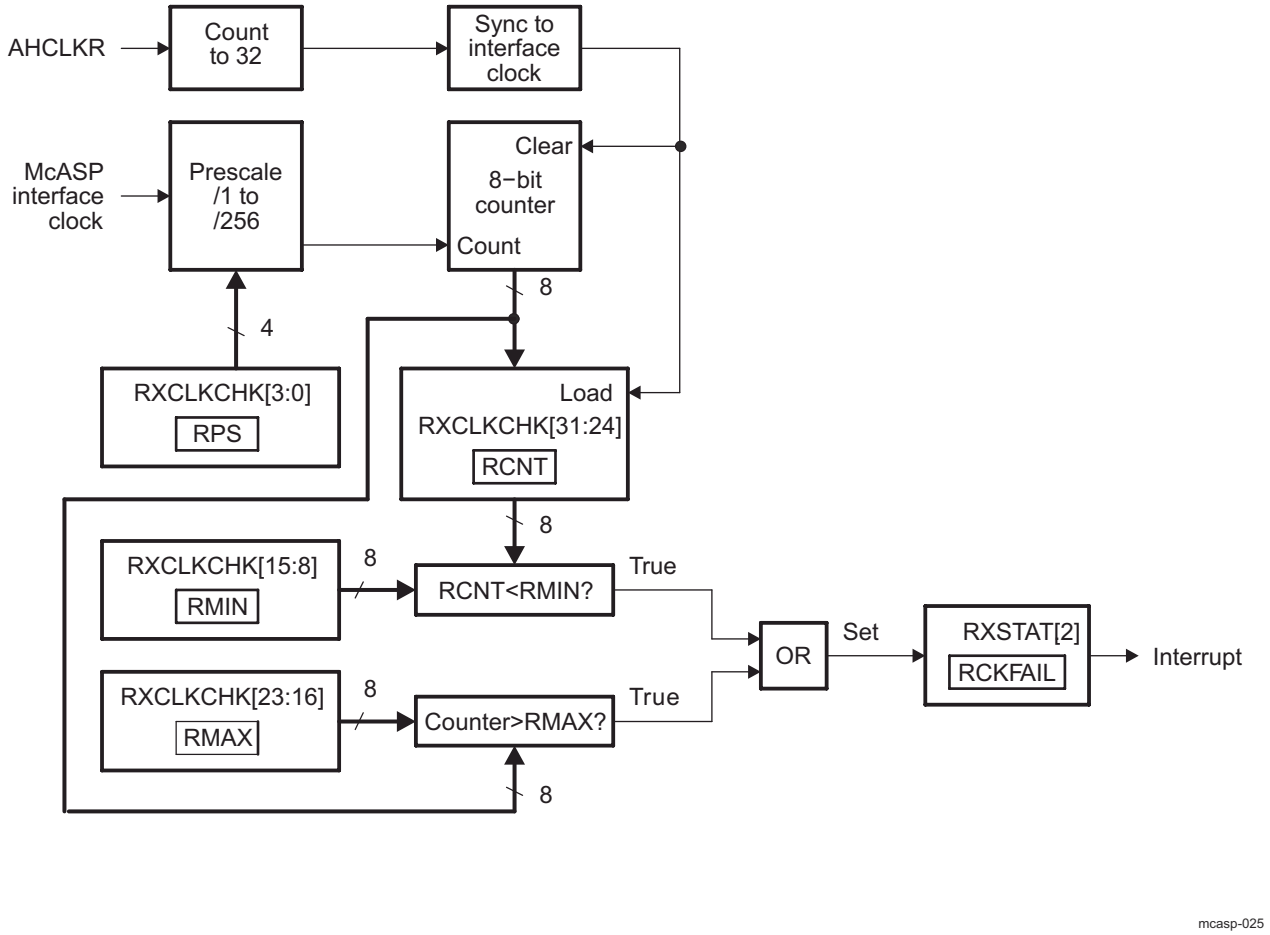

Figure 24-134. Receive Clock Failure Detection Circuit Block Diagram

24.6.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

24.6.5.1 Global Initialization

24.6.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see *McASP Integration*, and *McASP Environment*).

Table 24-338, describes the global initialization of surrounding modules.

Table 24-338. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See *Pad Configuration Registers*, in *Control Module*).
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to enable the interrupts from the McASP. For more details on IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
(Optional) DMA_CROSSBAR	DMA configuration must be done to enable the McASP DMA data channel requests. For more information on DMA_CROSSBAR module configuration, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
(Optional) L4_PER2 and L3_MAIN Interconnects	For more information about the interconnect configuration, see *L3_MAIN Interconnect Overview* in *L3 Interconnect*.

Note

The IRQ_CROSSBAR and the DMA_CROSSBAR configurations are required when the interrupt and DMA-based communication modes are used. Further initialization of the selected IRQ and DMA controllers of the host CPU must be done for full functionality of the McASP DMA and IRQ lines.

24.6.5.1.2 McASP Global Initialization

24.6.5.1.2.1 Main Sequence – McASP Global Initialization for DIT-Transmission

The procedure in Table 24-339 initializes the McASP serializers transmitters to operate in DIT-mode (S/PDIF-transmission protocol) after a power-on reset (POR).

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 24-339. McASP Transmitters Global Initialization for DIT-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 24.6.5.1.2.1.1.	
5. Configure the transmit frame sync generator.	See Section 24.6.5.1.2.1.2.	
6. Configure the transmit clock generator.	See Section 24.6.5.1.2.1.3.	

Table 24-339. McASP Transmitters Global Initialization for DIT-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
7. Configure the TDM sequencer—set all slots active.	MCASP_TXTDM[31:0] XTDMS	0xFFFF FFFF
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. (3)	MCASP_XRSRCTLn [1:0] SRMOD	0x1
9. Configure the McASP pins functionality.	See Section 24.6.5.1.2.1.4.	
10. Enable the McASP DIT - transmission mode.	MCASP_TXDITCTL[0] DITEN	0x1(2)
11. Configure DIT-specific subframe fields.	See Table 24-344.	
12. Release from reset state the divider that outputs the AHCLKX clock.(1)	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKX clock. (1)	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKXCTL and MCASP_ACLKXCT registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.
(2) This globally configures all active transmitters to operate in DIT-mode.
(3) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

24.6.5.1.2.1.1 Subsequence – Transmit Format Unit Configuration for DIT-Transmission

The procedure in Table 24-340 configures the transmit frame format unit of the McASP module for a DIT-transmission.

Note

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

Table 24-340. Transmit Format Unit Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_TXFMT[7:4] XSSZ	0xF
IF: the data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_TXMASK[31:0] XMASK	0x-(1)
Rotate data right by a multiple-of-4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- (1)
ELSE		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_TXMASK[31:0] XMASK	0x-(1)
Rotate data right by 0-bit positions.	MCASP_TXFMT[2:0] XROT	0x0
ENDIF		
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

(1) Refer to Section 24.6.4.4.1, *Transmit Fromat Unit* and Section 24.6.4.4.1.2, *DIT-Mode Transmission Data Alignment Settings.*

24.6.5.1.2.1.2 Subsequence – Transmit Frame Synchronization Generator Configuration for DIT-Transmission

The procedure in Table 24-341 configures the transmit frame synchronization generator of the McASP module.

Note

The frame synchronization signal is always rising-edge active and always has a single-bit width.

Table 24-341. Transmit Frame-Synchronization Generator Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_TXFMCTL[15:7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_TXFMCTL[1] FSXM	0x1

24.6.5.1.2.1.3 Subsequence – Transmit Clock Generator Configuration for DIT-Transmission

Note

By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in Table 24-342 configures the transmit clock generator of the McASP module.

Table 24-342. Transmit Clock Generator Configuration in DIT-Mode

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– AHCLKX.	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Set he divisor for the internally generated transmission clock– ACLKX.	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See Section 24.6.4.15.6.1, *Clock Failure Check Startup*.	

24.6.5.1.2.1.4 Subsequence - McASP Pins Functional Configuration

The procedure in Table 24-343 configures the McASP pins for McASP functionality.

Table 24-343. McASP Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins as outputs: AFSX AHCLKX ACLKX Desired i-th McASP data pin AXRi is configured as an output for DIT-transmission.	MCASP_PDIR[28] AFSX; MCASP_PDIR[27] AHCLKX; MCASP_PDIR[26] ACLKX; MCASP_PDIR [i] AXRi	0x1 0x1 0x1 0x1

24.6.5.1.2.1.5 Subsequence – DIT-specific Subframe Fields Configuration

The procedure in Table 24-344 configures the DIT-specific subframe fields as part of the S/PDIF format data.

Table 24-344. DIT-Specific Subframe Fields Configuration

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_TXDITCTL[3] VB	0x-
Configure the valid bit value for even time slots.	MCASP_TXDITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5 MCASP_DITUDRBi[31:0] DITUDRBi, where i = 0 to 5	0x- 0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRAi[31:0], where i = 0 to 5 MCASP_DITCSRBi[31:0], where i = 0 to 5	0x- 0x-

24.6.5.1.2.2 Main Sequence – McASP Global Initialization for TDM-Reception

The procedure in Table 24-345 initializes a McASP serializer n receiver(s) to operate in TDM-mode (the only mode supported by McASP receivers) after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols reception.

CAUTION

Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Note

The McASP receivers support only TDM-frames (including 384-TDM frames) reception. DIT-frames reception (i.e. S/PDIF stream) can be implemented indirectly via an external DIR-chip converter with DIT-input and TDM (I2S)-compatible output connected to device McASP receiver input (TDM-only compatible).

Table 24-345. McASP Receivers Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP receive components.	MCASP_GBLCTL[4:0]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[4:0]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the receive format unit.	See Section 24.6.5.1.2.2.1.	
5. Configure the receive frame sync generator.	See Section 24.6.5.1.2.2.2.	
6. Configure the receive clock generator.	See Section 24.6.5.1.2.2.3.	
7. Program all bits -RTDMSk (where k=0 to 31) according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_RXTDM [k] RTDMSk , where k=0 to 31	0x-
8. Configure the desired n-th serializer for receive mode operation. (4)	MCASP_XRSRCTLn [1:0] SRMOD	0x2
9. Configure the McASP pins functionality.	See Section 24.6.5.1.2.2.4.	
10. Optional: Configure a McASP Rx channel for a loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 24.6.4.14.1, *Loopback Mode Configurations*.	0x-(5)
11. Release from reset state the divider that outputs the AHCLKR clock.(1) See also (2).	MCASP_GBLCTL[1] RHCLKRST	0x1
12. Poll the bit to ensure that it is successfully latched in the register. See also (2).	MCASP_GBLCTL[1] RHCLKRST	=0x1
13. Release from reset state the divider that outputs the ACLKR clock. (1) See also (3).	MCASP_GBLCTL[0] RCLKRST	0x1
14. Poll the bit to ensure that it is successfully latched in the register. See also (3).	MCASP_GBLCTL[0] RCLKRST	=0x1

(1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKRCTL and MCASP_ACLKRCTL registers are ignored; hence, the reception clock does not stop during the reset state of the dividers.
(2) This step is necessary even if external high-frequency serial clocks are used.
(3) This step can be skipped if external serial clocks are used and they are running.
(4) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

(5) In this case the receiver clock and frame sync are derived from the McASP transmitter logic, so MCASP_ACLKXCTL[6] ASYNC must be set to 0b0. Neither McASP internal receiver clock and frame sync generators, nor external clock and frame sync source are used.

24.6.5.1.2.2.1 Subsequence – Receive Format Unit Configuration in TDM Mode

The procedure in Table 24-346 configures the receive frame format unit of the McASP module for TDM slots reception.

Table 24-346. Receive Format Unit Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_RXFMT[7:4] RSSZ	0x-(1)
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_RXMASK[31:0] RMASK	0x-(2)
Select a padding value for masked-out bits.	MCASP_RXFMT[14:13] RPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_RXBUFn which value to be used as a pad value in case MCASP_RXFMT[14:13] RPAD=0x2.	MCASP_RXFMT[12:8] RPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_RXFMT[2:0] RROT	0x- (3)
Received stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream reception (MSB-first).	MCASP_RXFMT[15] RRVRS	0x- (3)
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream reception.	MCASP_RXFMT[17:16] RDATDLY	0x-
Select to read data from active serializers receive buffers using peripheral (CFG) or DATA port	MCASP_RXFMT[3] RBUSEL	0x-

(1) Refer to Section 24.6.4.4.2, *Receive Format Unit*, regarding options for received TDM-slot sizes.
(2) For more details on Rx masking value, refer to Section 24.6.4.4.2.1, *TDM - Mode Reception Data Alignment Settings*
(3) For more details on rotation and received TDM stream bit order, refer to Section 24.6.4.4.2.1, *TDM - Mode Reception Data Alignment Settings* and Table 24-333, *McASP RFU Settings*.

24.6.5.1.2.2.2 Subsequence – Receive Frame Synchronization Generator Configuration in TDM Mode

The procedure in Table 24-347 configures the transmit frame synchronization generator of the McASP module.

Note

The same bit - MCASP_ACLKXCTL[6] ASYNC which is used to determine if McASP receivers and transmitters work synchronously on the same clock, is also used to define if receiver frame sync is derived from the transmit frame sync generator, or generated independently in the receiver (either inernally or externally sourced). Hence, the settings in below table Table 24-347 have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0.

Table 24-347. Receive Frame-Synchronization Generator Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame. Must be set to 0x2, in case of an I2S-reception. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[15:7] RMOD	0x-(1)
Choose the receive frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[4] FRWID	0x-
Select start of received frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[0] FSRP	0x-
IFreceive frame sync - FS is internally generated	Software test condition	

Table 24-347. Receive Frame-Synchronization Generator Configuration for TDM-Reception (continued)

Step	Register/Bit Field/Programming Model	Value
Select internally- generated receive frame sync. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[1] FSRM	0b1
If McASP receiver is required to output internally generated frame, AFSR pin must be set as an output in step 9 of the sequence documented in the Table 24-345. This must not be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSR pin outputting a frame to an external device.	MCASP_PDIR[31] AFSR	0b1
ELSE		
Select externally- generated receive frame sync. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_RXFMCTL[1] FSRM	0b0
Setup the AFSR pin as input (device level: mcaspi_fsr)	MCASP_PDIR[31] AFSR	0b0
ENDIF		
To generate McASP receive frame sync in receiver logic, select an asynchronous frame sync.	MCASP_ACLKXCTL[6] ASYNC	0b1

(1) Must be set to 0x180 in case of 384-TDM slot frame reception from a DIR component I2S-output. For more details on TDM-frame settings, refer to Section 24.6.4.9.2 .

24.6.5.1.2.2.3 Subsequence – Receive Clock Generator Configuration

The procedure in Table 24-348 configures the receive clock generator of the McASP module.

Note

The settings in below table Table 24-348 have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0 (i.e. receive clock is sourced from the inverted version of the transmit clock). For example, such is the case when McASP loopback mode is used.

Table 24-348. Receive Clock Generator Configuration

Step	Register/Bit Field/Programming Model	Value
To use the McASP receive clock generator, select an asynchronous receiver clock schema (ASYNC=1). Otherwise an inverted version of transmit clock XCLK is used (receiver synchronized with transmitter).	MCASP_ACLKXCTL[6] ASYNC	0b1
IF receive clock - RCLK is internally generated	Software test condition	
The high-speed receive clock - AHCLKR is internally generated based on AUXCLK		
Select an internally-generated high-frequency clock.	MCASP_AHCLKRCTL[15] HCLKRM	0b1
Select the internal high-speed clock source polarity: non-inverted or inverted.	MCASP_AHCLKRCTL[14] HCLKRP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKR in range (1 - 4096).	MCASP_AHCLKRCTL[11:0] HCLKRDIV	0x-
Select an internally-generated receive clock.	MCASP_ACLKRCTL[5] CLKRM	0b1
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Set the divisor for the internally generated receive clock– ACLKR in range (1 - 32).	MCASP_ACLKRCTL[4:0] CLKRDIV	0x-

Table 24-348. Receive Clock Generator Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Optional: If McASP receiver is required to output internally generated clock, ACLKR pin must be set as an output in step 9 of the sequence documented in the Table 24-345. This must not be done in current step because the clock control register - MCASP_ACLKRCTL must be appropriately configured prior to ACLKR pin outputting a receive clock to an external device.	MCASP_PDIR[29] ACLKR	0b1
ELSE		
Select an externally-generated receive clock. Note that in this case the AHCLKR signal path and the CLKRDIV divider are NOT used.	MCASP_ACLKRCTL[5] CLKRM	0b0
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Setup an input directon for the ACLKR pin	MCASP_PDIR[29] ACLKR	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 24.6.4.15.6.1, *Clock Failure Check Startup*.	

24.6.5.1.2.2.4 Subsequence—McASP Receiver Pins Functional Configuration

The procedure in Table 24-349 configures the McASP pins for McASP functionality.

Table 24-349. McASP Receiver Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSR ACLKR Desired n-th McASP data pin AXRn is configured as an input for receiving.	MCASP_PDIR[31] AFSR; MCASP_PDIR[29] ACLKR; MCASP_PDIR[n] AXRn;	0x-(1) 0x- (2) 0x0

(1) See Table 24-347.
(2) For more details on McASP clock configurations, refer to Table 24-348.

24.6.5.1.2.3 Main Sequence – McASP Global Initialization for TDM -Transmission

The procedure in Table 24-350 initializes a McASP serializer n transmitter(s) to operate in TDM-mode after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols transmission.

> **CAUTION**
>
> Before performing McASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 24-350. McASP Transmitters Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different McASP transmit components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	PWRIDLESYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 24.6.5.1.2.3.1.	
5. Configure the transmit frame sync generator.	See Section 24.6.5.1.2.3.2.	

Table 24-350. McASP Transmitters Global Initialization for TDM-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
6. Configure the transmit clock generator.	See Section 24.6.5.1.2.3.3.	
7. Program all bits - XTDMSk, where k=0 to 31, according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_TXTDM [k] XTDMSk, where k=0 to 31(4)	0x-
8. Configure the desired n-th serializer for transmit mode operation. (3)	MCASP_XRSRCTLn[1:0] SRMOD;	0x1
9. Setup all active transmitters to operate in TDM mode.	MCASP_TXDITCTL[0] DITEN	0x0(2)
10. Configure the McASP pins functionality.	See Section 24.6.5.1.2.3.4.	
11. Optional: Configure a McASP Tx channel for loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 24.6.4.14.1, *Loopback Mode Configurations*.	0x-
12. Release from reset state the divider that outputs the AHCLKR clock. See (1)	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKR clock. See (1)	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKX and MCASP_ACLKX registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.
(2) All active transmit channels operate either in TDM mode or in DIT mode depending on DITEN value. There is no option to choose Tx Mode between DIT and TDM separately per serializer transmitter.
(3) For an unused serializer n, write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.
(4) Appropriately program in bitfield MCASP_XRSRCTLn [3:2] DISMOD, the desired level (high-impedance state, 0, or 1) at AXRn output, during time of inactive slots. Note, that this setting does NOT apply when all slots are programmed to be active within a frame (in particular DIT-mode).

24.6.5.1.2.3.1 Subsequence – Transmit Format Unit Configuration in TDM Mode

The procedure in Table 24-351 configures the transmit frame format unit of the McASP module for TDM slots transmission.

Table 24-351. Transmit Format Unit Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_TXFMT[7:4] XSSZ	0x-(1)
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_TXMASK[31:0] XMASK	0x-(2)
Select a padding value for masked-out bits.	MCASP_TXFMT[14:13] XPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_TXBUFn which value to be used as a pad value in case MCASP_TXFMT[14:13] XPAD=0x2.	MCASP_TXFMT[12:8] XPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- (3)
transmitted stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream transmission (MSB-first).	MCASP_TXFMT[15] XRVRS	0x- (3)
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream transmission.	MCASP_TXFMT[17:16] XDATDLY	0x-
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

(1) Refer to Section 24.6.4.4.1, *Transmit Format Unit* , regarding options for transmitted TDM-slot sizes.

(2) For more details on Tx masking value, refer to Section 24.6.4.4.1.1, *TDM - Mode Transmission Data Alignment Settings*
(3) For more details on rotation and transmitd TDM stream bit order, refer to Section 24.6.4.4.1.1, *TDM - Mode Transmission Data Alignment Settings* and Table 24-331, *McASP TFU TDM Mode Settings*.

24.6.5.1.2.3.2 Subsequence – Transmit Frame Synchronization Generator Configuration in TDM Mode

The procedure in Table 24-352 configures the transmit frame synchronization generator of the McASP module.

Table 24-352. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame (2 - 32). Must be set to 0x2, in case of an I2S-transmission. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[15:7] XMOD	0x-
Choose the transmit frame sync width -single bit/single word. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[4] FXWID	0x-
Select start of transmit frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[0] FSXP	0x-
IF transmit frame sync - FS is internally generated	Software test condition	
Select internally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[1] FSXM	0b1
If McASP transmitter is required to output internally generated frame, AFSX pin must be set as an output in step 10 of the sequence documented in the Table 24-350. This must NOT be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSX pin outputting a frame sync to an external device.	MCASP_PDIR[28] AFSX	0b1
ELSE		
Select externally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 24.6.4.2.3.	MCASP_TXFMCTL[1] FSXM	0b0
Setup the AFSX pin as input	MCASP_PDIR[28] AFSX	0b0

24.6.5.1.2.3.3 Subsequence – Transmit Clock Generator Configuration for TDM Cases

The procedure in Table 24-353 configures the transmit clock generator of the McASP module.

Table 24-353. Transmit Clock Generator Configuration for TDM Cases

Step	Register/Bit Field/Programming Model	Value
IF transmit clock - XCLK is internally generated	Software test condition	
IF high-speed transmit clock - AHCLKX is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	MCASP_AHCLKXCTL[15] HCLKXM	0b1
Select the high-frequency clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKX in range (1 - 4096).	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-

Table 24-353. Transmit Clock Generator Configuration for TDM Cases (continued)

Step	Register/Bit Field/Programming Model	Value
Optional: If McASP transmitter is required to output internally generated high-frequency clock, AHCLKX pin must be set as an output in step 10 of the sequence documented in the Table 24-350. This must NOT be done in current step because the clock control register - MCASP_AHCLKXCTL must be appropriately configured prior to AHCLKX pin outputting a high-speed clock to an external device.	MCASP_PDIR[27] AHCLKX	0b1
ELSE		
Select an externally-generated high frequency clock (HCLKXDIV divider can not be used).	MCASP_AHCLKXCTL[15] HCLKXM	0b0
Select the high-speed transmit clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Setup an input directon for the AHCLKX pin	MCASP_PDIR[27] AHCLKX	0b0
ENDIF		
Select an internally-generated transmit clock.	MCASP_ACLKXCTL[5] CLKXM	0b1
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL[7] CLKXP	0x-
Set the divisor for the internally generated transmit clock– ACLKX in range (1 - 32).	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Optional: If McASP transmitter is required to output internally generated clock, ACLKX pin) must be set as an output in step 10 of the sequence documented in the Table 24-350. This must NOT be done in current step because the clock control register - MCASP_ACLKXCTL must be appropriately configured prior to ACLKX pin outputting a transmit clock to an external device.	MCASP_PDIR[26] ACLKX	0b1
ELSE		
Select an externally-generated transmit clock. Note that in this case the AHCLKX signal path and the CLKXDIV divider are NOT used.	MCASP_ACLKXCTL[5] CLKXM	0b0
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_ACLKXCTL[7] CLKXP	0x-
Setup an input directon for the ACLKX pin	MCASP_PDIR[26] ACLKX	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 24.6.4.15.6.1, *Clock Failure Check Startup*.	

24.6.5.1.2.3.4 Subsequence—McASP Transmit Pins Functional Configuration

The procedure in Table 24-354 configures the McASP pins for McASP functionality.

Table 24-354. McASP Transmit Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the McASP pins direction: AFSX AHCLKX ACLKX Desired n-th McASP data pin AXRn is configured as an ouput for transmission.	MCASP_PDIR[28] AFSR; MCASP_PDIR[27] AHCLKR; MCASP_PDIR[26] ACLKR; MCASP_PDIR[n] AXRn	0x-(1) 0x-(2) 0x- (2) 0x1

(1) See Table 24-352.

24.6.5.2 Operational Modes Configuration

24.6.5.2.1 McASP Transmission Modes

24.6.5.2.1.1 Main Sequence – McASP DIT- /TDM- Polling Transmission Method

Figure 24-135 shows the McASP DIT-/TDM- polling method.

Note

- The McASP polling transmission model considers the MPU/DSP as the source of audio data for the McASP transmission buffer.
- The transmit DMA request is disabled and the XDMAERR event is not analyzed.

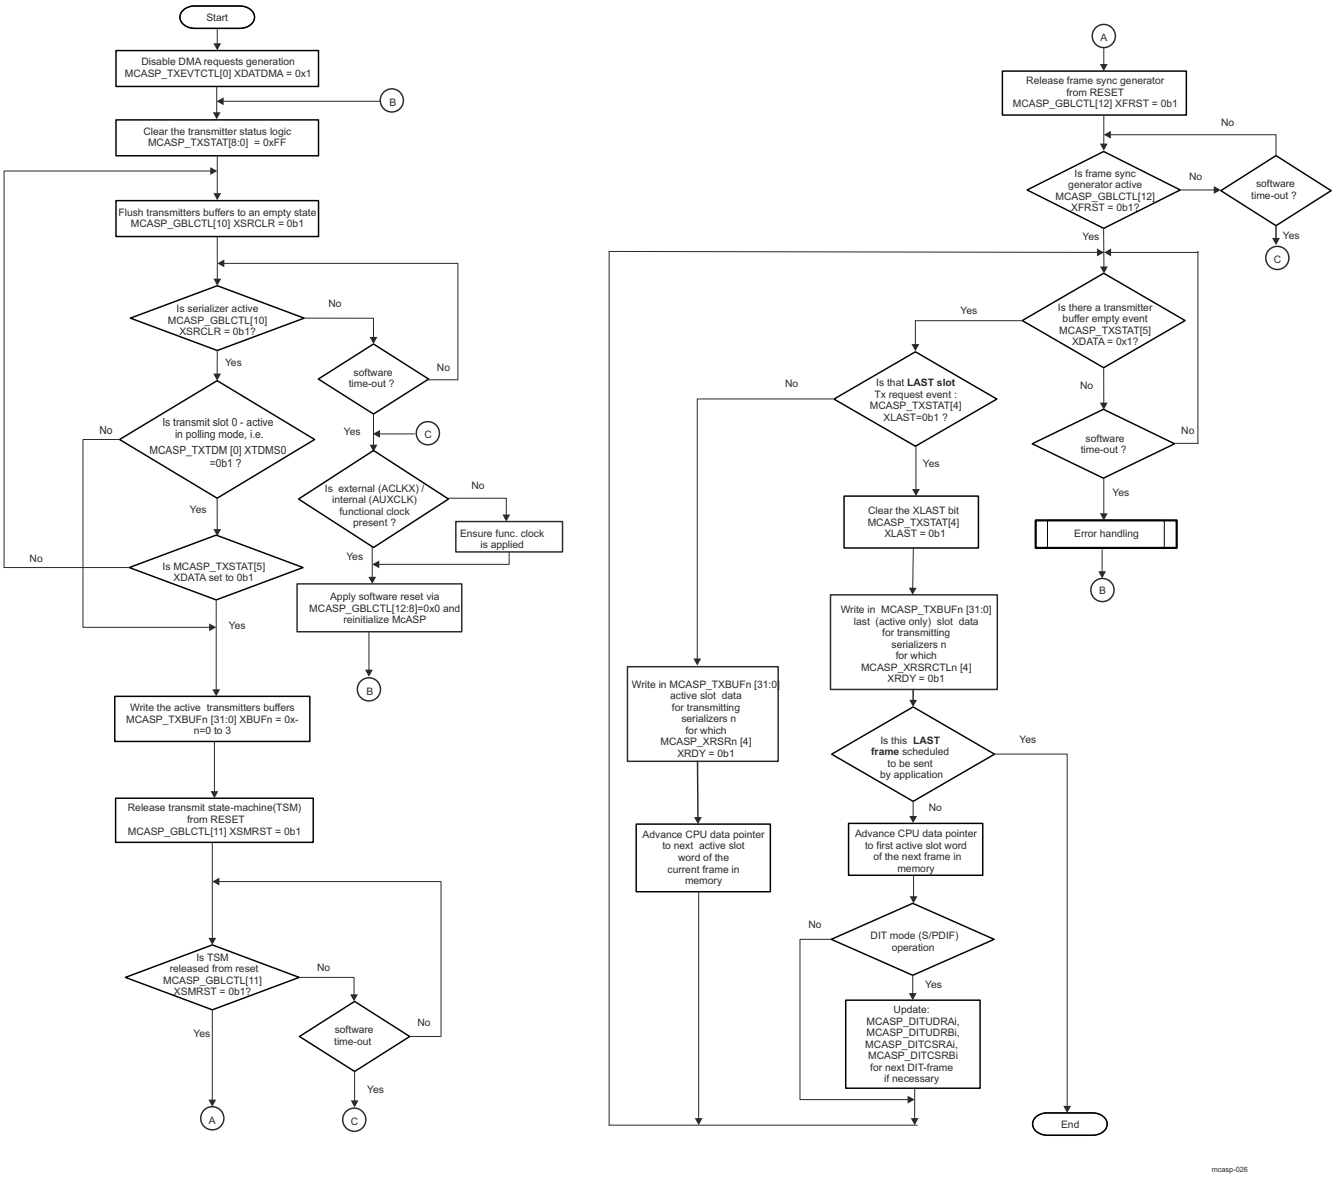

Figure 24-135. McASP DIT- /TDM- Transmission Polling Method

Table 24-355 summarizes the register call for the transmission DIT-/TDM- polling mode.

Table 24-355. Register Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method

Register Name
MCASP_XEVTCTL
MCASP_TXSTAT
MCASP_GBLCTL
MCASP_TXTDM
MCASP_TXBUFn
MCASP_XRSRCTLn
MCASP_DITUDRAi (i=0 to 5)
MCASP_DITUDRBi (i=0 to 5)
MCASP_DITCSRAi (i=0 to 5)
MCASP_DITCSRBi (i=0 to 5)

Table 24-356 summarizes the subprocess call for the DIT-/TDM- transmission polling mode.

Table 24-356. Subprocess Call Summary for Main Sequence – McASP DIT-/TDM- Transmission Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 24-141

24.6.5.2.1.2 Main Sequence – McASP DIT- /TDM - Interrupt Transmission Method

Figure 24-136 shows the initial setup for interrupt-based transmission.

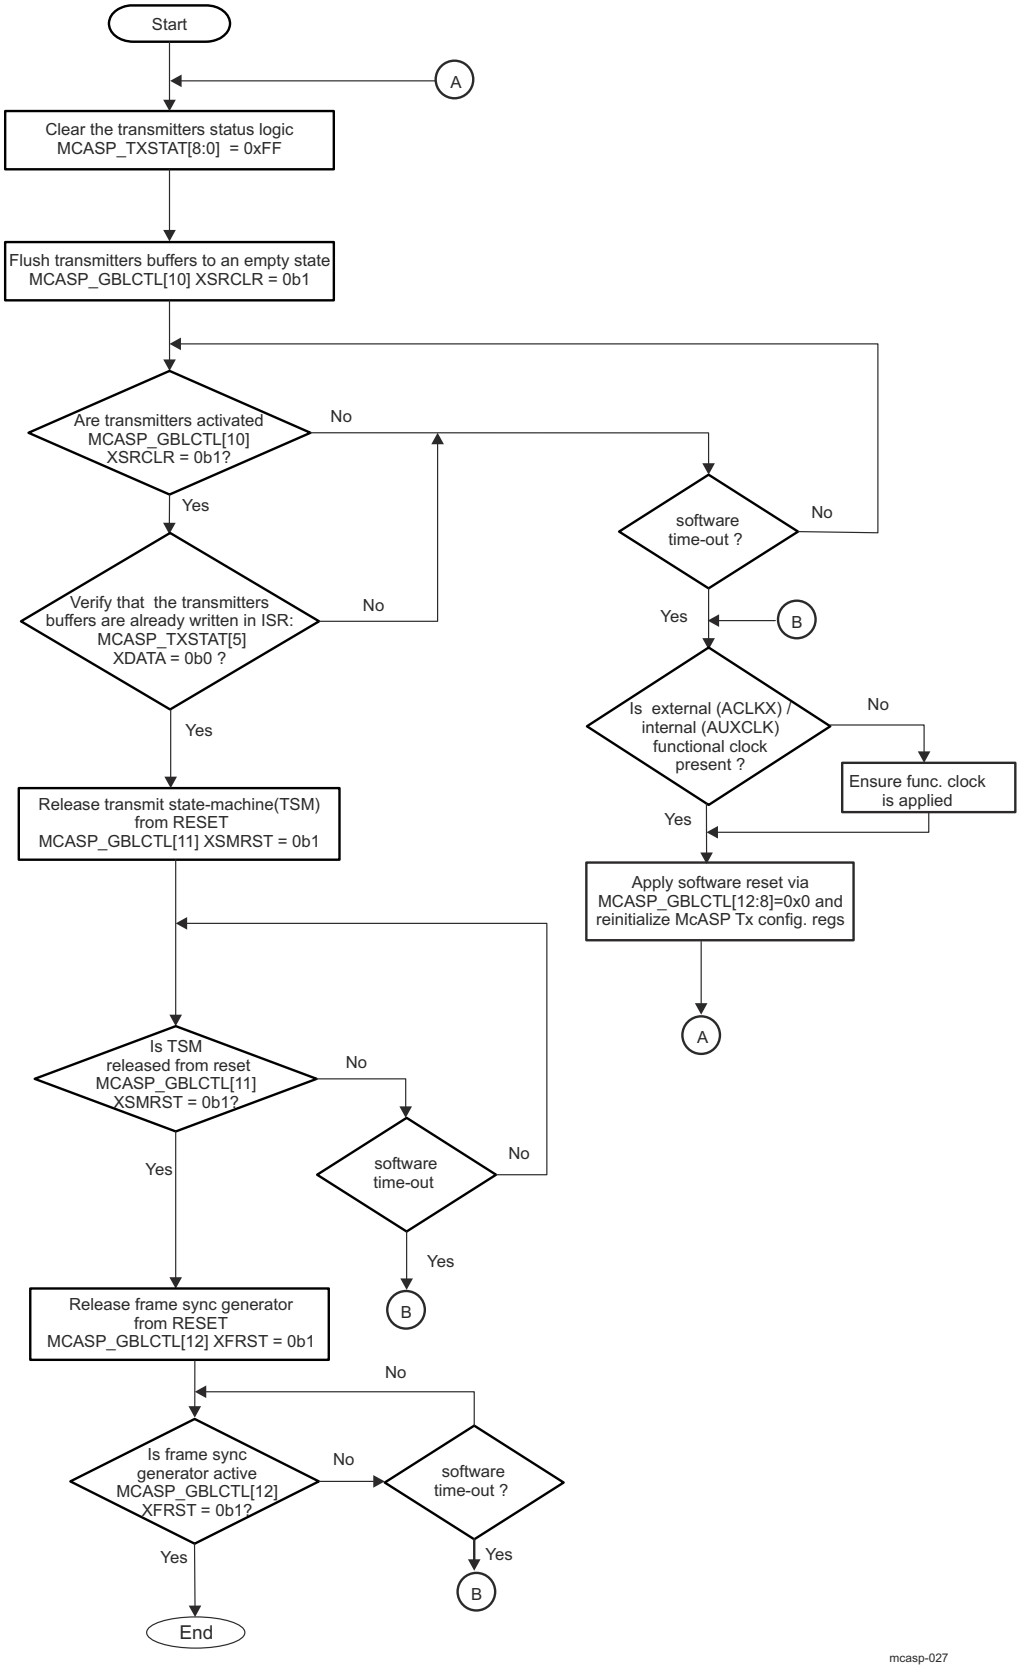

Figure 24-136. Subsequence – DIT-/TDM- Transmission Startup Procedure

Table 24-357 shows the configuration of the McASP using an interrupt method for DIT-/TDM- transmission.

Table 24-357. McASP DIT-/TDM- Interrupt Transmission Model

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update.)	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
IFwrite transfer is through the McASP DATA port (MCASP_TXFMT[3] XBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the *McASP Transmitters Global Initialization* - see Table 24-339)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x0
ENDIF		
DIT/TDM - Transmission Startup Procedure	See Figure 24-136.	

Table 24-358 summarizes the register call to initialize the McASP to transmit using interrupt events.

Table 24-358. Register Call Summary for Subsequence – McASP DIT-/TDM- Transmission Startup Procedure

Register Name	Register Name
MCASP_GBLCTL	MCASP_TXSTAT

24.6.5.2.1.3 Main Sequence –McASP DIT- /TDM - Mode DMA Transmission Method

Table 24-359 shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. Table 24-358 shows the initial setup for DMA - based transmission.

Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

Table 24-359. McASP DMA Transmission Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLX[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_EVTCTLX[5] XDATA	0x0

Table 24-359. McASP DMA Transmission Model with Interrupt Events Servicing (continued)

Step	Register/Bit Field/Programming Model	Value
DMA startup transmission procedure. This procedure is identical than the one shown in Figure 24-136. The only difference is that DMA automatically services all the AXEVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 24-139.	See Figure 24-136.	

24.6.5.2.2 McASP Reception Modes

24.6.5.2.2.1 Main Sequence – McASP Polling Reception Method

Figure 24-137 shows the McASP polling reception method.

Note

The McASP polling reception model considers thedevice CPUs as the accessor of audio data from the McASP receive buffers.

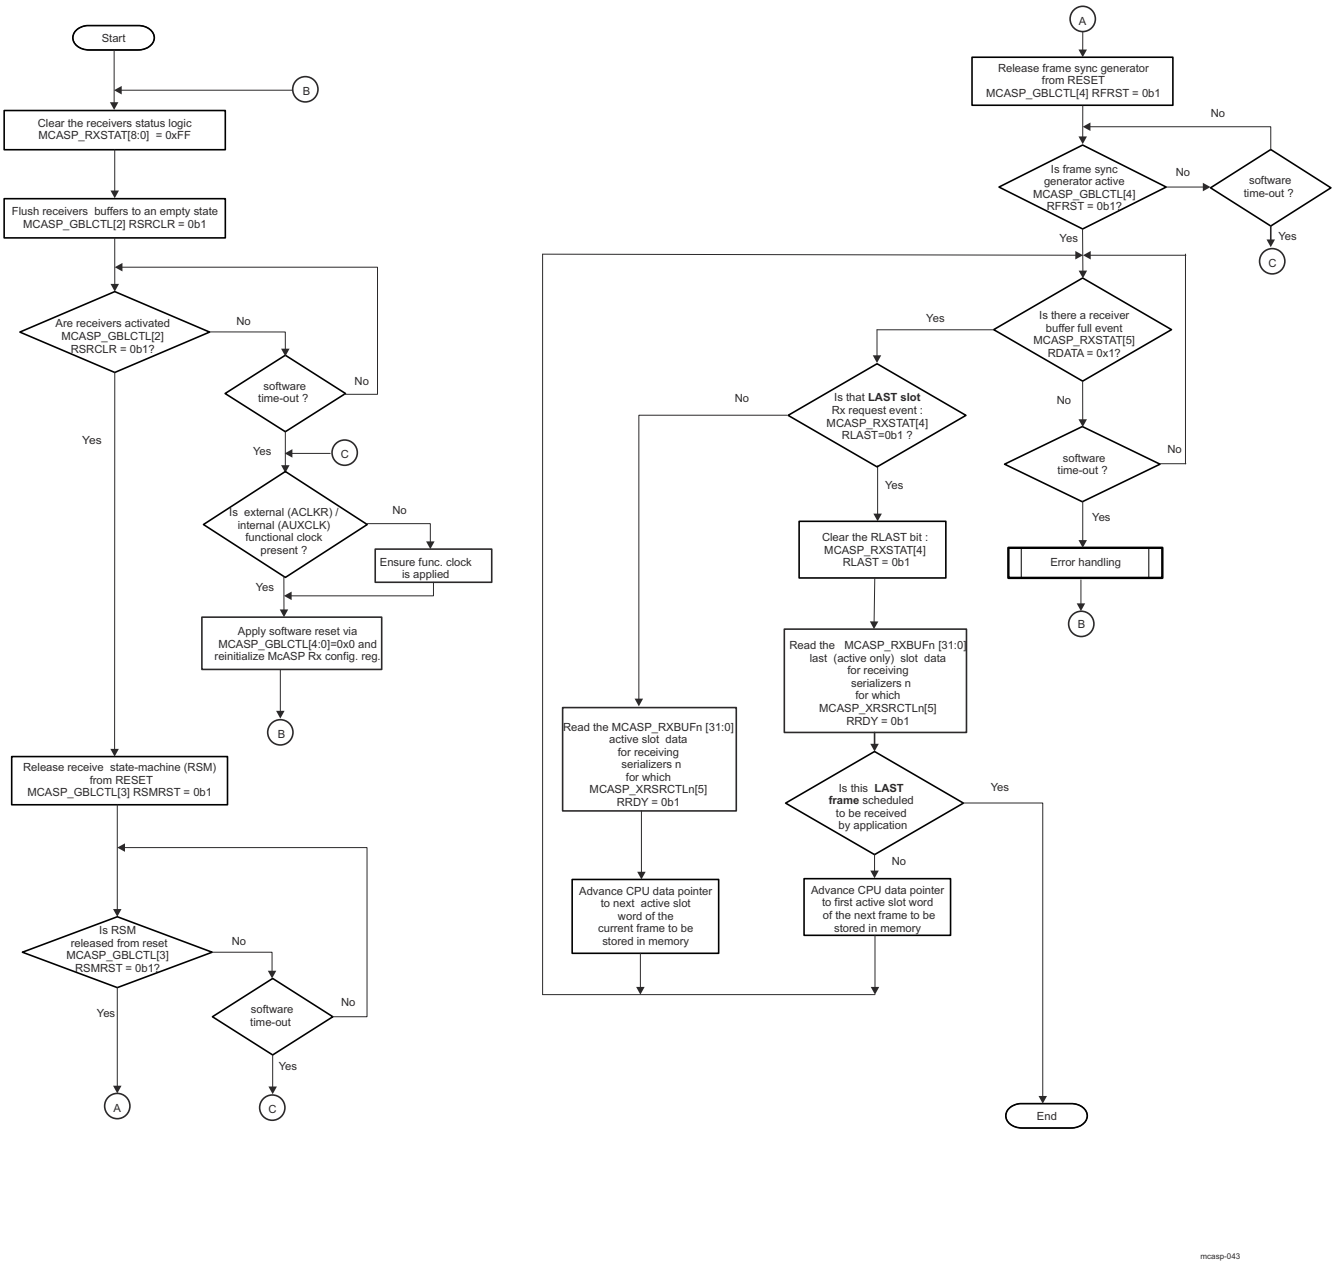

Figure 24-137. McASP Polling Reception Method

Table 24-360 summarizes the register call for the reception polling mode.

Table 24-360. Register Call Summary for Main Sequence – McASP Reception Polling Method

Register Name
MCASP_RXSTAT
MCASP_GBLCTL
MCASP_RXBUFn
MCASP_XRSRCTLn

Table 24-361 summarizes the subprocess call for the polling mode.

Subprocess Name	Cross-Reference
Error handling	Figure 24-142

24.6.5.2.2.2 Main Sequence – McASP TDM - Interrupt Reception Method

Figure 24-138 shows the initial setup for interrupt-based reception.

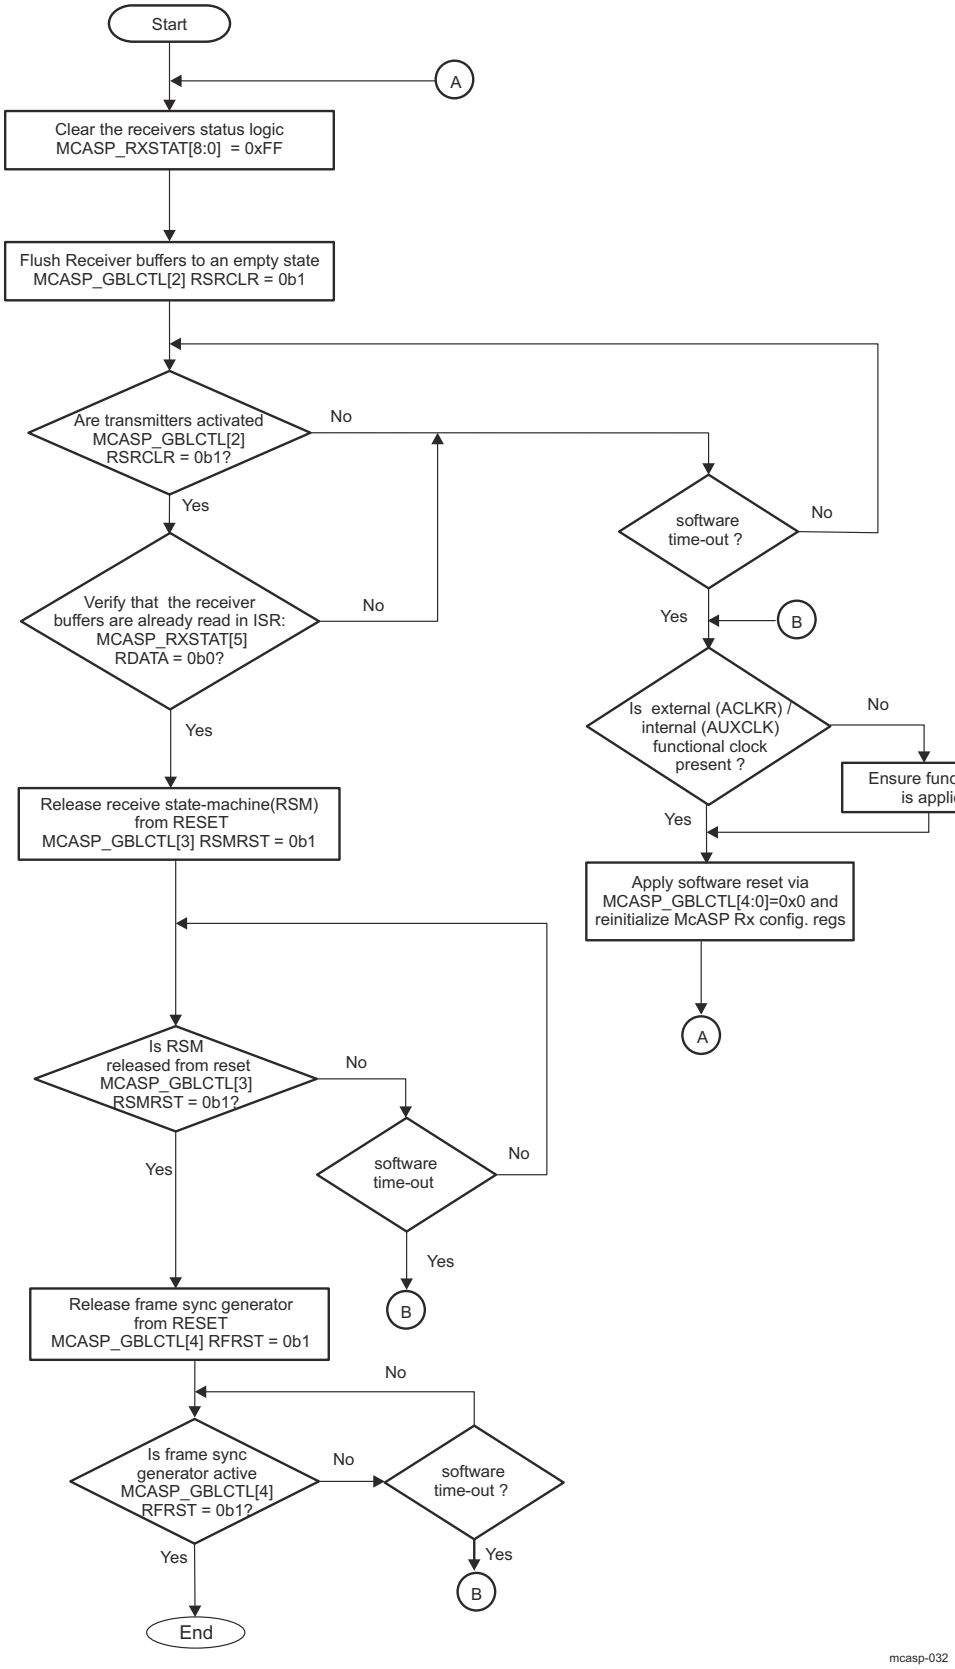

Figure 24-138. Subsequence – TDM - Reception Startup Procedure

Table 24-362 shows the configuration of the McASP using an interrupt method for TDM- reception.

Table 24-362. McASP TDM- Interrupt Reception Model

Step	Register/Bit Field/Programming Model	Value
Disable Rx DMA requests generation.	MCASP_REVTCTL[0] RDATDMA	0x1
Enable the data ready event receive interrupt.	MCASP_EVTCTLR[5] RDATA	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR[2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt	MCASP_EVTCTLR [7] RSTAFRM MCASP_EVTCTLR[4] RLAST	0x1 0x1
IF read transfer is through the McASP DATA port (MCASP_RXFMT[3] RBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the *McASP Receivers Global Initialization for TDM-Mode Operation* - see Table 24-345)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLR[3] RDMAERR	0x0
ENDIF		
TDM - Transmission Startup Procedure	See Figure 24-138.	

Table 24-363 summarizes the register call to initialize the McASP to transmit using interrupt events.

Table 24-363. Register Call Summary for Subsequence – McASP TDM- Reception Startup Procedure

Register Name	Register Name
MCASP_GBLCTL	MCASP_RXSTAT

24.6.5.2.2.3 Main Sequence – McASP TDM - Mode DMA Reception Method

Table 24-364 shows the configuration of the McASP using the DMA method for reception. Possible interrupt error event servicing is also considered. Table 24-358 shows the initial setup for DMA - based transmission.

Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the McASP DATA port.

Table 24-364. McASP DMA Reception Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_RXFMT[3] RBUSEL	0x0
Enable the Rx DMA requests generation.	MCASP_REVTCTL[0] RDATDMA	0x0
Enable the Rx DMA error event, because of McASP DATA port usage.	MCASP_EVTCTLR[3] RDMAERR	0x1
Optional: Enable the receive error event interrupts.	MCASP_EVTCTLR2] RCKFAIL MCASP_EVTCTLR[1] RSYNCERR MCASP_EVTCTLR[0] ROVRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLR [7] RSTAFRM MCASP_EVTCTLR[4] RLAST	0x1 0x1
Disable the data ready event receive interrupt, as DMA is used to service this request.	MCASP_EVTCTLR[5] RDATA	0x0

Table 24-364. McASP DMA Reception Model with Interrupt Events Servicing (continued)

Step	Register/Bit Field/Programming Model	Value
DMA startup reception procedure. This procedure is identical than the one shown in Figure 24-138. The only difference is that DMA automatically services all the AREVT events raised by the McASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 24-140.	See Figure 24-138.	

24.6.5.2.3 McASP Event Servicing

24.6.5.2.3.1 McASP DIT-/TDM- Transmit Interrupt Events Servicing

Figure 24-139 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the McASP module.

24.6.6.2 McASP Registers

24.6.6.2.1 MCASP_CFG Register Summary

Table 24-370 to Table 24-373 summarize the MCASP_CFG register mapping.

Table 24-370. MCASP_CFG Register Summary 1

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_CFG L4_PER2 Physical Address
MCASP_PID	R	32	0x0000 0000	0x4846 0000
PWRIDLESYSCONFIG	RW	32	0x0000 0004	0x4846 0004

(1) i = 0 to 5
(2) n = 0 to 15

Note

The address locations listed in Table 24-370 to Table 24-373 , *MCASP_CFG Register Mapping Summary*, are relevant for accessing:

- All McASP configuration registers
- MCASP_TXBUFn registers
- MCASP_RXBUFn registers

through the McASP peripheral configuration (CFG) port.

The MCASP_TXFMT[3] XBUSEL bit must be set to 0b1, to allow CFG port write accesses to the McASP XRBUFn buffer. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b1, to allow CFG port read accesses to the McASP XRBUFn buffer.

24.6.6.2.2 MCASP_CFG Register Description

The tables below describe the individual MCASP_CFG register bits.

Note

For all of the below described registers the indexes n and N are applying to serializers (not slots).

Register descriptions cover the superset McASP (16 serializers and all signals pinned out). For the particular McASP instantiation, please refer to *McASP Environment*, and *McASP Integration*.

Table 24-378. MCASP_PDOUT

Address Offset	0x0000 0018		
Physical Address	0x4846 0018	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4 MCASP4_CFG_PER2_L4 MCASP5_CFG_PER2_L4 MCASP6_CFG_PER2_L4 MCASP7_CFG_PER2_L4 MCASP8_CFG_PER2_L4

Description

Pin data output register - holds a value for data out at all times, and may be read back at all times. The value held by MCASP_PDOUT is not affected by writing to MCASP_PDIR and MCASP_PFUNC. However, the data value in MCASP_PDOUT is driven out onto the McASP pin only if the corresponding bit in MCASP_PFUNC is set to 1 (GPIO function) and the corresponding bit in MCASP_PDIR is set to 1 (output).

When reading data, it returns the corresponding bit value in MCASP_PDOUT[n]; it does not return the input from the I/O pin.

When writing data, writes to the corresponding MCASP_PDOUT[n] bit.

Table 24-378. MCASP_PDOUT (continued)

PDOUT has these aliases or alternate addresses:

- MCASP_PDSET - when written to at this address, writing a 1 to a bit in MCASP_PDSET sets the corresponding bit in MCASP_PDOUT to 1; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged.
- MCASP_PDCLR - when written to at this address, writing a 1 to a bit in MCASP_PDCLR clears the corresponding bit in MCASP_PDOUT to 0; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged

There is only one set of data-out bits, MCASP_PDOUT[31:0]. The other registers, MCASP_PDSET and MCASP_PDCLR, are just different addresses for the same control bits, with different behaviors during writes.

Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

8	AXR8	Determines drive on AXR8 output pin when the corresponding MCASP_PFUNC[8] and MCASP_PDIR[8] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
7	AXR	Determines drive on AXR7 output pin when the corresponding MCASP_PFUNC[7] and MCASP_PDIR[7] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
6	AXR6	Determines drive on AXR6 output pin when the corresponding MCASP_PFUNC[6] and MCASP_PDIR[6] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
5	AXR5	Determines drive on AXR5 output pin when the corresponding MCASP_PFUNC[5] and MCASP_PDIR[5] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
4	AXR4	Determines drive on AXR4 output pin when the corresponding MCASP_PFUNC[4] and MCASP_PDIR[4] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
3	AXR3	Determines drive on AXR3 output pin when the corresponding MCASP_PFUNC[3] and MCASP_PDIR[3] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
2	AXR2	Determines drive on AXR2 output pin when the corresponding MCASP_PFUNC[2] and MCASP_PDIR[2] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Bits	Field Name	Description	Type	Reset
1	AXR1	Determines drive on AXR1 output pin when the corresponding MCASP_PFUNC[1] and MCASP_PDIR[1] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
0	AXR0	Determines drive on AXR0 output pin when the corresponding MCASP_PFUNC[0] and MCASP_PDIR[0] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Table 24-379. MCASP_PDIN

Address Offset	0x0000 001C		
Physical Address	0x4846 001C	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4 MCASP4_CFG_PER2_L4 MCASP5_CFG_PER2_L4 MCASP6_CFG_PER2_L4 MCASP7_CFG_PER2_L4 MCASP8_CFG_PER2_L4
Description	Pin data input register - holds the state of all the McASP pins. MCASP_PDIN allows reading the actual value of the pin, regardless of the state of MCASP_PFUNC and MCASP_PDIR. Some register bits might not be functional for all McASP instances, due to corresponding McASP pin not being pinned out on a particular device part number. Refer to device-specific DM for more information on the supported McASP features.

Table 24-382. MCASP_GBLCTL

Address Offset	0x0000 0044		
Physical Address	0x4846 0044	**Instance**	MCASP1_CFG_PER2_L4 MCASP2_CFG_PER2_L4 MCASP3_CFG_PER2_L4 MCASP4_CFG_PER2_L4 MCASP5_CFG_PER2_L4 MCASP6_CFG_PER2_L4 MCASP7_CFG_PER2_L4 MCASP8_CFG_PER2_L4
Description	Global transmit control register - provides initialization of the transmit and receive sections. The bit fields in MCASP_GBLCTL are synchronized and latched by the transmitter and receiver corresponding clocks - ACLKX (bits [12:8]) and ACLKR (bits [4:0]), respectively. Before programming MCASP_GBLCTL, ensure that the serial clocks are running. If the corresponding external serial clocks - ACLKX and ACLKR, are not yet running, select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL and ACLKRCTL before programming the MCASP_GBLCTL. Also, after programming any bits in MCASP_GBLCTL, do not proceed until reading back from MCASP_GBLCTL and verifying that the bits in MCASP_GBLCTL are latched.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED	XFRST	XSMRST	XSRCLR	XHCLKRST	XCLKRST	RESERVED	RFRST	RSMRST	RSRCLR	RHCLKRST	RCLKRST

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	RW	0x00000
12	XFRST	Transmit frame-sync generator reset enable bit 0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
11	XSMRST	Transmit state-machine reset enable bit 0x0: The transmit state-machine is held in reset. AXR[n] pin state: If MCASP_PFUNC[n] = 0 and MCASP_PDIR[n] = 1, the corresponding serializer [n] drives the AXR[n] pin to the state specified for inactive time slot. 0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from XBUF[n] to XRSR[n]. The transmit state-machine sets the underrun flag (XUNDRN) in MCASP_XSTAT, if XBUF[n] have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released.	RW	0
10	XSRCLR	Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun occurs. 0x0: The transmit serializer is cleared. 0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in MCASP_XSTAT is set to indicate XBUF is ready to be written.	RW	0
9	XHCLKRST	Transmit high-frequency clock divider reset enable bit 0x0: The transmitter high-frequency clock divider is held in reset and passes through its input as divide-by-1. 0x1: The transmitter high-frequency clock divider is running.	RW	0
8	XCLKRST	Transmit clock divider reset enable bit 0x0: The transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: The transmit clock divider is running.	RW	0
7:5	RESERVED	Reserved	RW	0x0
4	RFRST	Receive frame sync generator reset enable bit. 0x0: Receive frame sync generator is reset. 0x1: Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
3	RSMRST	Receive state machine reset enable bit. 0x0: Receive state machine is held in reset. 0x1: Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.	RW	0

Bits	Field Name	Description	Type	Reset
2	RSRCLR	Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed. 0x0: Receive serializers are cleared. 0x1: Receive serializers are active.	RW	0
1	RHCLKRST	Receive high-frequency clock divider reset enable bit. 0x0: Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1. 0x1: Receive high-frequency clock divider is running.	RW	0
0	RCLKRST	Receive clock divider reset enable bit. 0x0: Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: Receive clock divider is running.	RW	0

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Reserved	RW	0x000 0000

Bits	Field Name	Description	Type	Reset
4	IOLBEN	If DLBEN=0b1, the IOLBEN bit selects between **internal-level (McASP module-level)** and **chip I/O-level** loopback modes. IOLBEN bit value is irrelevant, If DLBEN=0b0. 0x0: McASP internal loopback mode enabled. This selects a direct loopback between corresponding McASP AXRn and AXRn+1 pins, bypassing device pad I/O buffers. 0x1: Chip I/O-level loopback mode enabled. The McASP data is looped back through the device pad I/O buffers.	RW	0
3:2	MODE	Loopback generator mode bits. 0x0: RESERVED 0x1: MODE must be set to 0x1 when McASP operates in loopback mode (DLBEN =0b1). This is necessary to allow transmit clock and frame sync generators to be used by both transmit and receive sections. 0x2, 0x3: Reserved	RW	0x0
1	ORD	Loopback order bit when loopback mode is enabled (DLBEN = 1). 0x0: Odd serializers N + 1 transmit to even serializers N that receive. The corresponding serializers must be programmed properly. 0x1: Even serializers N transmit to odd serializers N+1 that receive. The corresponding serializers must be programmed properly.	RW	0
0	DLBEN	Loop back mode enable bit. 0x0: Loop back mode is disabled (normal McASP operation). 0x1: Loop back is enabled (TDM mode only). Loopback type is selected in IOLBEN bit.	RW	0

Description	The receiver status register (MCASP_RXSTAT) provides the receiver status and receive TDM time slot number.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							RERR	RDMAERR	RSTAFRM	RDATA	RLAST	RTDMSLOT	RCKFAIL	RSYNCERR	ROVRN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x00 0000
8	RERR	RERR bit always returns a logic-OR of: ROVRN | RSYNCERR | RCKFAIL | RDMAERR Allows a single bit to be checked to determine if a receiver error has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	RDMAERR	Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the DMA port in a given time slot than were programmed as receivers. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive DMA error did not occur. 0x1: Receive DMA error did occur.	RW	0

Bits	Field Name	Description	Type	Reset
6	RSTAFRM	Receive start of frame flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new receive frame sync (AFSR) is detected. 0x1: A new receive frame sync (AFSR) is detected.	RW	0
5	RDATA	Receive data ready flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new data in RBUF. 0x1: Data is transferred from XRSR to RBUF and ready to be serviced by the CPUs or DMA. When RDATA is set, it always causes a DMA event (AREVT).	RW	0
4	RLAST	Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. RDATA is also set.	RW	0
3	RTDMSLOT	Returns the LSB of RSLOT. Allows a single read of MCASP_RXSTAT to determine whether the current TDM time slot is even or odd. 0x0: Current TDM time slot is odd. 0x1: Current TDM time slot is even.	RW	0
2	RCKFAIL	Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive clock failure did not occur. 0x1: Receive clock failure did occur.	RW	0
1	RSYNCERR	Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Unexpected receive frame sync did not occur. 0x1: Unexpected receive frame sync did occur.	RW	0
0	ROVRN	Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receiver overrun did not occur. 0x1: Receiver overrun did occur.	RW	0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN | XSYNCERR | XCKFAIL | XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the DATA port of the McASP in a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0

Bits	Field Name	Description	Type	Reset
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0
5	XDATA	Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect 0x0: XBUF[n] is written and is full 0x1: Data is copied from XBUF[n] to XRSR[n]. XBUF[n] is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).	RW	0
4	XLAST	Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set.	RW	0
3	XTDMSLOT	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even.	R	0
2	XCKFAIL	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred	RW	0
1	XSYNCERR	Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred.	RW	0
0	XUNDRN	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF[n] to XRSR[n], but XBUF[n] has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred.	RW	0

RESERVED																										RRDY	XRDY	DISMOD		SRMOD	

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Reserved	RW	0x0000000
5	RRDY	Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSRn to RBUFn. Read 0x0: Receive buffer (MCASP_RXBUFn) is empty. Read 0x1: Receive buffer (MCASP_RXBUFn) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.	R	0

Bits	Field Name	Description	Type	Reset
4	XRDY	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0). Read 0x0: The transmit buffer (MCASP_TXBUFn) contains data. Read 0x1: The transmit buffer (MCASP_TXBUFn) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.	R	0
3:2	DISMOD	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0). 0x0: Drive on pin is 3-state. 0x1: Reserved 0x2: Drive on pin is logic low. 0x3: Drive on pin is logic high.	RW	0x0
1:0	SRMOD	Serializer mode bit 0x0:The serializer is inactive 0x1:The serializer is operating in transmit mode. 0x2: The serializer is operating in receive mode. 0x3: Reserved	RW	0x0

Description	The Write FIFO control register. The WNUMEVT and WNUMDMA values must be set prior to enabling the Write FIFO. If the Write FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED															WENA	WNUMEVT								WNUMDMA							

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Reserved	R	0x0000 0000
16	WENA	Write FIFO enable bit. 0x0: Write FIFO is disabled (default). Data access by the host must pass through the FIFO block to the McASP transparently. DMA requests must also pass through the FIFO block transparently. WLVL is reset to 0 and pointers are initialized, i.e., the write FIFO is "flushed." 0x1: Write FIFO is enabled. If write FIFO is to be enabled, it must be enabled prior to enabling McASP.	RW	0
15:8	WNUMEVT	Write word count (32-bit) to generate TX event to host. When Write FIFO has word space for more or equal to this value then transmit event will be generated to host/ DMA. This value must be set prior to enabling the write FIFO. 0x0: 0 words. 0x1: 1 word. 0x2: 2 words. 0x3 - 0x40: 3 to 64 words currently in write FIFO. 0x41 - 0xFF: Reserved.	RW	0x10
7:0	WNUMDMA	Write word count (32-bit words). On the transmit DMA event from McASP the WNUMDMA word will be transferred from DMA engine to McASP. This value must equal the number of McASP serializers used as transmitters. This value must be set prior to enabling the write FIFO. 0x0: 0 words. 0x1: 1 word. 0x2: 2 words. 0x3 - 0x10: 3 to 16 words. 0x11 - 0xFF: Reserved.	RW	0x04

7:0	WLVL	Write level (read-only). Number of 32-bit words currently in write FIFO. 0x0: 0 words currently in write FIFO. 0x1: 1 word currently in write FIFO. 0x2: 2 words currently in write FIFO. 0x3 - 0x40: 3 to 64 words currently in write FIFO. 0x41 - 0xFF: Reserved.	R	0

Table 24-424. RFIFOCTL

Address Offset	0x0000 0008		
Physical Address	0x4846 1008	**Instance**	MCASP1_AFIFO_PER2_L4 MCASP2_AFIFO_PER2_L4 MCASP3_AFIFO_PER2_L4 MCASP4_AFIFO_PER2_L4 MCASP5_AFIFO_PER2_L4 MCASP6_AFIFO_PER2_L4 MCASP7_AFIFO_PER2_L4 MCASP8_AFIFO_PER2_L4
Description	The Read FIFO control register. The RNUMEVT and RNUMDMA values must be set prior to enabling the Read FIFO. If the Read FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED															RENA	RNUMEVT								RNUMDMA							

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Reserved	R	0x0000 0000
16	RENA	Read FIFO enable bit. 0x0: Read FIFO is disabled (default). Data access by the host must pass through the FIFO block to the McASP transparently. DMA requests must also pass through the FIFO block transparently. RLVL is reset to 0 and pointers are initialized, i.e., the read FIFO is “flushed.” 0x1: Read FIFO is enabled. If read FIFO is to be enabled, it must be enabled prior to enabling McASP.	RW	0

Bits	Field Name	Description	Type	Reset
15:8	RNUMEVT	Read word count (32-bit) to generate RX event to host. When Read FIFO has number of word available which is more or equal to this value then receive event will be generated to host/DMA. This value must be set prior to enabling the write FIFO. 0x0: 0 words currently in read FIFO. 0x1: 1 word currently in read FIFO. 0x2: 2 words currently in read FIFO. 0x3 - 0x40: 3 to 64 words currently in read FIFO. 0x41 - 0xFF: Reserved	RW	0x10
7:0	RNUMDMA	Read word count (32-bit words). On receive DMA event from McASP, the DMA engine will read specified number of words from McASP. This value must equal the number of McASP serializers used as transmitters. This value must be set prior to enabling the read FIFO. 0x0: 0 words 0x1: 1 word 0x2: 2 words 0x3 - 0x10: 3-16 words 0x11 - 0xFF: Reserved		

Table 24-425. RFIFOSTS

7:0	RLVL	Read level (read-only). Number of 32-bit words currently in read FIFO. 0x0: 0 words currently in read FIFO. 0x1: 1 word currently in read FIFO. 0x2: 2 words currently in read FIFO. 0x3 - 0x40: 3 to 64 words currently in read FIFO. 0x41 - 0xFF: Reserved.	R	0

24.6.6.2.5 MCASP_DAT Register Summary

Table 24-426 to Table 24-429 summarize the MCASP_DAT register mapping.

Table 24-426. MCASP_DAT Register Summary 1

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_DAT L3_MAIN Physical Address
MCASP_RXBUF	R	32	0x0000 0000[1]	0x4580 0000

Table 24-426. MCASP_DAT Register Summary 1 (continued)

Register Name	Type	Register Width (Bits)	Address Offset	MCASP1_DAT L3_MAIN Physical Address
MCASP_TXBUF	W	32	0x0000 0000(1)	0x4580 0000

(1) 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP perfomrs accesses to XRBUFn RX/TX buffers through the McASP DATA port.

Table 24-427. MCASP_DAT Register Summary 2

Register Name	Type	Register Width (Bits)	Address Offset	MCASP2_DAT L3_MAIN Physical Address
MCASP_RXBUF	R	32	0x0000 0000(1)	0x45C0 0000
MCASP_TXBUF	W	32	0x0000 0000(1)	0x45C0 0000

(1) 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP perfomrs accesses to XRBUFn RX/TX buffers through the McASP DATA port.

Table 24-428. MCASP_DAT Register Summary 3

Register Name	Type	Register Width (Bits)	Address Offset	MCASP3_DAT L3_MAIN Physical Address	MCASP4_DAT L4_PER2 Physical Address	MCASP5_DAT L4_PER2 Physical Address
MCASP_RXBUF	R	32	0x0000 0000	0x4600 0000	0x4843 6000	0x4843 A000
MCASP_TXBUF	W	32	0x0000 0000	0x4600 0000	0x4843 6000	0x4843 A000

Table 24-429. MCASP_DAT Register Summary 4

Register Name	Type	Register Width (Bits)	Address Offset	MCASP6_DAT L4_PER2 Physical Address	MCASP7_DAT L4_PER2 Physical Address	MCASP8_DAT L4_PER2 Physical Address
MCASP_RXBUF	R	32	0x0000 0000(1)	0x4844 C000	0x4845 0000	0x4845 4000
MCASP_TXBUF	W	32	0x0000 0000(1)	0x4844 C000	0x4845 0000	0x4845 4000

(1) 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to base address, it is ignored (don't care) when MPU/DSP perfomrs accesses to XRBUFn RX/TX buffers through the McASP DATA port.

Note

For MCASP_RXBUF and MCASP_TXBUF buffer accesses through the McASP DATA port, the destination physical address is always the same regardless of current channel index or transfer direction. The MCASP_TXFMT[3] XBUSEL bit must be set to 0b0, to allow write transfers through the DATA port. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b0, to allow read transfers through the DATA port.

Note

The McASP DATA port is exclusively assigned for DMAs/device CPUs accesses to the McASP channels transmit and receive buffer registers. All other McASP module registers must be accessed through the McASP CFG (peripheral) port.

Note

McASP1, McASP2, and McASP3, whose data port are accessible directly via L3_MAIN, do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

24.6.6.2.6 MCASP_DAT Register Description

Table 24-430. MCASP_RXBUF

Address Offset	0x0000 0000

Table 24-430. MCASP_RXBUF (continued)

Physical Address	0x4580 0000 0x45C0 0000 0x4600 0000	**Instance**	MCASP1_DAT_MAIN_L3 MCASP2_DAT_MAIN_L3 MCASP3_DAT_MAIN_L3 MCASP4_DAT_PER2_L4 MCASP5_DAT_PER2_L4 MCASP6_DAT_PER2_L4 MCASP7_DAT_PER2_L4 MCASP8_DAT_PER2_L4
Description	Through the DATA port, the Host can service all serializers through a single address and the McASP automatically cycles through the appropriate serializers. For receive operations through the DATA port, the Host should read from the same RBUF DATA port address to service all of the active receive serializers upon each receive data ready event. To enable accesses from the Host to the McASP XRBUF registers through the DATA port, one must clear the RBUSEL bits to 0 in the respective MCASP_RXFMT registers in the MCASP_CFG Memory Map.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

24.7 SuperSpeed USB DRD

This section describes the SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem of the device.

Note

This chapter serves to describe the integration of the third party USB subsystem and should not be considered sufficient for those wishing to modify the existing Linux USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux USB driver(s), or create new drivers, contact TI for more information on how to obtain the third party documentation under NDA.

Note

This chapter describes a module (subsystem) in the superset device. The available number of instances and supported set of features is device part number dependent. Refer to device *Data Manual*, for more information.

Note

USB3 (ULPI) must not be used. Its functionality is not supported for this family of devices. This feature is subject to removal without notice on future device revisions. Any information regarding the unsupported feature is retained in the documentation solely for the purpose of clarifying signal names or for consistency with previous feature descriptions.

24.7.1 SuperSpeed USB DRD Subsystem Overview

SuperSpeed USB DRD Subsystem has three instances in the device providing the following functions:

- USB1: SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem with integrated SS (USB3.0) PHY and HS/FS (USB2.0) PHY
- USB2: High-Speed (HS) USB 2.0 Dual-Role-Device (DRD) subsystem with integrated HS/FS PHY
- USB3: HS USB 2.0 Dual-Role-Device (DRD) subsystem with ULPI (SDR) interface to external HS/FS PHYs

Figure 24-143 shows the USB1 subsystem overview.

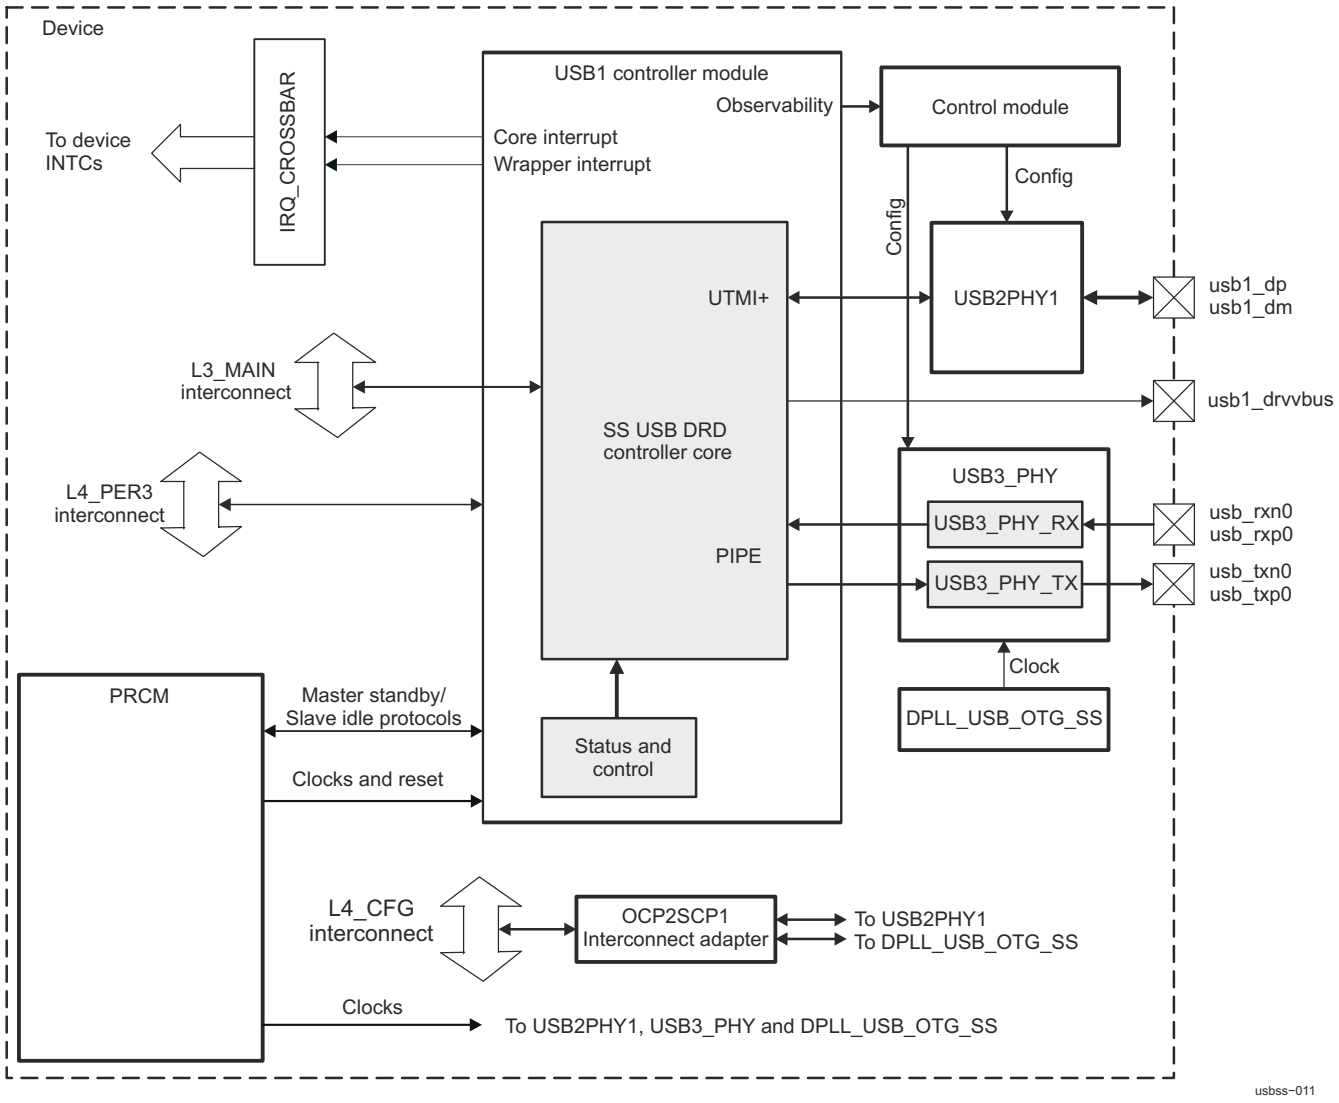

Figure 24-143. USB1 Highlight

Figure 24-144 shows the USB2 subsystem overview.

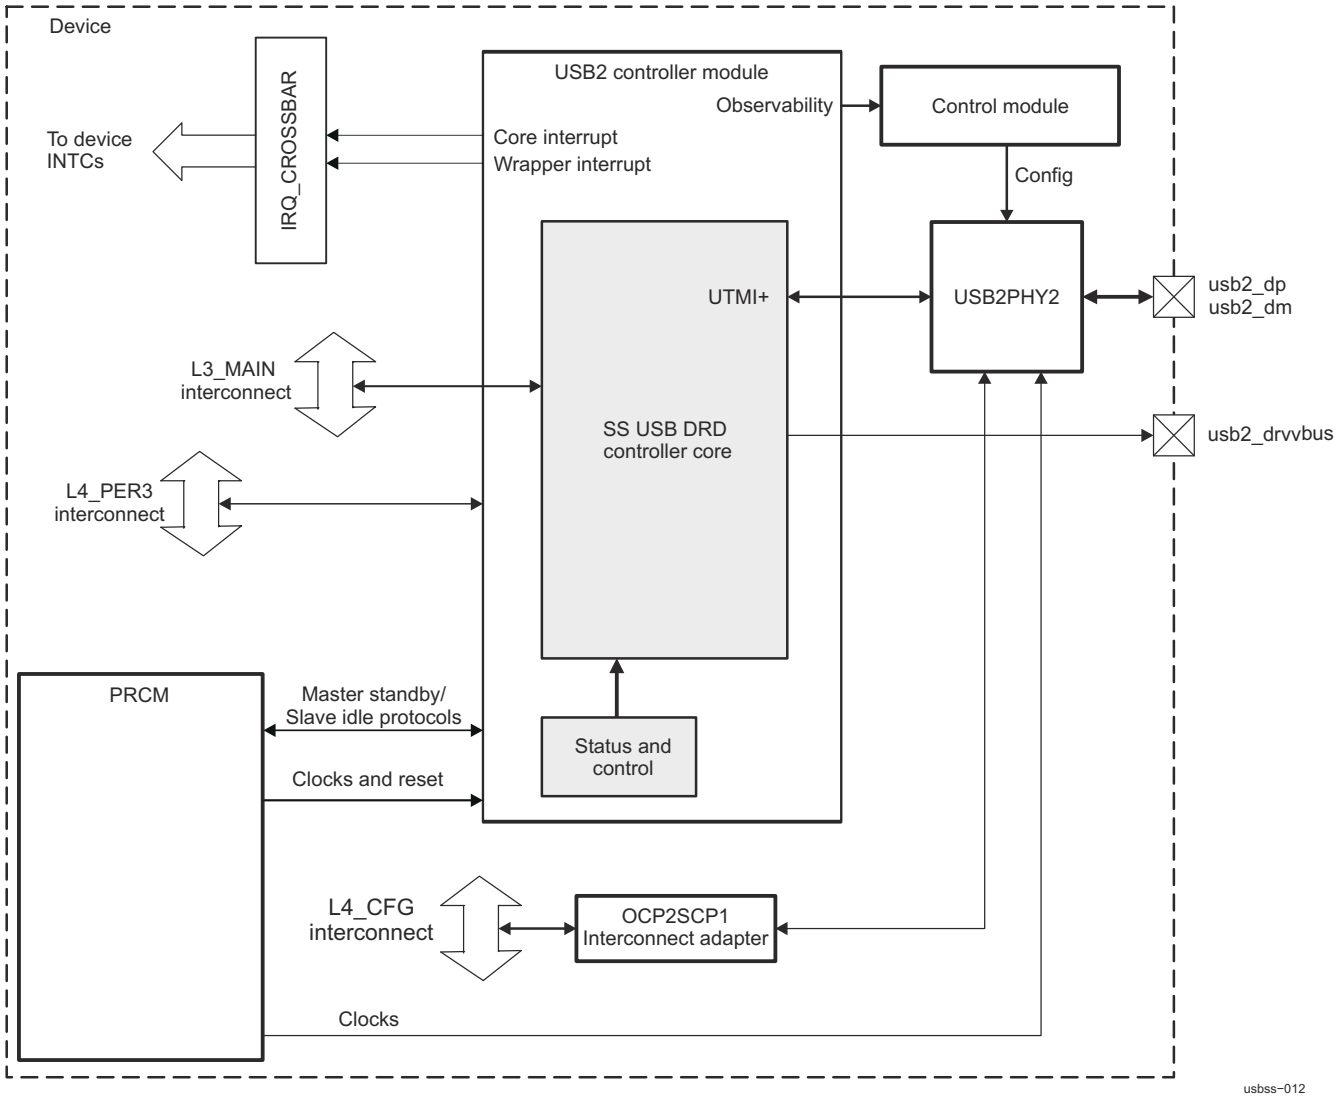

Figure 24-144. USB2 Highlight

Figure 24-145 shows the USB3 subsystem overview.

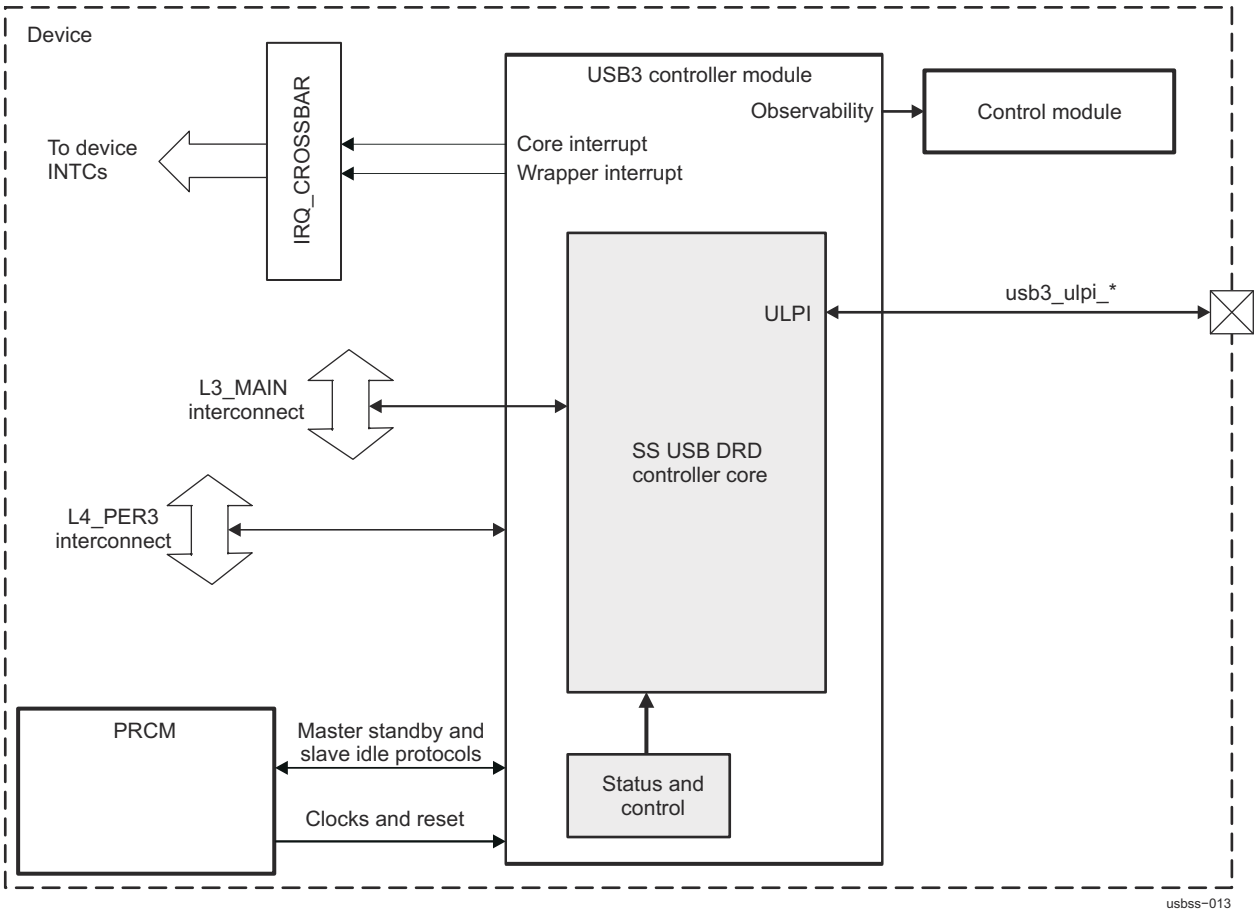

Figure 24-145. USB3 Highlight

24.7.1.1 Main Features

SuperSpeed USB DRD Subsystem has the following features:

- Dual-role-device (DRD) capability:
  - Supports USB Peripheral (or Device) mode at speeds SS (5Gbps)(USB1 only), HS (480 Mbps), and FS (12 Mbps)
  - Supports USB Host mode at speeds SS (5Gbps)(USB1 only), HS (480 Mbps), FS (12 Mbps), and LS (1.5 Mbps)
  - USB static peripheral operation
  - USB static host operation
  - Flexible stream allocation
  - Stream priority
  - External Buffer Control
- Each instance contains single xHCI controller with the following features:
  - Internal DMA controller
  - Descriptor caching and data prefetching
  - Interrupt moderation and blocking
  - Power management USB3.0 states for U0, U1, U2, and U3
  - Dynamic FIFO memory allocation for all endpoints
  - Supports all modes of transfers (control, bulk, interrupt, and isochronous)
  - Supports high bandwidth ISO mode
- Connects to an external charge pump for VBUS 5 V generation

- USB-HS PHY (USB2PHY1 and USB2PHY2 for USB1 and USB2, respectively): contain the USB functions, drivers, receivers, and pads for correct D+/D– signalling
- USB3_PHY. The USB3_PHY is embedded in the USB1 subsystem and contains:
  - USB3_PHY_RX deserializer to receive data at SuperSpeed mode
  - USB3_PHY_TX serializer to transmit data at SuperSpeed mode
  - Power sequencer that contains a power control state machine, generating the sequences to power up/down the USB3_PHY_RX/USB3_PHY_TX
  - Dedicated DPLL (DPLL_USB_OTG_SS)

24.7.1.2 Unsupported Features

Following features are not implemented in the current device:

- Battery charger support
- Accessory charger adaptor support
- OTG functionality
- Virtualization support
- USB 2.0 ECN: Link Power Management (LPM)

24.7.2 SuperSpeed USB DRD Subsystem Environment

24.7.2.1 SuperSpeed USB DRD Subsystem I/O Interfaces

Figure 24-146 describes the I/O signals of the SuperSpeed USB subsystem interfaces.

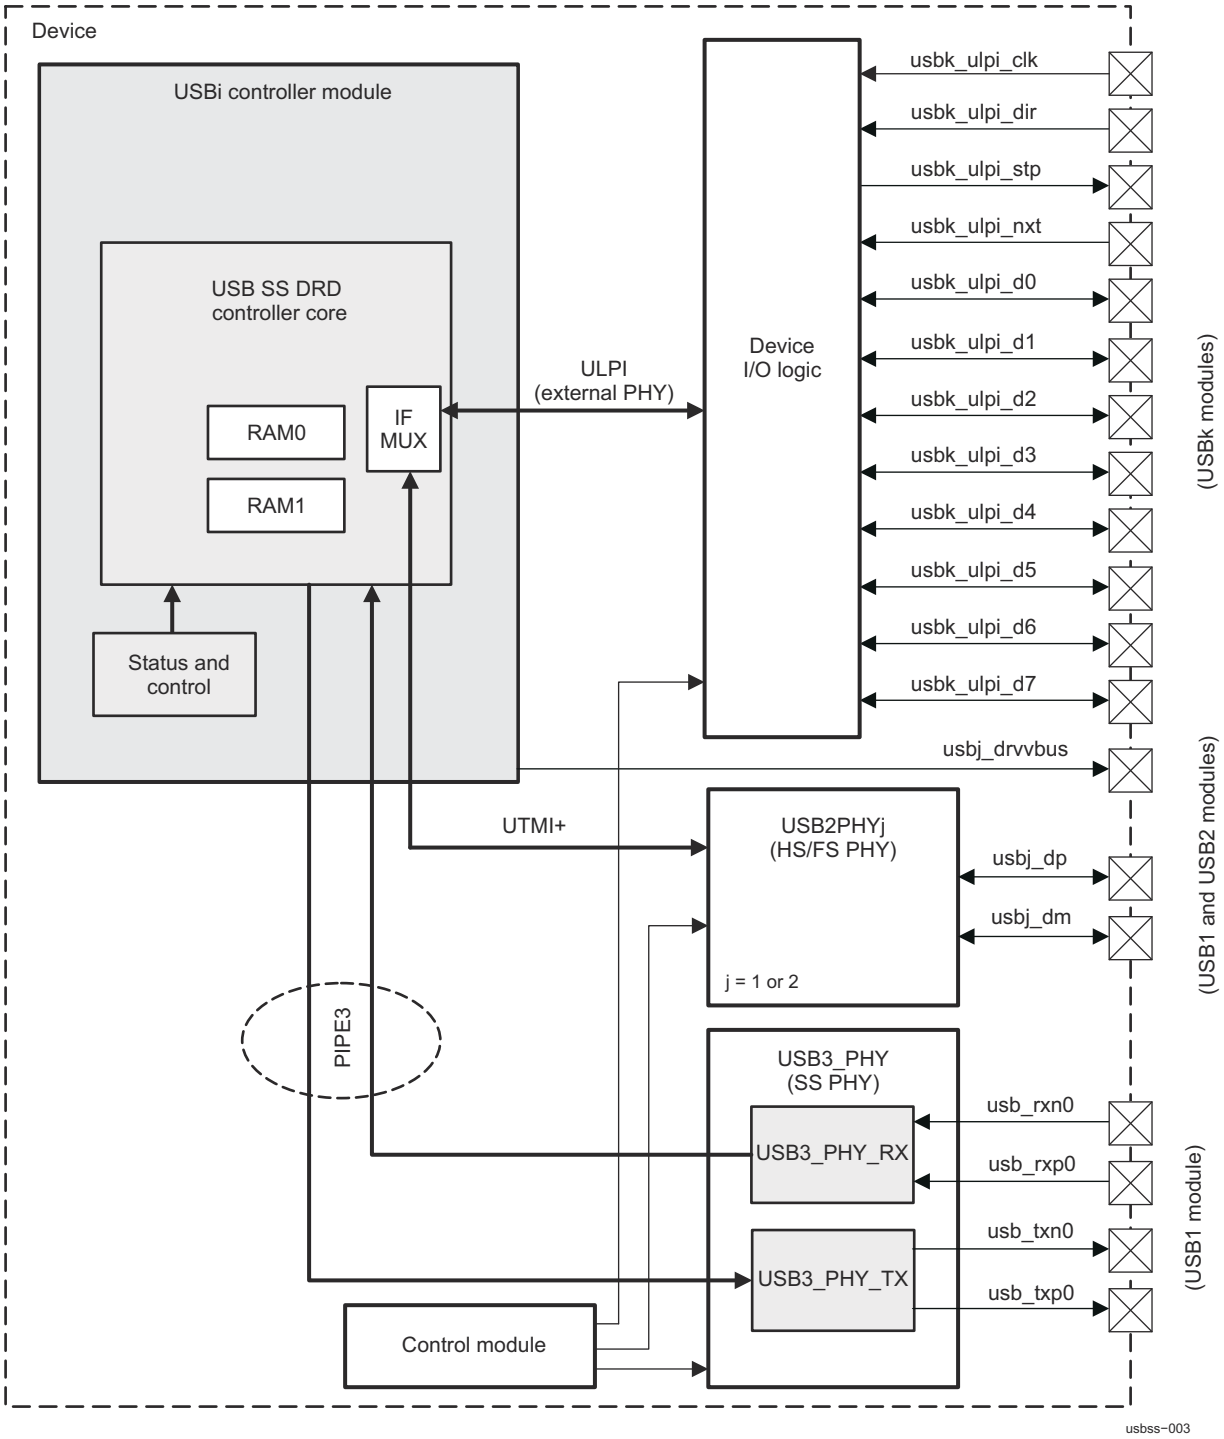

Figure 24-146. SuperSpeed USB Subsystem Environment

i = 1 to 3

k = 3

Table 24-432 through Table 24-434 describe the I/O signals of the SuperSpeed USB subsystem interfaces shown in Figure 24-146

Table 24-432. USB1 Input/Output Description

Module Pin	Device-Level Signal Name	I/O[1]	Description	Reset Value
USB2PHY1				
DRVVBUS	usb1_drvvbus	O	Drive-VBUS enable to external charge pump/power switch	0
DP	usb1_dp	I/O	USB2.0 half-duplex differential pair	HiZ
DM	usb1_dm	I/O		HiZ
USB3_PHY				
TX	usb_txn0	O	USB3.0 transmitter differential pair	HiZ
TY	usb_txp0	O		HiZ
RX	usb_rxn0	I	USB3.0 receiver differential pair	HiZ
RY	usb_rxp0	I		HiZ

(1) I = Input; O = Output; I/O = Bidirectional

Table 24-433. USB2 Input/Output Description

Module Pin	Device-Level Signal Name	I/O	Description	Reset Value
USB2PHY2				
DRVVBUS	usb2_drvvbus	O	Drive-VBUS enable to external charge pump/power switch	0
DP	usb2_dp	I/O	USB2.0 half-duplex differential pair	HiZ
DM	usb2_dm	I/O		HiZ

Table 24-434. USB3 Input/Output Description

Module Pin	Device-Level Signal Name	I/O	Description	Reset Value
ULPI interface				
ULPI_CLK	usb3_ulpi_clk	I	Clock input from external transceiver	HiZ
ULPI_DIR	usb3_ulpi_dir	I	Data direction control from external transceiver	HiZ
ULPI_STP	usb3_ulpi_stp	O	Output to external transceiver to stop data stream	1
ULPI_NXT	usb3_ulpi_nxt	I	Next signal control from external transceiver	HiZ
ULPI_DATA0	usb3_ulpi_d0	I/O	Data bit 0 to/from external transceiver	HiZ
ULPI_DATA1	usb3_ulpi_d1	I/O	Data bit 1 to/from external transceiver	HiZ
ULPI_DATA2	usb3_ulpi_d2	I/O	Data bit 2 to/from external transceiver	HiZ
ULPI_DATA3	usb3_ulpi_d3	I/O	Data bit 3 to/from external transceiver	HiZ
ULPI_DATA4	usb3_ulpi_d4	I/O	Data bit 4 to/from external transceiver	HiZ
ULPI_DATA5	usb3_ulpi_d5	I/O	Data bit 5 to/from external transceiver	HiZ
ULPI_DATA6	usb3_ulpi_d6	I/O	Data bit 6 to/from external transceiver	HiZ
ULPI_DATA7	usb3_ulpi_d7	I/O	Data bit 7 to/from external transceiver	HiZ

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers* in *Control Module*.

Note

USB3 (ULPI) must not be used. Its functionality is not supported for this family of devices. This feature is subject to removal without notice on future device revisions. Any information regarding the unsupported feature is retained in the documentation solely for the purpose of clarifying signal names or for consistency with previous feature descriptions.

24.7.2.2 SuperSpeed USB Subsystem Application

Note

Figure 24-147 through Figure 24-155 serve only to represent high-level pin connections between the SoC and the relevant USB socket for supported usage scenarios. Please refer to the *AM57xx USB Schematic Review Checklist* for complete interface requirements prior to beginning a system design.

Figure 24-147 shows typical application of the USB1 controller in the USB2.0 dual-role-device mode. TPS2051B power switch drives 5-V VBUS when required by monitoring the usb1_drvvbus output from the USB controller. VBUS sensing is exported to the companion PMIC. USB driver monitors VBUS status by listening to the PMIC interrupts and using the I2C1 (PMIC control) interface.

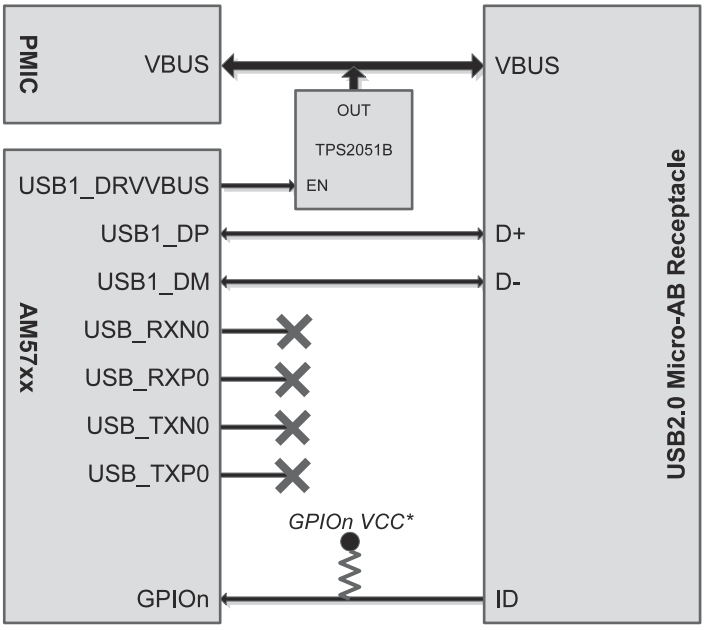

Figure 24-147. USB1 Controller Application: USB2.0 DRD

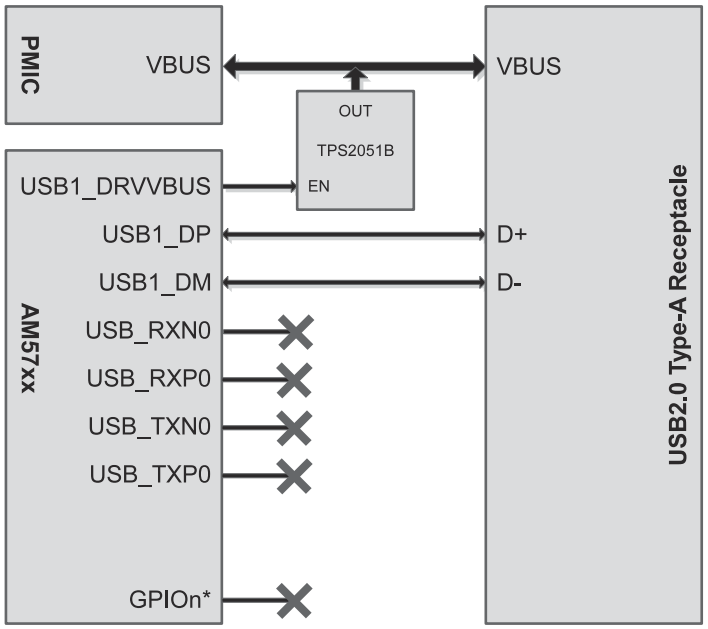
Figure 24-148 shows typical application of the USB1 controller in USB2.0 host mode. TPS2051B power switch drives 5-V VBUS when required by monitoring the usb1_drvvbus output from the USB controller. VBUS sensing is exported to the companion PMIC. USB driver monitors VBUS status by listening to the PMIC interrupts and using the I2C1 (PMIC control) interface.

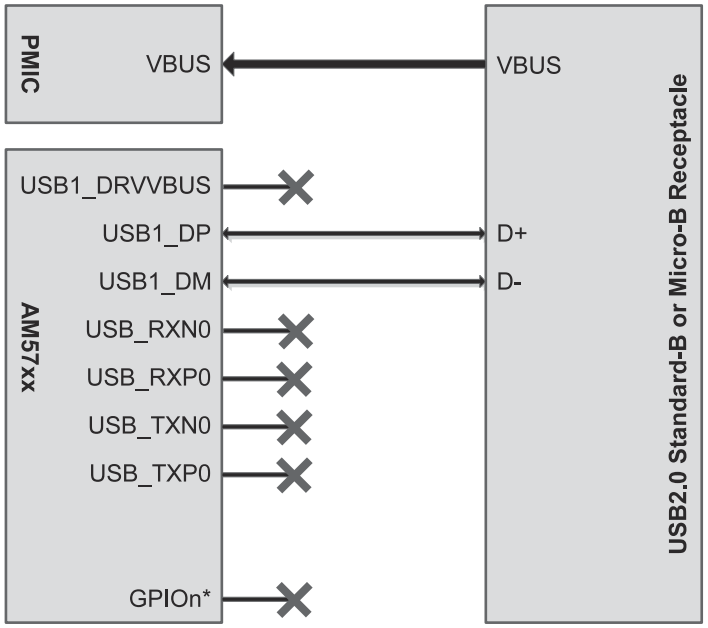


*GPIOn must be configured with internal pull-down enabled.

usbss-022

Figure 24-148. USB1 Controller Application: USB2.0 Host

Figure 24-149 shows typical application of the USB1 controller in USB2.0 device mode. VBUS sensing is exported to the companion PMIC. USB driver monitors VBUS status by listening to the PMIC interrupts and using the I2C1 (PMIC control) interface.



*GPIOn must be configured with internal pull-up enabled.

usbss-023

Figure 24-149. USB1 Controller Application: USB2.0 Device

Figure 24-150 shows typical application of the USB1 controller in the USB3.0 dual-role-device mode. TPS2065 power switch drives 5-V VBUS when required by monitoring the usb1_drvvbus output from the USB controller. VBUS sensing is exported to the companion PMIC. USB driver monitors VBUS status by listening to the PMIC interrupts and using the I2C1 (PMIC control) interface.

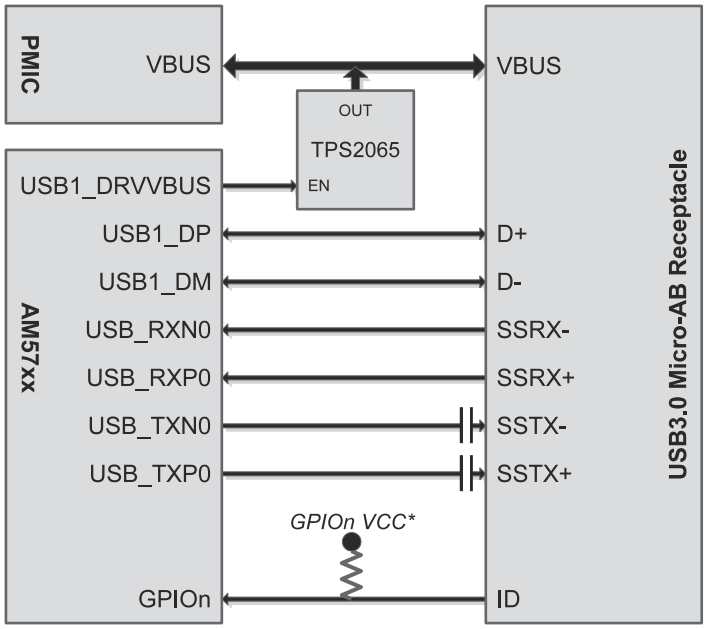


Figure 24-150. USB1 Controller Application: USB3.0 DRD

Figure 24-151 shows typical application of the USB1 controller in the USB3.0 host mode. TPS2065 power switch drives 5-V VBUS when required by monitoring the usb1_drvvbus output from the USB controller. VBUS sensing is exported to the companion PMIC. USB driver monitors VBUS status by listening to the PMIC interrupts and using the I2C1 (PMIC control) interface.

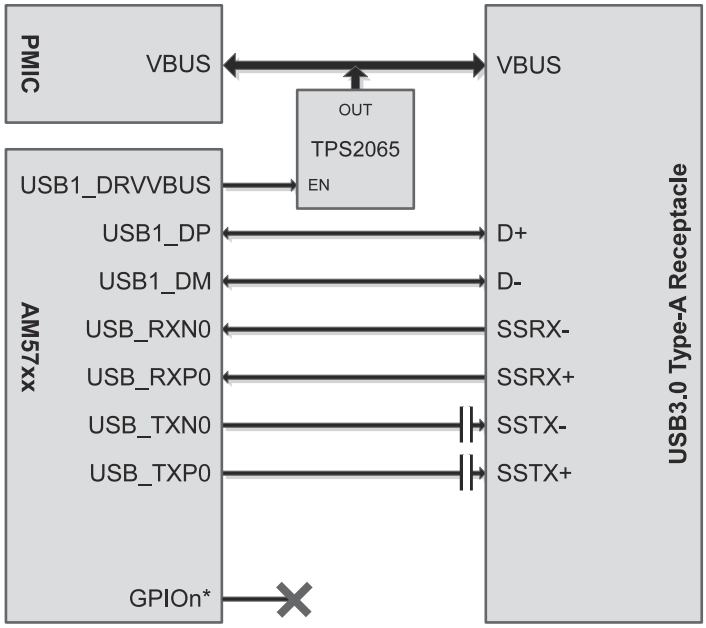

Figure 24-151. USB1 Controller Application: USB3.0 Host

Figure 24-152 shows typical application of the USB1 controller in the USB3.0 device mode. VBUS sensing is exported to the companion PMIC. USB driver monitors VBUS status by listening to the PMIC interrupts and using the I2C1 (PMIC control) interface.

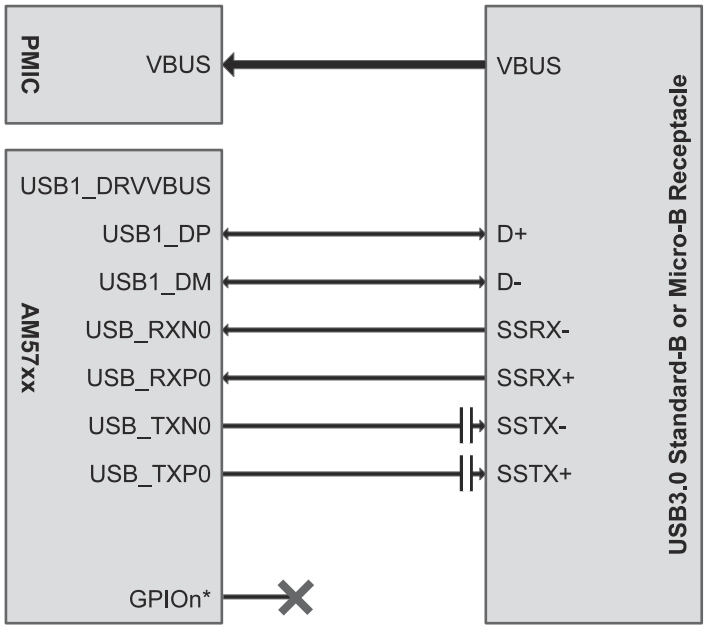

Figure 24-152. USB1 Controller Application: USB3.0 Device

Figure 24-153 shows typical application of the USB2 controller in the USB2.0 dual-role-device mode. TPS2051B power switch drives 5-V VBUS when required by monitoring the usb2_drvvbus output from the USB controller. VBUS sensing is exported to the companion PMIC. USB driver monitors VBUS status by listening to the PMIC interrupts and using the I2C1 (PMIC control) interface.

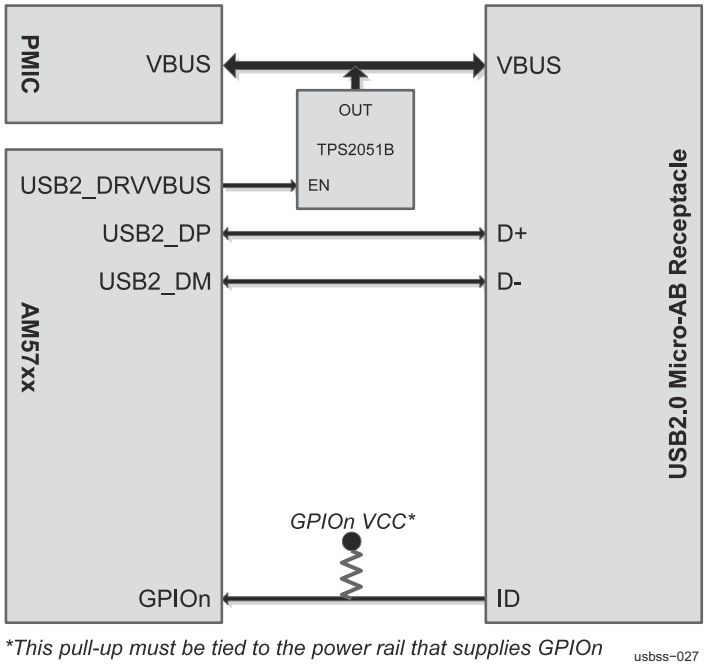

Figure 24-153. USB2 Controller Application: USB2.0 DRD

Figure 24-154 shows typical application of the USB2 controller in USB2.0 host mode. TPS2051B power switch drives 5-V VBUS when required by monitoring the usb2_drvvbus output from the USB controller. VBUS sensing

is exported to the companion PMIC. USB driver monitors VBUS status by listening to the PMIC interrupts and using the I2C1 (PMIC control) interface.

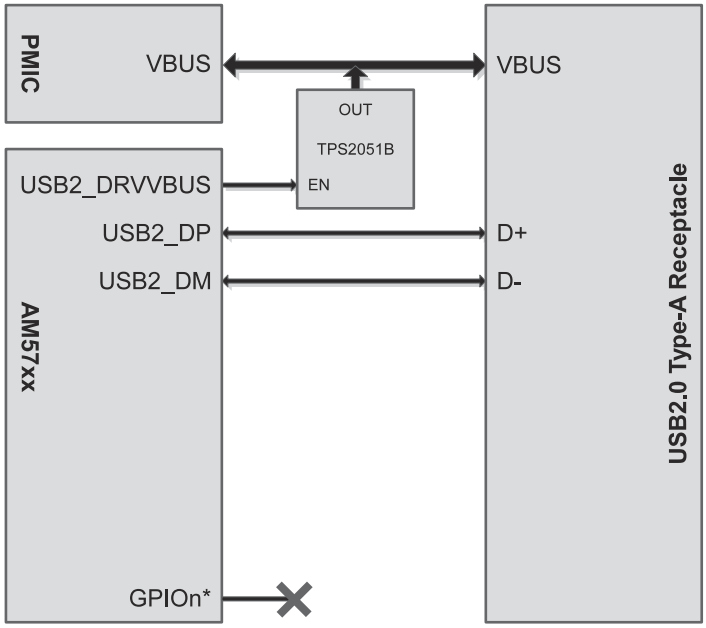

Figure 24-154. USB2 Controller Application: USB2.0 Host

Figure 24-155 shows typical application of the USB2 controller in USB2.0 device mode. VBUS sensing is exported to the companion PMIC. USB driver monitors VBUS status by listening to the PMIC interrupts and using the I2C1 (PMIC control) interface.

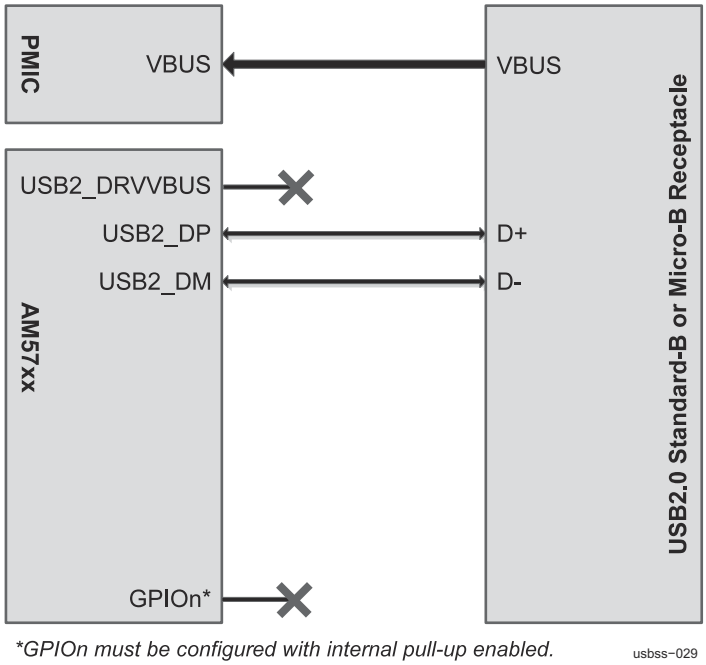

Figure 24-155. USB2 Controller Application: USB2.0 Device

24.7.3 SuperSpeed USB Subsystem Integration

The L3 (master) interconnect generates data traffic within the device. The L4 (slave) interconnect is a configuration port for register setting.

Figure 24-156 shows the SuperSpeed USB subsystem integration in the device.

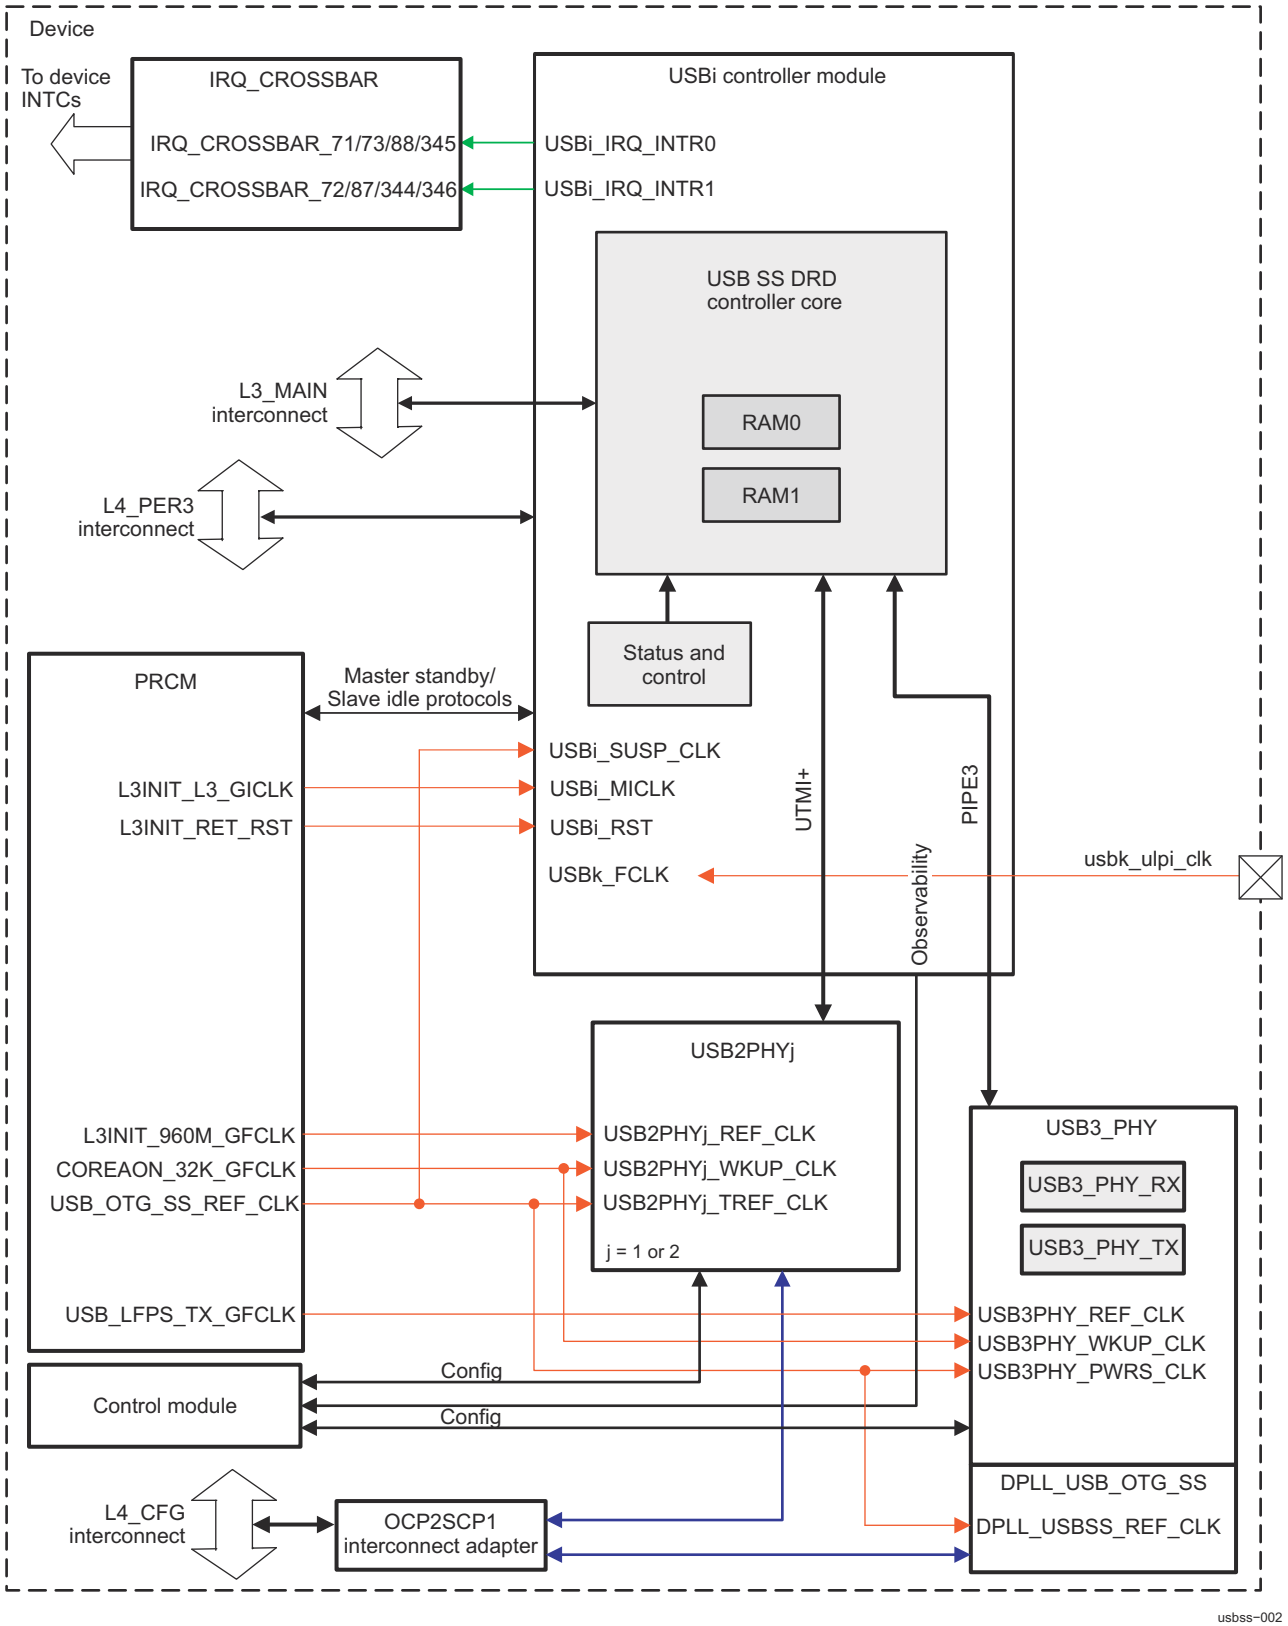

Figure 24-156. SuperSpeed USB Subsystem Integration

i = 1 to 3

k = 3

Table 24-435 through Table 24-437 summarize the integration of the module in the device.

Table 24-435. SuperSpeed USB Subsystem Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
USB1	PD_L3INIT	L3_MAIN L4_PER3
USB2	PD_L3INIT	L3_MAIN L4_PER3
USB3	PD_L3INIT	L3_MAIN L4_PER3
USB2PHY1	PD_L3INIT	L4_CFG
USB2PHY2	PD_L3INIT	L4_CFG
USB3_PHY	PD_L3INIT	L4_CFG

Table 24-436 lists the clocks provided to the SuperSpeed USB subsystem.

Table 24-436. SuperSpeed USB Subsystem Clocks and Resets

	Clocks			
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
USB1	USB1_FCLK	USB2PHY1_UTMI_CLK	USB2PHY1	60-MHz UTMI clock from PHY
	USB1_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface *CD_L3INIT Clock Domain* in *Power, Reset and Clock Management*.
	USB1_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
USB2	USB2_FCLK	USB2PHY2_UTMI_CLK	USB2PHY2	60-MHz UTMI clock from PHY
	USB2_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface.
	USB2_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
	USB2_125M_CLK	L3INIT_60M_FCLK	PRCM	125-MHz clock for the non-USB3.0 instances.
USB3	USB3_FCLK	OTG_60M_FCLK	usb3_ulpi_clk pad	60-MHz ULPI clock from PHY
	USB3_MICLK	L3INIT_L3_GICLK	PRCM	L3 interconnect clock, for the L3 master port interface .
	USB3_SUSP_CLK	USB_OTG_SS_REF_CLK	PRCM	Suspend clock
	USB3_125M_CLK	L3INIT_60M_FCLK	PRCM	125-MHz clock for the non-USB3.0 instances.
USB2PHY1	USB2PHY1_REF_CLK	L3INIT_960M_GFCLK	PRCM	Functional REF 960-MHz clock (from the DPLL_USB, PRCM controlled)
	USB2PHY1_WKUP_CLK	FUNC_32K_CLK	PRCM	Wakeup 32-kHz functional clock
	USB2PHY1_TREF_CLK	USB_OTG_SS_REF_CLK	PRCM	Functional TREF clock derived from SYS_CLK1
USB2PHY2	USB2PHY2_REF_CLK	L3INIT_960M_GFCLK	PRCM	Functional REF 960-MHz clock (from the DPLL_USB, PRCM controlled)
	USB2PHY2_WKUP_CLK	FUNC_32K_CLK	PRCM	Wakeup 32-kHz functional clock
	USB2PHY2_TREF_CLK	USB_OTG_SS_REF_CLK	PRCM	Functional TREF clock derived from SYS_CLK1
USB3_PHY	USB3PHY_REF_CLK	USB_LFPS_TX_GFCLK	PRCM	Fixed-frequency USB3 transmitter REF functional clock

Table 24-436. SuperSpeed USB Subsystem Clocks and Resets (continued)

DPLL_USBSS_REF_CLK	USB_OTG_SS_REF_CLK	PRCM	Functional DPLL REF clock derived from SYS_CLK1
USB3PHY_WKUP_CLK	COREAON_32K_GFCLK	PRCM	Wakeup and debounce 32-kHz functional clock

Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
USB1	USB1_RST	L3INIT_RET_RST	PRCM	USB1 controller module hardware retention reset
USB2	USB2_RST	L3INIT_RET_RST	PRCM	USB2 controller module hardware retention reset
USB3	USB3_RST	L3INIT_RET_RST	PRCM	USB3 controller module hardware retention reset

Table 24-437 lists the interrupt lines that are driven out from the SuperSpeed USB controller modules.

Table 24-437. SuperSpeed USB Subsystem Hardware Requests

Interrupt Requests

Module Instance	Source Signal Name	IRQ_CROSSBAR Input	Default Mapping	Description
USB1	USB1_IRQ_INTR0	IRQ_CROSSBAR_71	MPU_IRQ_76	USB1 main (core) interrupt request
	USB1_IRQ_INTR1	IRQ_CROSSBAR_72	MPU_IRQ_77 IPU1_IRQ_73 IPU2_IRQ_73	USB1 wrapper interrupt request
USB2	USB2_IRQ_INTR0	IRQ_CROSSBAR_73	MPU_IRQ_78 IPU1_IRQ_74 IPU2_IRQ_74	USB2 main (core) interrupt request
	USB2_IRQ_INTR1	IRQ_CROSSBAR_87	MPU_IRQ_92 IPU1_IRQ_76 IPU2_IRQ_76	USB2 wrapper interrupt request
USB3	USB3_IRQ_INTR0	IRQ_CROSSBAR_88	MPU_IRQ_93 IPU1_IRQ_77 IPU2_IRQ_77	USB3 main (core) interrupt request
	USB3_IRQ_INTR1	IRQ_CROSSBAR_344	-	USB3 wrapper interrupt request

Note

The **Default Mapping** column in Table 24-437 shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, see *Interrupt Controllers*.

24.8 SATA Controller

24.8.1 SATA Controller Overview

Note

SATA is not supported on the AM570x family of devices.

The SATA host controller handles data interactions between a local host system memory and a SATA mass storage device with minimal local host (LH) intervention.

In contrast to the parallel 16-bit - ATA (PATA) interface, the SATA interface takes advantage of serial data transmission/reception over a differential pair of conductors. SATA uses the command set from the ATA/ATAPI-6 standard augmented with native command queuing (NCQ) commands optimized for the serialized interface.

The device has one embedded SATA host bus adapter (HBA) controller with a single port. The device SATA host subsystem is composed of several functional components (see Figure 24-157):

- The core component of the SATA host controller subsystem (signified as SATA controller on the Figure 24-157) implements the transport and link layers of the SATA interface protocol, i.e. all SATA media access control (MAC) functionalities.
- SATA_PHY encompasses the physical layer (PHY) components - serializer, de-serializer, etc. which adapt the generated by the SATA controller MAC logic parallel 10-bit output data stream for serial electrical transmission and reception.
- DPLL_SATA is a programmable (through registers of the integrated PLL controller - PLLCTRL_SATA) DPLL clock source that provides a high-speed clock to the SATA_PHY serializer/de-serializer components.
- An L4_CFG interface adapter - OCP2SCP3, which enables accessing the PLLCTRL_SATA registers via L4_CFG interconnect accesses.

For details regarding the device SATA host subsystem components - SATA_PHY , PLLCTRL_SATA, DPLL_SATA and interface adapter), see Section 26.1.1, *SATA PHY Subsystem Overview*, in Chapter 26, *Shared PHY Component Subsystems*.

Figure 24-157 shows an overview of the device-embedded SATA host controller subsystem.

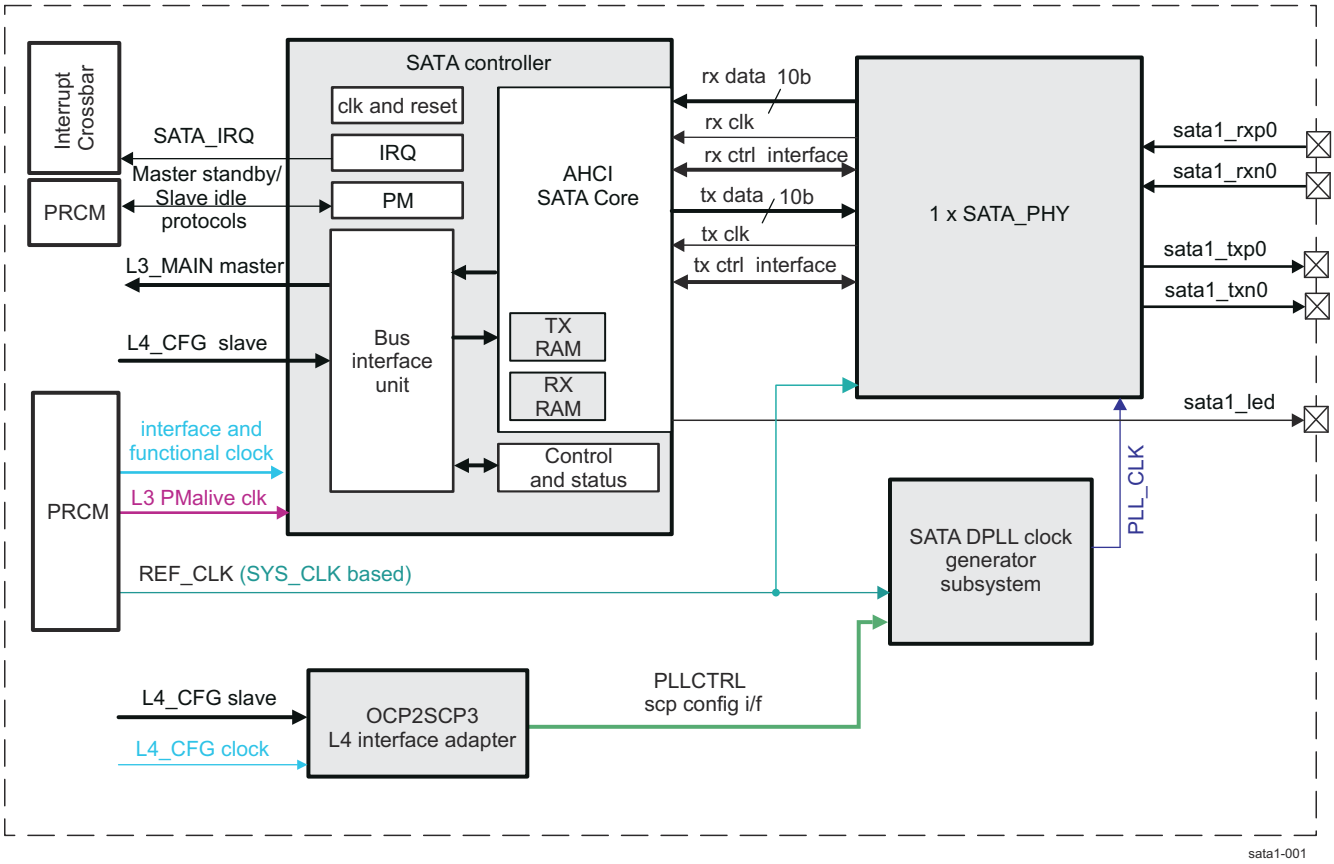

Figure 24-157. SATA Host Controller Subsystem Overview

24.8.1.1 SATA Controller

The SATA controller is the main functional component of the device-embedded SATA (Host Bus Adapter) HBA and is based on advanced host controller interface (AHCI) module. The SATA controller handles data transactions at the link and transport layers of the SATA interface using the advanced host controller interface (AHCI) mechanism. The SATA controller core engine is a generation 2-compliant host (supporting 3 Gbps transfer speed) with integrated DMA and FIFO RAM buffers.

The SATA controller AHCI-based interactions involve extensive DMA processing of both data and command transfers, reducing much of the user overhead associated with standard ATA task file register servicing. The SATA HBA port programmable DMA acts as a master on the device L3_MAIN interconnect, which facilitates direct command/data transfers between host system memory and attached SATA storage devices.

The SATA controller has a slave configuration port accessible on the device L4_CFG interconnect. This port provides the user with an appropriate register interface for HBA setup, control and status, interrupt settings, DMA configuration, etc.

24.8.1.1.1 AHCI Mode Overview

The SATA core supports the AHCI hardware mechanism, which provides the user software with a suitable HBA register interface to manage SATA interface operations. Generally, the AHCI introduces a system memory structure that includes some generic control and status area and a list of command entries (which can have a depth from 1 up to 32 entries) assigned per HBA port. Each of the command list entries contains information necessary to program a SATA device and pointers to data transfer descriptors.

The AHCI mode of operation disregards the master/slave communication model. A certain SATA AHCI host controller port establishes a point-to-point connectivity with only a single SATA peripheral device at a time, which is always a master device.

24.8.1.1.2 Native Command Queuing

The SATA AHCI engine supports NCQ and is capable of command queued protocol interactions with NCQ-compliant SATA mass storage devices. The NCQ commands generated by a SATA HBA port are loaded into command queues maintained at the peripheral device. The commands are stored in a queue and subsequently fetched and processed by peripheral device controller in sequences, which imply more native and highly-optimized for the device order of execution. The synchronization between an NCQ-aware SATA HBA and an NCQ-aware peripheral storage device involves implementation of the so called FPDMA queued command protocol, which ensures that HBA posts NCQ commands to the target SATA device in its demanded NCQ order.

24.8.1.1.3 SATA Transport Layer Functionalities

The SATA controller handles all of the transport layer functions of the SATA protocol. During reception it receives a frame information structure (FIS) from its link layer through the RX FIFO, decodes the type, and routes it to the proper location through the port DMA. During transmission it transfers a FIS constructed by the port DMA to the link layer through the TX FIFO. It also passes link layer errors and checks for transport layer errors to pass up to the system. The transport layer also contains the TX and RX FIFOs. These FIFOs are used as asynchronous data buffers between the serial domain and the bus clock domain. The size of these FIFOs affects the subsystem ability to buffer data before flow control must be asserted. It also affects the maximum transaction size that can be programmed into the port DMA.

24.8.1.1.4 SATA Link Layer Functionalities

The link layer maintains the link and supports all SATA link layer functionality, including:

- Out-of-band (OOB) transmit signaling
- Frame negotiation and arbitration
- Envelope framing/deframing
- Cyclic redundancy check (CRC) calculation (receive and transmit)
- 8b/10b encoding/decoding
- Flow control
- Frame acknowledgment and status
- Data width conversion
- Data scrambling/descrambling
- Primitive transmission
- Primitive detection and dropping
- Power management

24.8.1.2 SATA Controller Features

This section describes the features supplied by the SATA controller module. The SATA controller complies with the following standards:

- *Serial ATA Standard* specification (revision 2.6)
- *Serial ATA Advanced Host Controller Interface* specification (revision 1.1). The device SATA host controller also complies with the *Serial ATA Advanced Host Controller Interface* specification (revision 1.3), excluding support for the port multiplier FIS-based switching feature.

The main features of the SATA host controller are:

- Serial ATA 1.5-Gbps and 3-Gbps speeds (SATA-1 and SATA-2)
- Integrated RxFIFO and TxFIFO RAM data buffers
- Support of all SATA power management features
- AHCI support of 64-bit addressing mode (see device limitation note below)
- HBA port associated Internal DMA engine
- Hardware-assisted NCQ for up to 32 entries
- Command completion coalescing (CCC) interrupts
- Support of port multiplier with command-based switching
- Activity LED generation

Additionally, link layer supports:

- 8b/10b encoding and decoding functionality
- RX elasticity buffer
- TX OOB sequence generation
- RX OOB sequence generation

The differences between the SATA host controller and a standard SATA host controller defined by the *Serial ATA Gold Standard* specification (v2.6) are:

- Staggered spin-up is not supported (only one HBA AHCI port embedded).
- Only one port is supported by the device-embedded SATA HBA from up to 32 possible, according to the standard.
- The SATA controller is AHCI-mode compliant only and does not support standard ATA legacy modes of operation.
- Cold presence detection signals are not available. The SATA controller targets support for permanently attached SATA drives only.

The following features are NOT supported by the SATA host subsystem:

- Far-end analog loopback
- Cold presence detect (CPD) signal is not available at the system level. As a consequence, the SATA device hot-plug operation is not supported.
- Mechanical presence switch signal is not available at system level.
- Message signaled interrupts
- PHY layer functionalities of SATA controller are not integrated. These are assigned to the SATA_PHY transceiver integrated at the device level (outside SATA controller module itself).

The SATA controller master (DMA) interface features:

- 32-bit data
- 36 bits of the AHCI master address bus (byte-aligned addressing) implemented in the device. See device limitation note below.
- 1-bit tag-ID port, but the tag value is 1 on all accesses (that is, the feature is not used)
- Sequential burst support (16 x 32 bit – Dwords)

Note

Even though the SATA AHCI Controller supports 64-bit -addressing mode, only 36-lower bits of the 64-bit address bus are integrated (meaningful) in the device. This defines a 64-GiB AHCI master address space.

The SATA controller slave interface features:

- 32-bit data, 13-bit (byte-aligned) address
- Single access (no burst support)
- All accesses are expected to be 4 bytes wide, 32-bit aligned.

Note

Accesses smaller than 4 bytes wide (that is, byte enable patterns different from 4’b1111) are functional and do not generate an error. Misaligned addresses do not generate an error.

As can be seen in Figure 24-157, the SATA Controller has all events merged to a single interrupt output - SATA_IRQ, mapped to the device Interrupt Crossbar.

24.8.2 SATA Controller Environment

Note

SATA is not supported on the AM570x family of devices.

Apart from the SATA communication-dedicated electrical connections to the SATA_PHY component, there is an additional SATA-defined-led drive generation signal that can be output at the device pad: *spi1_cs[1]* . For more information about this signal pad configuration register mapping, see *Pad Configuration Registers* in *Control Module*. For more details regarding the behavior of activity LED generation, see Section 24.8.4.10, *Activity LED Generation Functionality*.

Table 24-438. SATA Controller I/O Signals

Module Pin Name	Device Level Signal Name	I/O(1)	Description	Reset Value
TXP(2)	sata1_txp0	O	TXP output of the SATA PHY differential transmission line	0
TXN(2)	sata1_txn0	O	TXN output of the SATA PHY differential transmission line	0
RXP(2)	sata1_rxp0	I	RXP input of the SATA PHY differential reception line	Hi-Z
RXN(2)	sata1_rxn0	I	RXN input of the SATA PHY differential reception line	Hi-Z
ACT0_LED	sata1_led	O	HBA port activity LED indication	Hi-Z

(1) I = Input; O = Output
(2) These signals are part of the interface between SATA PHY serializer / de-serializer and the externally attached SATA storage device.

Note

The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the sections *Pad Configuration Rregisters*, and *Control Module Register Manual*, in *Control Module*, for more information.

The Figure 24-158 shows the SATA host controller subsystem environment summarizing the interface signals exported directly from SATA controller at the device boundary, as well as those exported after SATA_PHY processing at the device boundary. For more information on the interface between the SATA controller and SATA_PHY , see Chapter 26, *Shared PHY Component Subsytsems*.

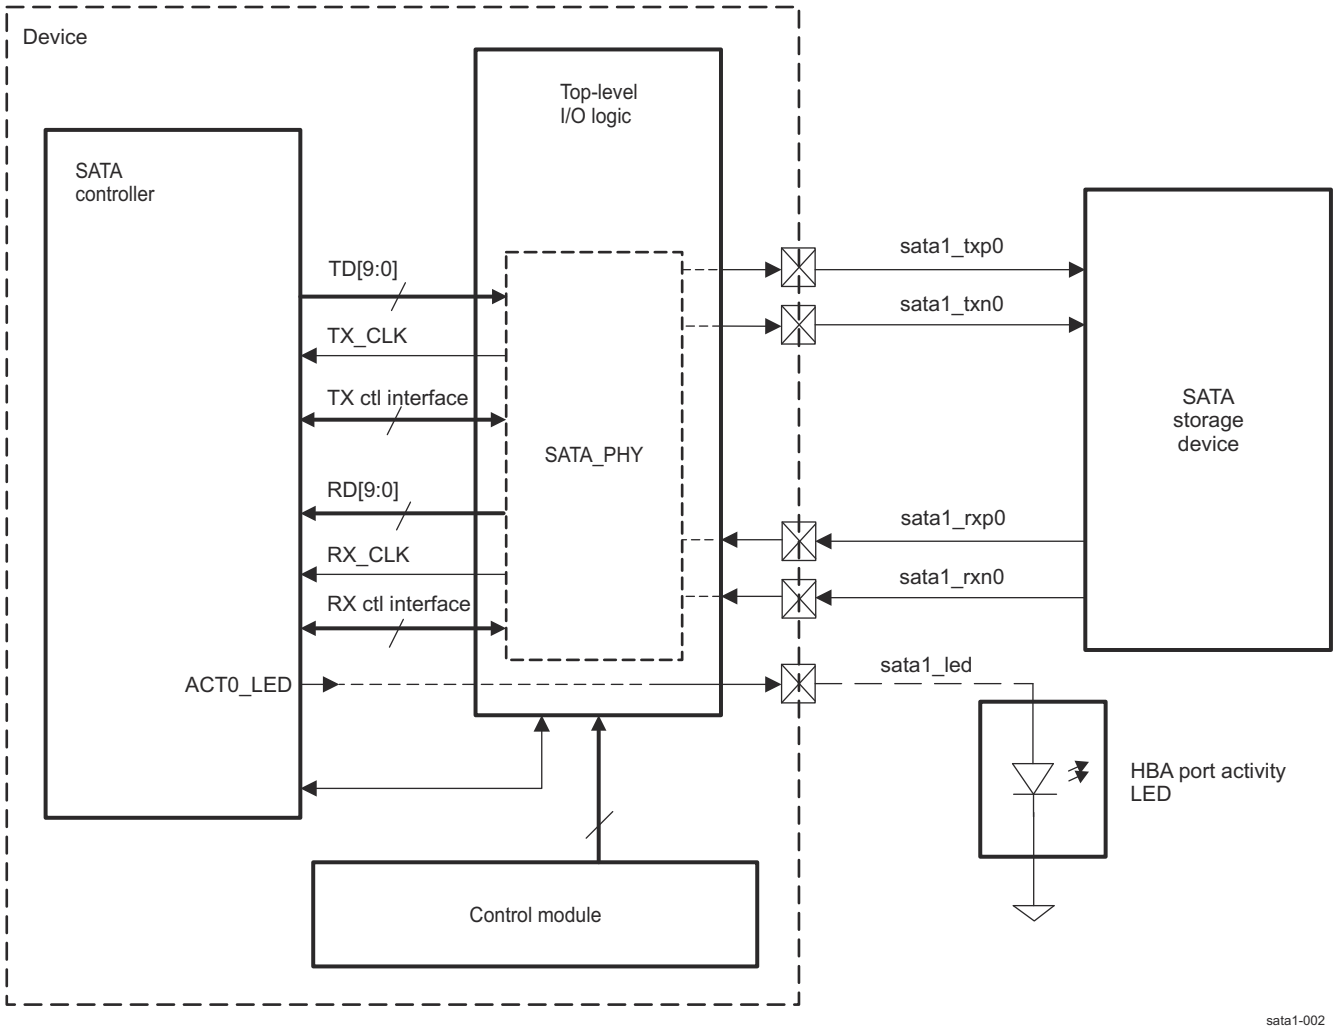

Figure 24-158. SATA Subsystem Environment

24.8.3 SATA Controller Integration

Note

SATA is not supported on the AM570x family of devices.

This section describes the SATA AHCI host controller integration in the device, including information about clocks, resets, and hardware requests. Figure 24-159 shows the SATA controller integration.

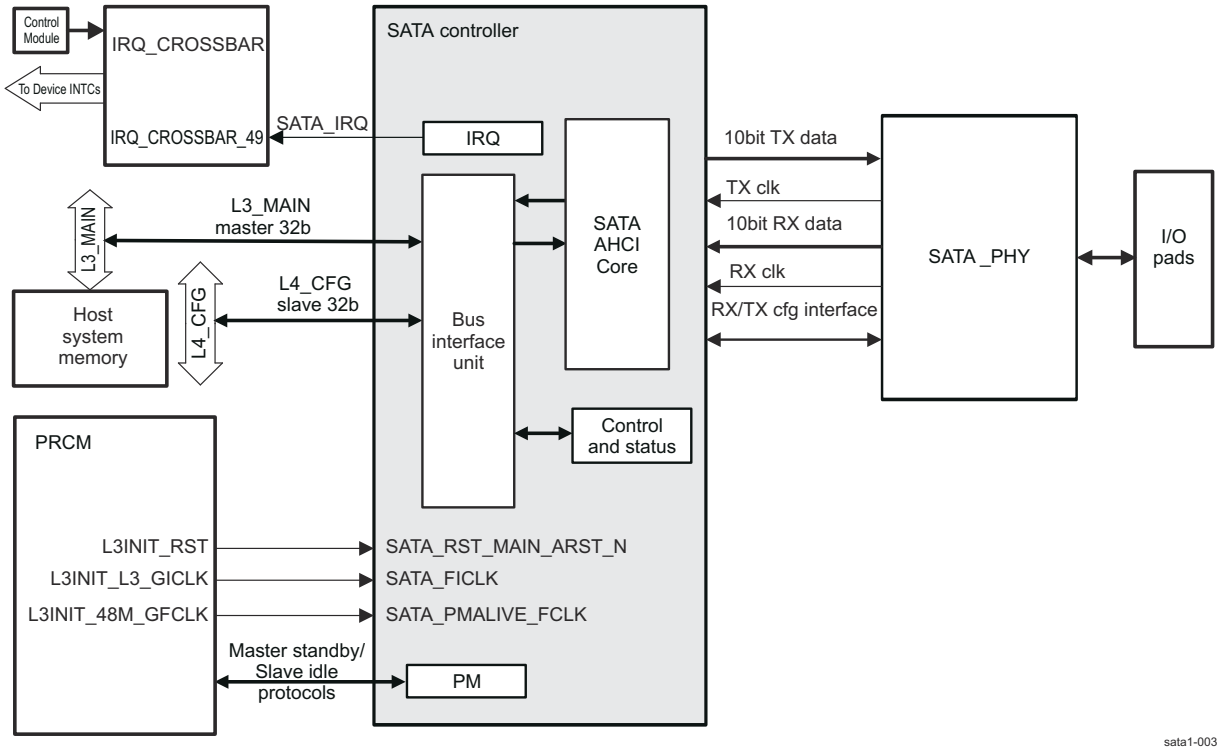

Figure 24-159. SATA Controller Integration

SATA controller integration includes these features:

- A single functional and interface clock (SATA_FICLK, shared between the master and the slave interfaces)
- A functional always-on clock (SATA_PMALIVE_FCLK to support entrance into and exit from the SATA defined low-power modes)
- A single hardware nonretention reset input (SATA_RST_MAIN_ARST_N)
- Master standby and slave idle protocols with the power, reset, and clock management (PRCM) module
- A single interrupt request generation line (SATA_IRQ, mapped to IRQ_CROSSBAR_49 line of IRQ CROSSBAR)
- No DMA or wakeup requests generation to surrounding modules
- L3_MAIN master interface
- L4_CFG-configuration slave interface

The SATA encoded symbol transmission/decoded symbol reception relies on two serial clocks , which are supplied indirectly from the DPLL_SATA through the SATA_PHY component.

Note

For more information about the slave idle protocol and the wakeup request, see *Module-Level Clock Management* in *Power, Reset, and Clock Management*.

Table 24-439 through Table 24-441 summarize the integration of the module in the device.

Table 24-439. SATA Controller Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SATA	PD_L3INIT	L4_CFG L3_MAIN

Table 24-440. SATA Controller Clocks and Resets

Clocks

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SATA	SATA_FICLK	L3INIT_L3_GICLK	PRCM	SATA interface and functional clock
	SATA_PMALIVE_FCLK	L3INIT_48M_GFCLK	PRCM	Always-on SATA-specific, power-management support clock

Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SATA	SATA_RST_MAIN_ARST_N	L3INIT_RST	PRCM	A nonretention hardware reset

Table 24-441. SATA Controller Hardware Requests

Interrupt Requests

Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
SATA	SATA_IRQ	IRQ_CROSSBAR_49	MPU_IRQ_54 DSP1_IRQ_80	SATA Controller IRQ line

Note

The "**Default Mapping**" column in Table 24-441 *SATA Controller Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

- For a description of the interrupt source, see *Interrupt Requests*.

Note

- The SATA HBA does not generate DMA and wakeup hardware requests to the surrounding modules integrated in the device

24.8.4 SATA Controller Functional Description

Note

SATA is not supported on the AM570x family of devices.

24.8.4.1 SATA Controller Block Diagram

Figure 24-160 shows a block diagram of the SATA host controller.

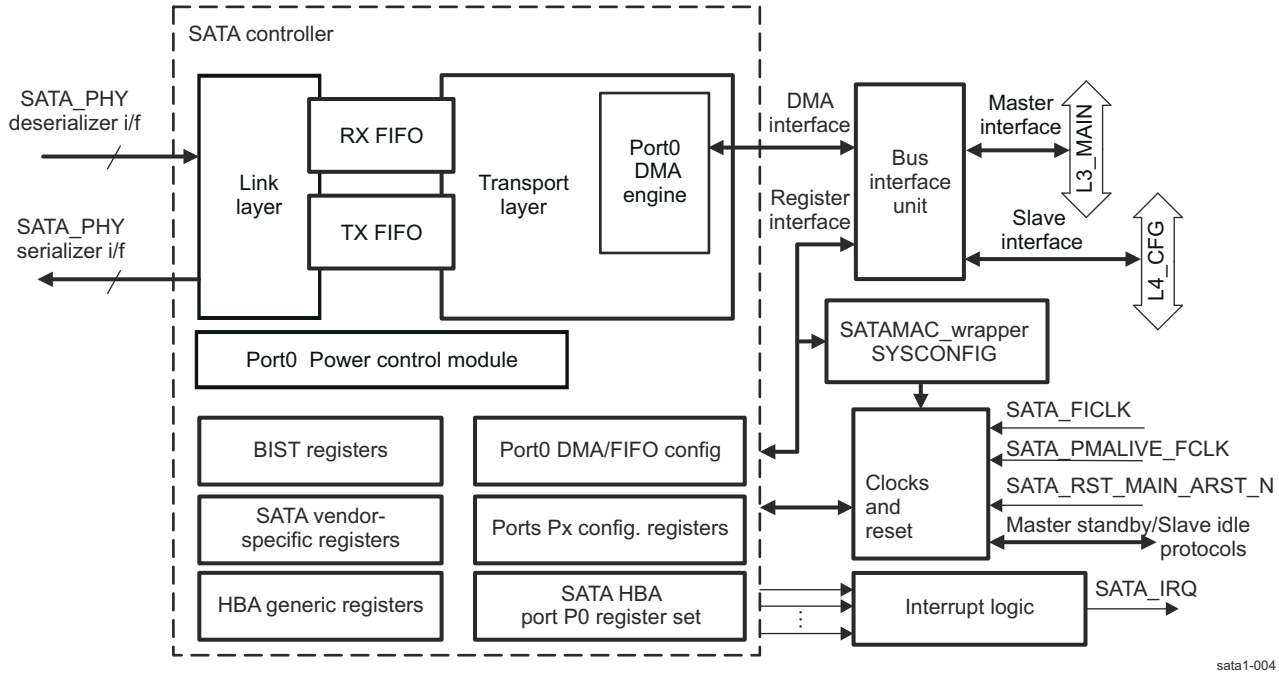

Figure 24-160. SATA Controller Functional Block Diagram

The SATA HBA port-associated DMA is a master on the device L3_MAIN interconnect. For a write to the attached storage device, this port reads FISs from the host system memory and pushes them into the transmit FIFO. When frame Dwords are received at RxFIFO, this interface is used to write the data out to the dedicated host system memory area. For details about DMA features and operation, see Section 24.8.4.8, *DMA Port Configuration*.

The SATA controller has a configuration slave interface used to read and write all system registers. The slave interface includes the following functions:

- Configuring the SATA AHCI core (and indirectly, to a certain extent, the SATA_PHY physical component)
- Configuring the DMA for transmit and receive operations
- Initiating write transfers to the attached storage device
- Responding to interrupts and reads

Both the slave and master interface of the SATA host controller share the same functional and interface clock, that is, operate on the same frequency (see also Section 24.8.3, *SATA Controller Integration*).

A bus interface unit adapts the SATA controller master and slave buses to the corresponding L3_MAIN and L4_CFG device interconnects.

Note

The **SATA controller AHCI Core registers** are part of the instance signified as **DWC_ahsata** inside the Section 24.8.6.1, *SATA Controller Instance Summary*.

24.8.4.2 SATA Controller Link Layer Protocol and Data Format

One of the main tasks of the SATA HBA Link layer is to perform a parallel 8-bit FIS data to a 10-bit parallel code conversion (8b/10b encoding) . The encoded stream, which is a sequence of 10-bit parallel-encoded characters, is subsequently passed to the SATA_PHY serializer component to adapt to a serial 10-bit character transmission to the SATA peripheral device. For more details, see Section 26.1.1, *SATA PHY Subsystem Overview*, and Section 26.1.4, *SATA PHY Subsystem Functional Description,* in Chapter 26, *Shared PHY Component Subsystems*.

One of the main tasks of the SATA HBA Link receiver is to perform a 8b/10b decoding, in which process the parallel 10-bit characters coming out from the SATA_PHY de-serializer are decoded to parallel data or control bytes. The received symbols with invalid codes are rejected by the link layer and corresponding illegal reception errors are generated. For more details regarding the SATA_PHY de-serializer, see Section 26.1.1, *SATA PHY Subsystem Overview*, and Section 26.1.4, *SATA PHY Subsystem Functional Description,* in Chapter 26, *Shared PHY Component Subsystems*.

There are also other data process stages at the link layer, such as CRC calculation, scrambling/descrambling, primitive insertion/detection, etc. Figure 24-161 shows the primary stages of link Dword data processing.

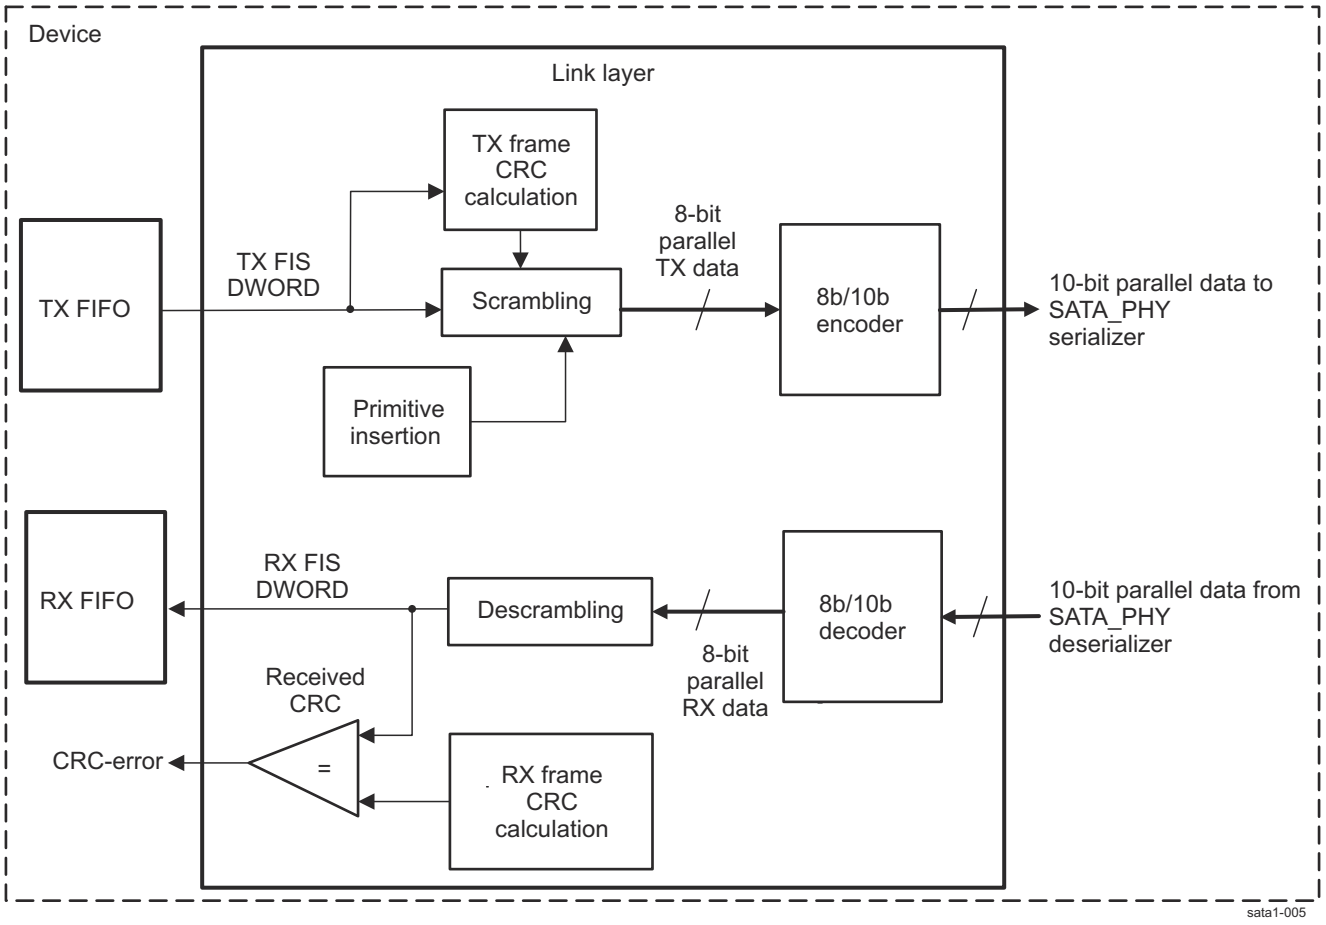

Figure 24-161. Simplified Schema of Link Dword Processing

24.8.4.2.1 SATA 8b/10b Parallel Encoding/Decoding

The input to the link coder logic is a parallel (unencoded) data byte and an associated control variable: Z with two possible values (K, D). The Z value signifies the byte to be encoded either as a control character (K value) or a data character (D value). The data byte (ABCDEFGH, where A matches the least significant bit [LSB]) is divided into two asymmetric portions: a 5-bit one ABCDE (range: 0 to 31) and a 3-bit one FGH (range: 0 to 7).

The encoding process is performed in two stages. At the first stage, the 5-bit portion is converted to a 6-bit subblock (abcdei); at the second stage, the 3-bit portion is converted to a 4-bit subblock (fghj). An additional parameter called running disparity (rd) is taken into account during code calculation at both the character transmission and reception link sides. It introduces code correlation between adjacent bytes so that the current subblock code can depend on the code of the previous subblock and its associated rd output value. As a consequence, depending on the input rd parameter and the 8b/10b encoded value, the encoding/decoding lookup tables might have two different entries for the same byte.

The 10-bit parallel-encoded character is passed to the 10-bit data input of the SATA_PHY serializer component, which further transmits it serially in a LSB to most significant bit (MSB) order (abcdeifghj). The receiver link receives and decodes the sequence in the same LSB to MSB order (abcdeifghj). While SATA encoder takes the full range of a data byte (0–255) encoding values, it uses only two values to encode control characters. For more information on the 8b/10b encoding/decoding process, see the SATA standard specification.

24.8.4.2.2 SATA Stream Dword Components

The basic unit of SATA information is Dword – a double sized word (32 bits). An encoded Dword has a 40-bit length (4 x 10 bits), but, for simplicity, unencoded Dword lengths are considered here. Each Dword is serially transmitted or received by the SATA_PHY components in LSB character to MSB character order.

- Primitives

  The shortest meaningful component of the SATA stream is the primitive, which consists of a single Dword. Different types of primitive characters are inserted into the SATA stream to maintain synchronization between the host and the SATA peripheral device. Primitives convey real-time state information regarding the SATA communication channel itself. For example, the SATA link layer generates primitives to perform flow control, synchronize power management state transitions, frame enveloping, etc. The transport layer is not aware of the lower level primitive Dwords. They are subject to processing only to the link layer.
- Primitive handshakes

  In some cases, the transmitter of a primitive can require that the receiver send an acknowledge Dword to confirm primitive reception, which is a primitive handshake.

  The first byte of a primitive Dword is always a control character (or Z = K) with two possible encodings. The remaining three data bytes (Z = D) contain the function of the primitive. According to the SATA standard, the transmitter and the receiver are not required to match the number of primitives sent and received.

  Table 24-442 briefly summarizes the primitives used by SATA.

Table 24-442. SATA Primitives Summary

Primitive Name	Short Description
ALIGNp	Sent in pairs to PHY component to readjust its internal operations
CONTp	After CONTp insertion, previous primitives are repeated continuously until a different primitive is inserted
DMATp	terminates DMA data transmission
EOFp	End of frame
HOLDp	Inserted to hold data when transmitter doesn't have data ready to transmit
HOLDAp	Acknowledges a HOLDp primitive
PMACKp	Acknowledges a power management request
PMNAKp	A power management request denial
PMREQ_Pp	Power management request to PARTIAL state
PMREQ_Sp	Power management request to SLUMBER state
R_ERRp	Reception error occurred
R_IPp	Current node is receiving data

Table 24-442. SATA Primitives Summary (continued)

Primitive Name	Short Description
R_OKp	Reception without error
R_RDYp	Receiver is ready for reception
SOFp	Start of frame
SYNCp	Synchronization primitive
WTRMp	Transmitter inserts this primitive while waiting to get the reception status from receiver
XRDYp	Transmitter has data ready for transmission

- SATA data frames

  SATA data frames incorporate data FISs constructed at the transport layer along with some primitives (see Figure 24-162). The maximum number of Dwords between SOFp to EOFp does not exceed 2064 Dwords, including the FIS type and CRC fields described here.
- Frame FIS components

  The FIS (Frame Information Structure) contents of a frame incorporate the Dwords that correspond to SATA target data structures. FIS Dwords are output from transport layer TxFIFO to the transmitter link 8b/10b encoder during transmission. In the case of reception, the FIS content is obtained at transport layer RxFIFO after being successfully decoded by the receiver link logic. The commands and data embedded into Frame FISs are generated/interpreted at a higher transport level of the SATA controller and are user software-accessible in the host system memory.
- CRC

  The CRC is the last Dword in a frame, immediately following the last FIS Dword of the frame and preceding the EOFp primitive. The 32-bit CRC calculation is performed only on the FIS Dwords of the frame contents, so that frame-inserted primitives such as HOLDp, CONTp, etc., are not taken into account. The CRC is aligned on a Dword boundary. CRC code computation expects an input of an even number of words and should be Dword-multiple. If an FIS block contains an odd number of words, the last FIS word is padded with 0s to a full Dword before the CRC is calculated.
  - During transmission: The CRC Dword is calculated on original FIS contents, before scrambling and serial 8b/10b encoding are performed.
  - During reception: The CRC Dword is calculated on the 8b/10b decoded and subsequently descrambled 8-bit FIS Dword contents. It is then compared to the CRC received from the source to perform error check analysis.
- Frame embedded primitives

  The beginning of a frame is marked with a SOFp primitive, and the end is marked with an EOFp primitive. Some primitives, such as HOLDp and HOLDAp acknowledge, can be inserted into frames between data FISs.
- SATA data stream

  As shown in Figure 24-162, the SATA data stream is composed of frames carrying the target data/command contents combined with various primitives generated to maintain consistency of transfers over the SATA interface.

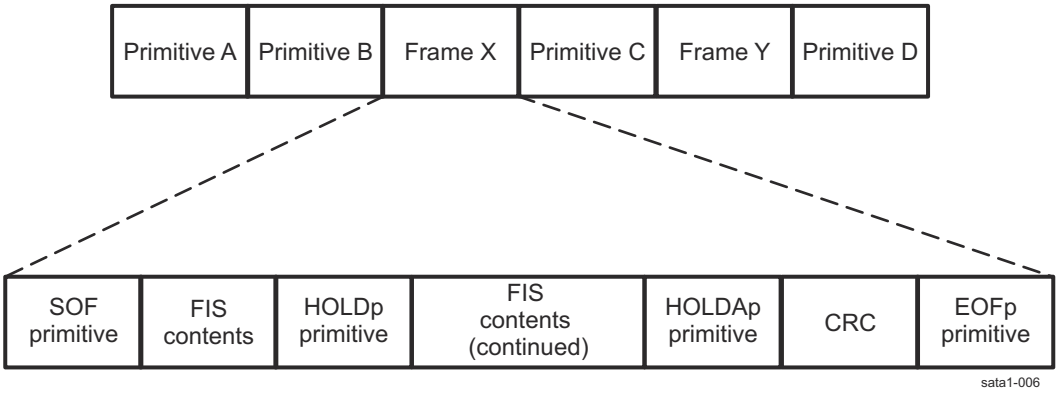

Figure 24-162. SATA Data Stream Components

24.8.4.2.3 Scrambling/Descrambling Processing

The contents of a frame are scrambled before being passed to the link 8b/10b encoder. Scrambling is performed on Dword quantities by XORing the data to be transmitted with the output of a linear feedback shift register (LFSR). All data words between the SOFp and EOFp are scrambled, including the CRC. Figure 24-161 shows the basic flow.

The SATA controller (as defined by the SATA standard) performs scrambling/descrambling processing for EMI reduction purposes. Two scramblers are instantiated within the SATA controller: The first, the data payload scrambler, scrambles FIS data payload contents (including the calculated CRC Dword); the second, the repeated primitive suppression scrambler, scrambles only the repeated primitive stream contents.

The scrambling runs as follows: A certain data payload Dword located between SOFp and EOFp is XORed with the data payload scrambler output. The resulting scrambled Dword is submitted to the 8b/10b encoder for transmission.

On reception, the Dword is decoded using a 10b/8b decoder, the scrambler output is XORed with the resulting Dword, and the resulting Dword is presented to the link layer. It is then used for CRC computation. The CRC Dword is scrambled in the same way as data payload characters.

For details on the scrambling/descrambling feature, see the *SATA Standard Specification* (rev.2.6).

24.8.4.3 Resets

24.8.4.3.1 Hardware Reset

The module is reinitialized in hardware upon activation of PRCM.L3INIT_RST reset signal (for more information about hardware reset, see Section 24.8.3, *SATA Controller Integration*).

For more information on the PRCM.L3INIT_RST hardware reset signal, refer to *Reset Domains*, in *Power, Reset, and Clock Management*.

This reset normally occurs on device power up or during a system bus failure. All components of the SATA AHCI core are initialized, including the HBA port and generic registers. The bus interface unit (BIU) and SATA AHCI core wrapper components are also impacted.

24.8.4.3.2 Software Initiated Resets

The SATA controller supports three levels of software reset, each of which has different impact over the SATA HBA hardware components and AHCI interface registers:

- Software reset (least intrusive)
- Port reset
- HBA reset (most intrusive)

Note

It is recommended that user software always starts with the least intrusive reset approach. Software chooses the next most intrusive reset only if the less intrusive reset does not succeed in clearing the condition.

24.8.4.3.2.1 Software Reset

Software reset impacts only the attached to the HBA port SATA peripheral device, without affecting the established communication between physical layers or HBA engine.

To issue a software reset, the user must prepare two H2D register FISs into the emptied command list of the port. The first FIS must have bits SRST = 0b1 and C = 0b0. The first FIS corresponding command header bits C and R are set as follows: C = 0b1 and R = 0b1.The second FIS has bits SRST = 0b0 and C = 0b0. The second FIS corresponding command header bits C and R are set as follows: C = 0b0 and R = 0b0.

However, steps must be taken before issuing the software reset to the peripheral device attached to the port. For details on software reset, see the AHCI specification.

24.8.4.3.2.2 Port Reset

The port reset (also known as COMRESET) must be applied when the HBA port does not function properly after a software reset is issued to the port. The effect is that the SATA HBA port is reinitialized and communication between the phy layers of both the SATA host and the SATA target device is reestablished.

To trigger a COMRESET sequence on the SATA interface, user software must write 0x1 to the SATA_PxSCTL[3:0]DET bit field. The host receives a COMINIT signal sequence, indicating that the peripheral device has successfully reestablished communication. For more information on port reset, see the AHCI specification (revision 1.1).

Note

The port reset (COMRESET) method is the preferred AHCI mechanism for error recovery and should be used instead of the software reset.

24.8.4.3.2.3 HBA Reset

Software can globally reset the SATA controller, if a port reset does not clear the conditions successfully. On HBA reset, all SATA AHCI core interface registers are reset, **excluding those from the hardware initialization domain** - the SATA_PxCLB, SATA_PxCLBU, SATA_PxFB and SATA_PxFBU registers. All state machines that relate to data transfers and queuing return to IDLE state, and the port is reinitialized by sending COMRESET. The global reset is triggered when user software sets the SATA_GHC[0]HR = 0b1 bit. The HBA indicates that global reset is finished, deasserting the SATA_GHC[0]HR bit to 0b0 in hardware. Hence, user software must poll the HR bit to detect this condition. For more information, see the mentioned AHCI standard specification.

24.8.4.4 Power Management

The device SATA host controller subsystem power management can be identified at the following levels:

- SATA controller low power-management features (defined also in the SATA standard specification, revision 2.6)
- Master standby and idle slave protocols established between SATA controller and the device PRCM through a SATA AHCI core wrapper interface (signified as SATAMAC_wrapper instance inside the Section 24.8.6.1, *SATA Controller Instance Summary*).

This section describes the relationships that exist between both levels of SATA Controller power management.

24.8.4.4.1 SATA Specific Power Management

The SATA controller core supports both PARTIAL and SLUMBER low-power states, as described in the SATA standard specification (revision 2.6). These modes allow power savings by powering down part of SATA_PHY

and gating off the clocks to the link layer. The port power control module is used to enter and exit these modes, which can have the normal functional clocks gated off.

24.8.4.4.1.1 PARTIAL Power Mode

In the PARTIAL power state, the SATA_PHY component transmits electrical IDLE to the device and the receiver is left on to receive OOB signals. This mode can also be used to support near-end analog loopback, if a device is attached.

24.8.4.4.1.2 Slumber Power Mode

In the SLUMBER power state, the transmitter is completely turned off. This allows for greater power savings but near-end analog loopback cannot be performed and there is a longer latency to exit the mode.

24.8.4.4.1.3 Software Control over Low Power States

The user has manual control over low power states through the SATA_PxCMD [31:28]ICC register bit field. This works if the link is in IDLE state; otherwise, writes to this field are ignored.

24.8.4.4.1.4 Aggressive Power Management

Low power modes can be initiated by software when there are no pending transactions, but the SATA AHCI core also supports aggressive power management. In this mode, the subsystem automatically initiates the PARTIAL or SLUMBER state when there are no inflight commands. This is useful for power savings, but the price is increased latency if a low-power mode is entered and a transfer request is made. Software enables aggressive link-layer power management by setting the SATA_PxCMD[26]ALPE bit to 0x1. The link aggressive power management state (PARTIAL or SLUMBER) is selected using the SATA_PxCMD[27]ASP bit.

24.8.4.4.2 Master Standby and Slave Idle Management Protocols

The master standby and slave idle protocols are implemented between the PRCM and SATA controller, with mode settings located in the SATAMAC_wrapper register (SATA_SYSCONFIG).

- The standard idle request/acknowledge handshake is associated with the L4_CFG slave port. The default idle mode is smart-idle, as indicated by the power-on reset (POR) value: SATA_SYSCONFIG[3:2]IDLEMODE = 0x2.

Note

No other mode is expected to be required in normal operation: no-idle and force-idle are used for debugging only. Because the module is not capable of asynchronous wakeup, the smart-idle/wakeup (IDLEMODE = 0x3) is strictly equivalent to smart-idle.

- The standby/wait handshake is associated with the L3_MAIN master port. Software is responsible to keep the DMA operations and the standby status in sync.

The default standby mode is smart-standby, as indicated by the POR value: SATA_SYSCONFIG[5:4]STANDBYMODE = 0x2. However, the SATA controller hardware does not provide any indication about DMA activity that could be used to drive the standby dynamically (that is, the smart mode): Smart-standby is therefore strictly equivalent to the force-standby mode (that is, the module remains in or goes to permanent standby).

The standby control procedures are therefore software-driven.

To exit standby:

1. Change the standby mode to no-standby by setting SATA_SYSCONFIG[5:4] = 0x1.
2. Optional: Confirm the SATA controller standby status through the PRCM. For more information, see *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
3. Only then, enable the controller DMA (AHCI list processor). For more information, see the AHCI specification.

To enter standby:

1. Disable the controller DMA (AHCI list processor). For more information, see the AHCI specification.
2. Ensure all pending transactions have completed. For more information, see the AHCI specification.
3. Change the standby mode to smart-standby (or force-standby) by setting SATA_SYSCONFIG[5:4] = 0x2.

CAUTION

The software is responsible to keep the DMA operations and the standby mode status in sync.

Note

Because the standby exit is software driven, it is by definition synchronous: the asynchronous wakeup is never activated, which means that the smart-standby and smart-standby/wakeup are equivalent (as well as force-standby).

Note

For more information on the SATA Controller master standby and slave idle management protocols with the device PRCM , see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

24.8.4.4.3 Clock Gating Synchronization

The bus clock can also be gated off in either the PARTIAL or SLUMBER state, if the software guarantees there is nothing in flight, the clock can be stopped and started without glitches, and the clock can be restarted quickly when activity is initiated from the device side.

The following steps outline the procedure to stop the clock:

1. Put the link in a low power state (either PARTIAL or SLUMBER)
   - SATA MAC link layer can enter low power either manually see Section 24.8.4.4.1.3, *Software Control over Low Power States*) or automatically (see Section 24.8.4.4.1.4, *Aggressive Power Management*)
   - If there is no device attached (making it impossible to enter a low power state), the SATA_SYSCONFIG[16] OVERRIDE0 override bit can be set to 0b1 to stop the interface/functional clock (SATA_FICLK) and save power.
2. Initiate the clock stopping procedure.

CAUTION

If a SATA drive attached to the SATA HBA port has not entered a low power state (PARTIAL or SLUMBER), the user must not set the SATA_SYSCONFIG[16]OVERRIDE0 bit; otherwise, the link layer can be ruined, resulting in indeterminate SATA controller behavior.

24.8.4.4.4

Table 24-443. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	SATA_SYSCONFIG [3:2]IDLEMODE bit field	The available modes are: Force-idle, no-idle, and smart-idle wakeup disabled modes are available.
Master standby modes	SATA_SYSCONFIG [5:4]STANDBYMODE bit field	The available modes are: Force-standby, no-standby, smart-standby wakeup disabled
Clock-gate overriding mode	SATA_SYSCONFIG [16]OVERRIDE0 bit field	Clock stopping override function. Should not be applied when attached to port SATA peripheral device has not entered a Low-power mode.

For more information on the L3INIT_L3_GICLK functional clock gating in the device PRCM , refer to Section 3.1.1.1.5, *Clock Domain-Level Clock Management*, in the chapter, *Power, Reset and Clock Management*.

24.8.4.5 Interrupt Requests

This section describes all of the conditions that can generate an interrupt. Each condition is subject to the masking capabilities described in Section 24.8.4.5.4, *Interrupt Condition Control*.

24.8.4.5.1 Interrupt Generation

Both level and pulse interrupts are available. Exercise care when using the pulse interrupt. Because of the synchronization and interrupt aggregation from the internal core, clearing one interrupt as another interrupt occurs can prevent a new pulse from being generated. A new pulse is generated only if the first interrupt is completely cleared (that is, the level interrupt goes away) before the new interrupt event occurs. Thus, an interrupt can occur after the register write is issued to clear the first interrupt but before the interrupt is fully cleared. In this case, a new pulse is not issued and the level interrupt remains asserted. After issuing the write to clear an interrupt, software must read the interrupt status registers to ensure that a new interrupt has not occurred.

24.8.4.5.2 Levels of Interrupt Control

The AHCI directs that interrupts be indicated in a two-tier structure and thus associated with different HBA ports. Considering the device SATA HBA single-port implementation for the first tier, only the SATA_IS[0] IPS bit should be considered. It indicates if the only port available to the user (HBA port 0) has pending interrupts.

For the second tier, the SATA_PxIS register (where x = 0) indicates which specific interrupt condition(s) occurs to trigger an interrupt on port 0. In most cases, software writes 0x1 (Write One to Clear) to clear these bits, and then writes 0x1 to the SATA_IS [0]IPS bit to clear the interrupt. However, some interrupts in the SATA_PxIS register have alternate methods of being cleared (for details, see Section 24.8.6.2.2, *DWC_ahsata Register Description*). Section 24.8.4.5.3, *Interrupt Events Description*, describes all interrupt generating conditions.

Figure 24-163 shows the SATA controller two-tier interrupt propagation structure. Besides SATA_IS[0], which gates all interrupts at the port 0 level, the tier 1 interrupt is globally gated by the SATA_GHC[1] IE bit.

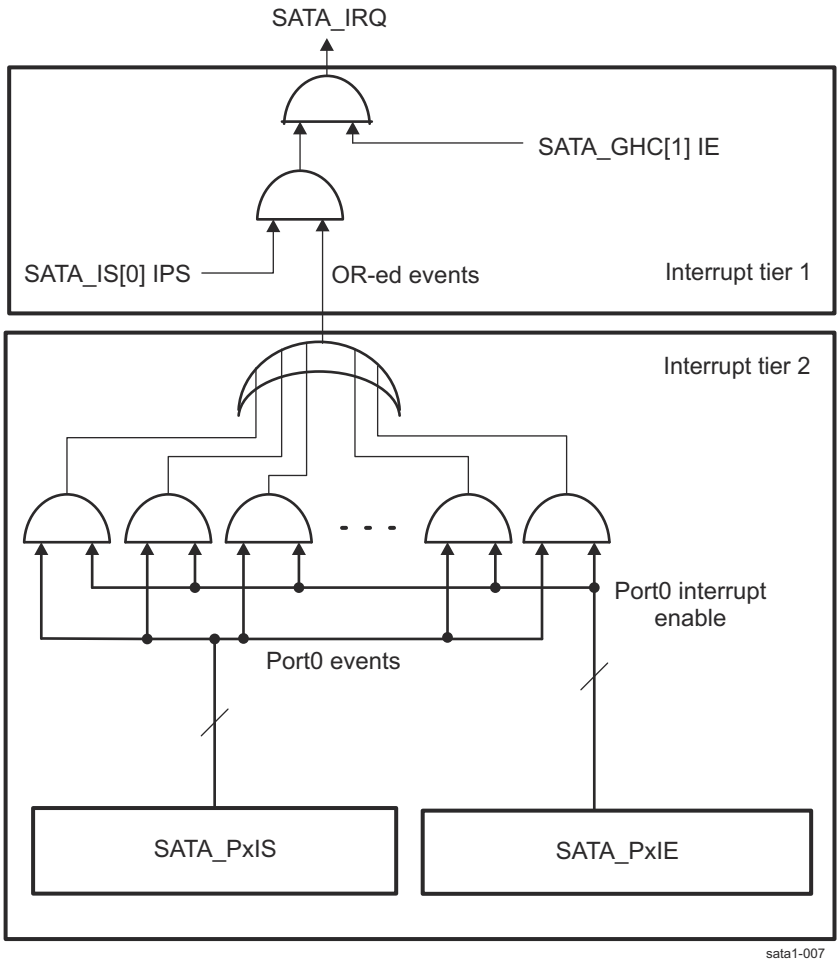

Figure 24-163. SATA Controller Interrupt Propagation Schema

Note

Regardless of the device SATA controller single HBA port implementation, user software must read/write the tier 1 SATA_IS[0] IPS register bit to process interrupts.

24.8.4.5.3 Interrupt Events Description

This section describes the different events that are reflected in the SATA_PxIS register and that cause SATA_IRQ interrupt generation, if enabled, in the SATA_PxIE register. For more information regarding SATA_IRQ handling at the IRQ CROSSBAR subsystem, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

24.8.4.5.3.1 Task File Error Status

This event is registered whenever the SATA_PxTFD[7:0] STS bit field is updated by the device and the error bit SATA_PxTFD[0]STS_ERR is set. SATA_PxTFD[7:0] STS is updated when a new register FIS, PIO setup FIS, or set device bits FIS is received from the device.

24.8.4.5.3.2 Host Bus Fatal Error

This event is registered whenever an error is received by the SATA controller internal DMA master port from the configuration slave port.

24.8.4.5.3.3 Interface Fatal Error Status

This event is registered if an error is generated on the interface. The following conditions can cause this:

- SYNC escape during an H2D register or data FIS transmission
- One of the following errors during a data FIS transfer:
  - Protocol (SATA_PSERR[10] ERR_P)
  - CRC (SATA_PSERR[21] DIAG_C)
  - Handshake (SATA_PSERR[22] DIAG_H)
  - SATA_PHY not ready (SATA_PSERR[9] ERR_C)
- Unknown FIS received with a good CRC, but length greater than 64 bytes
- Physical region descriptor (PRD) table byte count of 0

Note

This is a fatal error in which the DMA is in an error state until software clears the SATA_PxCMD[0] ST bit or resets the interface with a port or global reset. For more information about software-initiated resets, see Section 24.8.4.3.2, *Software Initiated Resets*.

24.8.4.5.3.4 Interface Non-Fatal Error Status

This event is registered on the following error conditions:

- One or more of the following errors are registered during a non-data FIS transfer:
  - Protocol (SATA_PSERR[10] ERR_P)
  - CRC (SATA_PSERR[21] DIAG_C)
  - Handshake (SATA_PSERR[22] DIAG_H)
  - SATA_PHY not ready (SATA_PSERR[9] ERR_C)
- Command list underflow during a read operation when software builds a command table that has more total bytes than the transaction given to the device

Note

The conditions previously described are non-fatal and the SATA host controller continues to operate normally.

24.8.4.5.3.5 Overflow Status

This event is registered if command list overflow is detected during read or write when software builds a command table with fewer total bytes than the transaction given to the device.

Note

This is a fatal error in which the DMA is in an error state until software clears the SATA_PxCMD[0] ST bit or resets the interface with a port or global reset. For more information about software-initiated resets, see Section 24.8.4.3.2, *Software Initiated Resets*.

24.8.4.5.3.6 Incorrect Port Multiplier Status

This event is registered when the SATA controller receives a FIS from a device with a PM field not matching what is expected. The SATA_PxIS[23] IPMS event corresponding bit can be set during device enumeration, but software should ignore it until enumeration is finished.

24.8.4.5.3.7 PHYReady Change Status

This event is registered when the status of PHYReady changes. Its corresponding status bit (SATA_PxIS[22] PRCS) reflects the SATA_PxSERR[16]DIAG_N bit.

24.8.4.5.3.8 Port Connect Change Status

This event is registered when there was a change in the current connect status as reflected by the SATA_PxSERR[26]DIAG_X bit.

24.8.4.5.3.9 Descriptor Processed

This event is registered when a transaction completes. Its corresponding flag (SATA_PxIS[5] DPS) is set whenever a PRD with the I bit set transfers all of its data.

Note

The PRD interrupt is an opportunistic interrupt and should not be used to definitely indicate the end of a transfer. Two PRD interrupts can happen close in time so that the second interrupt is missed while the first PRD interrupt is being cleared.

When a PRD entry is exhausted, the HBA can be directed to generate an interrupt through the I bit in the PRD entry (although a PRD is not considered exhausted until all data FISs that transfer data pointed to by that PRD entry is complete). For example, if the data FIS is 8 KiB, and this is covered by three PRD entries, the data is not considered valid at the end of the first or second PRD because the CRC has not been checked, even though the data has been copied to memory or to the device. Therefore, if the I bit is set in the PRD entry, the HBA must hold onto it internally and not set PxIS.DPS until the data FIS is complete and the CRC is correct. Once correct, PxIS.DPS can be set and, if PxIE.DPE and GHC.IE are set, the HBA generates an interrupt.

Conversely, if the PRD entry is 16 KiB and two 8 KiB Data FISS are used to transfer all of the data pointed to by the PRD entry, the PRD interrupt associated with that PRD entry is not signaled until after the second data FIS transfer completes successfully.

24.8.4.5.3.10 Unknown FIS Interrupt

This status event indicates that an unknown FIS is received and copied into system memory.

24.8.4.5.3.11 Set Device Bits Interrupt

This status event indicates that a Set Device Bits FIS is received with the I bit set and copied to system memory.

24.8.4.5.3.12 DMA Setup FIS Interrupt

This status event indicates that a DMA Setup FIS is received with the I bit set and copied into system memory.

24.8.4.5.3.13 PIO Setup FIS Interrupt

This status event indicates that a PIO Setup FIS with the I bit set is copied into system memory and the data related to that FIS is transferred.

24.8.4.5.3.14 Device to Host Register FIS Interrupt

This status event indicates that a D2H Register FIS is received with the I bit set and copied to system memory.

24.8.4.5.4 Interrupt Condition Control

There are several ways for software to control the conditions causing a non - command completion coalescing **(non-CCC)** SATA_IRQ interrupt assertion. The SATA_GHC[1] IE register bit serves as a global mask. If it is 0x0, all interrupts are masked. If it is 0x1, interrupts not masked by the SATA_IS (all interrupts for port 0) and SATA_PxIE registers can trigger an interrupt. The SATA_PxIE register matches the SATA_PxIS register bit for bit. If the corresponding bit in the SATA_PxIE register is set to 0x1, the interrupt is unmasked. If the corresponding is 0x0, the interrupt is masked off.

Table 24-444 summarizes the SATA controller interrupt status bits and their corresponding interrupt enable bits at the second tier of the SATA controller interrupt generation schema.

Table 24-444. Interrupt Events Summary

Event Status Flag	Interrupt Event Mask	Mapped to Interrupt Output	Brief Interrupt Event Description
SATA_PxIS [30]TFES	SATA_PxIE [30]TFEE	SATA_IRQ	Task File Error
SATA_PxIS [29]HBFS	SATA_PxIE [29]HBFE	SATA_IRQ	Host Bus Fatal Error
SATA_PxIS [27]IFS	SATA_PxIE [27]IFE	SATA_IRQ	Interface Fatal Error
SATA_PxIS [26]INFS	SATA_PxIE [26]INFE	SATA_IRQ	Interface Non-Fatal Error
SATA_PxIS [24]OFS	SATA_PxIE [24]OFE	SATA_IRQ	Overflow
SATA_PxIS [23]IPMS	SATA_PxIE [23]IPME	SATA_IRQ	Incorrect Port Multiplier
SATA_PxIS [22]PRCS	SATA_PxIE [22]PRCE	SATA_IRQ	Phy Ready Change
SATA_PxIS [6]PCS	SATA_PxIE [6]PCE	SATA_IRQ	Port Connect Change
SATA_PxIS [5]DPS	SATA_PxIE [5]DPE	SATA_IRQ	Descriptor Processed
SATA_PxIS [4]UFS	SATA_PxIE [4]UFE	SATA_IRQ	Unknown FIS Received
SATA_PxIS [3]SDBS	SATA_PxIE [3]SDBE	SATA_IRQ	Set Device Bits FIS Received
SATA_PxIS [2]DSS	SATA_PxIE [2]DSE	SATA_IRQ	DMA Setup FIS Received
SATA_PxIS [1]PSS	SATA_PxIE [1]PSE	SATA_IRQ	PIO Setup FIS Received
SATA_PxIS[0]DHRS	SATA_PxIE [0]DHRE	SATA_IRQ	Device to Host Register FIS Received

Note

To ensure normal generation of the standard (single-event driven, non-CCC) interrupts described in Table 24-444, the user must ensure that the CCC feature is disabled (that is, the SATA_CCC_CTL[0] EN bit is set to 0x0).

24.8.4.5.5 Command Completion Coalescing Interrupts

The SATA controller supports CCC, which can be thought of as interrupt pacing. Instead of being generated for every command completed, an interrupt can be triggered based on a certain number of commands completed and/or a timer time-out. This significantly reduces the load on the CPU by not allowing software to receive an interrupt every time a command is processed. Software can thus queue many commands or wait for many received FISes and process them as a batch. All CCC functions are controlled by the SATA_CCC_CTL, SATA_CCC_PORTS, and SATA_TIMER1MS registers. Setting SATA_CCC_PORTS[0]PRT = 0x1 makes the only available SATA controller HBA port 0 - CCC-aware. The SATA_CCC_CTL register can be used to program CCC logic to trigger an interrupt whenever a certain number of commands are complete and/or a timeout value (as specified by the TV field of SATA_CCC_CTL and SATA_TIMER1MS registers) occurs. For specific programming instructions, see the SATA_CCC_CTL description.

24.8.4.5.5.1 CCC Interrupt Based on Expired Timeout Value

To trigger a CCC interrupt on a port after an elapsed timer value, the following programming sequence must be implemented by user software:

1. Software disables the CCC feature, clearing SATA_CCC_CTL[0] EN to 0b0.
2. Software sets SATA_CCC_PORTS[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets SATA_CCC_CTL[15:8] CC = 0x0, which provides that the expired timeout trigger condition is selected.
4. Software defines the 1-ms time-based unit by loading an appropriate number of interface/functional clock cycles into the 20-bit SATA_TIMER1MS[19:0] TIMV bit field. For example, its reset value of 0x186A0 (100 000 x SATA_FICLK cycles) provides that a 1-ms timeout base will be generated if SATA_FICLK = 100 MHz.
5. Software chooses the timeout value as the number of 1-ms intervals through the 16-bit SATA_CCC_CTL[31:16]TV bit field.
6. Software enables the CCC-interrupt feature, asserting SATA_CCC_CTL[0] EN bit to 0b1.

Assertion of bit SATA_CCC_CTL[0] EN to 0x1 is required to start the 1MS TIMER after the above described configuration steps are completed.

Note

On CCC event configuration, the CCC feature should be disabled (that is, SATA_CCC_CTL[0] EN should be kept at 0b0).

Note

Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the SATA_CCC_CTL[7:3] INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA_IS[0] IPS bit is set to 0x1.

24.8.4.5.5.2 CCC Interrupt Based on Completion Count

If the desired method to receive an interrupt is based on the completion of a certain number of commands, the following settings must be performed:

1. Software disables the CCC feature, clearing SATA_CCC_CTL[0] EN to 0b0.
2. Software sets SATA_CCC_PORTS[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets SATA_CCC_CTL[15:8] CC! = 0x0 to the desired number (1–255) of commands to be completed. The CC! = 0x0 provides that the count completion condition is selected.
4. Software enables the CCC-interrupt feature, asserting the SATA_CCC_CTL[0] EN bit to 0b1.

Note

On CCC event configuration , the CCC feature should be disabled (that is, SATA_CCC_CTL[0] EN should be kept at 0b0).

Note

Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the SATA_CCC_CTL [7:3]INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA_IS[0] IPS bit is set to 0x1.

24.8.4.6 System Memory FIS Descriptors

The SATA AHCI mode supports a command list of from 1 up to 32 entries (command slots) assigned to HBA port 0, which should be allocated and built into host system memory by user software. After receiving command/data messages from the attached port 0 SATA mass-storage drive, the HBA extracts the FIS Dwords, sorts them out, and stores them into different areas of RX FIS-allocated host system memory.

24.8.4.6.1 Command List Structure Basics

Each command list entry has an associated command header (CH) that takes 32 bytes in host system memory, from which only the first 4 Dwords (16 bytes) are used. The CH contains different fields that detail the direction of transfer (H2D or D2H), type of command (ATA/ATAPI), reset behavior, PM ID, byte count and byte length of the PRD table, etc.

A command list slot CH specifies the base address of the underlying command table and information about the associated command FIS length. The command table in system memory has three main areas:

- A 64-byte command FIS area in which the user loads the command-associated FIS contents
- An ATAPI area in which a 12- or 16-byte ATAPI command is loaded, if specified in the CH (through bit A)
- A PRD table area that allows up to 65535 data descriptor entries

An entry of a PRD table (that is, a scatter/gather list item) specifies descriptor parameters of a data block transfer handled by the HBA port DMA.

Figure 24-164 shows the interrelations between the FIS-related structures that user software must allocate and build into the host system memory.

For details on command and data structures in host system memory, see the AHCI and SATA standard specifications.

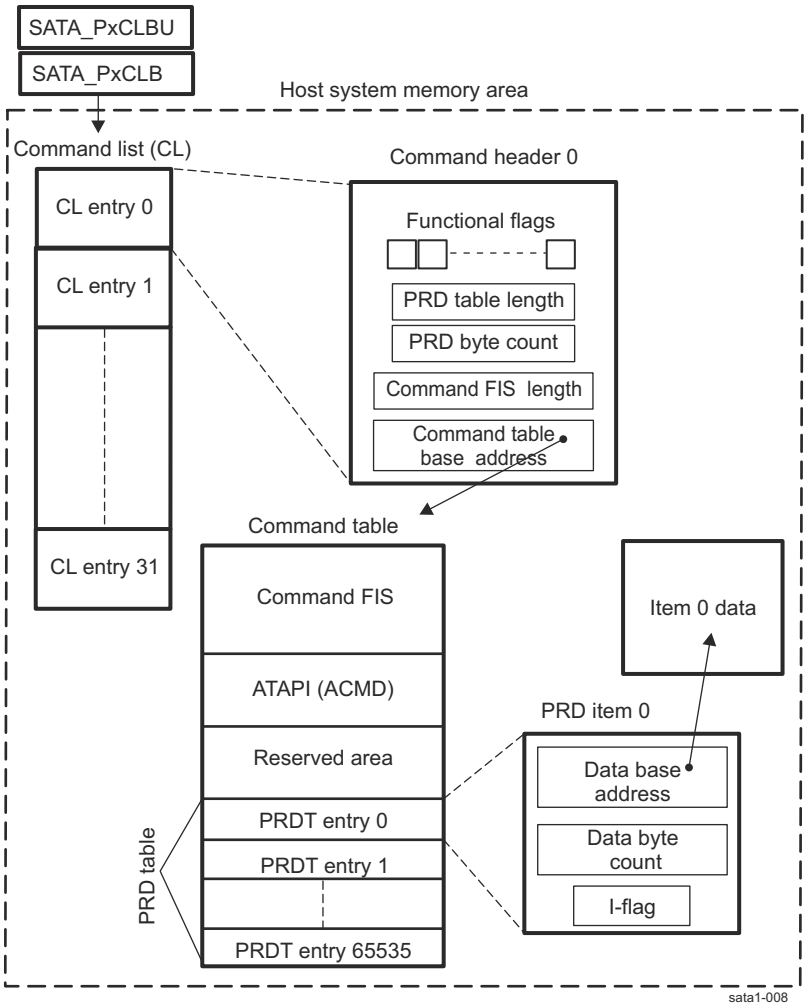

Figure 24-164. Command List Descriptor Structures

After allocating the necessary portions for the CL, command slots underlying data descriptors, and received FISs into host system memory, the base addresses of these memory locations must be provided by user software to the HBA through the hardware init domain registers: SATA_PxCLB (command list base address - lower bits), SATA_PxCLBU (command list base address-upper bits), SATA_PxFB (received FISs system memory area base address-lower bits) and SATA_PxFBU (received FISs system memory area base address-upper bits) . Thus, the command and data DMA engines can access the transfer context programming structures.

Note

SATA_PxCLBU / SATA_PxFBU registers store the upper half of the native 64-bit AHCI addresses. Because only 36-lower bits of the AHCI 64-bit address bus are integrated in the device, actually only the 4-lower bits within SATA_PxCLBU / SATA_PxFBU are meaningful. **The remaining 28-bits must be always written to '0'-s in the descriptors (SATA_PxCLBU[31:4]=0x0 / SATA_PxFBU[31:4]=0x0) .**
Default value for the SATA_PxCLBU / SATA_PxFBU registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the SATA_PxCLB / SATA_PxFB registers.

24.8.4.6.2 Supported Types of Commands

The following types commands are supported:

- Standard serial ATA nonqueued commands set.

  As opposed to NCQ, these commands are serviced, acknowledged one by one after a successful completion. The nonqueued SATA CL entries can take advantage of the PRD prefetching option indicated by the P flag in the corresponding CH (for more information, see the SATA specification). The ATA legacy commands are not supported by the SATA AHCI core.
- ATAPI commands

  ATAPI commands are supported by the SATA HBA engine. A request for an ATAPI command service is indicated by setting CH bit A to 0b1. The ATAPI command that the user builds into the ATAPI area of the command table can be 12 or 16 bytes in length and is indicated by the PIO Setup FIS sent by the SATA peripheral storage device requesting the ATAPI command. In addition, the SATA controller supports ATAPI active-LED generation (See Section 24.8.4.10, *Activity LED Generation Functionality*).
- NCQ-commands

  NCQ-commands are supported by the SATA controller HBA engine, the execution of which can be greatly facilitated by the CCC interrupt feature (for more information, see Section 24.8.4.5.5, *Command Completion Coalescing Interrupts*). As described in Section 24.8.1.1.2, *Native Command Queuing*, the NCQ commands have FPDMA queued command protocol mechanism, which implies that they are treated in a different way then standard SATA commands. The AHCI interface register set include specific registers, such as SATA_PxSACT, etc., to make the HBA aware of the outstanding NCQ slots in a command list. As opposed to standard nonqueued commands, NCQ commands are acknowledged before their actual completion, which accelerates the CL servicing for NCQ slots. The queue tag of the command requested by the SATA peripheral device is indicated to the HBA port by the TAG field in a DMA Setup FIS that an attached SATA peripheral device sends to the SATA controller host . The HBA then uses the tag value to index the NCQ commands updated by user software in the command list. The NCQ command descriptors are not allowed to use the prefetching option in CH because their order of execution is determined by the SATA target device.

24.8.4.6.3 Received FIS Structures

After stream decoding and primitive removal by the link layer, the validated FIS Dwords are extracted from the RxFIFO buffer by the transport layer DMA, and the original SATA storage drive FIS structures are recovered to a dedicated host system memory space. The DMA stores the received FISs into different memory areas based on FIS type. The unknown FIS reception is legal to HBA, as long as the length of the unknown FIS does not overrun the 64-byte size limit of the FIS descriptors. For details on received FISs memory area organization, see the AHCI and SATA standard specifications.

24.8.4.6.4 FIS Descriptors Summary

The FISs that encapsulate SATA target commands and data contents can be divided into:

- FISs transmitted from the host to an attached SATA peripheral device (H2D FISs)
- FISs sent by an attached SATA peripheral device to the host (D2H FISs)

The H2D FISs are constructed by user software into system memory. he H2D FIS types are:

- H2D Register FIS
- H2D DMA Setup FIS
- H2D Data FIS

The D2H FISs are constructed by the attached SATA peripheral device transport layer. The D2H FIS types are as follows:

- D2H Register FIS
- D2H DMA Setup FIS
- PIO Setup FIS
- DMA Activate FIS
- Set Device Bits FIS
- D2H Data FIS

For details on different type of FIS contents, see the SATA standard specification (revision 2.6).

24.8.4.7 Transport Layer FIS-Based Interactions

24.8.4.7.1 Software Processing of the Port Command List

After user software instantiates the CL structures in host system memory, it must maintain them appropriately. The command list is advanced when the BSY, DRQ, and ERR bits of a serial ATA device task file are cleared, which is communicated through a D2H register FIS to HBA port. The HBA port 0 hardware clears the corresponding to the i-th completed command: SATA_PxCI [i] CI (SATA_PxCI [TAG] CI for NCQ) bit to notify user software that the next command FIS can be advanced into the CL. The software then builds the command slot components: CH fields, command table, and associated PRD data descriptors in system memory. Software asserts the SATA_PxCI[i+1] CI (or SATA_PxCI[TAG] CI bit for an NCQ indicated command) to activate the prepared CL command, which is possible only when SATA_PxCMD[0] ST = 0x1. The nonqueued commands in the CL are processed in ascending order of slots (linear processing). The SATA_PxCMD [12:8]CCS read-only field indicates the CL index of the command currently being issued by the HBA port.

The processing of NCQ command slots invokes additional register update/check steps. Before setting the SATA_PxCI[TAG] CI bit to 0b1 and posting an active NCQ command to the SATA HBA port, software must indicate an NCQ outstanding command at the position defined by the SATA peripheral device queue TAG by setting SATA_PxSACT[TAG] DS = 0x1. After the queued command is posted, the peripheral SATA device sends a Set Device Bits FIS to the HBA port to clear the SATA_PxSACT bits corresponding to the successfully completed NCQ commands.

Command-list processing is initially triggered by software setting SATA_PxCMD[0] ST = 0x1, which requires certain conditions to be satisfied.

Note

There are some restrictions to setting SATA_PxCMD[0] ST to 0x1. For more information, see the AHCI specification (revision 1.1).

The SATA controller is capable of command list override (CLO) operation. CLO is activated by setting SATA_PxCMD[3] CLO = 0b1, which is expected only when SATA_PxCMD[0] ST = 0x0 (that is, the command list is not processed by the HBA) to avoid HBA-indeterminate behavior. As a consequence of a CLO operation, the SATA_PxTFD register STS_DRQ and STS_BSY flags are cleared. For example, CLO is necessary when the DRQ and BSY flags cannot be cleared by HBA before issuing a software reset (because of some hang condition). For more information on CLO behavior, see the AHCI standard specification.

24.8.4.7.2 Handling the Received FIS Descriptors

The HBA DMA facilitates the reception of the D2H FISs into host system memory. The reception is enabled by the user setting SATA_PxCMD[4] FRE to 0b1. The software is allowed to change the SATA_PxFB / SATA_PxFBU contents and thus move the FIS reception area to different system memory locations, if SATA_PxCMD[14] FR is cleared, which occurs after software writes SATA_PxCMD[4] FRE = 0b0. In this case, further FIS reception is blocked when the internal RxFIFO becomes full. Before setting SATA_PxCMD[4] FRE

to 0x1, the user software must ensure that a valid address is programmed into the SATA_PxFB / SATA_PxFBU registers.

Note

The HBA port stores the unknown FISs (up to 64 bytes) in system memory but does not have a specified behavior to indicate an error condition on reception. The unknown FISs must be handled specifically by user software.

24.8.4.8 DMA Port Configuration

The SATA controller handles all data operations on its port with an internal DMA integrated in SATA AHCI core.

The SATA controller DMA transfers all information between system memory and the attached SATA peripheral device, as well as configuration and status FISs. The transmit and receive DMA data paths are independently programmable.

The burst size in both directions is fixed to 16 Dwords. The DMA issues transactions of this size or smaller (in Dword increments), depending on programmed transaction size.

Note

If the programmed transaction size is lower than 16-Dwords (burst size), then the DMA maxes out at transaction size.

The user can also separately program the transaction size for receive and transmit channels by setting the SATA_PxDMACR[7:4] RXTS and SATA_PxDMACR[3:0] TXTS bit fields. The transaction size is the minimum amount of data on which the DMA works. For example, if a FIS comes from the device to the host, the DMA does not begin transferring data into system memory until there is at least SATA_PxDMACR[7:4] RXTS number of Dwords in the receive FIFO. During transmit, the DMA reads data from system memory in SATA_PxDMACR[3:0] TXTS Dword increments to put into the transmit FIFO. Transactions can be broken up into multiple bursts of 16 Dword - size, crossing of a 1-KiB boundary (boundary between 1-KiB address blocks in memory), or end-of-frame. RXFIFO and TXFIFO transaction sizes are limited to maximum half the size of the integrated RXFIFO and TXFIFO buffers. For more information on maximum transaction sizes and RXFIFO/TXFIFO depths, see the SATA_PxDMACR and SATA_PPARAMR descriptions.

24.8.4.9 Port Multiplier Operation

The SATA controller HBA port supports connection to a bunch of maximum 15 devices through a port multiplier (PM). The communication mechanism is based on PM command-based switching.

24.8.4.9.1 Command-Based Switching Mode

In this mode of operation, user software must initiate transfers to different PM ports so that multiple commands are not outstanding to different devices connected to the PM extension ports.

24.8.4.9.1.1 Port Multiplier NCQ and Non-NCQ Commands Generation

The PM port command servicing order depends on the type of commands in the CL:

- Non-queued command generation to PMs

  When processing commands that are non-queued, the HBA executes each command entry in its entirety before moving to the next entry in the command list. The next entry can include a command to a different PM device port. Because the HBA operates in the order of its command list, system software must not fill the list in sequential order with commands to a single device; otherwise, another device might get starved. For more information, see the AHCI standard specification.
- NCQ command generation to PMs

  Because the SATA controller supports command-based switching only, system software must only add NCQ commands to the command list that target a single port behind the PM, wait for the commands to finish

(SATA_PxSACT bits all cleared), and then add commands for a different port. For more information, see the AHCI standard specification.

24.8.4.9.2 Port Multiplier Enumeration

To enumerate PM devices, a software reset should be issued by SATA controller to the PM port #0xF (this is a point of connection for the PM or a single endpoint device). The software must prepare two H2D Register FISs into the host system memory for a software reset with the PM-port select (PMP) field set to 0xF. To ensure reliable PM device enumeration, software must also perform a CLO operation. For more information, see the AHCI standard specification.

24.8.4.10 Activity LED Generation Functionality

The HBA port drives the device-level sata1_led signal that is active on the following conditions (see also Table 24-438):

- If (SATA_PxCI [31:0]! = 0x0 or SATA_PxSACT[31:0]! = 0x0) and SATA_PxCMD[24] ATAPI = 0b0 (for active nonATAPI commands indication)
- If (SATA_PxCI [31:0]! = 0x0 or SATA_PxSACT[31:0]! = 0x0) and SATA_PxCMD[24] ATAPI = 0b1 and SATA_PxCMD[25] DLAE = 0b1 (for active ATAPI commands indication)

When SATA_PxCI and SATA_PxSACT are cleared to 0x0, the LED on the sata1_led signal-associated pad is driven off.

24.8.4.11 Supported Types of SATA Transfers

SATA controller AHCI mode defines two types of transfers between the host system memory and a SATA peripheral device: DMA and PIO data transfers. Whether the transaction is of a DMA type or PIO type, the HBA fetches and stores data to memory, offloading the CPU. No register is implemented for direct user access to the data port.

PIO transfers specified by PIO Setup FISs are strongly discouraged because of their limited support of error indication. PIO commands use is limited to only few cases in which commands support only PIO mechanism, such as execution of the IDENTIFY DEVICE command and ATAPI command transfers in which the PACKET command is invoked. The SATA controller AHCI mechanism allows multiple DRQ blocks of data per PIO command.

24.8.4.11.1 Supported Higher Level Protocols

The following DMA, PIO, FPDMA-queued, and ATAPI command/data protocols are supported by the SATA controller AHCI engine:

- Standard SATA command-related
  - Nondata command protocol
  - PIO write protocol
  - PIO read protocol
  - DMA write protocol
  - DMA read protocol
- NCQ command-related
  - Write FPDMA-queued protocol
  - Read FPDMA-queued protocol
- ATAPI PACKET command-related
  - PACKET Nondata command protocol
  - PACKET PIO read/write protocol
  - PACKET DMA read/write protocol

24.8.4.12 SATA Controller AHCI Hardware Register Interface

Table 24-445 summarizes the SATA host controller subsystem registers and divides them into functional categories.

Table 24-445. Summary of SATA Host Subsystem Functional Registers

Register	Functional Category	Brief Register Description
SATA_SYSCONFIG	Device-level registers (wrapper of SATA AHCI core)	TI wrapper idle/standby power management configuration register
SATA_CDRLOCK (3)		TI wrapper register which defines default delay of received data valid information.
SATA_IDR	SATA vendor-specific (VS) register	TI high lander identification register
SATA_CAP	SATA controller generic registers	SATA HBA capabilities set 1
SATA_CAP2		SATA HBA capabilities set 2
SATA_VS		SATA HBA register showing supported AHCI specification revision
SATA_GPARAM1R		SATA HBA global parameters set 1
SATA_GPARAM2R		SATA HBA global parameters set 2
SATA_GHC		SATA HBA global AHCI settings
SATA_PPARAMR	SATA HBA ports-related registers	SATA HBA port x(1) parameter settings
SATA_PI		Enables SATA HBA port x(1) functionalities
SATA_IS		Enables all SATA HBA port x(1) associated interrupts (first tier of interrupt schema)
SATA_CCC_PORTS		Enables SATA CCC feature for the port x(1)
SATA_CCC_CTL		CCC feature parameters control and status
SATA_TIMER1MS		Time base for 1-ms unit of CCC timeout
SATA_PxCLB	SATA HBA Port Px(1) SATA Specification- defined Functional Registers	CL base address (lower-half of AHCI 64-bit address)
SATA_PxCLBU		CL base address (upper-half of AHCI 64-bit address) (2)
SATA_PxFB		Received FISs base address (lower-half of AHCI 64-bit address)
SATA_PxFBU		Received FISs base address (upper-half of AHCI 64-bit address)(2)
SATA_PxIE		Port x(1) non-CCC interrupt enable
SATA_PxIS		Port x(1) non-CCC interrupt event status
SATA_PxCMD		Port x(1) command register
SATA_PxTFD		Port x(1) task file data register
SATA_PxSIG		Port x(1) associated SATA signature register
SATA_PxSSTS		Port x(1) SStatus SATA register (See the SATA standard specification.)
SATA_PxSCTL		Port x (1)SControl SATA register (See the SATA standard specification.)
SATA_PxSERR		Port x (1)SError SATA register (See the SATA standard specification.)
SATA_PxSACT		Port x(1) SActive SATA register (See SATA standard specification.)
SATA_PxCI		Port x (1)command activation/completion indication register
SATA_PxSNTF		Port x(1) SNotification register (See the SATA standard specification.)
SATA_OOBR		OOB detection counters setup
SATA_PxDMACR	Non-standard Port Px(1) Control register	Port x(1) associated DMA configuration register

Table 24-445. Summary of SATA Host Subsystem Functional Registers (continued)

Register	Functional Category	Brief Register Description
SATA_TESTR	SATA HBA BIST related registers	Test/normal mode switching
SATA_BISTAFR		BIST FIS-activate register
SATA_BISTCR		BIST control register
SATA_BISTFCTR		BIST FIS count register
SATA_BISTSR		BIST status register
SATA_BISTDECR		BIST Dword error count register

(1) x = 0, as only SATA HBA port 0 is implemented
(2) Only the 4-lower bits meaningful in the device, the others must be kept at '0'
(3) Under normal conditions, the user is supposed to keep this register at its default (power-on-reset) value.

24.8.5 SATA Controller Low Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the SATA host controller.

Note

SATA is not supported on the AM570x family of devices.

24.8.5.1 Global Initialization

24.8.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements to initialize the surrounding modules when the SATA host controller is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SATA host controller (for more information, see Section 24.6.3 and Section 24.6.2). Table 24-446 describes the global initialization of surrounding modules.

Table 24-446. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled (see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*).
Control Module	Module-specific pad muxing and other PHY power configurations must be set in the control module (see *Pad Configuration Registers* and *Control Module Register Manual*, in *Control Module*).
IRQ_CROSSBAR	IRQ_CROSSBAR must be configured to enable the interrupt from the SATA controller (see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*).
L4_CFG and L3_MAIN interconnects	For more information about the interconnect configuration, see *L3_MAIN Interconnect Agents* and *L4 Interconnect*, in *Interconnect*.

Note

The MPU INTC configuration is required when using the interrupt communication mode.

24.8.5.1.2 SATA Controller Global Initialization

24.8.5.1.2.1 Main Sequence SATA Controller Global Initialization

Table 24-447 describes the procedure to initialize the SATA host controller after a POR.

Table 24-447. SATA Controller Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the OCP2SCP3 adapter for PLLCTRL_SATA.	See Section 26.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 26, *Shared PHY Component Subsytems*.	-

Table 24-447. SATA Controller Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Configure the DPLL_SATA.	See Section 26.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 26, *Shared PHY Component Subsytems*.	-
Configure the SATA_PHY.	See Section 26.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 26, *Shared PHY Component Subsystems*.	-
Perform all firmware capability writes. (1)	See Section 24.8.5.1.2.2, *SubSequence – Firmware Capability Writes*.	-
Set up all appropriate structures in memory per the AHCI standard specification.	See Section 24.8.4.6, *System Memory FIS Descriptors*. See also the AHCI standard specification.	-
Write a valid CL memory base address to the SATA_PxCLB register.	SATA_PxCLB [31:10] CLB	CL Base address (lower-half)
	SATA_PxCLBU [3:0] CLBU	CL Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Write a valid Rx FIS memory base address to the SATA_PxFB register.	SATA_PxFB [31:8] FB	Rx FIS Base address (lower-half)
	SATA_PxFBU [3:0] FBU	Rx FIS Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Issue a software type of reset depending on the error condition.	See Section 24.8.4.3.2, *Software Initiated Resets*.	-
Set the appropriate bits in the SATA_PxCMD register.	See Section 24.8.4.7.1, *Software Processing of the Port Command List*. See also the AHCI standard specification.	-
Program the SATA_PxSCTL register to configure SATA interface capabilities.	See the AHCI standard specification.	-
Program the SATA_PxDMACR register.	See Section 24.8.4.8, *DMA Port Configuration*.	-
Enable the interrupts at port 0.	SATA_IS[0] IPS	0x1
Enable the involved port 0 specific interrupts.	See Section 24.8.4.5.2, *Levels of Interrupt Control*, and Section 24.8.4.5.4, *Interrupt Condition Control*.	-
Enable the FIS reception in the SATA_PxCMD register.	SATA_PxCMD[4] FRE	0x1
Spin up the device (if required).	See the AHCI standard specification and the SATA standard specification.	-

(1) This step has an effect only on hardware initialization.

Note

The SATA AHCI Controller always manipulates 64-bit memory pointers, and the master interface has 64-bit addresses, but the actual AHCI master interface integration in the device uses ONLY the 36-lower bits. In that case, even though the AHCI support indicates “64-bit” in the SATA_CAP[31] S64A, ONLY the 4-lower bits (SATA_PxCLBU [3:0] / SATA_PxFBU [3:0]) are meaningful in the device.**The upper 28 bits of the address, i.e.** SATA_PxCLBU [31:4] / SATA_PxFBU [31:4] **, must be always SW-programmed to '0'.**

Note

Default value of the SATA_PxCLBU / SATA_PxFBU registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the SATA_PxCLB / SATA_PxFB registers.

24.8.5.1.2.2 SubSequence – Firmware Capability Writes

Table 24-448 lists the firmware capability write sequence by which SATA HBA initialization is performed.

Note

In the following sequence, SATA controller accesses hardware initialization domain registers that can be written only one time after POR.

Table 24-448. Firmware Capability Writes

Step	Register/Bit Field/Programming Model	Value
Disable the staggered spin-up support feature.(1)	SATA_CAP[27] SSS	0x0
Enable the SATA controller port 0.	SATA_PI[0] PI	0x1
Disable the mechanical presence detect feature.(1)	SATA_CAP[28] SMPS	0x0
Disable the external signal-only connector.(1)	SATA_PxCMD[22:21] ESP	0x0
Disable the cold presence detect feature. (1)	SATA_PxCMD[20] CPD	0x0
Disable support for the mechanical presence switch.	SATA_PxCMD[19] MPSP	0x0
Disable the hot-plug-capable port feature.	SATA_PxCMD[18] HPCP	0x0
If PM is attached:		
Set the SATA_PxCMD [17] PMA bit to notify HBA that the PM is attached to HBA port 0.	SATA_PxCMD[17] PMA	0x1
ELSE		
Clear the SATA_PxCMD[17] PMA bit as a notification that a single-target SATA device is attached to port 0.	SATA_PxCMD[17] PMA	0x0

(1) It makes no sense to enable staggered spin-up because only one HBA port is used.

24.8.5.1.3 Issue Command - Main Sequence

The procedure in Table 24-449 prepares a command list entry and issues its corresponding command.

Table 24-449. Prepare and Issue a Command

Step	Register/Bit Field/Programming Model	Value
Build command header and command table into host system memory.	For details, see Section 24.8.4.6.1, *Command List Structure Basics*.	-
Create the command corresponding PRD table.		
Queue the command to the command list.	See Section 24.8.4.7.1, *Software Processing of the Port Command List*.	-
Set the SATA_PxCMD[0] ST bit to direct the DMA to start processing the CL.	SATA_PxCMD[0] ST	0x1(1)
IF a nonNCQ command is issued:		
Set the corresponding SATA_PxCI.CI bit to activate a command already prepared in the i-th slot of the CL .	SATA_PxCI[i] CI	0x-
ELSE		
Indicate the NCQ slot positions through the SATA_PxSACT register. For details on TAG tracking, see Section 24.8.4.7.1.	SATA_PxSACT[TAG] DS	0x-

Table 24-449. Prepare and Issue a Command (continued)

Step	Register/Bit Field/Programming Model	Value
Set the corresponding SATA_PxCI.CI bit to activate the NCQ command already prepared in the i-th slot of the CL.	SATA_PxCI[TAG] CI	0x-

(1) See the AHCI standard specification for important restrictions when PXCMD[0] ST can be software-asserted to 1.

24.8.5.1.4 Receive FIS—Main Sequence

The procedure in Table 24-450 is used to handle a FIS reception.

Table 24-450. FIS Reception

Step	Register/Bit Field/Programming Model	Value
Read SATA_PxIS to determine the type of FIS.	For more information, see Section 24.8.4.7.2, *Handling the Received FIS Descriptors*.	-

24.8.6 SATA Controller Register Manual

Note

SATA is not supported on the AM570x family of devices.

24.8.6.1 SATA Controller Instance Summary

Table 24-451. SATA Instance Summary

TV																CC								INT					RESERVED		EN

Bits	Field Name	Description	Type	Reset
31:16	TV	Time-out value. Specifies the CCC time-out value in 1-ms intervals Loaded prior to enabling CCC; becomes read-only when SATA_CCC_CTL.EN = 1 0x0: Reserved value; do not use. 0x1 - 0xFFFF: timeout slectable between within the range (1 - 65535) ms.	RW	0x0001
15:8	CC	Command completions Number of command completions necessary to cause a CCC interrupt Loaded prior to enabling CCC, becomes read-only when SATA_CCC_CTL.EN = 1 0x0: CCC interrupts generated based on the timer, not on completed commands count 0x1 - 0xFF: specifies the number of commands upon which completion a CCC interrupt is generated. The number of commands to complete before interrupt is triggered are selectable within the range (1 - 255) commands.	RW	0x01
7:3	INT	Interrupt Number of the interrupt used by the CCC feature, using the number of ports configured for the core When a CCC interrupt occurs, the SATA_IS.IPS[INT] bit is set to 1.	R	0x01
2:1	RESERVED		R	0x0
0	EN	Enable CCC enable 0x0: CCC feature is disabled and no CCC interrupts are generated. SATA_CCC_CTL.TV and .CC are writable. 0x1: CCC feature is enabled and CCC interrupts can be generated based on the time-out or command completion conditions. All other SATA_CCC_CTL fields are read-only.	RW	0

Table 24-478. SATA_PxIS

Address Offset	0x0000 0110		
Physical Address	0x4A14 0110	**Instance**	DWC_ahsata
Description	Port interrupt status Bits are set by internal conditions and cleared (when possible) by writing 1 to them. Reset on global reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CPDS	TFES	HBFS	HBDS	IFS	INFS	RESERVED	OFS	IPMS	PRCS	RESERVED														DMPS	PCS	DPS	UFS	SDBS	DSS	PSS	DHRS

Bits	Field Name	Description	Type	Reset
31	CPDS	Cold port detect status Set when the pX_cp_det input changes its state due to the insertion or removal of a device Valid only if the port supports cold presence detection as indicated by the SATA_PxCMD.CPD bit set to 1. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
30	TFES	Task file error status Set whenever the SATA_PxTFD.STS register is updated by the device and the error bit (bit 0) is set. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
29	HBFS	Host bus fatal error status Set when master (DMA) detects an ERROR response from the slave Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
28	HBDS	Host bus data error status This bit is always cleared to 0. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
27	IFS	Interface fatal error status This bit is set when any of the following conditions is detected: 1) SYNC escape is received from the device during H2D register or data FIS transmission. 2) One or more of the following errors are detected during data FIS transfer: - 10B to 8B Decode Error (SATA_PxSERR.DIAG_B) - Protocol (SATA_PxSERR.ERR_P) - CRC (SATA_PxSERR.DIAG_C) - Handshake (SATA_PxSERR.DIAG_H) - PHY not ready (SATA_PxSERR.ERR_C) 3) Unknown FIS is received with good CRC, but the length exceeds 64 bytes. 4) PRD table byte count is 0. 5) DMA setup FIS is received with a TAG corresponding to inactive (SATA_PxSACT bit is cleared) command slot. Port DMA transitions to a fatal state until the software clears SATA_PxCMD.ST bit or resets the interface by way of port reset or global reset. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
26	INFS	Interface nonfatal error status Set when any of the following conditions is detected: 1) One or more of the following errors are detected during nondata FIS transfer: - 10b to 8b decode error (SATA_PxSERR.DIAG_B) - Protocol (SATA_PxSERR.ERR_P) - CRC (SATA_PxSERR.DIAG_C) - Handshake (SATA_PxSERR.DIAG_H) - PHY not ready (SATA_PxSERR.ERR_C) 2) Command list underflow during read operation (that is, DMA read) when the software builds a command table that has more total bytes than the transaction given to the device. In both cases port operation continues normally. When an error is detected during nondata FIS transmission, this FIS is retransmitted continuously until it succeeds, or until the software times out and resets the interface. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
25	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
24	OFS	Overflow status Set when command list overflow is detected during read or write operation when the software builds command table that has fever total bytes than the transaction given to the device. Port DMA transitions to a fatal state until the software clears SATA_PxCMD.ST bit or resets the interface by way of port reset or global reset. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
23	IPMS	Incorrect PM status FIS received from a device in which the PM field did not match what was expected May be set during enumeration of devices on a PM due to the normal PM enumeration process Must be used only after enumeration is complete on the PM Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
22	PRCS	PhyRdy change status Reflects the state of SATA_PxSERR.DIAG_N To clear this bit, clear the SATA_PxSERR.DIAG_N bit to 0. Read 0x1: Internal pX_phy_ready signal changed state Read 0x0: Internal pX_phy_ready signal has not changed state since its last reset.	R	0
21:8	RESERVED		R	0x0000
7	DMPS	Device mechanical presence status Set when the pX_mp_switch input changes its state as a result of a mechanical switch attached to this port opening or closing Valid only when SATA_CAP.SMPS and SATA_PxCMD.MPSP are set Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
6	PCS	Port connect change status This bit reflects the state of the SATA_PxSERR.DIAG_X bit. Cleared only when SATA_PxSERR.DIAG_X is cleared Read 0x1: Change in current connect status Read 0x0: No change in current connect status	R	0

Bits	Field Name	Description	Type	Reset
5	DPS	Descriptor processed A PRD with the I bit set has transferred all of its data. Note. This is an opportunistic interrupt and must not be used to definitively indicate the end of a transfer. Two PRD interrupts could occur close enough together that the second interrupt is missed when the first PRD interrupt is cleared. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
4	UFS	Unknown FIS interrupt An unknown FIS was received and has been copied into system memory. Cleared to 0 by the software clearing the SATA_PxSERR.DIAG_F bit to 0. Note: The UFS bit does not directly reflect the SATA_PxSERR.DIAG_F bit. SATA_PxSERR.DIAG_F bit is set immediately when an unknown FIS is detected, whereas the UFS bit is set when that FIS is posted to memory. The software should wait to act on an unknown FIS until the UFS bit is set to 1 or the two bits may become out of sync. Read 0x1: IRQ event active Read 0x0: Event inactive	R	0
3	SDBS	Set device bits interrupt A Set Device Bits FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
2	DSS	DMA setup FIS interrupt A DMA Setup FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
1	PSS	PIO setup FIS interrupt A PIO Setup FIS is received with the I bit set, copied into system memory, and the data related to the FIS is transferred. Note: This bit is set even when the data transfer resulted in an error. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
0	DHRS	Device to host register FIS interrupt A D2H register FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Table 24-479. SATA_PxIE

Address Offset	0x0000 0114		
Physical Address	0x4A14 0114	**Instance**	DWC_ahsata
Description	Port interrupt enable Enables and disables the reporting of the corresponding interrupt to system software When a bit is set (1), SATA_GHC.IE = 1, and the corresponding interrupt condition in SATA_PxIS is active, then the SATA controller interrupt output is asserted. When a bit is cleared (0), interrupt sources are still reflected in the status registers. Reset on global reset

Bits	Field Name	Description	Type	Reset
31:28	ICC	Interface communication control Control of power management states of the interface If the link layer is in the L_IDLE state, writes cause the port to request a transition to a given interface state. If the link layer is not in the L_IDLE state, writes have no effect. When a nonreserved, non-0 (No-Op) value is written, the core performs the action and clears the field back to 0 (Idle) Write 0x0: No-Op Read 0x0: Port is ready to accept a new interface control command, although the transition to the previously selected state might not have occurred yet. 0x1: Active 0x2: PARTIAL. SATA device can reject the request and the interface then remains in its current state. 0x6: SLUMBER. SATA device can reject the request and the interface then remains in its current state.	RW	0x0
27	ASP	Aggressive SLUMBER/PARTIAL 0x0: If SATA_PxCMD.ALPE = 1, the port aggressively enters the PARTIAL state when it clears the SATA_PxCI register and the SATA_PxSACT register is cleared when it clears the SATA_PxSACT register and SATA_PxCI is cleared. 0x1: If SATA_PxCMD.ALPE = 1, the port aggressively enters the SLUMBER state when it clears the SATA_PxCI and the SATA_PxSACT register is cleared or when it clears the SATA_PxSACT register and SATA_PxCI is cleared.	RW	0
26	ALPE	Aggressive link power management enable 0x0: Aggressive power management state transition is disabled. 0x1: Port aggressively enters a lower link power state (PARTIAL or SLUMBER) based on the setting of SATA_PxCMD.ASP.	RW	0
25	DLAE	Drive LED on ATAPI enable 0x0: LED is never enabled. 0x1: Port asserts the pX_act_led output when commands are active and SATA_PxCMD.ATAPI = 1.	RW	0
24	ATAPI	Device is ATAPI Used by the port to determine whether or not to assert pX_act_led output when commands are active. 0x0: Connected device is not an ATAPI. 0x1: Connected device is an ATAPI.	RW	0
23	APSTE	Auto PARTIAL to SLUMBER transition enable 0x0: No automatic transition from PARTIAL to SLUMBER 0x1: Link layer transitions from its PARTIAL power management state to SLUMBER state automatically, whether host software-, port (aggressive)-, or device-initiated.	RW	0
22	FBSCP	FIS-based Switching Capable Port May only be set to ? 1? if CAP.SPM = CAP.FBSS = 1 (not the case). Writable once after power up, read-only afterwards. 0x0: port does not support FIS-based switching. 0x1: Port supports Port Multiplier FIS-based switching.	RW	0x0

Bits	Field Name	Description	Type	Reset
21	ESP	External SATA port Writable once after power up, read-only afterward 0x0: Port signal-only connector is not externally accessible. 0x1: Port signal-only connector is externally accessible. SATA_CAP.SXS is also set to 1. Mutually exclusive with SATA_PxCMD.HPCP	RW	0x0
20	CPD	Cold presence detect Writable once after power up, read-only afterward 0x0: Platform does not support cold presence detection on this port. 0x1: Platform supports cold presence detection on this port. SATA_PxCMD.HPCP should be set to 1.	RW	0
19	MPSP	Mechanical presence switch attached to port Writable once after power up, read-only afterward 0x0: Platform does not support a mechanical presence switch on this port. 0x1: Platform supports a mechanical presence switch attached to this port. SATA_PxCMD.HPCP should be set to 1.	RW	0
18	HPCP	Hot plug capable port Writable once after power up, read-only afterward 0x0: Port signal and power connectors are not externally accessible. 0x1: Port signal and power connectors are externally accessible through a joint signal-power connector for blindmate device hot plug.	RW	0
17	PMA	PM attached Software is responsible for detecting the presence of a PM. There is no autodetection. 0x0: No port Multiplier is attached to this Port 0x1: Port Multiplier is attached to this Port	RW	0
16	CPS	Cold presence state Reports whether a device is currently detected on this port as indicated by the pX_cp_det input state (assuming SATA_PxCMD.CPD = 1). Read 0x1: Device detected Read 0x0: No device detected	R	0
15	CR	Command list running For details, see the AHCI state-machine in Section 5.3.2 of the AHCI specification. Read 0x1: Command list DMA engine for this port is running. Read 0x0: Command list is stopped for this port.	R	0
14	FR	FIS receive running For details, see Section 10.3.2 of the AHCI specification. Read 0x1: FIS receive DMA engine for the port is running. Read 0x0: FIS receive DMA engine for the port is stopped.	R	0

Bits	Field Name	Description	Type	Reset
13	MPSS	Mechanical presence switch state Reports the state of a mechanical presence switch attached to this port as indicated by the pX_mp_switch input state (assuming SATA_CAP.SMPS = 1 and SATA_PxCMD.MPSP = 1) Cleared to 0 when SATA_CAP.SMPS = 0 Read 0x1: Switch is open. Read 0x0: Switch is closed.	R	0
12:8	CCS	Current command slot This field is valid when SATA_PxCMD.ST is set to 1 and is set to the command slot value of the command currently issued by the port. When SATA_PxCMD.ST transitions from 1 to 0, this field is reset to 0x00. After SATA_PxCMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command is issued, the highest priority slot to issue from next is SATA_PxCMD.CCS + 1. For example, after the port issues its first command, if CCS = 0x00 and SATA_PxCI is set to 0x3, the next command issued is from command slot 1.	R	0x00
7:5	RESERVED		R	0x0
4	FRE	FIS receive enable Must not be set until SATA_PxFB / SATA_PxFBU is programmed with a valid pointer to the FIS receive area Base can be moved after clearing FRE and waiting for FR to clear to 0. 0x0: Received FISes are not accepted by the port, except for the first D2H register FIS after the initialization sequence, and no FISes are posted to the FIS receive area. 0x1: Port can post received FISes into the FIS receive area pointed to by SATA_PxFB and SATA_PxFBU.	RW	0
3	CLO	Command list override Write 0x0: No effect Write 0x1: Request to clear SATA_PxTFD.STS_BSY and SATA_PxTFD.STS_DRQ to 0. Use only immediately prior to setting SATA_PxCMD.ST bit to 1 from a previous value of 0. Any other case results in indeterminate behavior. Read 0x1: Override is active, SATA_PxTFD.STS_BSY and SATA_PxTFD.STS_DRQ are being cleared. Read 0x0: Override is inactive.	RW	0
2	POD	Power-on device Writable if SATA_PxCMD.CPD = 1 (cold presence detection enabled), otherwise read-only -1. 0x0: Disabled 0x1: Port asserts the pX_cp_pod output pin so that it can be used to provide power to a cold-presence detectable port.	RW	0

Bits	Field Name	Description	Type	Reset
1	SUD	Spin-up device Writable if SATA_CAP.SSS = 1 (staggered spin-up supported), else read-only 1. Read-only-0 on power-up until SATA_CAP.SSS bit is written with the required value. 0x0: Clearing the bit from 1 to 0 causes no action on the interface. 0x1: On edge-detect from 0 to 1, the port starts a COMRESET initialization sequence to the device.	RW	0
0	ST	Start 0x0: Port does not process the command list. On transition from 1 to 0, the SATA_PxCI register is cleared by the port on transition to an IDLE state. 0x1: Port processes the command list. On transition from 0 to 1, the port starts processing the command list at entry 0. SATA_PxSERR must be cleared prior to setting ST to 1. For important restrictions on when ST can be set to 1, See Section 10.3.1 of the AHCI specification.	RW	0

15:12	SPM	Select power management: This field is not used by the AHCI.	R	0x0
11:8	IPM	Interface power management transitions allowed: Indicates which power states the HBA is allowed to transition to. If an interface power management state is disabled, the HBA is not allowed to initiate that state and the HBA must PMNAK_P any request from the device to enter that state. The two MSBs are always 2'b00 (not writable), as for all unreserved field values. 0x0: No interface power management state restrictions 0x1: Transitions to the PARTIAL state disabled 0x2: Transitions to the SLUMBER state disabled 0x3: Transitions to both PARTIAL and SLUMBER states disabled	RW	0x0
7:4	SPD	Speed allowed: Highest allowable speed of the interface The two MSBs are always 2'b00 (not writable), as for all unreserved field values. 0x0: No speed negotiation restrictions 0x1: Limit speed negotiation to generation 1 communication rate. 0x2: Limit speed negotiation to a rate not greater than generation 2 communication rate.	RW	0x0
3:0	DET	Device detection initialization: Controls the HBA device detection and interface initialization. Can be modified only when SATA_PxCMD.ST = 0. Must have a value of 0x0 when SATA_PxCMD.ST = 1. MSB is always 1'b0 (not writable), as for all unreserved field values. 0x0: No device detection or initialization action requested 0x1: Perform interface communication initialization sequence to establish communication. This is functionally equivalent to a hard reset and results in the interface being reset and communications reinitialized. While this field is 1h, COMRESET is transmitted on the interface. Software must leave the DET field set to 1h for a minimum of 1 ms to ensure that a COMRESET is sent on the interface. 0x4: Disable the serial ATA interface and put PHY in offline mode.	RW	0x0

Table 24-485. SATA_PxSERR

Address Offset	0x0000 0130		
Physical Address	0x4A14 0130	**Instance**	DWC_ahsata
Description	Port SATA error Detected interface errors accumulated since the last time it cleared. When set, indicates that the corresponding error condition became true one or more times since the last time cleared. Write 1 to a bit to clear it. Cleared by global reset or port reset (COMRESET).

DS																															

Bits	Field Name	Description	Type	Reset
31:0	DS	Device status: Field is bit-significant. Each bit corresponds to the TAG and command slot of a native queued command, where bit 0 corresponds to TAG 0 and command slot 0. Set by Software prior to issuing a native queued command for a particular command slot. Prior to writing SATA_PxCI[TAG] to 1, software sets DS[TAG] to 1 to indicate that a command with that TAG is outstanding. The device clears bits by sending a set device bits FIS to the port. The port clears bits in this field that are set to 1 in the SActive field of the set device bits FIS. The port only clears bits that correspond to native queued commands completed successfully. Write only when SATA_PxCMD.ST bit is set to 1. Cleared when SATA_PxCMD.ST is written from 1 to 0. Not cleared by a port reset (COMRESET) or a software reset.	RW	0x0000 0000

RESERVED															OVERRIDE0	RESERVED								STANDBYMODE		IDLEMODE		RESERVED			

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0000

Bits	Field Name	Description	Type	Reset
16	OVERRIDE0	Override for clock stopping. Normally the functional clock can be stopped only if the link is put into PARTIAL or SLUMBER power state. However, if there is no device attached (such as in a removable media situation) or the device is not started, the user can stop the functional clocks but not be able to enter a low-power state. In this case, software can set the OVERRIDE bit to 1, removing the requirement for a low-power state WARNING: If there is a device attached, the OVERRIDE bit is used, and the functional clock is stopped when the link is not in a low-power state it ruins the link and causes undetermined behavior. A port reset or full SATASS reset might be required to recover. 0x0: Normal mode 0x1: Override mode	RW	0
15:6	RESERVED		R	0x000
5:4	STANDBYMODE	Configuration of the local initiator-state management mode. By definition, the initiator can generate a read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: Local initiator is unconditionally placed in STANDBY state. Backup mode, for debug only 0x1: No-standby mode: local initiator is unconditionally placed out of STANDBY state. Backup mode, for debug only. 0x2: Smart-standby mode: Local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. The IP module does not generate (initiated-related) wakeup events. 0x3: Smart-Standby wakeup-capable mode: Local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. The IP module can generate (master related) wakeup events when in STANDBY state. Mode is relevant only if the appropriate IP module mwakeup output is implemented.	RW	0x2

Bits	Field Name	Description	Type	Reset
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, the target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: The local target IDLE state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the internal requirements of th e IP module. Backup mode, for debug only. 0x1: No-idle mode: The local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: The local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the internal requirements of the IP module. IP module does not generate (IRQ- or DMA-request-related) wakeup events. 0x3: Smart-idle wakeup-capable mode: The local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the internal requirements of the IP module. IP module can generate (IRQ- or DMA-request-related) wakeup events when in IDLE state. Mode is only relevant if the appropriate IP module swakeup output(s) is (are) implemented.	RW	0x2

(1) Under normal conditions, this bitfield must be kept at its default (power-on-reset) value.

24.9 PCIe Controller

This section describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) Controller which provides a high-speed glueless serial interconnect to peripherals utilizing high bandwidth applications.

24.9.1 PCIe Controller Subsystem Overview

The Peripheral Component Interconnect Express (PCIe) module is a multi-lane I/O interconnect that provides low pin-count, high reliability, and high-speed data transfer at rates of up to 5.0 Gbps per lane, per direction, for serial links on backplanes and printed wiring boards. It is a 3-rd Generation I/O Interconnect technology succeeding PCI and ISA bus that is designed to be used as a general-purpose serial I/O interconnect. It is also used as a bridge to other interconnects like SATA, USB2/3.0, GbE MAC, and so forth.

The device instantiates two PCIe subsystems (PCIe_SS1 and PCIe_SS2) . The PCIe controller is capable to operate either in Root Complex (RC) or in End Point (EP) PCIe mode. The device PCIe_SS1 controller supports up to two 16-bit data lanes on its PIPE port. The device PCIe_SS2 controller supports only one 16-bit data lane on its PIPE port.

When the PCIe_SS1 controller PIPE port is configured to operate in a single-lane mode, it operates on a single pair of PCIe PHY serializer and deserializer - PCIe1_PHY_TX/PCIe1_PHY_RX. When PCIe_SS1 PIPE is configured to operate in dual-lane mode, it operates on two pairs of PCIe PHY serializer and deserializer - PCIe1_PHY_TX/PCIe1_PHY_RX and USB_PHY_TX/USB_PHY_RX, respectively. The single-lane PCIe_SS2 controller PIPE port (if enabled) can operate only on the USB_PHY_TX/USB_PHY_RX pair. Hereby, if PCIe_SS2 controller is used, the PCIe_SS1 can operate only in a single-lane mode on the PCIe1_PHY_TX/PCIe1_PHY_RX. In addition, PCIe PHY subsystem encompasses a PCIe PCS (physical coding sublayer), a PCIe power management logic, APLL, a DPLL reference clock generator and an APLL clock low-jitter buffer. For more details on PCIe PHY subsystem, please refer to Section 26.4, *PCIe Shared Phy Subsystem*.

- The PCIe Controller implements the transport and link layers of the PCIe interface protocol.
- PCIe PCS (a physical coding sublayer component) converts a 8-bit portion of parallel data over a PCIe lane to a 10-bit parallel data to adapt the process of serialization and deserialization in the TX/RX PHYs to various requirements. At the same time it transforms the transmission rate to maintain the PCIe Gen2 bandwidth (5 Gbps) on both sides (PCIe controller and PHY).
- A multiplexer logic which adds flexibility to connect a PCIe controller hardware mapped PCS logic output to a single (for the single-lane PCIe_SS2 controller) or to a couple (for the 2-lane PCIe_SS1 controller) of PHY ports at a time
- Physical layer (PHY) serializer/deserializer components with associated power control logic, building the so called PMA (physical media attachment) part of the PCIe_PHY transceiver, as follows:
  - PCIe physical port 0 associated serializer (TX) - PCIe1_PHY_TX and deserializer (RX) - PCIe1_PHY_RX
  - USB port associated serializer (TX) - USB_PHY_TX and deserializer (RX) - USB_PHY_RX
- DPLL_PCIe_REF is a DPLL clock source, controlled from the device PRCM, that provides a 100-MHz clock to the PCIe PHY serializer/deserializer components reference clock inputs.
- Both the PCIe_SS1 and PCIe_SS2 share the same APLL (APLLPCIe) which by default multiplies the DPLL_PCIe_REF (typically 100 MHz or 20 MHz) clock to 2.5 GHz.
- The APLLPCIe low-jitter buffer (ACSPCIE) and additional logic takes care to provide the PCIe APLL reference input clock.

Figure 24-165 shows an overview of a device PCIe subsystem with its integrated components.

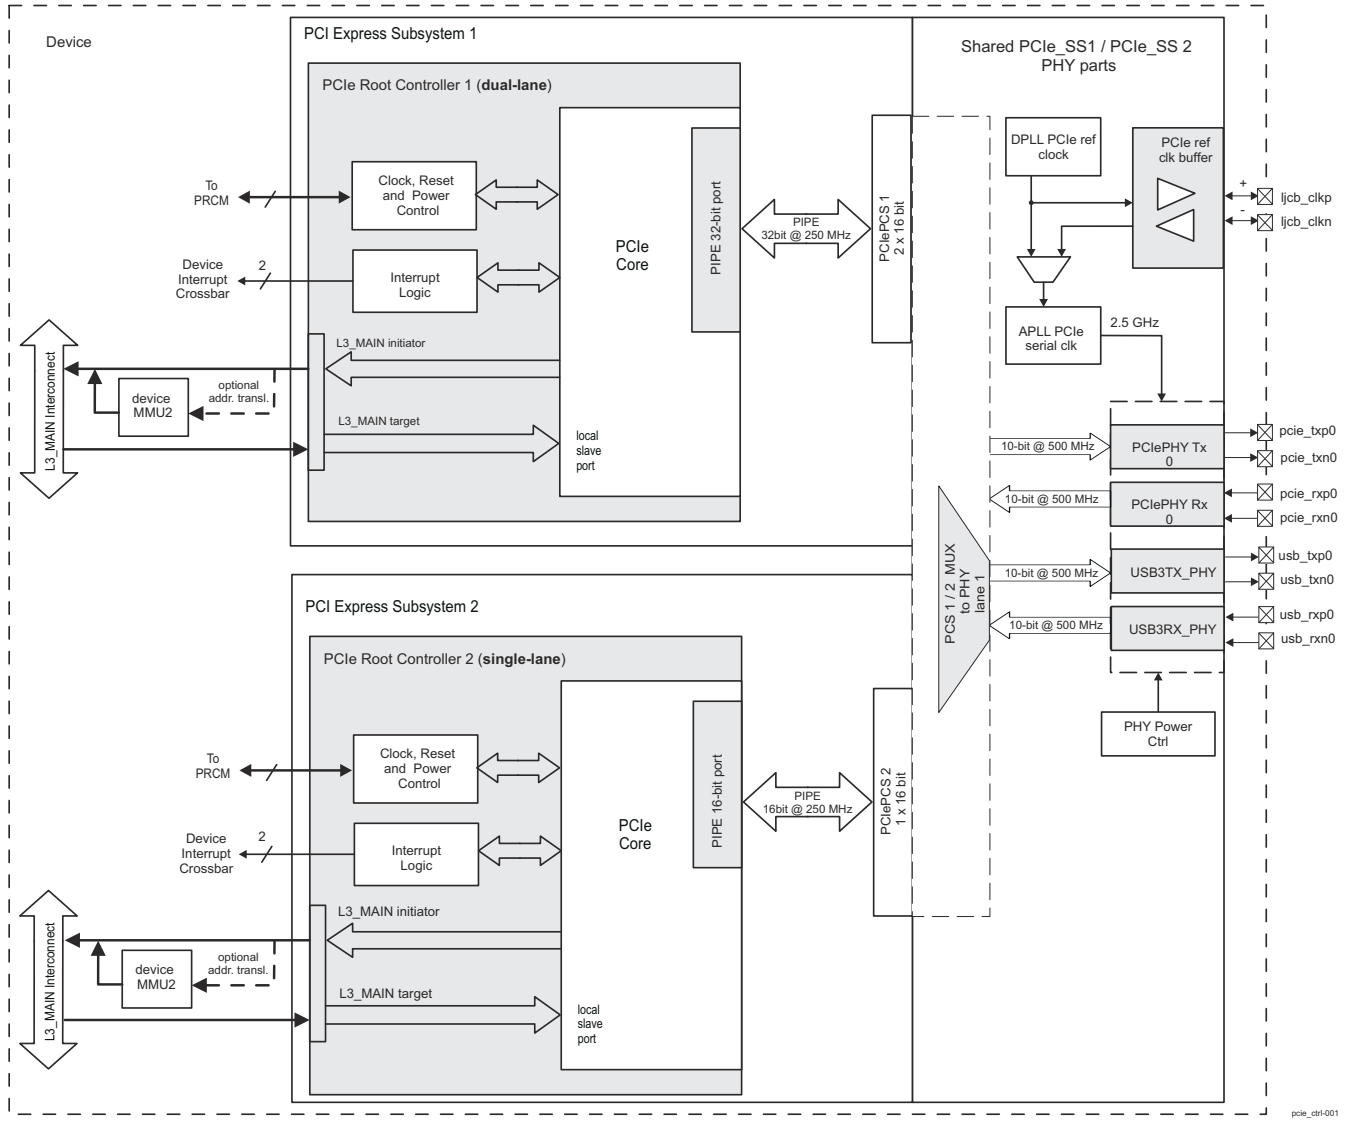

Figure 24-165. PCIe Controller Subsystem Overview

24.9.1.1 PCIe Controllers Key Features

This section describes the features supplied by the PCIe controller modules (including PCIe at device level). The PCIe_SS1 and PCIe_SS2 controllers comply with the following standards:

- PCI Local Bus Specification revision 3.0
- PCI Express Base 3.0 Specification, revision 1.0.

At system level the device supports PCI express interface in the following configurations:

- Each PCIe subsystem controller has support for PCIe Gen2 mode (5.0 Gbps per lane) and Gen1 mode (2.5 Gbps per lane).
- One PCIe (PCIe_SS1) operates as Gen2 2-lanes supporting in either root-complex (RC) or end-point EP.
- Two PCIe (PCIe_SS1 and PCIe_SS2) operates Gen2 1-lane supporting either RC or EP with the possibility of one operating in Gen1 and one in Gen2.
- PCIe_SS1 can be configured to operate in either 2-Lane (dual lane) or 1-Lane (single lane) mode, as follows:
  - Single Lane - lane 0 mapped to the PCIe port 0 of the device
  - Flexible dual lane configuration - lanes 0 and 1 can be swapped on the two PCIe ports

- PCIe_SS2 can only operate in 1-Lane mode, as follows:
  - Single Lane - lane 0 mapped to the device PCIe port 1

  When PCIe_SS1 is configured to operate in dual-lane mode, PCIe_SS2 is not available.

The main features of a device PCIe controller are:

- 16-bit operation at 250 MHz on PIPE interface (per 16-bit lane)
- One master port on the L3_MAIN supporting 32-bit address and 64-bit data bus.
- PCIe_SS1/PCIe_SS2 master port dedicated MMU (device MMU2) on L3_MAIN path, to which PCIe traffic can be optionally mapped.
- One slave port on the L3_MAIN supporting 29-bit address and 64-bit data bus.
- Maximum outbound payload size of 64 Bytes (the L3 Interconnect PCIe1/2 target ports split bursts of size >64 Bytes to the into multiple 64 Byte bursts)
- Maximum inbound payload size of 256 Bytes (internally converted to 128 Byte - bursts)
- No remote read request size limit: implicit support for 4 KiB-size and greater
- Support of EP legacy mode
- Support of inbound I/O accesses in EP legacy mode
- PIPE interface features fixed-width (16-bit data per lane) and dynamic frequency to switch between PCIe Gen1 and Gen2.
- Ultra-low transmit and receive latency
- Automatic Lane reversal as specified in the PCI Express Base 3.0 Specification, revision 1.0 (transmit and receive)
- Polarity inversion on receive
- Single Virtual Channel (VC0) and Single Traffic Class (TC0)
- Single Function in End point mode
- Automatic credit management
- ECRC generation and checking
- All PCI Device Power Management D-states with the exception of $D3_{cold}$/L2 state
- PCI Express Active State Power Management (ASPM) state L0s and L1 (with exceptions)
- PCI Express Link Power Management states except for L2 state
- PCI Express Advanced Error Reporting (AER)
- PCI Express messages for both transmit and receive
- Filtering for Posted, Non-Posted, and Completion traffic
- Configurable BAR filtering, I/O filtering, configuration filtering and completion lookup/timeout
- Access to configuration space registers and external application memory mapped registers through ECAM mechanism.
- Legacy PCI Interrupts reception (RC) and generation (EP)
- 2× hardware interrupts per PCIe_SS1and PCIe_SS2 controller mapped via the device Interrupt Crossbar (IRQ_CROSSBAR) to multiple device host (MPU, DSP, and so forth) interrupt controllers in the device
- MSIs generation and reception
- PCIe_PHY Loopback in RC mode

24.9.2 PCIe Controller Environment

The below Table 24-493 shows the device integrated PCI Express subsystem interface signals to external PCIe devices.

Table 24-493. PCIe_SS I/O Signals

(1) See CTRL_CORE_PCIE_CONTROL register in *CTRL_MODULE_CORE Registers*

For more information on the interface between PCIe_SS controller and PCIe_PHY, see Section 26.4.4.1, *PCIe Shared PHY Subsystem Block Diagram*, and Section 26.4.4, *PCIe Shared PHY Subsystem Functional Descriptions* in Section 26.4, *PCIe Shared PHY Subsystem*.

24.9.3 PCIe Controllers Integration

This section describes the PCIe controllers integration in the device, including information about clocks, resets, and hardware requests. Figure 24-166 shows the PCIe controllers integration.

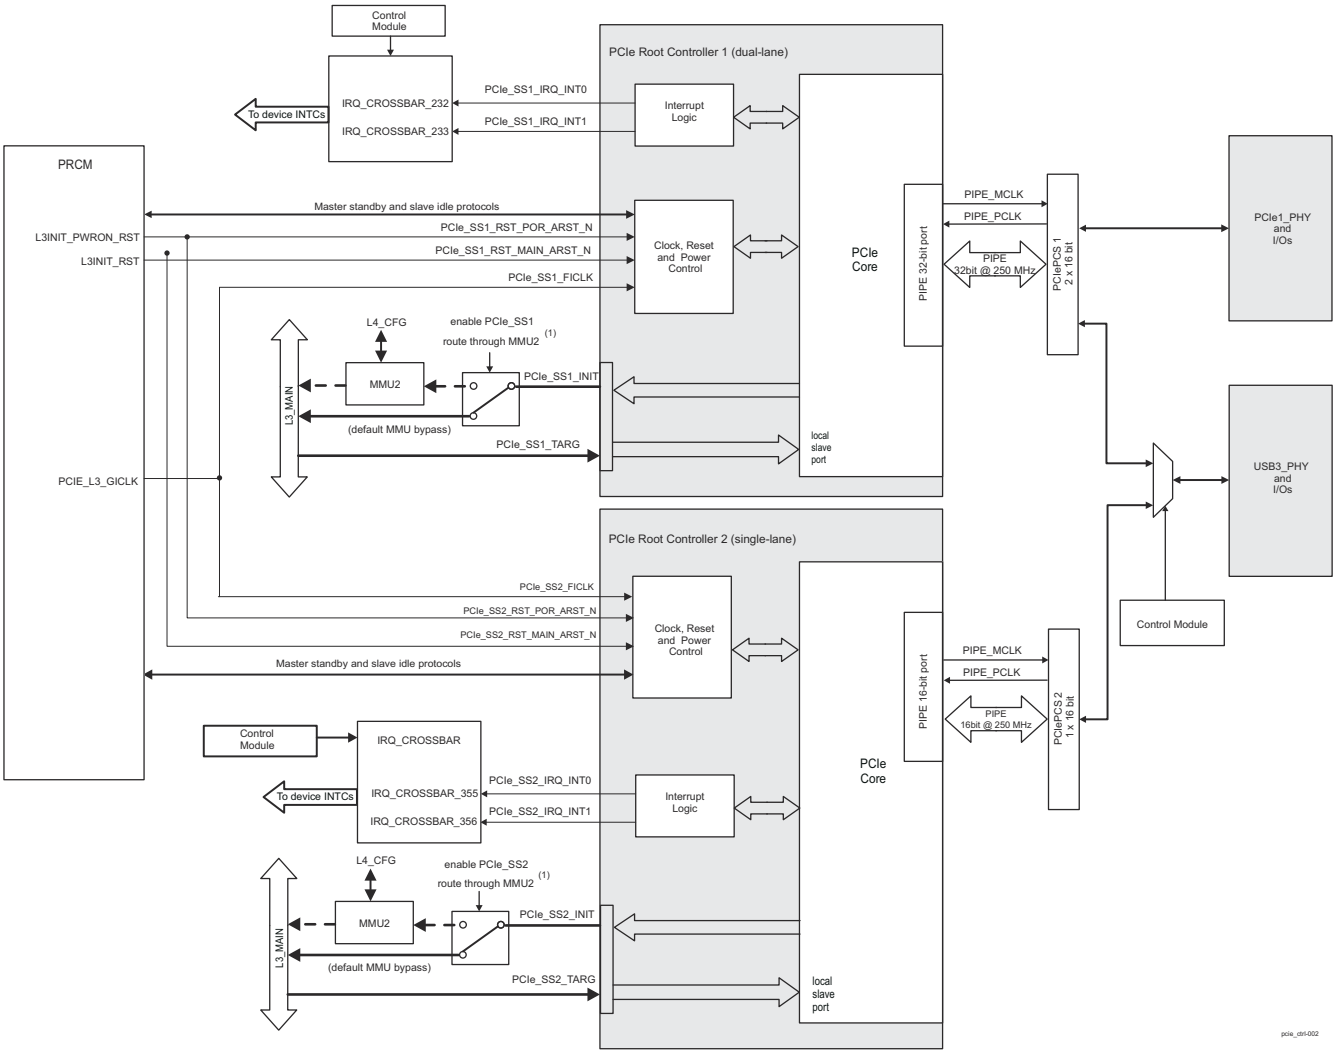

Figure 24-166. PCIe Controllers Integration

Note

By default, the traffic from the PCIe_SS1 and PCIe_SS2 controller master (initiator) port - PCIe_SS1_INIT/PCIe_SS2_INIT to the L3_MAIN interconnect, bypasses the device MMU2. Mapping the PCIe traffic from the PCIe master port to MMU2 on the L3_MAIN path is enabled via a bit in the device Core Control Module. For more details, refer to the Section 24.9.4.3.1.1.

PCIe controller integration includes these features:

- A single interface/functional clock (PCIe_SS_FICLK, shared between the master and the slave interfaces)
- A couple of functional clocks:
  - A PCIE controller clock input which receives the PIPE_PCLK generated by the assocaited PCIe PHY PCS logic
  - A PCIE controller clock output PIPE_MCLK which mirrors PIPE_PCLK back to the PCIe PHY PCS component

- Two hardware non-retention resets - PCIe_SS_RST_POR_ARST_N and PCIe_SS_RST_MAIN_ARST_N by PRCM
- Master standby and slave idle protocols with the power, reset, and clock management (PRCM) module
- Two interrupt request lines (per each PCIe controller):
  - PCIe_SS1_IRQ_INT0/PCIe_SS2_IRQ_INT0 - a main interrupt line
  - PCIe_SS1_IRQ_INT1/PCIe_SS2_IRQ_INT1 - a MSI interrupt line
- No DMA requests generation to surrounding modules
- One 64-bit data/32-bit address master port on the L3_MAIN interconnect (with an option to pass the PCIe initiator traffic to L3_MAIN through device MMU2). For details, refer to the Section 24.9.4.3.
- One 64-bit data/29-bit address slave port on the L3_MAIN interconnect (No MMU included on the slave address path). For details, refer to the Section 24.9.4.3.

For more details on the MMU2 integration in the device, refer to the Section 20.2, *MMU Integration* of the Chapter 20, *Memory Management Units*.

Note

For more information about the slave idle protocol and the wakeup request, see *Module-Level Clock Management* in *Power, Reset, and Clock Management*.

Table 24-495 through Table 24-497 summarize the integration of the module in the device.

Table 24-495. PCIe Controllers Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
PCIe_SS1	PD_L3INIT	L3_MAIN
PCIe_SS2	PD_L3INIT	L3_MAIN

Table 24-496. PCIe Controllers Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
PCIe_SS1	PCIe_SS1_FICLK	PCIE_L3_GICLK	PRCM	PCIe_SS1 root controller interface and functional clock (shared between slave and master ports)
PCIe_SS2	PCIe_SS2_FICLK	PCIE_L3_GICLK	PRCM	PCIe_SS2 root controller interface and functional clock (shared between slave and master ports)
Resets				
PCIe_SS1	PCIe_SS1_RST_POR_ARST_N	L3INIT_PWRON_RST	PRCM	A nonretention hardware power-on reset to the PCIe_SS1 controller
	PCIe_SS1_RST_MAIN_ARST_N	L3INIT_RST	PRCM	A nonretention hardware main reset to the PCIe_SS1 controller
PCIe_SS2	PCIe_SS2_RST_POR_ARST_N	L3INIT_PWRON_RST	PRCM	A non-retention hardware power-on reset to the PCIe_SS2 controller
	PCIe_SS2_RST_MAIN_ARST_N	L3INIT_RST	PRCM	A non-retention hardware main reset to the PCIe_SS2 controller

Table 24-497. PCIe Controllers Hardware Requests

Interrupt Requests				
Module Instance	**IRQ Source Name**	**IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
PCIe_SS1	PCIe_SS1_IRQ_INT0	IRQ_CROSSBAR_232	N/A	PCIe_SS1 controller main interrupt request.

Table 24-497. PCIe Controllers Hardware Requests (continued)

Interrupt Requests				
Module Instance	**IRQ Source Name**	**IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
	PCIe_SS1_IRQ_INT1	IRQ_CROSSBAR_233	N/A	PCIe_SS1 controller MSI interrupt request.
PCIe_SS2	PCIe_SS2_IRQ_INT0	IRQ_CROSSBAR_355	N/A	PCIe_SS2 controller main interrupt request
	PCIe_SS2_IRQ_INT1	IRQ_CROSSBAR_356	N/A	PCIe_SS2 controller MSI interrupt request.

Note

The **Default Mapping** column in Table 24-497, *PCIe Controller Hardware Requests* shows the default mapping of the IRQ sources listed in column **IRQ Source Name** to a certain interrupt line of one of the device interrupt controllers. These IRQ sources can also be mapped to other interrupt lines of each device interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*. For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

No DMA requests are generated by the PCIe controller to the surrounding modules.

For more details on interrupt request management at the PCIe subsystem local level, refer to the Section 24.9.4.6, *PCIe Controller Interrupt Requests*.

24.9.4 PCIe SS Controller Functional Description

24.9.4.1 PCIe Controller Functional Block Diagram

This section describes how the overall PCI express functionality is implemented by the current controller, both as EP and as RC, and how each type of traffic is transmitted and received.

The PCI express interface allows memory-mapped read and write transactions to be performed across different partners of the same PCIe fabric. Locally the device local PCIe system is composed of the PCIe_SS controller itself, device local hosts (such as MPU, DSP, and so forth), device DMAs (EDMA, and so forth) and device system memory (EMIFs SDRAM), connected to the PCIe controller via L3_MAIN interconnect.

Figure 24-167 summarizes the functional components of the PCIe_SS controller, as well as the connectivity between PCIe_SS and other components (MMU2, IRQ_CROSBBAR, PRCM, and so forth) within the device.

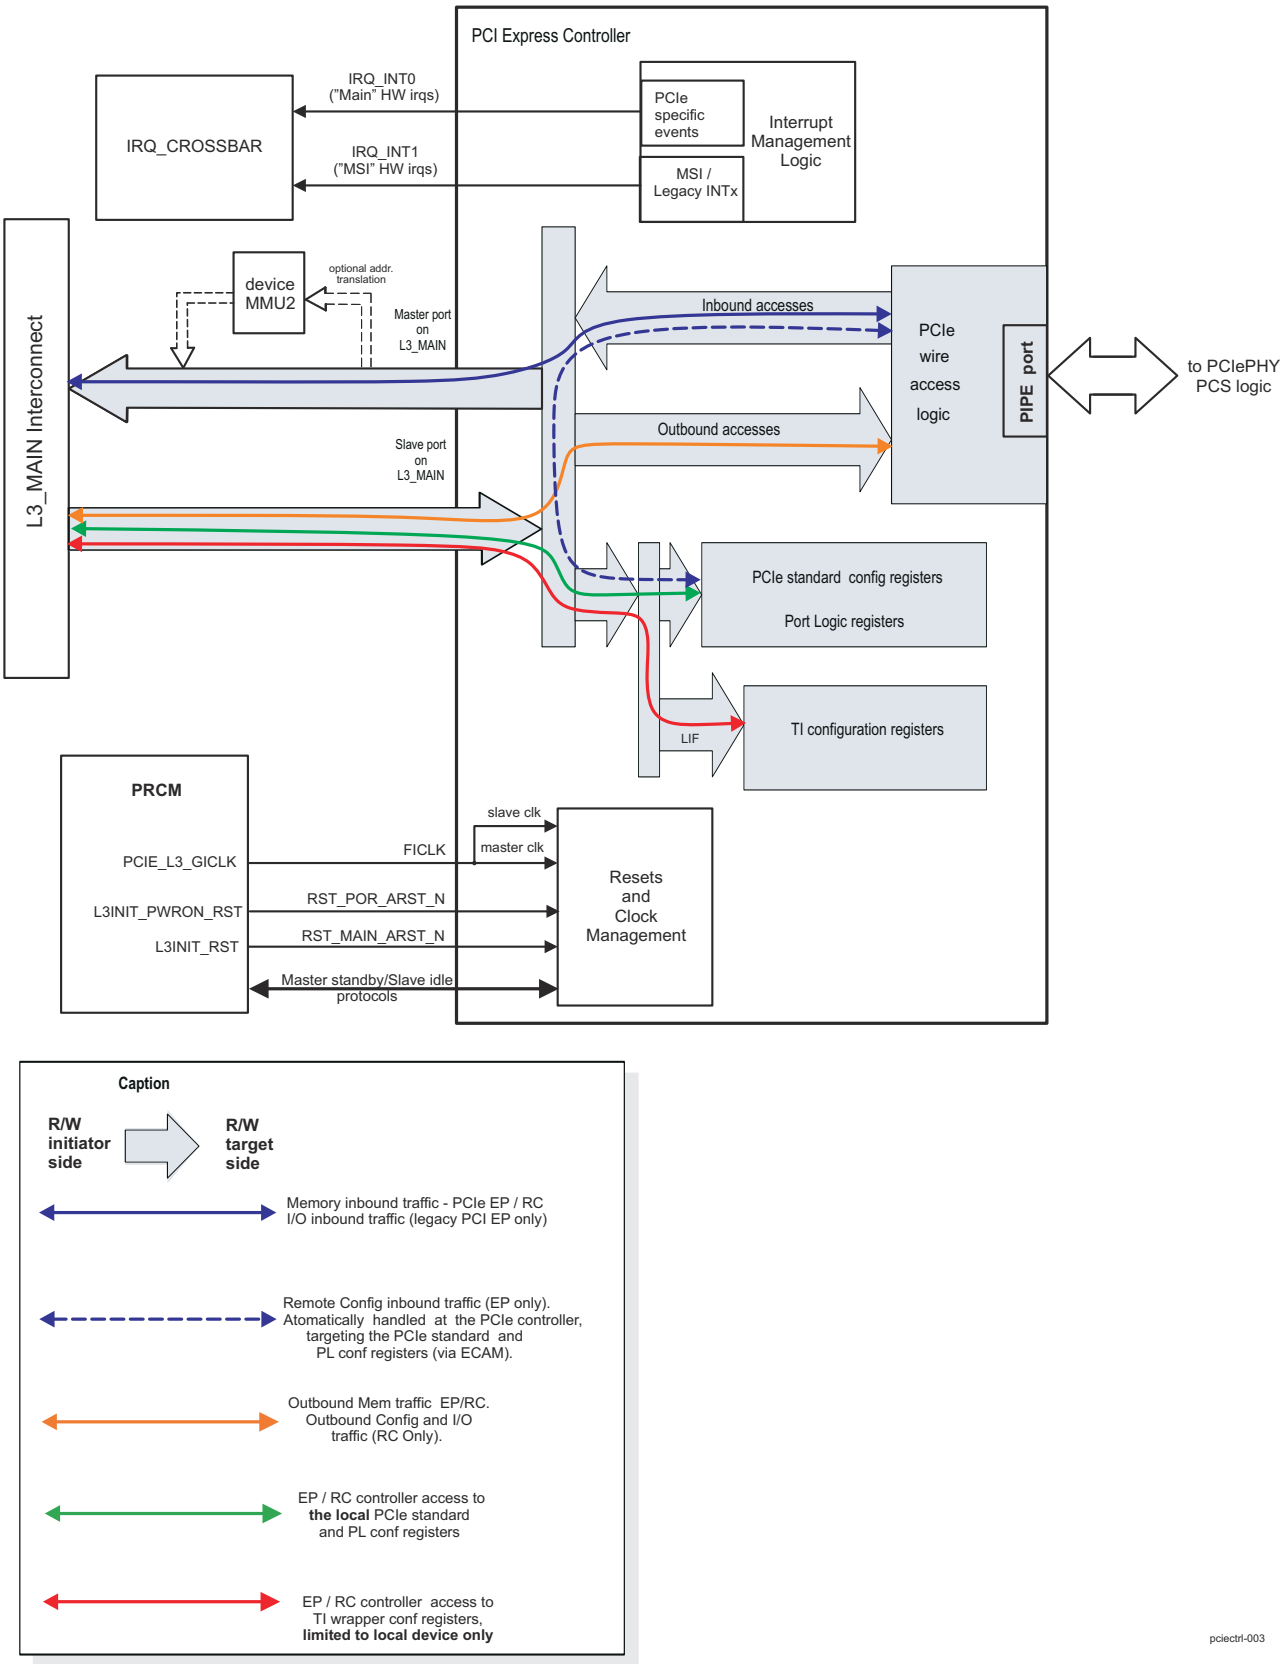

Figure 24-167. PCIe Controller Functional Block Diagram

24.9.4.2 PCIe Traffics

Most of the accesses (Memory-space) are typically flowing straight through the controller, from PCIe bus to L3_MAIN or the other way. However, some transactions are accesses to the PCIe device's configuration registers:

- The source of those accesses is either the local running application, through the PCIe slave port, or a distant PCIe device on the bus, as an inbound transaction from the PCIe wire. Access may or may not be possible depending on the mode of operation (see also transfer descriptions on the Figure 24-167).
- The destination of those accesses is either the PCIe controller core, for the PCIe-standard configuration registers and the non-standard port logic (PL) registers, or the TI wrapper configuration registers accessed over the local interface (LIF).

Figure 24-167 also gives a simplified view of the accesses allowed by device PCIe controller.

On the right hand side of the diagram is the PCIe_PHY (PCS+PMA), itself connected to the PCIe wires. The same structure is expected in the link partner on the other side of the link. Each partner can initiate and complete transactions on the link, using a packet-based protocol. Each lane is a full-duplex serial channel, that is, packets can be exchanged in both directions simultaneously. When more than one lane is used, each packet is transmitted in parallel over all active lanes.

The bidirectional accesses, initiated from components on the PCIe bus (fabric) to/from the device local PCIe subsystem are identified as *Inbound traffic*, while the bidirectional accesses, initiated by device local PCIe system to/from the PCIe bus are identified as *Outbound traffic*.

Note that there are two ways to transmit data from the local PCIe system to a distant PCIe partner:

- **Outbound write accesses**, locally initiated by, for example, a local DMA accessing controller through the PCIe slave port, connected on L3_MAIN, to push data towards a distant PCIe partner.
- **Inbound read accesses**, remotely initiated by, for example, a distant DMA though the PCIe wire, and issued on the PCIe master port, connected on L3_MAIN, to fetch data from the local memory.

Likewise, there are two ways for the local PCIe system to receive data from a distant PCIe partner:

- **Outbound read accesses**, locally initiated by, for example, a local DMA accessing the PCIe slave port, connected on L3_MAIN, to fetch data from a distant PCIe partner.
- **Inbound write accesses**, remotely initiated by, for example, a distant DMA though the PCIe wire, and issued on the PCIe master port towards the local system memory.

Note

Inbound PCIe I/O transfers are supported by the PCIe controller only in EP mode (typically for legacy PCI - EPs).

24.9.4.3 PCIe Controller Ports on L3_MAIN Interconnect

The PCIe controller to L3_MAIN connectivity is illustrated, on the left-hand side of the Figure 24-167. Read/write accesses from external PCIe components to the device local system memory on L3_MAIN are performed through the PCIe_SS master (initiator) port - PCIe_SS_INIT. The addresses issued on this port are by default directly routed to the L3_MAIN, but they can be optionally routed to and further translated by the device memory management unit - MMU2 before they reach the L3_MAIN target. For more details on MMU port, refer to Section 24.9.4.3.1.1.

On the other hand, the device local hosts (MPU, DSP, and so forth) initiate accesses to the PCIe controller local registers and PCIe bus remote devices via a PCIe_SS slave (target) port - PCIe_SS_TARG on the L3_MAIN. No MMU is included on the slave path. The slave interface has two uses: manage the local PCIe controller, and carry outbound PCIe traffic, that is initiated locally by PCIe hosts (MPU, DSP, DMAs, and so forth) within the device.

24.9.4.3.1 PCIe Controller Master Port

The PCIe controller master port (using AXI protocol with an adapter to the device L3_MAIN interconnect) has the following key fetures:

- 64-bit data, 32-bit address bus width
- Up to 16 simultaneous outstanding transactions, on up to 16 different IDs (4-bit ID port) total for read and write ports together, as follows:
  - Posted incoming PCIe transactions are all mapped to AXI ID 0, which ensures that they are executed in order. This includes all high-bandwidth writes, which are memory-type - posted.
  - Non-posted incoming PCIe transactions are mapped to AXI ID 1 and above. This includes the high-bandwidth memory-type reads.
- uses the same clock source as the PCIe slave port, but potentially on a different divider ratio
- PCIe master port, does not use a disconnect interface, because unlike the PCIe slave port, it is expected to be always active when the PCIe controller has to initiate a transaction over the device L3_MAIN.
- The PCIe controller maximum inbound payload size is 256 Bytes. The PCIe master port burst maximum length is 16 words (16 x 64-bit data words = 128 Bytes per burst). Hence a 256 Byte inbound data payload is converted by the PCIe master port to 2 max-sized bursts (128 Byte each) towards the device L3_MAIN interconnect PCIe slave port which is 128 Byte-burst compatible.
- Only incremental bursts (INCR) are supported by the PCIe controller master port.
- Non-aligned bursts can be generated - bursts that are not aligned with their own size: a burst-aligned portion of 2^N-bytes aligned burst starts on a byte address multiple of 2^N, that is a byte address with the N LSBs at '0').

The PCIe memory space supports a 64-bit address mode but in the device PCIe controller, the AXI master port address size is restricted to 32 bits.

Note

A PCIe controller remains fully functional, and able to receive transactions from , for example, anywhere within the 64-bit PCIe memory space, as long as they are correctly remapped by the inbound address translation unit (ATU) to a 32-bit L3_MAIN space address (device L3_MAIN 4 GiB - memory space). The limitation is that the range addressable by the PCIe master is reduced, and that regions larger than 2^{32} bytes (4GiB) total, cannot be mapped to the AXI master port on L3_MAIN.

24.9.4.3.1.1 PCIe Controller Master Port to MMU Routing

A standalone MMU2 module is included at the system level, primarily for use by the PCIe_SS1 and PCIe_SS2 controller. This provides several benefits including protection of the MPU host memory regions from corruption by PCIe_SS1 and PCIe_SS2 accidental accesses.

PCIe controller initiated (by remote side) traffic can be optionally routed through the MMU2 as controlled by a Control Core Module register bit. The PCIe_SS1 and PCIe_SS2 routing allows these sub-systems to be used to perform transfers.

Note

By default, the CTRL_MODULE_CORE instance located CTRL_CORE_CONTROL_IO_1[20] MMU2_DISABLE bit is set to 0b0 and the MMU2 is functionally enabled. Despite this, the PCIe_SS1 and PCIe_SS2 controller traffic still bypasses this MMU.
In order, for PCIe_SS1 and PCIe_SS2 master traffic
to be routed through the MMU2, the CTRL_MODULE_CORE
bits: CTRL_CORE_SMA_software_7[13] PCIE_SS1_MMU_ROUTE_ENABLE and CTRL_CORE_SMA_software_7[12] PCIE_SS2_MMU_ROUTE_ENABLE, must be set to 0b1 by user software.

Accesses are directed to the MMU2 by the L3_MAIN switch fabric through the use of a 33-rd address bit. For the PCIe_SS1 and PCIe_SS2 master port, the value of the 33rd bit is actually defined by the above mentioned control module CTRL_CORE_SMA_software_7 register bits. For descriptions of the CTRL_CORE_SMA_software_7 register bitfields related to MMU2 route controls, refer to the *Control Module Register Manual*, in the chapter, *Control Module*.

For more information on device MMU2 functionality and register settings, refer to the *MMU Functional Description* and *MMU Register Manual*, in the chapter, *Memory Management Units*, respectively.

24.9.4.3.2 PCIe Controller Slave Port

The PCIe controller slave port gives access to two internal targets: the local target, to manage the local controller, and the outbound window, which forwards accesses onto the PCIe wire.

The PCIe slave port (using AXI protocol with an adapter to the device L3_MAIN interconnect) has the following key features:

- **64-bit data, 29-bit address** bus width
- Up to 16 simultaneous outstanding transactions, up to 16 different IDs (4-bit ID port).
- Uses the same clock source as the PCIe controller master port, but potentially on a different divider ratio.
- Supports L3_MAIN disconnect protocol
- Exclusive and locked accesses are not supported for read and write port

PCIe Controller slave port purposes are:

- **Configuration and management of the PCIe controller:**
  - This low-bandwidth activity accesses the device PCIe controller local configuration/status registers, the Port Logic registers and the PCIe controller wrapper TI-specific registers.
  - The L3_MAIN base address corresponding to the PCIe_SS1 controller local configuration/status registers (DIF access targets) is 0x5100_0000. For the PCIe_SS2 controller local configuration/status registers (DIF access targets), the L3_MAIN base address is 0x5180_0000.
  - Bursts are not supported when accessing these registers.
- **Outbound PCIe traffic**:
  - This activity can consume the entire bandwidth available on the PCIe wires (up to 1 Gbyte/s in each direction for 2-lane, Gen2 operation), in concurrence with the AXI master ports' operation (that carries inbound PCIe traffic).
  - PCIe controller maximum outbound payload size is 64 Bytes (the L3 Interconnect PCIe1/2 target ports split bursts of size > 64 Bytes to the into multiple 64 Byte bursts). Only bursts of incremental type (INCR) are supported on the PCIe controller slave port.
  - Non-aligned bursts can be generated.
  - All outbound traffic activities are mapped within a device L3_MAIN space region which is 256 MiB in size.
  - For the PCIe_SS1 controller the PCIe outbound window is mapped within range 0x2000_0000 - 0x2FFF_FFFF of the device L3_MAIN memory space. For the PCIe_SS2 controller the PCIe outbound window is mapped within range 0x3000_0000 - 0x3FFF_FFFF (256 MiB) of the device L3_MAIN memory space.

Note

The PCIe controller remains fully functional, and able to send transactions to, for example, anywhere within the 64-bit PCIe memory space, with the appropriate remapping of the 28-bit address by the outbound address translation unit (iATU). The limitation is that the total size of addressed PCIe regions (in config, memory, IO spaces) must be less than 2^{28} bytes.

24.9.4.3.3

Note

Because only incremental burst mode is supported, the PCIe addresses can not be in a cacheable memory space. Subsequently, cache coherence protocol is not involved, and the PCIe controller is not expected to receive coherent PCIe TLPs (NS=0). For safety purpose, the PCIe controller coherent feature must be permanently disabled (and this applies for the device by default) by keeping PCIECTRL_TI_CONF_SYSCONFIG[16] MCOHERENT_EN at value 0b0. In that case, inbound coherent PCIe TLPs (that means with NS=0) proceed normally, but coherence will not be guaranteed by the device.

24.9.4.4 PCIe Controller Reset Management

The PCIe controller has two hardware reset inputs - a hardware **main** and **fundamental** resets which are asynchronous and active low.

In addition, a number of internal reset conditions can cause some sections of the controller to reset, depending on the power transitions and configuration. All reset conditions and categories are described below.

24.9.4.4.1 PCIe Reset Types and Stickiness

Three types of reset conditions are defined by the PCI standard. Each reset condition listed below falls into one of these categories. The same reset condition can take different types depending on the usecase:

- Cold reset condition: upon device power-up.
- Warm reset condition: does not follow a device power-up.
- Hot reset condition: transmitted over the PCIe link.

A reset including the physical layer (PCIe_PHY) is **called a fundamental reset**. According to the PCI Express Base 3.0 Specification, revision 1.0, it clears the programming registers non-sticky bits, and may clear or may not clear the sticky bits as well, depending on a Vaux power supply. If Vaux integrated in a PCIe subsystem, it is enabled via PM specific sticky bits - PM_CSR[8] PME_EN and DEV_CAS[10] AUXPM_EN register bits.

CAUTION

No Vaux power supply source is defined in hardware for the device integrated PCIe_SS. Subsequently, all PCIe bits defined by the PCIe standard or device specific implementation as "sticky", are reset along with the "non-sticky" bits upon a PCIe fundamental reset assertion. Because it is mandatory to communicate the permanent Vaux absence to the device PCIe EP/RC controller, the EP/RC DEV_CAS[10] AUXPM_EN (or PM_CSR[8] PM_EN) and PCIECTRL_TI_CONF_PM_CTRL [11] AUX_PWR_DET bits have to be always software written ‘0’ during initialization.

A function-level reset (FLR) impacts only one of the EP device’s functions.

Note

The device PCIe controller supports only a single function, so it does not support FLR.

24.9.4.4.2 PCIe Reset Conditions

24.9.4.4.2.1 PCIe Main Reset

Main hardware reset: Assertion of the reset signal on the main hardware reset input of the PCIe subsystem unconditionally brings the entire PCIe controller back to its default state. The main HW reset impacts both non-sticky and sticky bits of the PCIe controller.

Note

The PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE (RC/EP) bitfield and the remaining TI wrapper configuration registers (PCIe_SS_TI_CONF) are sensitive to main hardware reset only.

24.9.4.4.2.1.1 PCIe Subsystem Cold Main Reset Source

The cold main reset has as a source - the device PRCM L3INIT_PWRON_RST power-on reset. For more information on the PCIe controller hardware reset inputs see Section 24.9.3, *PCIe Controller Integration*).

The L3INIT_PWRON_RST assertion by PRCM resets all PCIe controller registers including the TI wrapper configuration registers (note that the PCIe device type in the PCIECTRL_TI_CONF_DEVICE_TYPE register is reset by default to "Root Complex").

For more information on the PRCM.L3INIT_PWRON_RST hardware reset, refer to *Reset Domains*, in *Power, Reset, and Clock Management*.

24.9.4.4.2.1.2 PCIe Subsystem Warm Main Reset Sources

The warm main reset of the PCIe controller is sourced by the device PRCM L3INIT_RST output. For more information on the PCIe controller hardware reset inputs see Section 24.9.3, *PCIe Controller Integration*). For more information on the PRCM.L3INIT_RST hardware reset, refer to *Reset Domains*, in *Power, Reset, and Clock Management*.

The L3INIT_RST main reset is tiggered from different warm reset sources within the PD_L3INIT power domain (global warm software reset, MPU watchdog reset, and so forth).

Software triggered main reset to PCIe controller : To the above group of PRCM warm main reset sources, there is also a software-triggered reset which can be asserted locally and independently to each of the PCIe_SS1 and PCIe_SS2 in the PD_L3INIT domain. The main software reset is triggered via assertion of bit:

- RM_PCIESS_RSTCTRL[0] RST_LOCAL_PCIE1 for the device PCIe_SS1 controller
- RM_PCIESS_RSTCTRL[1] RST_LOCAL_PCIE2 for the device PCIe_SS2 controller

The software (warm) reset completion triggered through device PRCM is flagged in the *Write-one to Clear* PRCM register:

- RM_PCIESS_RSTST[0] RST_LOCAL_PCIE1 for the device PCIe_SS1 controller
- RM_PCIESS_RSTST[1] RST_LOCAL_PCIE2 for the device PCIe_SS2 controller

The user software running on PCIe controller is supposed to clear the reset status bit upon reset completion event via writing 0b1 to RM_PCIESS_RSTST[0] RST_LOCAL_PCIE1 and RM_PCIESS_RSTST[1] RST_LOCAL_PCIE2 bit in PRCM.

For more details on above PCIe controller software reset bits, refer to the *PRCM Register Manual*, in the *Power, Reset and Clock Management*

Note

The warm main reset (icluding PCIe subsystem software reset) from PRCM impacts all PCIe core register bits (sticky and non-sticky) and the PCIe TI wrapper configuration registers (PCIe_SS_TI_CONF). Note that the PCIe device type in the PCIECTRL_TI_CONF_DEVICE_TYPE register is reset by default to "Root Complex".

For more details on sticky/non-sticky bits behaviour refer to the PCI Express Base 3.0 Specification, revision 1.0.

24.9.4.4.2.2 PCIe Standard Specific Resets to the PCIe Core Logic

Fundamental hardware reset - This reset impacts all non-sticky PCIe core bits. It is automatically triggered:

- upon a software initiated device type change in the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE (to RC/EP)

- upon exitting certain low-power modes
- upon PCIe controller's main power supply (Vmain) being powered-up or Vmain detected below a defined threshold by the PCIe RC. This is a cold fundamental reset.

Note

All (sticky and non-sticky bits) of the PCIe controller core are reset upon fundamental hardware reset assertion because of Vaux not implemented. Hereby all PCIe core registers have to be re-initialized from scratch after a PCIe fundamental reset.

Hardware fundamental reset operation: The hardware fundamental reset is an input to the PCIe core, to be controlled by the local PCIe software driver. Its impact is conditional: a fundamental reset clears the entire controller (including the PCIe_PHY part), with the following exceptions:

- DEVICE_TYPE register (unconditional) and all other PCIe_SS_TI_CONF registers
- PCIe link PM FSM, if the module is out of "IDLE"

The fundamental reset is applied to PCIe core in the following two cases :

- After reprogramming the device type (to EP or RC) in the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE bitfield, to latch in the new type and clear the programming registers. Remain out of idle and clear PCIECTRL_TI_CONF_PM_CTRL[11] AUX_PWR_DET to 0 beforehand, in order to reset also the sticky bits.
- L3 exit at initial power-up unless the restart is already initiated by the other side of the link

Note

The TYPE value ("EP", "legacy EP" or "RC") has to be read back by software until desired type-value is seen. This insures that the fundamental reset triggered by "TYPE" change has completed successfully. The user software must not change the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE register value during PCIe core operation.

Note

The fundamental hardware reset does not impact the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE (RC/EP) bitfield and the remaining TI wrapper configuration registers (PCIe_SS_TI_CONF). These can be reset only by a PCIe main reset input assertion.

PCIe link-down reset condition - When the PCIe link has gone down and goes up again, namely transitions from D3cold/L3 back to D0, the PCIe core auto-applies this **internal fundamental reset** and reports it on IRQ event (PCIECTRL_TI_CONF_IRQSTATUS_MAIN[11] LINK_REQ_RST) after link-up.

PCIe hot-reset condition - As defined by the PCIe standard: reset condition propagated in-band (over the PCIe wire) from an upstream port to a downstream port, using the TS1 and TS2 OS (see the PCI Express Base 3.0 Specification, revision 1.0). Requires the link to be already powered and up. The hot reset causes the link to go down and up again, causing a link-down reset condition, and as such is a fundamental reset.

The hot reset sequence can be tracked in the LTSSM by the transition to "hot reset" state, then on to "detect" and the rest of the link-up sequence.

- When RC, a hot reset is generated by writing the bit “Secondary Bus Reset” of the PCIe standard “Bridge Control Register” - BRIDGE_INT [22] SEC_BUS_RST bit .
- When EP, a host reset is automatically processed by the controller hardware.

PCIe soft reset condition - As defined by the PCIe standard: When the D-state of a device is changed from $D3_{hot}$ to D0 by software, namely by the RC doing a remote CFG write to the EP (EP) PM_CSR [1:0] PWR_STATE register, the EP device reacts depending on its DIF CS (local) setting of the no-soft-reset (NSR) bit (EP) PM_CSR [3] NSR:

- If bit NSR=0, the soft reset is applied, and the device transitions to the $D0_{unitialized}$ state (see Figure 24-168). Non-sticky bits are reset.
- If bit NSR=1, the soft reset is inhibited, the device transitions directly to the $D0_{active}$ state (see Figure 24-168), no reset is applied. Full context is retained, including non-sticky bits.

Note

The soft reset is a hot reset. The soft reset is not a fundamental reset; that means that it does not reset the PHY, only the programming registers.

24.9.4.5 PCIe Controller Power Management

This section is a brief summary of the supported power modes and power transitions, as well as the consequences (clock gating, power gating, resets, and so forth) on the PCIe controller.

24.9.4.5.1 PCIe Protocol Power Management

The power state of a PCIe controller port is described by four different FSMs, each running at a different level of the protocol, each with its own independent state. The FSMs are covered in Section 24.9.4.5.1.1 through Section 24.9.4.5.1.2.

Table 24-498summarizes the typical power stable state combinations, namely the combinations of states the controller can settle into, after a number of potential transitions and transient states, and assuming that the lowest power state possible is used.

The PCIe standard defined optional gating of the reference clock on PCIe_PHY PLL input (and therefore of the PIPE clock) when in L1-state is not supported. As shown in the Table 24-498, the PIPE clock is always running while link is in L1.

Table 24-498. Power States Summary

Device D-state	Link L-state	PHY LTSSM state	PIPE power down	PIPE clock(1)	Vmain	LP_CLK(4) (auxiliary clock)	Slave Idle	Master Standby
D0_uninitialized(2)	LDn	Detect	P1	OFF	don't care	ON	1	1
D0_uninitialized	L0	n/a	P0	ON	ON	ON	0	1
D0_active	L0	L0	P0	ON	ON	ON	0	0/1(3)
D0_active	L0s	L0s	P0s	ON	ON	ON	0	0/1(3)
D0_active	L1	L1	P1	ON	ON	ON	0	0/1(3)
D1	L1	L1	P1	ON	ON	ON	0	1
D2	L1	L1	P1	ON	ON	ON	0	1
D3_hot	L1	L1	P1	ON	ON	ON	0	1
D3_cold	L3	n/a	P2	OFF	OFF	OFF	1	1

(1) The PIPE clock activity, as visible from the PCIe core boundary, implies the activity of the high-speed PLL it is derived from, which implies the activity of the reference clock on the PLL input.
(2) Default controller state after reset. Not a real PCIe state.
(3) Master standby value depends on the PCI express application (MSE, ISE, and so forth)
(4) See Section 24.9.4.5.2

24.9.4.5.1.1 PCIe Device/function power state (D-state)

The function power state machine is the highest-level PM FSM in a PCIe device. The power state control bitfield is part of standard PCIe register bitfield- (EP)PM_CSR/(RC)PM_CSR [1:0] PWR_STATE.

Note

A Vaux power source is not tied to the PCIe core, that is why the state D3_cold with Vaux switched-on is unsupported by the PCIe PM FSM.

Note

The six available D-states are, by order of decreasing power: D0_uninitialized (default), D0_active, D1, D2, D3_hot, D3_cold. Note that the function power state Cfg field - is only 2 bit, encoding only 4 combinations: D0, D1, D2, D3. The difference between uninitialized and active (D0), and between hot and cold (D3) is implicit.

The eventual (“stable” or “quiescent”) power state of a PCIe link (link state) is determined by the D-state of the downstream device. For the current controller, it means that the D-state determines the link state in EP type mode, but not in RC type mode.

Note also that the device may go through a number of transient link states before entering/after exiting its quiescent link state, so that a device, for example, in D3_hot may be consuming maximum instantaneous power .

D0_uninitialized is the function’s default state, entered after powerup and/or reset. It is used by the RC software to enumerate the function (Cfg transactions). Mem and IO transaction are disabled. It can only be entered though a reset, partial or total. Together with D0_active, it is the highest-power D-state.

D0_active is the function’s active state, where all Memory and I/O transactions take place. By definition, a function transitions from D0_uninitialized to D0_active after the RC software enables Memory and I/O transactions, either as completer ("Cfg" write 0b1 to memory space enable: MSE/IO space enable: ISE) or as requester ("Cfg" write 1 to bus master enable: BME). D0_active can be exited to/entered from D1, D2, or D3_hot by the RC software writing to the function’s (EP)PM_CSR[1:0] PWR_STATE power state. Together with D0_uninitialized, it is the highest-power D-state.

D1 and D2 are two optional states, with reduced power compared to D0. Both operate the same way, and have the same action on lower-level PM FSM, with D1 expected to have a faster wakeup and D2 a lower power. Both are supported by the current controller. D1 and D2 can be exited to/entered from D0_active, D1, D2, or exited to D3_hot , by the RC software writing to the function’s (EP)PM_CSR[1:0] PWR_STATE power state bitfield. The current controller supports D1 and D2 but a fully compliant implementation also depends on the system providing the right combination of HW and software.

D3_hot is a lower-power state (compared to D0, D1, D2). It can be entered from D0_active, D1, or D2 by the RC software writing to the function’s (EP)PM_CSR[1:0] PWR_STATE. Transition to D3_hot is typically continued to D3_cold and main power (VMAIN) shutdown. It can also be exited to D0 by the RC writing (0b00) to the (EP)PM_CSR[1:0] PWR_STATE. The state transition to either D0_active or D0_uninitialized depends on the NSR value written in the bit (EP)PM_CSR[3] NSR (No_Soft_Reset bit) of 0b1 (that means - function is not reset) or 0b0 (that means - function is reset, link is restarted and must be reconfigured) respectively.

D3_cold is the lowest-power state, defined by the VMAIN being turned off. It it typically entered from D3_hot as shown in the figure below, but any turn-off request will actually place the function in that state. It can only be exited to D0_uninitialized, by restoring VMAIN and after resetting the function, totally or partially (see link states below).

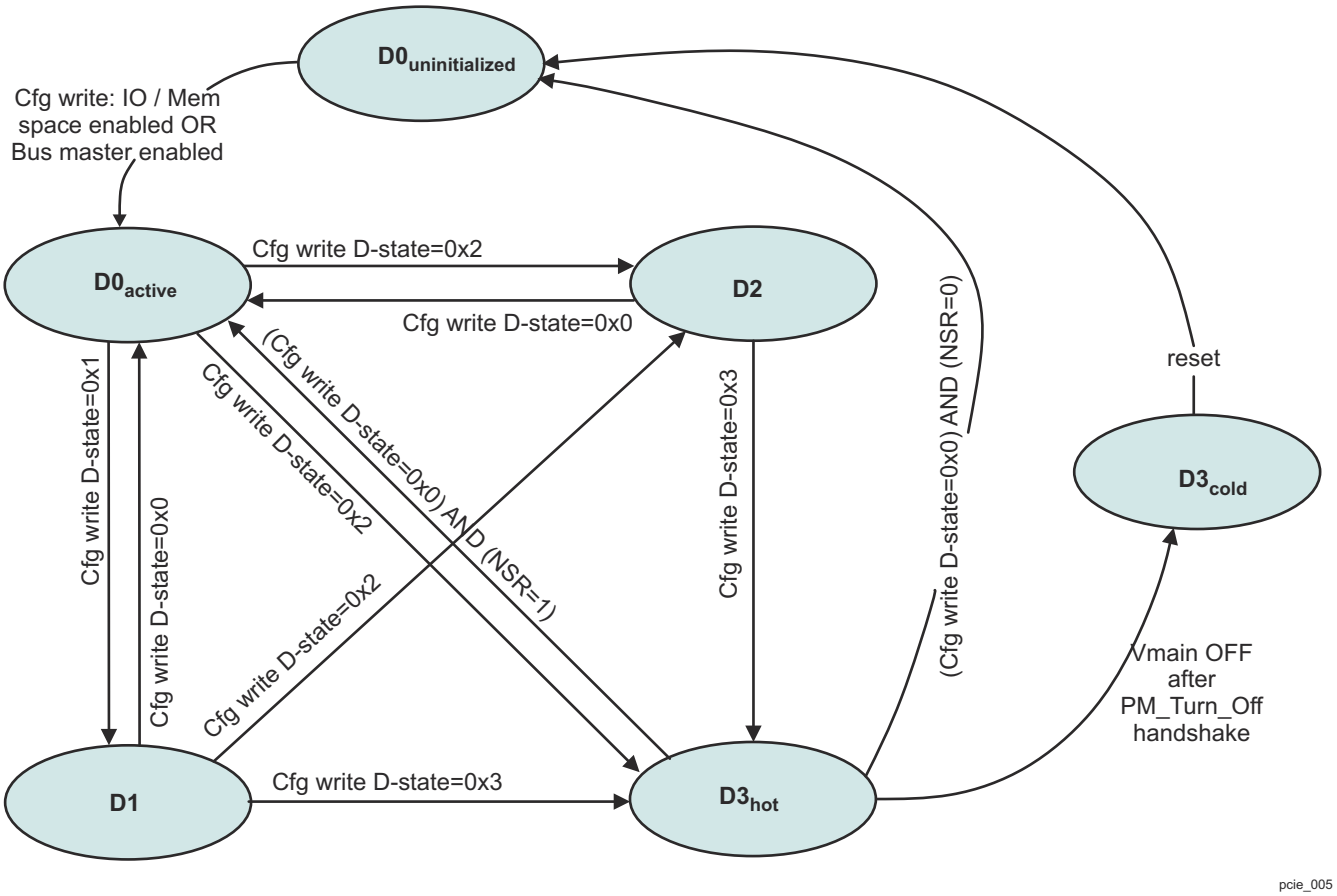

Figure 24-168. PCIe D-state (function power state) FSM diagram

The Figure 24-168 shows the state transitions in the power state. NSR is the “No_Soft_Reset” bit in the function’s (EP)PM_CSR configuration register. NSR advertizes the ability of the device to go into D3_hot while retaining its register settings (when 1), or conversely, the inability to do so and the reset of those setting upon D3_hot exit (when 0).

NSR is read-only to the RC software over Cfg accesses, but it can be set by the EP's local software over DIF (CS access) prior to enumeration. The controller shall apply the NSR to itself accordingly.

Most function power state transitions are done explicitly by the RC-side software writing into the EP function’s (EP)PM_CSR[1:0] PWR_STATE, over the PCIe wire. This is one of the two PM control mechanisms of PCIe, the other one being ASPM . The remaining function power state transitions are caused by resets.

The D-state of a device sets the link power state (L-state) for the PCIe link above. In other words, the L-state of a PCIe link (connecting an upstream device, closer to the RC, and a downstream device, closer to an EP) is set by the downstream device.

24.9.4.5.1.2 PCIe Controller PIPE Powerstate (Powerdown Control)

The PIPE interfaces the MAC, or controller, above PIPE in the protocol hierarchy and the PHY, or transceiver, below PIPE. The current controller implementation has a PIPE interface at its boundary.

CAUTION

The physical layer as defined by the PCIe standard extends into the PCIe MAC layer, to include, for example, the LTSSM, so that “physical layer” and PHY do not coincide, with the latter included in the former.

The PIPE interface has its own power state, driven by the PCIe controller towards PCIe_SS PHY on a 2-bit powerdown signal, depending on the PM state machines above. It has four states: P0, P0s, P1, P2:

- **P0 (pipe_powerdown = 0b00):** active state, for high-speed (HS) data transmission and reception. Used for L0 link state.
- **P0s (pipe_powerdown = 0b01):** active HS receiver, suspended transmitter. Used for L0s link state.
- **P1 (pipe_powerdown = 0b10):** Suspended HS receiver and transmitter, but PIPE clock still running.
- **P2 (pipe_powerdown = 0b11):** Suspended HS receiver and transmitter, PIPE clock stopped - asynchronous mode.

24.9.4.5.2 PCIE Controller Clocks Management

24.9.4.5.2.1 PCIe Clock Domains

The controller has two main clock domains: the L3_MAIN bridge (ports) and the PCIe core.

The L3_MAIN bridge runs on a single clock. That same clock is used to run both the PCIe controller master and slave ports. It can be divided, with independently ratios for master and slave. However, both sides are typically expected to run at the same speed, as both are capable of the same performance.

There is an auxiliary clock - LP_CLK which is a PCIe_SS internal low-power clock, used when pipe clock is stopped. It is assumed to be always available when the module is not idle.

The PCIe core runs on the PIPE clock whenever that clock is provided by the relevant PCIe_PHY. When the PCIe link is in a low-power state and the PIPE clock is not available, the core splits in two sub-domains:

- Most of the core stops
- A small “auxiliary” part of the core (which includes the configuration registers) switches to a low-power clock LP_CLK
- The two subdomains can still be considered synchronous despite their different clocking scheme, since they are either running on the same clock, or one of the subdomain clocks is stopped.

24.9.4.5.2.2 PCIe Controller Idle/Standby Clock Management Interfaces

A PCIe controller has two clock management (CM) interfaces with device PRCM:

- A master port clock management interface based on master standby protocol with the device PRCM
- A slave port clock management interface based on slave idle protocol with the device PRCM

The PCIe wrapper logic located register PCIECTRL_TI_CONF_SYSCONFIG[3:2] IDLEMODE and PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE bitfields are used to software configure the idle / standby CM behaviour locally for the PCIe_SS controller. The Table 24-499, shows the available CM options.

Table 24-499. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	PCIECTRL_TI_CONF_SYSCONFIG [3:2] IDLEMODE bit field	The available modes are: Force-Idle, No-Idle, wakeup-disabled Smart-Idle and wakeup-capable Smart-Idle.
Master standby modes	PCIECTRL_TI_CONF_SYSCONFIG [5:4] STANDBYMODE bit field	The available modes are: Force-Standby, No-Standby, wakeup-disabled Smart-Standby and wakeup-capable Smart-Standby.

For more information on the PCIeSS functional clock gating in the device PRCM (clock PCIE_L3_GICLK), refer to *Clock Domain-Level Clock Management*, in the chapter, *Power, Reset and Clock Management*.

The relations between the PCIeSS master (standby)/slave (idle) behaviour to various PCIe protocol link power management features are covered in the Section 24.9.4.5.2.2.1 and Section 24.9.4.5.2.2.2, respectively.

24.9.4.5.2.2.1 PCIe Controller Master Standby Behavior

As a master (initiator) on the device L3_MAIN interconnect, the PCIe controller supports the standby protocol over the standard three signals: mstandby/mwait/mwakeup. The behavior of that interface can be configured in the PCIeSS controller wrapper (PCIe_SS_TI_CONF) register - PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE bitfield.

The standby protocol notifies the local system if inbound PCIe transactions are likely to be routed to the controller's master port.

Note

Note that CFG-type transactions are typically not part of the PCIe controller master port transfers: in RC mode they are only outbound, and in EP mode they are processed inside the controller.

Automatic mode (default): most operations are expected to take place in "smart-standby" mode. In that mode, the master standby interface is automatically managed by the PCIe status, featuring (Mstandby = 0) if (D-state=$D0_{active}$ and MSE=1 that is bit (RC) STATUS_COMMAND_REGISTER/(EP) STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN) :

- D-state = D0_active indicates that the link is up, that data can be exchanged. It's also a condition for memory-type transactions to take place.
- The Memory Space Enable bit (RC) STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN, indicating that the RC has enumerated the PCIe fabric and configured the memory space for operation, before EP writing the MSE bit in the local CFG register - (EP) STATUS_COMMAND_REGISTER via DIF CS access.

In automatic (smart-standby) mode, the standby is therefore controlled remotely by the RC software, which sets both the D-state and the MSE.

Note that the master does not go to standby during ASPM (so called active state power management) transitions to L0s or L1 on the link, as it remains in "D0_active" during that time. Although the physical layer is partially or fully stopped during L0s and L1, the short restart time of a few microseconds does not justify a transition to standby by the master. In other words, the master goes or doesn't go to standby after a link layer transition to L1, depending on the cause, if a transition in "D-state" or "ASPM" occured, respectively.

More generally, the link state is not directly correlated to the automatic standby state of the master:

- Master in standby (mstandby=1): link can be in L0 (link startup), L1 (D1, D2, D3hot), L3 (D3cold)
- Master out of standby (mstandby=0): link can be in L0, L0S/L1 (ASPM)

The "Mstandby" status depends on the possibility of transactions, not on actual transactions. The master may remain out of standby indefinitely without any transaction, and an incoming transaction shall not cause the master to exit standby. The latter is an error case which occurance is prevented in hardware.

The mwait=0 handshake, eventually returned after the mstandby=0 transition, should prevent the master from issuing transactions until the system is ready. However, no back-pressure can actually be applied to the PCIe to prevent inbound accesses after, for example, MSE has been set. It is assumed that there will be sufficient time for the mwait to transition, that is typically for the system to reopen the path to its local memory, before the first inbound transaction is routed to the master.

When the PCIe local controller itself is in RC mode, note that the D-state may remain D0active even after the has gone down. It is therefore advised to use the clearing of the local MSE bit to set the master in standby. Alternatively, the RC can be placed in D3hot mode, or the standby can be forced (to mstandby = 1) by setting the standbymode to "force-standby". Whatever the method, the RC is aware of the state of the entire PCIe fabric, and is expected to put its master in standby in full knowledge of the situation.

For more information on the PCIe Controller Standby Management Protocol with the device PRCM , see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

Manual control, EP type: When incoming transactions are not memory-type (e.g.: IO type), the master is capable of issuing transactions while the automatic out-of-standby conditions above are not met.

Note

In the EP, non-memory type transaction cases, it is the user software responsibility to manually force the master out of standby via setting the bit PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE = 0x1, that means - "No-Standby", before the first transaction, and to return it to automatic mode via setting PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE = 0x2, that means - "Smart-Standby" after the last transaction.

For instance, an EP shall have to monitor the ISE (IO space enable) bit and the link status, and set the PCIECTRL_TI_CONF_SYSCONFIG [5:4] STANDBYMODE bitfield accordingly if EP is configured to have an IO BAR.

24.9.4.5.2.2.2 PCIe Controller Slave Idle/Disconnect Behavior

As a target of the device L3_MAIN bus (with target being the PCIe controller slave port on L3_MAIN respectively), the controller supports the "Idle" protocol. The behaviour of that interface can be configured in the PCIeSS controller wrapper register - PCIECTRL_TI_CONF_SYSCONFIG[3:2] IDLEMODE bitfield.

Additionally, the slave port clock management supports a disconnect protocol which is controlled automatically.

The idle transition of the PCIe controller is strictly synchronized to PIPE clock. The PRCM places the PCIe controller to an "Idle state" before PCIePCS generated PIPE clock is stopped due to some reason: g.h. PCIe PHY low power transition with gating local PLL clocks, the APLL_PCIe clock or gating PCIeREF_DPLL clock. The IDLE state is automatically maintained by PRCM during periods in which PIPE clock is stopped.

PCIe controller transitions to IDLE initiated by the system PRCM are strictly synchronized with the PCIe operational state. The PRCM allows the PCIe controller to be brought out of "IDLE" state, only if the generation of the PIPE clock is enabled by configuring the high-frequency PLL (source of the PIPE clock) and the 100 MHz PCIe reference clock scheme (source of the high-frequency clock). For more details on the PCIe PLL and PHY related clocks, refer to the Section 26.4, *PCIe Shared PHY Susbsystem* in the chapter, *Shared PHY Component Subsystems* .

CAUTION

All accesses to the device PCIe controller on its slave port, namely to the local target configuration PL/PCIe standard/wrapper registers or to the PCIe bus, require the PIPE clock to be running. The presence of the PCIe interface clock - PCIE_L3_GICLK is not sufficient to perform such accesses.

24.9.4.5.2.2.2.1 PCIe Controller Idle Sequence During D3cold/L3 State

When the link of a RC enters L3 mode, the PIPE interface must go to P2 mode for power saving. The PCIe controller maintains the PIPE interface in P1 mode (PIPE clock running) and the internal registers accessible until the system requests entry into "Idle", and only then transition to P2: it is the device PRCM responsibility to Idle the module (PCIECTRL_TI_CONF_SYSCONFIG [3:2] IDLEMODE set to 0x2 - *Smart Idle mode* should be selected), in order to reach a low-power state. Transitioning to "P2", stops the PIPE clock and makes the register inaccessible, which in turn corresponds to an "IDLED" and disconnected from L3_MAIN PCIe slave port.

Note

The "L3" state can only be exited when the RC re-enabling the Vmain power supply, and reconfiguring all PCIe registers from scratch: In both EP and RC cases, the system should detect Vmain power assertion, apply a fundamental reset, then bring the module out of "IDLE" and restart the link normally. All registers are reset.

24.9.4.6 PCIe Controller Interrupt Requests

In the rest of this section, and for clarity:

- "**Interrupts**" refer by default to the virtual interrupt lines emulated by the PCIe protocol using either the PCI legacy or PCIe Message-Signaled Interrupts (MSI) methods, and used for non-PCIe purposes by the system.
- "**Hardware interrupts**" refer to the actual interrupt signals coming out of the current PCIe controller, and used to manage various events of the PCIe protocol, including PCI interrupts.

Each PCIe controller has two **hardware interrupt lines** described in Table 24-500 and Table 24-502, which are level-sensitive. PCIe pulse interrupts are unsupported in the device.

The main HW interrupt line - PCIe_SS1_IRQ_INT0/PCIe_SS2_IRQ_INT0 receives all interrupt events related to the control of the PCIe operation, including power management and errors.

The MSI HW interrupt line - PCIe_SS1_IRQ_INT1/PCIe_SS2_IRQ_INT1 receives all interrupt events propagated by a remote EP over the PCIe interface, for specific (non-PCIe) applicative purposes, in conjunction with the PCIe transactions. This includes the legacy interrupts (INTx) as well as the Message Signaled Interrupts (MSI) proper, as defined by the PCIe standard.

Note

MSI-X is unsupported by PCIe controller.

The difference between the two hardware interrupt types - "main" and "MSI" is that the main interrupt events are used by the PCIe interface, whereas the MSI interrupt uses the PCIe interface.

Note

Incoming MSI events only exist in RC mode when MSI events are received over the PCIe wire. In EP mode, other mechanisms allow controller to generate (transmit) of the same type of interrupt events onto the PCIe bus.

The main interrupt events are further divided into PCI management and error events. The MSI interrupts are divided into legacy and MSI proper. Each of these four categories of events is described in Section 24.9.4.6.1 and Section 24.9.4.6.2.2.

24.9.4.6.1 PCIe Controller Main Hardware Management

24.9.4.6.1.1 PCIe Management Interrupt Events

The events described here trigger the main interrupt line. Each status bit is set to one by a specific PCIe event, and must be cleared by the local SW.

CFG_MSE_EVT: (EP mode) PCIe controller's Memory Space Enable (MSE) config bit has been set by the RC software - written to 1 by a configuration write. This notifies the local EP that incoming memory-type PCIe transactions may now target the local function, over the AXI master port.

CFG_BME_EVT: (EP mode) PCIe controller's Bus Master Enable (BME) config bit has been set by the RC software - written to 1 by a configuration write. This allows the local EP to initiate (outgoing) PCIe transactions, over the AXI slave's outbound window.

LINK_UP_EVT: Link layer has successfully booted and reached L0active state. Data can be transmitted and received over the PCIe wire.

LINK_REQ_RST: Link-down reset was triggered (by link-down condition). Non-sticky bits have been reset.

PM_PME: (RC mode) PCIe controller has received a power management event PM message on its PCIe downstream port, requesting wakeup.

PME_TO_ACK: (RC mode) PCIe controller has received a Turn-Off Acknowledge PM message on its PCIe downstream port, acknowledging a previously transmitted turnoff message (PME_Turn_Off).

PME_TURN_OFF: (EP mode) PCIe controller has received a Turn-Off PM message on its PCIe upstream port, requesting an acknowledge (PME_TO_Ack) and the transition of the link to L2/L3

24.9.4.6.1.2 PCIe Error Interrupt Events

The events described here trigger the main interrupt line.

ERR_COR: (RC mode) Correctable Error message received on PCIe downstream port.

ERR_NONFATAL: (RC mode) Uncorrectable Error message received on PCIe downstream port.

ERR_FATAL: (RC mode) Fatal Error message received on PCIe downstream port.

ERR_SYS: (RC mode) Either of the three error messages above (correctable, non-fatal, fatal) was reported and enabled in the root control register.

ERR_ECRC: End-to-end CRC error detected.

ERR_AXI: AXI slave error caused by response table overflow. This error is not supposed to happen.

24.9.4.6.1.3 Summary of PCIe Controller Main Hardware Interrupt Events

Table 24-500 describes the events, related to control of the PCIe interface operation itself, including power management, reset and error handling, that trigger the "main" hardware interrupt line.

Table 24-500. PCIe Main Hardware Interrupt Events Summary

Event Status and Clear	Interrupt Enable	Interrupt Disable	Mapping	Description
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[14] CFG_MSE_EVT	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[14] CFG_MSE_EVT_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[14] CFG_MSE_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	CFG "Memory Space Enable" change event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[13] CFG_BME_EVT	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[13] CFG_BME_EVT_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[13] CFG_BME_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	CFG "Bus Master Enable" change event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[12] LINK_UP_EVT	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[12] LINK_UP_EVT_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[12] LINK_UP_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Link-up state change" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[11] LINK_REQ_RST	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[11] LINK_REQ_RST_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[11] LINK_REQ_RST_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Link Request Reset" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[10] PM_PME	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[10] PM_PME_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[10] PM_PME_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Power Management PME message received" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[9] PM_TO_ACK	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[9] PM_TO_ACK_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[9] PM_TO_ACK_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Power Management acknowledge" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[8] PM_TURNOFF	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[8] PM_TURNOFF_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[8] PM_TURNOFF_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Power Management Turn-off" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[5] ERR_AER	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[5] ERR_AER_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[5] ERR_AER_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"ECRC Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[4] ERR_AXI	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[4] ERR_AXI_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[4] ERR_AXI_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"AXI tag lookup fatal error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[3] ERR_COR	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[3] ERR_CORR_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[3] ERR_CORR_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Correctable Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[2] ERR_NONFATAL	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[2] ERR_NONFATAL_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[2] ERR_NONFATAL_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Non-Fatal Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[1] ERR_FATAL	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[1] ERR_FATAL_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[1] ERR_FATAL_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Fatal Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[0] ERR_SYS	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[0] ERR_SYS_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[0] ERR_SYS_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"System Error" event

Note

While the PCIECTRL_TI_CONF_IRQSTATUS_MAIN register is updated only if corresponding interrupt is enabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN register, the PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN register always provides the Legacy/MSI event status regardless of an interrupt being enabled or disabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN register.

24.9.4.6.2 PCIe Controller Legacy and MSI Virtual Interrupts Management

The PCIe protocol uses TLPs to create “virtual” interrupt lines across the PCIe fabric. Interrupts do not constitute a separate transaction type like Mem, Cfg, I/O, and so forth, but reuse the existing types.

24.9.4.6.2.1 Legacy PCI Interrupts (INTx)

Legacy PCI interrupts are supported over PCIe by dedicated message codes (posted-write in Msg space) that flag the assertion or deassertion of one of four "virtual" interrupt lines (or pins): INTA, INTB, INTC, INTD. They can only be sent by EPs, and routed to/received by the RC.

PCIe controller supports single-function mode and can send only INTA when configured as EP.

Note

Use of legacy PCI interrupt is exclusive with use of MSI (defined in Section 24.9.4.6.2.1.2). MSI should be the preferred method whenever possible.

24.9.4.6.2.1.1 Legacy PCI Interrupt Events Overview

Legacy INTx (with x= A/B/C/D) are interrupt events inherited from PCI, where each was implemented on a physical bus wire. The RC can allocate each line to a given EP function, which is then allowed to assert/deassert that line (and only that line). PCI legacy interrupt events are mapped on the MSI interrupt line of PCIe controller. For more details, refer to Section 24.9.4.6.2.1.2 and Section 24.9.4.6.2.1.3.

The controller HW shall both set and clear the IRQ status bit according to the assert and deassert messages received over the PCIe wire, respectively. In other words, the legacy interrupt status bit do not need to be cleared by the local software after processing.

Typical legacy interrupt service routine (ISR) on the RC-configured PCIe controller is:

- Remote EP function transmits an "assert INTx" message. Value of x (within A/B/C/D) was previously assigned by the RC software using configuration accesses.
- "assert INTx" message is routed up the PCIe topology to the RC (local controller)
- PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit INTx goes to 1
- MSI interrupt line is asserted
- software reads PCIECTRL_TI_CONF_IRQSTATUS_MSI status register. The asserted bit (A,B,C,D) allows to determines the EP function that generated the event.
- software accesses this EP function over PCIe to process the interrupt: ad-hoc service routine
- As a result of the processing, remote EP function transmits the “deassert INTx” message
- software clears the PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit INTx to 0.
- MSI interrupt line is deasserted, assuming there is no other asserted event.

24.9.4.6.2.1.2 Legacy PCI Interrupt Transmission (EP mode only)

Writing 0b1 to TI wrapper register PCIECTRL_TI_CONF_INTX_ASSERT[0] ASSERT_F0 bit sends an ASSERT message on the “interrupt pin” specified in the config header space.

Writing 0b1 to TI wrapper register PCIECTRL_TI_CONF_INTX_DEASSERT[0] DEASSERT_F0 bit will send a DEASSERT message on the “interrupt pin” specified in the config header space.

A status of the virtual “interrupt line” is available by reading out either bitfield.

Note

This status is just a local record of the last message sent, it is not the result of any feedback from the PCIe fabric, since messages are posted, no response is generated. For that reason, the PCIe protocol does not guarantee the coherence between assertion and deassertion INTx messages, that means that it's up to the application to ensure that the INTx assertion has been seen by the RC before sending the deassertion, and vice versa.

CAUTION

The operations above should only be used when in EP mode, and will produce undefined results if applied to an RC-configured controller.

24.9.4.6.2.1.3 Legacy PCI Interrupt Reception (RC mode only)

The reception of either of the 8 INTX message codes (ASSERT/DEASSERT of INTA/B/C/D) shall assert/deassert the corresponding HW interrupt event in status register:

- PCIECTRL_TI_CONF_IRQSTATUS_MSI[0] INTA
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[1] INTB
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[2] INTC
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[3] INTD

This implies that the status of an asserted event does not need to be cleared locally (by software writing 1 to the PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[n] INTx_EN bit, where n=0 to 3 and x=A, B, C, D, respectively) as it is expected to be cleared remotely over PCIe, by the EP function.

Note

The RC does not keep track of the INTx requester, even though the information is available in the incoming TLP's RequesterID: each legacy interrupt is expected to be used by only one EP function, known apriori by the RC.

When messages are posted, there is no response generated by the RC.

INTx messages can only be received (and the corresponding HW interrupts asserted) when in RC mode.

Note

The HW interrupts have to be maintained disabled when in EP mode.

24.9.4.6.2.2 PCIe Controller Message Signaled Interrupts (MSI)

Message Signal Interrupts are the preferred option to map interrupt over PCIe. It allows up to 32 interrupts vectors/events to be triggered by each EP function. MSI interrupts are implemented memory-space (posted) writes, 1-DWORD long. They should only be sent by EPs to the RC.

Note

While legacy PCI interrupts are mapped onto PCIe messages (Msg), the Message Signaled Interrupts are mapped onto PCIe memory writes (MWr), not onto messages.

Use of MSI is exclusive with use of legacy PCI interrupts (defined above).

An MSI is a memory (posted) write done by an EP to a mailbox in the RC. The data size is always 32 bit, the address and the data are programmed by the RC during PCIe enumeration, into the EP function's MSI capability descriptor (in the EP function's PCI config space).

Like legacy PCI interrupts, MSI does pass any status information to the RC, other than the interrupt vector (event) itself: the data payload of the write access is used exclusively to identify the interrupt's requester and its vector. The exchange of status information is outside the scope of MSI.

Note

Unlike the legacy PCI interrupts, MSI does not emulate an interrupt "level" that is either high or low, gets asserted or deasserted. Each MSI interrupt vector corresponds to a univocal event, that does not get "cleared" later on.

Note

The device integrated PCIe controller does not support extended MSI-X message signaled interrupts.

24.9.4.6.2.2.1 PCIe Specific MSI Interrupt Event Overview

MSI are interrupts designed specifically for PCIe, unlike the legacy PCI events seen in the Section 24.9.4.6.2.1. They are mapped on the MSI interrupt line of PCIe controller, using a single status bit in the PCIECTRL_TI_CONF_IRQSTATUS_MSI register. The "MSI controller" decodes and records each received MSI write as a specific "vector" coming from a specific EP function. Each application assigns a dedicated meaning to a given vector. Each function can use up to 32 vectors, as configured by the RC. MSI vectors can only be "asserted" by the EP function, unlike PCI legacy events that can be asserted and deasserted. In other words, the local software has to "clear" the asserted vector before it can be reused.

The PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit MSI must remain set as long as a vector is still set. Once the last vector has been cleared, the MSI bit must be cleared by software.

See also Section 24.9.4.6.2.2.3.

Typical MSI interrupt service routine on the RC-configured PCIe controller:

1. Software reads PCIECTRL_TI_CONF_IRQSTATUS_MSI status register, and identifies an (unspecified) MSI event, as opposed to a PCI legacy event.
2. Software clears PCIECTRL_TI_CONF_IRQSTATUS_MSI[4] MSI.
3. Software reads PCIECTRL_PL_MSI_CTRL_INT_STATUS_N and identifies EP functions that raised MSI.
4. Software clears PCIECTRL_PL_MSI_CTRL_INT_STATUS_N status bit.
5. Software calls the EP function specific interrupt handlers for each of the vectors.
6. Repeat steps 3 to 5 until PCIECTRL_PL_MSI_CTRL_INT_STATUS_N reads 0.
7. Exit MSI IRQ handler, only if PCIECTRL_PL_MSI_CTRL_INT_STATUS_N is 0.

24.9.4.6.2.2.2 PCIe Controller MSI Transmission Methods (EP mode)

There are two methods for MSI transmission: hardware and software. MSI transmission applies only to EP configured local PCIe system.

24.9.4.6.2.2.2.1 PCIe Controller MSI transmission, hardware method

The device PCIe controller (EP) transmits an MSI by writing 0b1 to the TI config wrapper register PCIECTRL_TI_CONF_MSI_XMT[0] MSI_REQ_GRANT bit. The other fields indicate function number, TC, vector, for the MSI. The address, data (potentially modulated by the vector) are automatically extracted from the EP function's MSI capability descriptor, previously programmed by the remote RC during enumeration.

For status, PCIECTRL_TI_CONF_MSI_XMT[0] MSI_REQ_GRANT can be polled. The bit remains HIGH (0b1) following a request (write to 0b1) and goes back LOW (0b0) once the MSI transmit request has been granted.

Note

Bit PCIECTRL_TI_CONF_MSI_XMT[0] MSI_REQ_GRANT reflects only the PCIe local status, that is a confirmation that the MSI has been transmitted. Since the MSI is a posted write, there is no way for the EP to ensure that it has been correctly received by the RC.

24.9.4.6.2.2.2 PCIe Controller MSI transmission, software method

Alternatively, an MSI can also be sent as a SW-composed memory write (MWr). MSI address and data shall be taken from the local EP function's MSI capability descriptor, where they were programmed by the RC at enumeration, along with the "multiple message enabling". If more than one vector is enabled, MSI data can be modulated accordingly. Furthermore, the transaction shall match the mandatory characteristics of an MSI MWr access, as follows :

- Header attribute bits ATTR = 2'b00 (no snoop = 0, relaxed ordering = 0)
- 1 DWORD long
- First byte enable: 0b0000
- Last byte enable: 0b0011 (16 bits of data)

Such a SW-generated MSI can be scheduled at the end of a series of memory transactions (MRd/MWr), with the PCI transaction ordering rules guaranteeing that the MSI will not overtake the other transactions.

24.9.4.6.2.2.3 PCIe Controller MSI Reception (RC mode)

Unlike legacy PCI interrupts, MSI must be configured by the RC in each function before use. Depending on its reception capacities, the RC can enable between 1 and 32 vectors (individual events) per MSI-enabled EP function.

The current RC implementation supports MSI reception for up to 8 different EP functions, with up to the protocol's maximum (32) vectors a piece, all mapped to a single MSI address. MSI reception is handled by the "MSI controller" though non-standard "port logic" (PL) registers (mapped in the PCI config space): For more details see the PCIe controller port logic associated PCIECTRL_PL_MSI_CTRL_x registers in the Section 24.9.7.5.1.

The reception of MSI implicitly requires the MSI mailbox address (in PCI memory space) to be routed to the RC: refer to Section 24.9.4.7, *PCIe Controller Address Spaces and Address Translation* for that. The MSI address (32-bit or 64-bit) is programmed in dedicated PCIe PL registers.

The MSI message data (MWr DWORD) is encoded as follows for the current RC. This encoding shall be used by the RC to configure the remote EP discovered at enumeration.

Table 24-501. MSI Message Data Encoding (RC)

Bit range	Size	Value	Comment
31:16	16	0x0000	Reserved as per PCI standard
15:8	8	0x00	Unused, always zero
7:5	3	0 to 7	Identifier of EP function in MSI controller (8 possible values)
4:0	5	0 to 31	Interrupt vector for the EP (32 possible values)

An inbound access recognized as MSI is terminated inside the controller, and does not appear on the PCIe controller's master port like other inbound memory writes in the same range.

24.9.4.6.3 PCIe Controller MSI Hardware Interrupt Events

Table 24-502 describes the events, related to non-PCIe interrupts (PCI legacy and PCIe MSI interrupts), which trigger the "MSI" hardware interrupt line.

Table 24-502. MSI Hardware Interrupt Events Summary

Event Status and Clear[1]	Interrupt Enable Bit	Interrupt Disable Bit	Mapping	Description
PCIECTRL_TI_CONF_IRQSTATUS_MSI[0] INTA	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[0] INTA_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[0] INTA_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	Legacy interrupt caused by EP sending inband ASSERT/ DEASSERT event on virtually emulated by PCIe pin INTA. Typically set and cleared by the remote EP, without local software intervention.
PCIECTRL_TI_CONF_IRQSTATUS_MSI[1] INTB	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[1] INTB_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[1] INTB_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[2] INTC	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[2] INTC_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[2] INTC_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[3] INTD	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[3] INTD_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[3] INTD_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[4] MSI	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[4] MSI_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[4] MSI_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	MSI interrupt status. It is cleared by clearing all vectors in the MSI controller (PL) registers.

(1) The MSI hardware interrupts have to be maintained disabled when in EP mode.

Note

While the PCIECTRL_TI_CONF_IRQSTATUS_MSI register is updated only if corresponding interrupt is enabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MSI register, the PCIECTRL_TI_CONF_IRQSTATUS_RAW_MSI register always provides the Legacy/MSI event status regardless of an interrupt being enabled or disabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MSI register.

24.9.4.7 PCIe Controller Address Spaces and Address Translation

The PCIe controller acts as a general-purpose bridge between the device local PCIe system and the PCIe fabric. Both are address-based mappings, and the bridging requires address translation between the different spaces.

The Table 24-503 lists the memory-mapped spaces interconnected by each of the PCIe_SS1 and PCIe_SS2 controllers. For each address space (row), the local PCIe subsystem (including the PCIe core) provides “entry points” (4th column) to inject transactions into the specified space, and ”exit points” (5th column) to receive transactions from the specified space.

Table 24-503. PCIe_SS Address Space Map

Space name	Address width	Size (bytes)	Entry point	Exit point	Comments
Device L3_MAIN memory space visible through PCIe controller's master port	32-bit	4 GiB	iATU IBR output	device system RAM, miscellaneous modules	Accessed over PCIe controller initiator (master) port; Includes the outbound window below.
PCIe_SS controller outbound window in device	28-bit	256 MiB	Device CPU hosts (MPU, DSPs, and so forth) of PCIe subsystem on device L3_MAIN interconnect	iATU OBR input	Mapped within PCIe controller target (slave) port, the outbound window is itself remapped within the device L3_MAIN memory space (256 MiB sized region).
PCIe memory space	32-bit/64-bit[1]	4 GiB/16 EiB	ATU OBR output (mem mode)	ATU IBR input (mem mode)	Contains all memory BARs
PCIe I/O space	32-bit	4 GiB	ATU OBR output (I/O mode)	ATU IBR input (I/O mode)	Contains all I/O BARs
PCIe config space (ECAM)	28-bit	256 MiB	ATU OBR output (configuration mode)	Configuration registers inside PCIe controller	Contains the PCIe-standard configuration spaces for EP functions (a 4 KiB- descriptor per function).

(1) Regarding the PCIe address space shared between all devices identified on the PCIe fabric, the local PCIe controller OBR iATU output generates a 32-bit address (it addresses a total of 4 GiB external PCIe space), while the IBR iATU input receives accesses from within a total of 16 ExaBytes of external PCIe space (a 64-bit address).

By definition, an iATU (Address Translation Unit) has an input (the space the access originates from) and an output (the space the access is headed for), with the required address translation taking place in the middle. An iATU inbound region (IBR) routes from PCIe (input) to device L3_MAIN space (output), an iATU outbound region (OBR) routes from the L3_MAIN space (input) to the PCIe (output).

Table 24-504summarizes the action of the different ATU regions. It contains the same information as the table above, organized differently. Note that inbound regions are not required to managed incoming configuration accesses, which are completed automatically by the PCIe controller hardware.

PCIe controller core outbound and inbound ATUs define:

- 16 outbound iATU regions
- 4 inbound iATU regions

Table 24-504. Address Translation Unit Region Access Summary

ATU region direction	ATU region type	Source space	Destination space
Outbound (OBR)	Memory	PCIe controller outbound window	PCIe memory space
Inbound (IBR)	Memory	PCIe memory space	Device PCIe subsystem space
Outbound (OBR)	I/O	PCIe controller outbound window	PCIe I/O space
Inbound (IBR)	I/O	PCIe I/O space	Device PCIe subsystem space
Outbound (OBR)	Configuration	PCIe controller outbound window	PCIe Cfg space

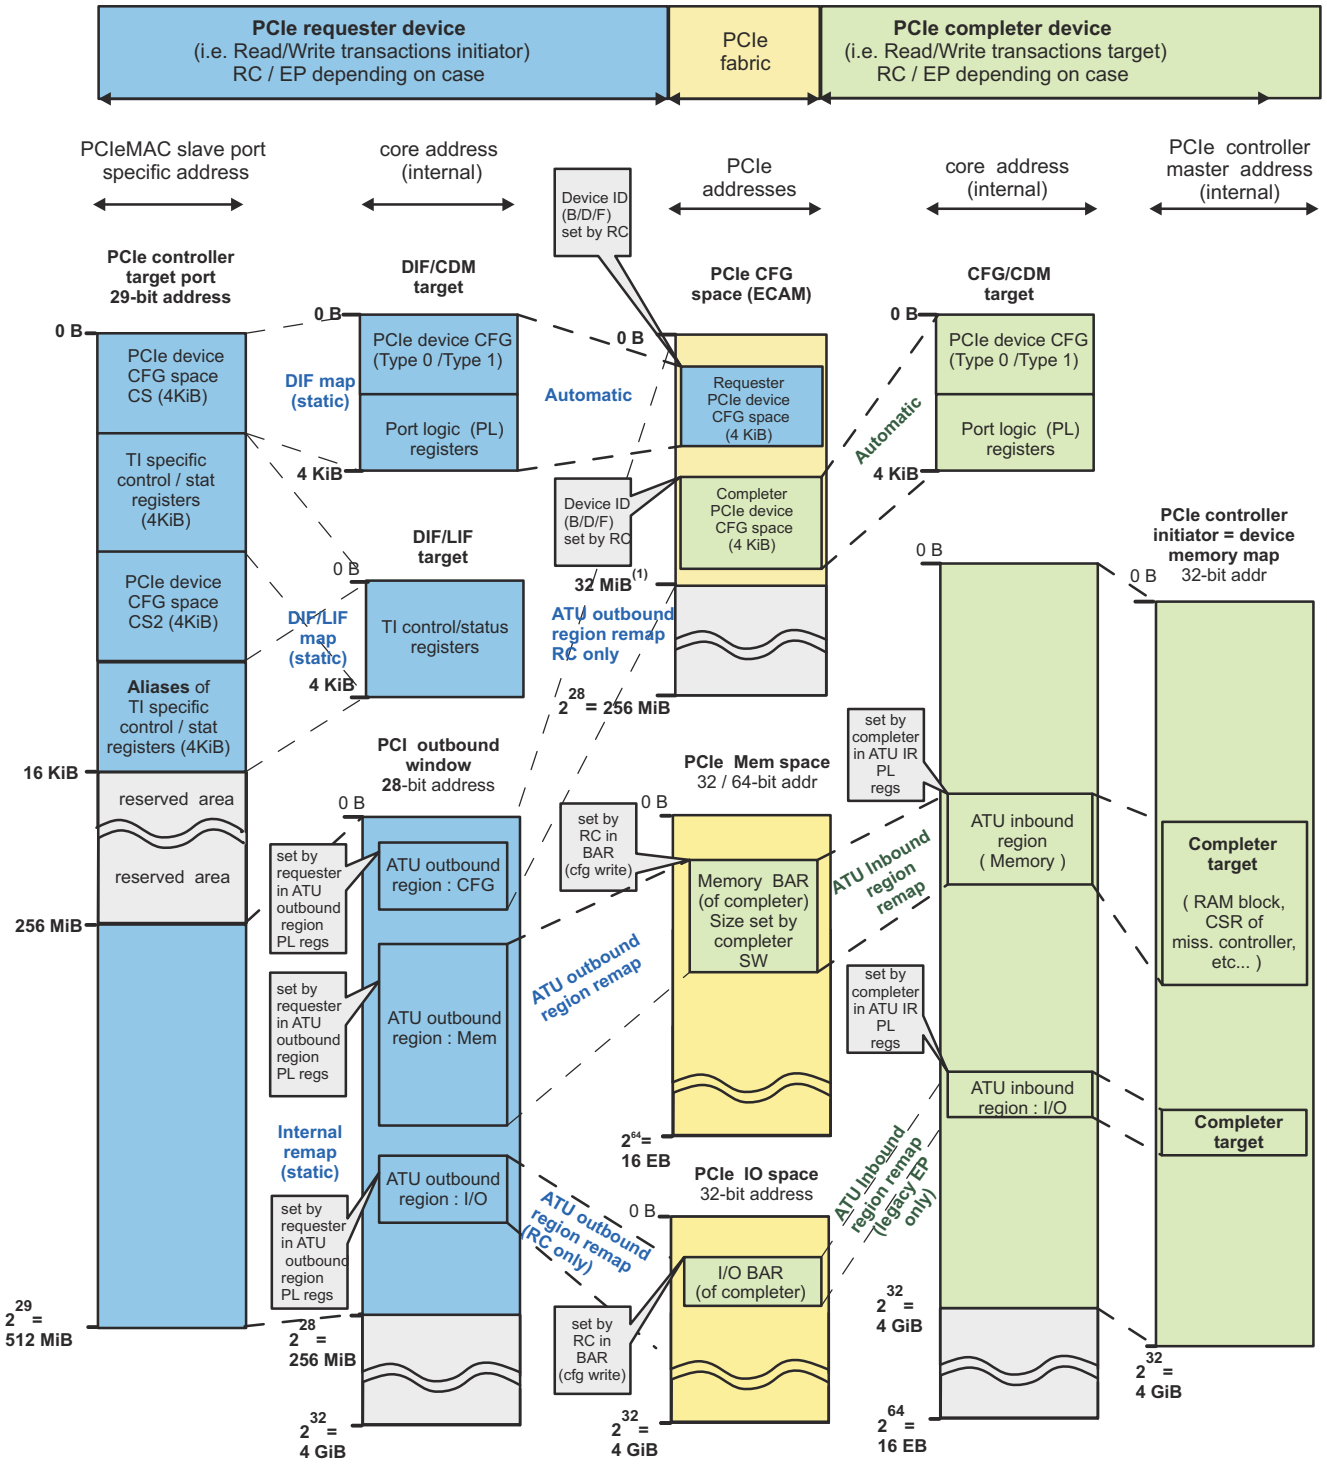
In a read/write access to an iATU outbound region (input), which is mapped in the PCIe controller target's 256 MiB-wide outbound window, do not confuse:

- Physical address accessed in the device L3_MAIN address space - 4 GiB
- Physical address within the PCIe_SS1/PCIe_SS2 controller target (slave) port:
  - PCIe outbound window - Cfg ; Memory and I/O space accessible within (0x2000_0000 - 0x2FFF_FFFF)/ (0x3000_0000 - 0x3FFF_FFFF)
  - PCIe controller local configuration/status registers accessible within (0x5100_0000 - 0x517F_FFFF)/ (0x5180_0000 - 0x51FF_FFFF)
- Address offset within the outbound window (0 - 256 MiB)

CAUTION

In the calculation of an ATU outbound region translation, the input is the address offset within the outbound window, ranging from 0x0000_0000 (0 bytes) to 0x0FFF_FFFC (256 MiB – 4 Bytes), they are the third and last address type in the list above.

PCI express is an interconnect that propagates read/write accesses from/to systems beyond the local device PCIe subsystem. The figure below shows such a link, where the transaction initiator (PCIe requester device, on the left) and the transaction target (PCIe completer device, on the right) are two instances of the PCIe controller subsystem, connected over the PCI express fabric (in the middle). The physical routing of the transaction over the PCIe topology (through switches) is implicit and transparent for addresses. A simplified chain of address translation is represented for each PCIe transaction type (Configuration, Memory or IO).



Note(1): The EP PCIe CFG space (EP function descriptors) occupies 32 MiB of the whole 256 MiB Outbound window. This because only a single EP function (#0) is implemented out of 8 possible.

pcie_ctrl-004

Figure 24-169. PCIe Core to PCIe Core Address Mapping and Translation

Note

There is a difference between requester/completer and RC/EP relationships, an EP device can be either the requester or the completer in a memory transaction.

24.9.4.8 PCIe Traffic Requesting and Responding

The PCIe wire can carry several types of packet-based traffic. The current chapter details how the current controller can be requester and completer of each type:

- **Requester:** initiates and transmits an outbound request, receives a response if required by (non-posted) request type.
- **Completer:** receives and processes an inbound request, generates and transmits a response if required by (non-posted) request type.

24.9.4.8.1 PCIe Memory-type (Mem) Traffic Management

The bulk of PCIe traffic is expected to take place in the memory (MEM) space, making use of large TLP/large L3_MAIN interface bursts.

Before PCI activity starts, one or several BAR of each device (EP function or RC) shall be initialized in Memory mode, as described in the Section 24.9.4.9.3, *Base Address Registers (BAR) Initialization*.

The following fields shall be set, using (CS) access (they are RO over PCI) :

- BARn[0]= "space decoder" shall be set to 0 = MEM space. This is the default setting for all BAR.
- BARn[2:1] = "type" shall be configured to either 32 or 64-bit. In the latter case, BARn+1 above shall contain the 32-bit upper part of the BAR base address.
- BARn[3] = "prefetchable" (P)

The BAR shall be enabled, using (CS2) access to BARn[0]:

- Write 1: BARn is enabled, can be configured by the RC writing to the MSBits of the BARn base address field.
- Write 0: BARn is disabled: register is read-only and return 0 over PCIe.

As part of the standard enumeration process, the RC then maps all the Memory BARs it finds (while discovering the connected EP functions) into the memory address space (32 or 64-bit address), using Cfg accesses over the PCIe wire. Optionally, the RC can also configure its own two BAR, over the DIF interface.

Once that process is complete, memory requests can take place point-to-point, that means that the requests can be initiated by any device (EP or RC) towards any other device function.

24.9.4.8.1.1 PCIe Memory Requesting

An ATU outbound region can then be programmed to remap the desired parts of the memory space (which correspond to BARs on other devices) into the local controller target's outbound window, accessed through the L3_MAIN slave port.

Alternatively, the iATU can be bypassed, and the outgoing access forwarded to the PCIe wire without address translation. In that *pass-through* mode, the PCIe address is equal to the 28 LSBits of the PCIe controller target address, that is, the address offset within the 256 MiB-wide outbound window. This gives access to the lowest 256 MiB of the PCIe memory space, from 0x0 to 0x0FFF_FFFC.

The forwarded PCIe TLPs shall have the following (hardcoded) header field values:

- TYPE = 0 = MRd/ MWr (Memory read or write)
- EP (poisoned bit) = 0 (not poisoned)
- ATTR (Attributes) = 2b01:
  - ATTR[1] = RO (relaxed ordering) = 0
  - ATTR[0] = NS (no snoop) = 1
- TC (traffic class) = 0

Initiators in the device local PCIe subsystem (typically CPUs or DMA) can then access memory space by initiating read/write accesses on the controller's slave port over L3_MAIN, either to the range of an enabled ATU outbound region, for the translated mode (with all TLP fields configurable), or outside any enabled ATU outbound region, for the pass-through mode (with the TLP fields hardcoded as explained above).

24.9.4.8.1.2 PCIe Memory Responding

An ATU inbound region can be programmed in BAR matching mode to remap (part or all of) each memory BAR to the controller's inbound window (this means to translate their address to the memory space of the device chip), and issue them on the PCIe controller's master port towards L3_MAIN. BAR matching mode is expected to be the most common method for an EP. In that mode, the ATU can be set up before enumeration - before the BAR's actual range (offset) is configured by the remote RC.

Alternatively, the ATU inbound region can be programmed in address matching mode. In that case, any access routed to the device (EP or RC) and matching the range specified in the ATU is remapped to the controller's inbound window (this means to translate their address to the memory space of the device), and issued on the master port towards L3_MAIN.

Address matching is the preferred method for an RC, which would route any access outside its base/limit range, as defined in its PCIe standard (Type-1) configuration space, and independently of any BAR so that BAR matching is not possible. In that case, only space not already taken up by a BAR can be used. Note the setup of an address matching iATU inbound region can only be done after enumeration, that is, after the RC has discovered and mapped all enabled Memory BAR of all EP functions to their address.

Finally, in case an incoming access does not match any enabled ATU inbound region (BAR or address matching), the transaction is just passed through untranslated, that is, with the address unchanged and the TLP attributes stripped off. This is not expected to be commonly used.

Incoming memory requests (to the local EP's Memory BAR) shall then cause the master port on L3_MAIN to access a given address range of the local system (potentially the entire 32-bit address range).

24.9.4.8.2 PCIe Configuration Type (Cfg) Traffic Management

Configuration (Cfg) traffic is not symmetrical: it can only be requested by the RC, and completed (in the case of PCIe controller) by the EP. It is used by the RC for the enumeration of the fabric: EP, functions, switches.

Note

The RC cannot use configuration traffic over the PCIe wire to access its own 4 KiB configuration space. To do that, it uses DIF accesses (CS) with bit PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN = 0b0.

24.9.4.8.2.1 RC Self-configuration (RC Only)

Like any other device on the PCIe fabric, the RC has its own 4-KiB configuration space, where RC local configuration registers are stored.

Note

Since the RC configuration registers are programmed by the RC itself, no remote access over the PCIe wire (Cfg TLP) is required. Local DIF accesses (CS) are used instead.

However, some register fields normally defined as read-only by the PCI standard are actually programmable over DIF (see Section 24.9.4.9.2), which may cause a standard software driver to fail. In that case, the CS-writability of those fields has to be disabled by reprogramming the located in the PCIe controller port logic bit PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN to 0b0. Note that this is normally done after CS-writable fields have been configured by the non-standard initialization "firmware", thus making the RC's configuration space PCI compliant.

The Section 24.9.4.8.2.2 and Section 24.9.4.8.2.3 only covers configuration of an EP function by an RC, using actual Configuration TLPs (transport layer packets).

24.9.4.8.2.2 Configuration Requests over PCIe (RC Only)

After coming out of reset, the PCI fabric is enumerated by the RC through configuration (Cfg) transactions to the switches and EP present in the topology. The enumeration process is covered by the PCI and PCIe standards - for more details refer to the PCI Express Base 3.0 Specification, revision 1.0.

Configuration transactions are created by an outbound ATU region set up to translate the PCIe controller slave port accesses into Cfg TLP on the PCIe wire.

- The L3_MAIN interconnect port (read or write) determines the TLP type (CfgRd/CfgWr)
- The data is passed unchanged from the L3_MAIN interconnect to the PCI world (write) and reciprocally (read)
- The entire PCI configuration space can be mapped as a standard, contiguous block, as specified in the **Enhanced Configuration Access Mechanism (ECAM)**. The ATU maps this 256 MiB block at a programmable base address within the controller slave port's 256 MiB "outbound window", using the ATU "Cfg shift" feature.
- The other parameters are programmed beforehand in the ATU's configuration registers (IATU_*)

The (28-bit) address offset within the 256 MiB ECAM block is the concatenation of :

- **Cfg register address** (Offset[11:0] = 12-bit = 4 KiB configuration space per EP function)
- **Function number** (Offset[14:12] =3 bit = 8 functions per PCIe EP)
- **Device number** (Offset[19:15] = 5 bit = 32 devices per bus, always 0 for PCIe controller itself)
- **Bus number** (Offset[27:20] = 8-bit = 256 busses in the PCIe fabric)
- Total for ECAM: 8 + 5 + 3 + 12 = 28-bit offset, or 256 x 32 x 8 x 4 KiB = 256 MiB

Note

The device PCIe controller itself supports only one function in EP mode. On the PCIe fabric, however when in RC mode, the PCIe controller may need to configure up to 8 functions per EP (potentially for all 65536 EPs). Hence the ECAM config. space visible to RC is 256 MiB in size.

A Cfg read access to the Vendor ID register is used by the RC to detect the presence of a function. If that specific read (address 0x000 in the 4-KiB PCI config space) fails with an UR PCIe response (Unsupported Request: no function present), the PCIe controller shall return a correct response to L3_MAIN with data 0xFFFF. This indicates the absence of the function to the application, without triggering an error on L3_MAIN.

24.9.4.8.2.3 Configuration Responding over PCIe (EP Only)

As an EP, the device only expects to receive (and never transmit) configuration transactions, and expects those to be CFG0 and not CFG1.

Incoming Cfg accesses with the appropriate Target ID are automatically routed to the targeted EP function's 4-KiB PCI configuration space, which contains both the PCI standard registers (header, descriptors, extende descriptors, and so forth) and the PL registers. The request read/write complete automatically, with no transaction appearing on the PCIe controller master port. Since Cfg accesses are non-posted, each incoming request shall generate a response.

Note

An ATU inbound region is also capable of processing incoming Cfg transactions, and translating them into read/write accesses on the master port towards L3_MAIN. However, this method is not expected to be used, and automatic completion –described above– is expected to be used instead.

24.9.4.8.3 PCIe I/O-type (IO) traffic management

I/O traffic is not symmetrical: it can only be requested by the RC, and responded to by the EP. It is a mostly deprecated feature of PCI, and could be replaced by Memory traffic. However, it is still required by the standard for a PCIe RC. It is supported by the current controller in both RC (requester) and **legacy EP mode (completer)**.

24.9.4.8.3.1 PCIe I/O requesting (RC only)

As part of the standard enumeration process, the RC maps all the I/O BARs it finds (while discovering the connected EP functions) into the 4 GiB I/O address space (32-bit address).

An ATU outbound region shall then be programmed to map a zone of the I/O space into the controller target's outbound window, accessed through the slave port.

Initiators in the RC host (typically a local CPU) can then access I/O space by initiating (1 DWORD) read/write accesses to the ATU region's range on the controller's slave port on L3_MAIN.

Note

There is NO specific hardware mechanism to notify the RC that it is allowed to issue I/O requests, since that configuration decision comes from the RC in the first place.

24.9.4.8.3.2 PCIe IO BAR initialization before enumeration (EP only)

Before PCI enumeration, each BAR can be initialized/enabled individually for IO space, using the DIF access (CS or CS2). The size of an enabled IO BAR (that is, the number of writable bits in the base address) is fixed to 256 bytes, that is, a mask of 0xFF that is, the writable BAR base address range for the RC is BARn[31:8], while BARn[7:0] is read-only.

In (CS) access, the BARn[0] "space decoder" field becomes RW and shall be written to 1 = IO space

In (CS2) access, BARn[0] becomes a write-only BAR enable :

- Write '1': BARn is enabled, can be configured by the RC writing to the MSBits of the BARn base address field.
- Write '0': BARn is disabled: register is read-only and return 0x0 over PCIe.

24.9.4.8.3.3 PCIe I/O responding (PCI legacy EP only)

I/O support is permitted only for the "legacy EP" type, that is, EP's side it is required that PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE has been preliminary set to 0x1 by EP's local software. Before PCI activity starts, one or several BAR of the EP function shall be enabled in I/O mode, to get enumerated by the RC as per the PCI standard.

An iATU (internal address translation unit) inbound region can be programmed in **BAR matching mode** to map the BAR to the controller's inbound window (that is, translate their address to the memory space of the SoC), and issue them on the PCIe master port towards device L3_MAIN.

BAR matching mode is expected to be the most common method for an EP. In that mode, the iATU can be set up before enumeration, that is, before the BAR's actual range (offset) is configured by the remote RC.

Alternatively, the ATU inbound region could be programmed in address matching mode. However, a valid I/O access coming into an EP is necessarily within a BAR, so BAR matching should be used. Additionally, BAR matching can be configured before enumeration, that is, before the RC has mapped the I/O BAR to their actual address.

Incoming I/O requests to the local EP's IO BAR shall then cause the PCIe master port to access a given address range of the local system (potentially the entire 32-bit address range), in 32-bit read/write accesses.

24.9.4.8.4 PCIe Message-type (Msg) traffic management

Most messages are generated and received automatically by logic in the controller HW, and do not require any specific intervention from the user.

The application can transmitted the following power management messages by writing to the TI configuration wrapper instance PCIECTRL_TI_CONF_PM_CTRL register:

- PCIECTRL_TI_CONF_PM_CTRL [0]PME_TURN_OFF: (power management event, turn off) request from RC to turn off, broadcasted downstream.

- PCIECTRL_TI_CONF_PM_CTRL[1] PM_PME: (power management event): request from EP to wake up, routed upstream towards RC.

No dedicated logic exists in the controller to support vendor-defined messages.

The ATU is capable of generating (outgoing) messages, and receiving (incoming) ones, by translating them from read/write accesses on the PCIe controller slave port, or to read/write accesses on the PCIe controller master port, respectively. However, this functionality is not required for standard PCI operation.

24.9.4.9 PCIe Programming Register Interface

PCI is an memory-mapped, dynamically reconfigurable interconnect protocol, so that the same physical register may be accessed in several different ways. The current chapter targets to describe only the statically-mapped programming registers of the local PCIe controller, accessed over the local AXI slave.

They are composed of:

- **PCIe-standard configuration registers:** by definition accessible over the PCIe wire through the PCIe configuration (and extended configuration - ECAM) space. Those registers are different depending on the selected mode (Type-0: EP or Type1: RC).
- **Port Logic (PL) registers:** non-standard user-accessible registers for additional PCIe functionality. They are also accessible over PCIe wire, in the configuration (ECAM) space.
- **TI-specific control and status registers:** more non-standard registers, accessible only locally. These are associated with the PCIe controller wrapper level functional control and status.

24.9.4.9.1 PCIe Register Access

The Table 24-505 summarizes how the resources of the local controller can be accessed. Note that the rightmost column represent accesses to the PCIe controller hosts system memory.

Table 24-505. Summary of Access Types related to PCIe Controller Local Resources

Access	PCIe standard configuration registers	Port Logic (PL) registers	TI-specific registers	System memory available to PCIe
Local DIF access (over PCIe controller target (slave) port, from device host CPUs and DMAs)	Yes(1) (CS or CS2)	Yes	Yes	No
Remote PCIe config (Cfg) transaction (over PCIe wire)	EP: Yes(1) RC: No(2)	EP: Yes RC: No(2)	No	No
Remote PCIe Memory transaction (over PCIe wire)	No	No	No	Yes (iATU)
Remote PCIe IO transaction (over PCIe wire)	No	No	No	EP: Yes (iATU) RC: No(3)

(1) 1. Read and writes to PCIe standard configuration registers (in PCIe config space, address 0x0 to 0x700) will give different results depending on the access method (DIF CS/CS2, PCIe): see (1).
(2) 2. PCIe Cfg transactions can only be issued by the RC (to an EP): A RC cannot receive one.
(3) 3. PCIe IO transactions can only be issued by the RC (to an EP): A RC cannot receive one.

24.9.4.9.2 Double Mapping of the PCIe Local Control Registers

Each local programming register is mapped twice inside the controller's local target, with an offset of 0x1000 (4 KiB) between the two mappings.

The "low" mapping is the Data Interface (DIF) chip-select (CS) access. In DIF CS mode, some fields that are read-only (RO) over PCI become writable if PL bit PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN=0b1 (default). This access is used by the local host (e.g. BIOS) for the initialization of the PCI device, prior to PCI protocol startup (LTSSM enable). Fields and registers that are CS-sensitive are labeled (CS) in the Section 24.9.7.

The "high" mapping is the Data Interface (DIF) chip-select-2 (CS2) access. In DIF CS2 mode, some fields that are read-only (RO) over PCI or in DIF CS mode, become writable if PL bitfield

PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN=0b1 (default). This access is also used by the local host for further initialization of the PCI device. Fields and registers that are CS2-sensitive are labeled (CS2) in the tables below.

Note

The following important notes on accesses must be considered by user for device PCIe controller:

- If PCIe_SS_PL_CONF instance located bitfield PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN is cleared to 0b0, the "CS and CS2-sensitive" fields become read-only (RO) again, that is, they revert to the behaviour defined in the PCI/PCIe standards.
- The standard PCI configuration registers (header, descriptors, extended descriptors) are the only ones that can change their behaviour in CS and CS2 access.
- The port logic (PL) registers and the PCIe controller wrapper TI configuration registers are not affected by the CS: for those, the two mappings have the same properties, that is, they are perfect aliases
- For an RC, which by definition cannot access its own (locally stored) configuration registers over the PCIe wire, the DIF access is the only alternative. The PCIe controller must present a PCI-standard-compliant type-1 configuration space to the RC software driver, that is, with none of the read-only bits actually writable, as follows:
  - the DIF CS access should be used
  - PL bitfield PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN should be cleared to 0b0 (after a pre-initialization, if required)

24.9.4.9.3 Base Address Registers (BAR) Initialization

The 6 base address registers ((EP) BAR0 through (EP) BAR5) supported in EP mode (Type0), get discovered and configured by the RC during PCI enumeration, as per the PCIe standard. Via the PCIe ECAM (enhanced configuration access) mechanism the **RC** maps a remote EP function's BAR registers in 64-bit PCIe memory space and software run on RC access them as the PCIECTRL_EP_PCIEWIRE_BAR0 through PCIECTRL_EP_PCIEWIRE_BAR5 registers. Note that the configuration space of the RC (Type1 registers) also contains two BARs ((RC) BAR0 and (RC) BAR1), but they are not expected to be used.

Before enumeration, BARs can be initialized by the local software, using DIF access (CS or CS2), to modify the properties seen by the RC at enumeration. The following can be configured in each BAR: enabling, IO or memory type, size (mask width). Even BAR numbers (0,2,4) can also be paired with the BAR number above (1,3,5) to create a single, 64-bit address (memory).

Note

If PCIe_SS_PL_CONF instance located register PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN bit is cleared, most BAR fields become read-only again, behaving like in over-the-wire PCI Cfg writes by the RC. Only the BAR base address (MSbits) is still writable. The size/mask, type, and enabling become read-only.

Table 24-506. PCIe Default BAR Configuration

	Enabled(1)	Space(2) BARn[0]	Type(2) BARn[2:1]	Prefetch(2) BARn[3]	Mem Size(1) (M-bit mask)	I/O Size (M-bit mask)
(EP) BAR0	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	1 MiB (20-bit)	256 Bytes (8-bit)
(EP) BAR1	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)
(EP) BAR2	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	1 MiB (20-bit)	256 Bytes (8-bit)
(EP) BAR3	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)
(EP) BAR4	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	4 KiB (12-bit)	256 Bytes (8-bit)
(EP) BAR5	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)

(1) reprogrammable with DIF (CS2) access

(2) reprogrammable with DIF (CS) access

The Table 24-507 and Table 24-508 describe how a memory and IO BAR can be accessed, respectively. A single address of the PCIe config space is accessed for a given BAR, with each line of the table showing a different mode: read vs. write; PCIe Cfg access vs. DIF (CS) access vs. DIF (CS2) access.

"M" is the width of the BAR mask in bits, with 2^M the BAR size in bytes. Bits M and above are writable by the RC over the PCIe wire to set the BAR base address, as follows:

- The value of M for a Memory BAR varies from 4 (2^4=16 Byte = minimum size) to 32 (2^{32} = 4 GiB for a 32-bit BAR, potentially more for a 64-bit BAR) depending on the BAR and on the configuration.
- The current implementation forces M=8 for an I/O BAR, that is, an IO BAR has a fixed size of 2^8=256 bytes, the maximum allowed by the PCIe protocol.

Table 24-507. BARn Register Access Methods (Mem BAR)

Method	BAR[31:M](1)	BAR[M-1:4]	BAR[3]	BAR[2:1]	BAR[0]
PCI read	Base address readout	Read returns zero	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder"(2)
PCI write	Base address write	No effect (masked = R/O)	No effect	No effect	No effect
CS read	Base address readout	Read returns zero (masked)	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder"(2)
CS write	Base address write	No effect (masked = R/O)	Write "Prefetchable"	Write "Type"	Write "space decoder"(2)
CS2 read	Base address readout	Read returns zero (masked)	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder"(2)
CS2 write	Write 0 to unmask (Sets M)	Write 1 to mask (Sets M)	Write 1	Write 1	Write "BAR enable"

(1) For M=32, the BAR mask is 32-bit wide, the BAR size is 4 GiB and the column disappears.
(2) Space decoder is Memory = 0 in this table.

Table 24-508. BARn Register Access Methods (IO BAR)

Method	BAR[31:8]	BAR[7:2]	BAR[1]	BAR[0]
PCI read	Base address readout	Read returns zero	Read out 0 (reserved bit)	Read out 1 "space decoder"(1)
PCI write	Base address write	No effect (masked = R/O)	No effect	No effect
CS read	Base address readout	Read returns zero (masked)	Read out 0 (reserved bit)	Read out 1 "space decoder"(1)
CS write	Base address write	No effect (masked = R/O)	Write 0 No effect	Write "space decoder"(1)
CS2 read	Base address readout	Read returns zero (masked)	Read out 0 (reserved)	Read out 1 "space decoder"(1)
CS2 write	Write 0. No effect in fixed-sized I/O BAR	Write 1. No effect in fixed-sized I/O BAR	Write 0 No effect	Write "BAR enable"

(1) Space decoder is I/O = 1 in this table.

24.9.5 PCIe Controller Low Level Programming Model

24.9.5.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the PCIe_SS1 and PCIe_SS2 controllers are used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the PCIe_SS (for more information, see PCIe Controllers Integration and PCIe Controllers Environment). Table 24-509 describes the global initialization of the surrounding modules.

Table 24-509. Global Initialization of the PCIe Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See Section 3.1.1.1.5, *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.)
Control Module	Module configuration must be done in control module. See *CTRL_MODULE_CORE Registers* and Table 24-494, *PCIe Port Configuration*
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to map the interrupts from the PCIe Controllers to a certain device processor INTC via the IRQ_CROSSBAR module. For more details on IRQ_CROSSBAR programming, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
(Optional) A local INTC	The local interrupt controller must be configured to enable the interrupt once IRQ output is mapped on INTC via the IRQ_CROSSBAR. See *Interrupt Controllers*.
L4 and L3_MAIN interconnects	For more information about the interconnect configuration, see *L3_MAIN Interconnect Agents*, and *L4 Interconnect Overview*, in *Interconnects*.
(Optional) Device MMU2	For more information on the configuration for routing the PCIe_SS1,2 master port traffic through the device MMU2, see Section 24.9.4.3.1.1, as well as Chapter 20, *Memory Management Units*.

Note

The interrupt configuration is required when using interrupt communication mode.

24.9.5.2 Main Sequence of PCIe Controllers Initalization

Note

This section aims to describe only the basic steps that must be followed by PCIe application software in order for a PCIe RC or EP type device to initialize, establish PCIe connectivity and interact with devices on the PCIe fabric. For this reason, it focuses on settings of the PCIe controllers wrapper registers (and not on PCI/PCIe standard and non-standard (PL) registers), through which PCIe application interacts with PCIe devices.

Table 24-510. Main Sequence PCIe Controller Global Initialization

RC and/or EP Initialization Step[1]	Register/Bit Field/Programming Model	Value
1. Initialize the DPLL_PCIe_REF (clock source, dividers, power dependencies) in PRCM	Refer to Section 26.4.5	
2. Assert a local software main reset to the PCIe_SS1 controllers	PRCM.RM_PCIESS_RSTCTRL[0] RST_LOCAL_PCIE1	0b1
3. Poll main reset completion status for the PCIe_SS1 controllers	PRCM.RM_PCIESS_RSTST[0] RST_LOCAL_PCIE1	=0b1
4. Perform tuning of the PCIe PHY	Refer to Section 26.4.5	
IF: required operation mode for PCIe controller is “RC”	Software Test Condition	
5. Select RC type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x4 (default)
6. Poll to insure a fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x4
7. Make sure LTSSM_EN is kept by RC’s software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize RC PCIe controller’s core registers.	See Table 24-512	

Table 24-510. Main Sequence PCIe Controller Global Initialization (continued)

RC and/or EP Initialization Step[1]	Register/Bit Field/Programming Model	Value
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ msi status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. [optional step] Enable INTx (x=A,B,C,D) interrupts reception (generated from legacy EPs to RC) but disable MSI interrupts reception at the same time. OR Enable the MSI interrupts reception (MSI interrupts are generated to RC from PCIe EPs only) but disable the INTx interrupts reception at the same time	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI [3:0] INTx_EN	0x-
	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4] MSI_EN	0b1
	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI [4] MSI_EN	0b1
	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [3:0] INTx_EN	0xF
ELSE IF: required operation mode for PCIe controller is “PCIe EP”		
5. Select “PCIe EP” type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x0
6. Poll to insure fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x0
7. Make sure LTSSM_EN is kept by EP’s software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize EP PCIe controller’s core registers	See Table 24-511	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable –PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ msi status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. Disable both INTx (x=A,B,C,D) and MSI interrupts reception.	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4:0]	0x1F
ELSE:		
5. Select “PCI Legacy EP ” type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x1
6. Poll to insure fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x1
7. Make sure LTSSM_EN is kept by EP’s software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize EP controller local registers via DIF CS/CS2 accesses	See Table 24-511	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. Disable both INTx (x=A,B,C,D) and MSI interrupts reception	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4:0]	0x1F
ENDIF		
13. PCIe (RC/EP) controller enables the link. It is supposed that all active EPs attached on the PCIe fabric synchronously enable their LTSSM engine with the RC.	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b1

Table 24-510. Main Sequence PCIe Controller Global Initialization (continued)

RC and/or EP Initialization Step(1)	Register/Bit Field/Programming Model	Value
14. Local CPU polls until the PCIe Controller link is up (that is, brought into L0- power state)	PCIECTRL_TI_CONF_PHY_CS[16] LINK_UP	=0b1
15. If PCIECTRL_TI_CONF_IRQSTATUS_MAIN[3] LINK_UP_EVT has been enabled in step (10), this means it should be cleared	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[12] LINK_UP_EVT	0b1
16. RC host starts link training sequence, negotiation with EPs, enumeration of the EPs, and initializes the descriptors per each of the discovered EP functions. Example: RC Initializes the MSI message vectors table per each of the EPs. RC maps the EPs global PCIe Memory per each EP function appropriately initializing the BARn registers MSB part.		
17. [RC only] **IF:** an EP is a requester, the RC remotely enables its BME bit via an ECAM access to the EP's command /status register.	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[2] BUSMASTER_EN	0b1
18. [RC only] **IF:** an EP is a completer, the RC remotely enables its MSE (for Mem transfers) or ISE bits (for legacy I/O transfers) via an ECAM access to the EP's command/status register.	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN OR PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[0] IO_SPACE_EN	0b1
19. [EP only] Before EP's application generates a request (that is, requester EP), the EP application must insure that its local BME_EVT status has already been asserted to 0b1 by the RC host controller.	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[13] BME_EVT_MSG OR PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN[13] BME_EVT_MSG	=0b1
The EP must locally clear the BME interrupt, writing BME_EVT_MSG flag to 0b1 (Wr1toClr).	Wr1ToClr PCIECTRL_TI_CONF_IRQSTATUS_MAIN[13] BME_EVT_MSG	0b1
20. [RC only] Before RC application initiates a request to an completer EP function with a *Memory type BAR*, the RC must check that EP's MEM_SPACE_EN flag has already been asserted by the RC host. This is done via an ECAM remote access by RC to EP's command/status register. [EP Only] The EP's CPU is notified about remote MEM_SPACE_EN flag assertion in a dedicated bit that can be enabled to generate an interrupt. The interrupt flag is cleared via writing to 0b1 (Wr1ToClr).	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN	=0b1
	The EP application may receive an interrupt (if enabled – see step 10) indicated in the PCIECTRL_TI_CONF_IRQSTATUS_MAIN[14] MSE_EVT_MSG. Or poll this in PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN[14] MSE_EVT_MSG.	0b1
20. [RC only] Before RC application initiates a request to a completer EP function with an *I/O type BAR*, the RC must check that EP's IO_SPACE_EN flag has already been asserted by the RC host. This is done via an ECAM remote read access by RC to EP's command/status register.	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[0] IO_SPACE_EN	=0b1
[EP Only] Unlike Mem type EPs, there is no interrupt event to notify the EP about its ISE flag being asserted by the RC. So, to be aware of an incoming transaction, I/O legacy EP must poll local IO_SPACE_EN flag until its asserted by RC to 0b1.	PCIECTRL_EP_DBICS_STATUS_COMMAND_REGISTER[0] IO_SPACE_EN	=0b1
[EP Only] 21. IF IO_SPACE_EN bit has been set to '1' for a legacy EP, user must force the legacy EP master port out-of-standby (before first transaction). There is no automatical standby generation for I/O transfers.	PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE	0x1

(1) Unless a step is not marked as "[EP Only]" or "[RC Only]", the initialization step should be considered as applicable in both EP and RC modes of PCIe controller.

Table 24-511. Local EP (Type 0) PCIe Standard and Port Logic Registers Initialization Subsequence

8.1 Initialize PCI standard configuration header registers via corresponding DIF CS/CS2 accesses. Example: BAR MASK0 – BAR MASK5 (that must be entirely initialized by the EP, and LSB part of the BAR0 – BAR5 registers)	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*
8.2 Initialize the RC PCIe capability registers via corresponding DIF CS/CS2 accesses.	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*
8.3 Initialize the RC PCIe Port Logic registers. Example: iATU settings of internal local address ranges, link settings – link powers, timings, and so forth	

Table 24-512. RC (Type 1) PCIe Standard and Port Logic Registers Initialization Subsequence

RC must enable write operation to be able to configure its own PCIe standard and PL registers.	PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN	0b1
8. 1 Initialize RC PCI standard configuration header registers via corresponding DIF CS/CS2 accesses. (Example: RC BAR 0,1 and BAR MASK0,1 registers.)	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.2 Initialize the RC PCIe capability registers via corresponding DIF CS/CS2 accesses.	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.3 Initialize the RC PCIe Port Logic registers. Example: iATU settings of internal local address ranges, link settings – link power, timings, and so forth Prepare the MSI vectors, Setup of the MSI, others.		
Disable write operation in RC PCIe standard and PL registers.	PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN	0b0

Note

When the PCIe_SS1 controller is configured to operate in two lane mode, by default lane 0 is mapped to the PCIe1_PHY (device PCIe PHY port 0), and lane 1 is mapped to the USB_PHY (USB PHY port). The PCIe_SS1_TI_CONF wrapper located software control - PCIECTRL_TI_CONF_PHY_CS[0] REVERSE_LANES allows user software to swap mapping of the PCIe_SS1 controller lane 0 and lane 1 on the two device PCIe PHY ports (swapping the RX and TX paths simultaneously with polarity of an individual lane unchanged). Note that the identical control is not functional in the PCIe_SS2_TI_CONF, because the PCIe_SS2 can operate in a single lane mode only, and (if selected) its lane 0 is always mapped to the PCIe PHY port 1 (that is, PCIe2_PHY).

24.9.6 PCIe Standard Registers vs PCIe Subsystem Hardware Registers Mapping

The below tables provide the PCIe/PCI standard logical registers versus PCIe controller hardware registers mapping in the device.

Table 24-513. PCIe Type-0 (EP) Configuration Standard Capability Registers vs PCIe Controller Hardware Registers Mapping

PCIe Standard Register Name	PCIe_SS1_EP_CFG_PCIe and PCIe_SS2_EP_CFG_PCIe Corresponding Register(1)	PCIe_SS1_EP_CFG_DBICS and PCIe_SS2_EP_CFG_DBICS Corresponding Register(2)	PCIe_SS1_EP_CFG_DBICS2 and PCIe_SS2_EP_CFG_DBICS2 Corresponding Register(3)
PCIE_CAP	PCIECTRL_EP_PCIEWIRE_PCIE_CAP	PCIECTRL_EP_DBICS_PCIE_CAP	PCIECTRL_EP_DBICS2_PCIE_CAP

24.9.7 PCIe Controller Register Manual

24.9.7.1 PCIe Controller Instance Summary

Table 24-517. PCIe_SS1 Instance Summary

Module Name	Module Base Address	Size
PCIe_SS1_EP_CFG_PCIe	ECAM_Param_Base_Addr(1) + 0x2000 0000	4 KiB
PCIe_SS1_EP_CFG_DBICS	0x5100 0000	128 Bytes
PCIe_SS1_RC_CFG_DBICS	0x5100 0000	128 Bytes
PCIe_SS1_PL_CONF	0x5100 0700	500 Bytes
PCIe_SS1_EP_CFG_DBICS2	0x5100 1000	128 Bytes
PCIe_SS1_RC_CFG_DBICS2	0x5100 1000	128 Bytes
PCIe_SS1_TI_CONF	0x5100 2000	332 Bytes

(1) ECAM_Param_Base_Addr = 0x0000_0000 to 0x0FFF_F000

Table 24-518. PCIe_SS2 Instance Summary

Module Name	Module Base Address	Size
PCIe_SS2_EP_CFG_PCIe	ECAM_Param_Base_Addr(1) + 0x3000 0000	4 KiB
PCIe_SS2_EP_CFG_DBICS	0x5180 0000	128 Bytes
PCIe_SS2_RC_CFG_DBICS	0x5180 0000	128 Bytes
PCIe_SS2_PL_CONF	0x5180 0700	500 Bytes
PCIe_SS2_EP_CFG_DBICS2	0x5180 1000	128 Bytes
PCIe_SS2_RC_CFG_DBICS2	0x5180 1000	128 Bytes
PCIe_SS2_TI_CONF	0x5180 2000	332 Bytes

(1) ECAM_Param_Base_Addr = 0x0000_0000 to 0x0FFF_F000

Note

The *ECAM_Param_Base_Addr* variable is the 16-bit **base address** (this address is 4 KiB-aligned with value in the range: 0x0000_0000 - 0x0FFF_F000) of the relevant EP function descriptor (relevant EP's function PCIe standard and PL configuration registers) **in a contiguous 256-MiB ECAM space** (0x0000_0000 - 0x0FFF_FFFF). For more information on the PCIe ECAM configuration space mapping mechanism, refer to the section *PCI Express Enhanced Configuration Access Mechanism (ECAM)*, in the *PCI Express Base 3.0 Specification, Revision 1.0*.

For information on the EP's function PL register offsets and descriptions, refer to the Section 24.9.7.5.

24.9.7.2 PCIe_SS_EP_CFG_PCIe Registers

Note

This section describes the PCIe EP mode (PCIe type-0) standard configuration registers as they are accessed over PCIe wire logic and not via DIF CS/CS2 accesses. These register names are prefixed with "PCIECTRL_EP_PCIEWIRE".

24.9.7.2.1 PCIe_SS_EP_CFG_PCIe Register Summary

Table 24-519. PCIe_SS1_EP_CFG_PCIe Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	PCIe_SS1_EP_CFG_PCIe Physical Address
PCIECTRL_EP_PCIEWIRE_DEVICE_VENDORID	R	32	0x0	ECAM_Param_Base_Addr(1) + 0x2000 0000

PCIECTRL_EP_PCIEWIRE_DEV_CAS_2	RW	32	0x98	ECAM_Param_Base_Addr(1) + 0x3000 0098
PCIECTRL_EP_PCIEWIRE_LNK_CAP_2	R	32	0x9C	ECAM_Param_Base_Addr(1) + 0x3000 009C
PCIECTRL_EP_PCIEWIRE_LNK_CAS_2	RW	32	0xA0	ECAM_Param_Base_Addr(1) + 0x3000 00A0

(1) ECAM_Param_Base_Addr = 0x0000_0000 to 0x0FFF_F000

Note

The *ECAM_Param_Base_Addr* variable is the 16-bit base address (this address is 4 KiB-aligned with value in the range: 0x0000_0000 - 0x0FFF_F000) of the relevant EP function descriptor (relevant EP's function PCIe standard and PL configuration registers) in a contiguous 256-MiB ECAM space (0x0000_0000 - 0x0FFF_FFFF). For more information on the PCIe ECAM configuration space mapping mechanism, refer to the section *PCI Express Enhanced Configuration Access Mechanism (ECAM)*, in the *PCI Express Base 3.0 Specification, Revision 1.0*.

For information on the EP's function PL register offsets and descriptions, refer to *PCIe_SS_PL_CONF Registers*.

Bits	Field Name	Description	Type	Reset
31:24	BIST	BIST	R	0x0
23	MFD	MultiFunction Device	R	0x0
22:16	HEAD_TYP	Header Type 0x0 = EP header 0x1 = RC header	R	0x0
15:8	MSTR_LAT_TIM	Master Latency Timer, Not Applicable for PCIe hence hardwired to 0	R	0x0
7:0	CACH_LN_SZE	Cache Line Size, No impact on write, write is allowed only for legacy purpose	RW	0x0

24.9.7.2.3

Note

Because only incremental burst mode is supported, the PCIe addresses can not be in a cacheable memory space. Subsequently, cache coherence protocol is not involved, and the PCIe controller is not expected to receive coherent PCIe TLPs (NS=0). For safety purpose, the PCIe controller coherent feature must be permanently disabled (and this applies for the device by default) by keeping PCIECTRL_TI_CONF_SYSCONFIG[16] MCOHERENT_EN at value 0b0. In that case, inbound coherent PCIe TLPs (that means with NS=0) proceed normally, but coherence will not be guaranteed by the device.

24.9.7.3 PCIe_SS_EP_CFG_DBICS Registers

Note

This section describes the PCIe EP mode (PCIe type-0) standard configuration registers as they are locally accessed within the DIF CS space. These register names are prefixed with "PCIECTRL_EP_DBICS".

24.9.7.3.1 PCIe_SS_EP_CFG_DBICS Register Summary

Table 24-525. PCIe_SS1_EP_CFG_DBICS Registers Mapping Summary

Bits	Field Name	Description	Type	Reset
31	DETECT_PARERR	Detected Parity Error	RW	0x0
30	SIGNAL_SYSERR	Signaled System Error	RW	0x0
29	RCVD_MASTERABORT	Received Master Abort	RW	0x0
28	RCVD_TRGTABORT	Received Target Abort	RW	0x0
27	SIGNAL_TRGTABORT	Signaled Target Abort	RW	0x0
26:25	DEVSEL_TIME	DevSel Timing, Harsdwired to 0 for PCIExpress	R	0x0
24	MASTERDATA_PARERR	Master Data Parity Error	RW	0x0
23	FAST_B2B	Back to Back Capable, Harsdwired to 0 for PCIExpress	R	0x0
22	RESERVED	Reserved	R	0x0
21	C66MHZ_CAP	66MHz Capable, Harsdwired to 0 for PCIExpress	R	0x0
20	CAP_LIST	Capabilities List Hardwired to 1	R	0x1
19	INTX_STATUS	INTx Status	R	0x0
18:11	RESERVED		R	0x0
10	INTX_ASSER_DIS	INTx Assertion Disable	RW	0x0
9	FAST_BBEN	Bit hardwired to 0 for PCIExpress	R	0x0
8	SERR_EN	SERR Enable	RW	0x0
7	IDSEL_CTRL	Bit hardwired to 0 for PCIExpress	R	0x0
6	PARITYERRRESP	Parity Error Response	RW	0x0
5	VGA_SNOOP	Not Applicable forPCI Express; Bit hardwired to 0 for PCIExpress	R	0x0
4	MEMWR_INVA	Not Applicable for PCI Express; Bit hardwired to 0 for PCIExpress	R	0x0
3	SPEC_CYCLE_EN	Not Applicable for PCI Express; Bit hardwired to 0 for PCIExpress	R	0x0
2	BUSMASTER_EN	Bus Master Enable (BME)	RW	0x0
1	MEM_SPACE_EN	Memory Space Enable (MSE)	RW	0x0
0	IO_SPACE_EN	IO Space Enable (ISE)	RW	0x0

Table 24-561. PCIECTRL_RC_DBICS_CLASSCODE_REVISIONID

Address Offset	0x0000 0008		
Physical Address	0x5100 0008 0x5180 0008	**Instance**	PCIe_SS1_RC_CFG_DBICS PCIe_SS2_RC_CFG_DBICS
Description	Class code and Revision ID		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:24	BASE_CLS_CD	Base Class Code (CS)	RW	0x0

Bits	Field Name	Description	Type	Reset
23:16	SUBCLS_CD	Sub Class Code (CS)	RW	0x0
15:8	PROG_IF_CODE	Programming Interface Code (CS)	RW	0x0
7:0	REVID	Revision ID (CS)	RW	0x1

Table 24-562. PCIECTRL_RC_DBICS_BIST_HEAD_LAT_CACH

Address Offset	0x0000 000C		
Physical Address	0x5100 000C 0x5180 000C	**Instance**	PCIe_SS1_RC_CFG_DBICS PCIe_SS2_RC_CFG_DBICS
Description	BIST, Header Type, Latency Timer, Cache Line Size		
Type	RW		

31 30 29 28 27 26 25 24	23	22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
BIST	MFD	HEAD_TYP	MSTR_LAT_TIM	CACH_LN_SZE

Bits	Field Name	Description	Type	Reset
31:24	BIST	BIST	R	0x0
23	MFD	MultiFunction Device	R	0x0
22:16	HEAD_TYP	Header Type 0x0: EP header (Type0) 0x1: RC header (Type1)	R	0x1
15:8	MSTR_LAT_TIM	Master Latency Timer, Not Applicable for PCIe hence hardwired to 0	R	0x0
7:0	CACH_LN_SZE	Cache Line Size, No impact on write, write is allowed only for legacy purpose	RW	0x0

Table 24-563. PCIECTRL_RC_DBICS_BAR0

Address Offset	0x0000 0010		
Physical Address	0x5100 0010 0x5180 0010	**Instance**	PCIe_SS1_RC_CFG_DBICS PCIe_SS2_RC_CFG_DBICS
Description	Base Address Register 0 Bit #0 is also a WO BAR enable (CS2) BAR Mask is writable (CS2)		
Type	RW		

31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4	3	2 1	0
BASE_ADDR_RW	BASE_ADDR_RO			PREFETCHABLE	AS	SPACE_INDICATOR

Bits	Field Name	Description	Type	Reset
31:20	BASE_ADDR_RW	Base address bits (for a 64-bit BAR, upper base address bits are in BAR above). Unmasked MSBs, as set by BAR mask. **NOTE: The RO and RW division between bits 19 and 20 is based on the assumption that BAR mask is 20 bits (1MB).**	RW	0x0

Bits	Field Name	Description	Type	Reset
19:4	BASE_ADDR_RO	Base address bits (for a 64-bit BAR, upper base address bits are in BAR above). Masked LSBs, as set by BAR mask. **NOTE: The RO and RW division between bits 19 and 20 is based on the assumption that BAR mask is 20 bits (1MB).**	R	0x0
3	PREFETCHABLE	MEM BAR: Prefetchable (CS) I/O BAR: bit 1 is part of I/O address	RW	0x1
2:1	AS	MEM BAR: Address Size (CS) I/O BAR: bit 0 is always 0, bit 1 is LS Bit of I/O address Read 0x0 = 32 bit Read 0x2 = 64 bit	RW	0x0
0	SPACE_INDICATOR	BAR I/O vs memory space indicator (CS) 0x0: BAR type is Memory (MEM) 0x1: BAR type is I/O (IO)	RW	0x0

Table 24-564. PCIECTRL_RC_DBICS_BAR1

Address Offset	0x0000 0014		
Physical Address	0x5100 0014 0x5180 0014	**Instance**	PCIe_SS1_RC_CFG_DBICS PCIe_SS2_RC_CFG_DBICS
Description	Base Address Register 1 If BAR0.AS = 64-bit: upper half of BAR0 base address If BAR0.AS = 32-bit: independent 32-bit BAR Bit #0 is also a WO BAR enable (CS2) BAR Mask is writable (CS2)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BASE_ADDR_RW												BASE_ADDR_RO																PREFETCHABLE	AS		SPACE_INDICATOR

Bits	Field Name	Description	Type	Reset
31:20	BASE_ADDR_RW	Base address bits (for a 64-bit BAR, lower base address bits are in BAR below). Unmasked MSBs, as set by BAR mask. **NOTE: The RO and RW division between bits 19 and 20 is based on the assumption that BAR mask is 20 bits (1MB).**	RW	0x0
19:4	BASE_ADDR_RO	Base address bits (for a 64-bit BAR, lower base address bits are in BAR below). Masked LSBs, as set by BAR mask. **NOTE: The RO and RW division between bits 19 and 20 is based on the assumption that BAR mask is 20 bits (1MB).**	R	0x0
3	PREFETCHABLE	MEM BAR: Prefetchable (CS) I/O BAR: bit 1 is part of I/O address	RW	0x1
2:1	AS	MEM BAR: Address Size (CS) I/O BAR: bit 0 is always 0, bit 1 is LSBit of I/O address Read 0x0 = 32 bit Read 0x2 = 64 bit	RW	0x0

Bits	Field Name	Description	Type	Reset
0	SPACE_INDICATOR	BAR I/O vs memory space indicator (CS) 0x0: BAR type is Memory (MEM) 0x1: BAR type is I/O (IO)	RW	0x0

Table 24-565. PCIECTRL_RC_DBICS_BUS_NUM_REG

Address Offset	0x0000 0018		
Physical Address	0x5100 0018 0x5180 0018	**Instance**	PCIe_SS1_RC_CFG_DBICS PCIe_SS2_RC_CFG_DBICS

24.9.7.5 PCIe_SS_PL_CONF Registers

Note

The Section 24.9.7.5.1 lists the implementation-specific (that is, not PCIe-standard) “port logic” - PL registers, mapped in the 4-KiB PCIe configuration space along with the PCIe-standard registers already described. Unlike the standard registers, port logic (PL) registers are not affected by the device type (Type-0/EP vs. Type-1/RC).

Note

Besides at the (DIF CS space) physical addresses listed in below tables, the PCIe PL configuration registers are also locally accessible (aliased) at the (DIF CS2 space) base address 0x5100_1700 (PCIe_SS1) and 0x5180_1700 (PCIe_SS2), without any difference in PL registers behaviour between CS and CS2 spaces. There is also no difference in PL registers behaviour between PCIe wire remote accesses and local (DIF CS,CS2) accesses.

24.9.7.5.1 PCIe_SS_PL_CONF Register Summary

24.9.7.5.2 PCIe_SS_PL_CONF Register Description

Table 24-590. PCIECTRL_PL_LAT_REL_TIM

Address Offset	0x0000 0000		
Physical Address	0x5100 0700 0x5180 0700	**Instance**	PCIe_SS1_PL_CONF PCIe_SS2_PL_CONF
Description	Ack Latency and Replay Timer Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REPLAY_TIME_LIMIT																ACK_LATENCY_TIME_LIMIT															

Bits	Field Name	Description	Type	Reset
31:16	REPLAY_TIME_LIMIT	The replay timer expires when it reaches this limit; The core initiates a replay upon reception of a Nak or when the replay timer expires; The default value depends on number of bytes (NB) per cycle, which is defined by the maximum core base frequency of the device PCIe core, corresponding to 250 MHz for PCIe-Gen2 (5 Gbps) operation. The default is then updated based on the Negotiated Link Width and Max_Payload_Size; Note: If operating at 5 Gb/s, then the rounded-up value of an additional (153/CX_NB) cycles is added, where CX_NB correspond to the number of PCIEPCS 8-bit input symbols per single 16-bit lane, that is, CX_NB=2. This means at 5Gbps, 77 extra cycles should be considered for the replay time limit. This is for additional internal processing for received TLPs and transmitted DLLPs.	RW	0xc0

Bits	Field Name	Description	Type	Reset
15:0	ACK_LATENCY_TIME_LIMIT	The Ack/Nak latency timer expires when it reaches this limit; The default value depends on number of bytes (NB) per cycle, which is defined by the maximum core base frequency of the device PCIe core, corresponding to 250 MHz for PCIe-Gen2 (5 Gbps) operation. The default is then updated based on the Negotiated Link Width and Max_Payload_Size. Note: If operating at 5 Gb/s, then the rounded-up value of an additional (51 /CX_NB) cycles is added, where CX_NB correspond to the number of PCIEPCS 8-bit input symbols per single 16-bit lane, that is, CX_NB=2. This means at 5Gbps, 26 extra cycles should be considered for the acknowledge latency time limit. This is for additional internal processing for received TLPs and transmitted DLLPs.	RW	0x40

24.9.7.6 PCIe_SS_EP_CFG_DBICS2 Registers

Note

This section describes the PCIe EP mode (PCIe type-0) standard configuration registers as they are locally accessed within the DIF CS2 space. These register names are prefixed with "PCIECTRL_EP_DBICS2".

24.9.7.6.1 PCIe_SS_EP_CFG_DBICS2 Register Summary

Table 24-631. PCIe_SS1_EP_CFG_DBI_CS2 Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	PCIe_SS1_EP_CFG_DBICS2 Physical Address

24.9.7.7 PCIe_SS_RC_CFG_DBICS2 Registers

Note

This section describes the PCIe RC mode (PCIe type-1) standard configuration registers as they are locally accessed within the DIF CS2 space. These register names are prefixed with "PCIECTRL_RC_DBICS2".

24.9.7.7.1 PCIe_SS_RC_CFG_DBICS2 Register Summary

Table 24-659. PCIe_SS1_RC_CFG_DBI_CS2 Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	PCIe_SS1_RC_CFG_DBICS2 Physical Address

24.9.7.8 PCIe_SS_TI_CONF Registers

24.9.7.8.1 PCIe_SS_TI_CONF Register Summary

Note

Though the PCIe controller wrapper TI configuration registers are also accessible (aliased) at base address 0x5100_3000 (PCIe_SS1) and 0x5180_3000 (PCIe_SS2), the preferable base addresses to access them are the ones used in above table, that is, 0x5100 2000 and 0x5180 2000. These registers are visible only within the device L3_MAIN space.

Table 24-693. PCIECTRL_TI_CONF_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x5100 2010 0x5180 2010	**Instance**	PCIe_SS1_TI_CONF PCIe_SS2_TI_CONF
Description	Controls various parameters of the master and slave interfaces.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED															MCOHERENT_EN	RESERVED										STANDBYMODE		IDLEMODE		RESERVED	

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
16	MCOHERENT_EN	Allows the no-snoop (NS) attribute of inbound PCIe TLPs to be passed to SoC system bus (AXI) master as a 'coherent' inband flag. 0x0: DIS AXI not coherent 0x1: EN AXI coherent = not(PCIE "NS") that is, cache-coherence is preserved	RW	0x0
15:6	RESERVED		R	0x0
5:4	STANDBYMODE	PM mode of local initiator (master); Initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode = Initiator is unconditionally placed in standby state. 0x1: No-standby mode = initiator is unconditionally placed out of standby state. 0x2: Smart-standby mode = initiator's standby state depends on internal conditions, that is, the module's functional requirements. Asynchronous wakeup events cannot be generated. 0x3: Smart-Standby, wakeup-capable mode = initiator's standby state depends on internal conditions, ie the module's functional requirements. Asynchronous wakeup events can be generated.	RW	0x2
3:2	IDLEMODE	PM mode of local target (slave); Target shall be capable of handling read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode = local target's idle state follows (acknowledges) the system's idle requests unconditionally, regardless of the IP module's internal requirements. 0x1: No-idle mode = local target never enters idle state. 0x2: Smart-idle mode = local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. Module shall not generate (IRQ- or DMA-request-related) wakeup events. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.	RW	0x2
1:0	RESERVED		R	0x0

Table 24-694. PCIECTRL_TI_CONF_IRQ_EOI

Address offset	0x18		
Physical Address	0x5100 2018 0x5180 2018	**Instance**	PCIe_SS1_TI_CONF PCIe_SS2_TI_CONF
Description	Software End-Of-Interrupt: Allows the generation of further pulses on the interrupt line, if an new interrupt event is pending, when using the pulsed output. Unused when using the level interrupt line (depending on module integration).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												LINE_NUMBER			

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x000 0000

Bits	Field Name	Description	Type	Reset
3:0	LINE_NUMBER	Write the IRQ line number to apply software EOI to it. Write 0x0: software EOI on main interrupt line Read 0x0: Read always returns zeros Write 0x1: software EOI on message-signalled (MSI) interrupt line	RW	0x0

Table 24-695. PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN

24.10 DCAN

This chapter describes the controller area network modules (DCAN) in the device.

24.10.1 DCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time applications. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The device supports two DCAN modules, referred to as DCAN1 and DCAN2, connecting to the CAN network through external (for the device) transceivers. The DCAN modules support bit rates up to 1 Mbit/s and are compliant to the CAN 2.0B protocol specification

Figure 24-170 shows the DCAN1 module highlights.

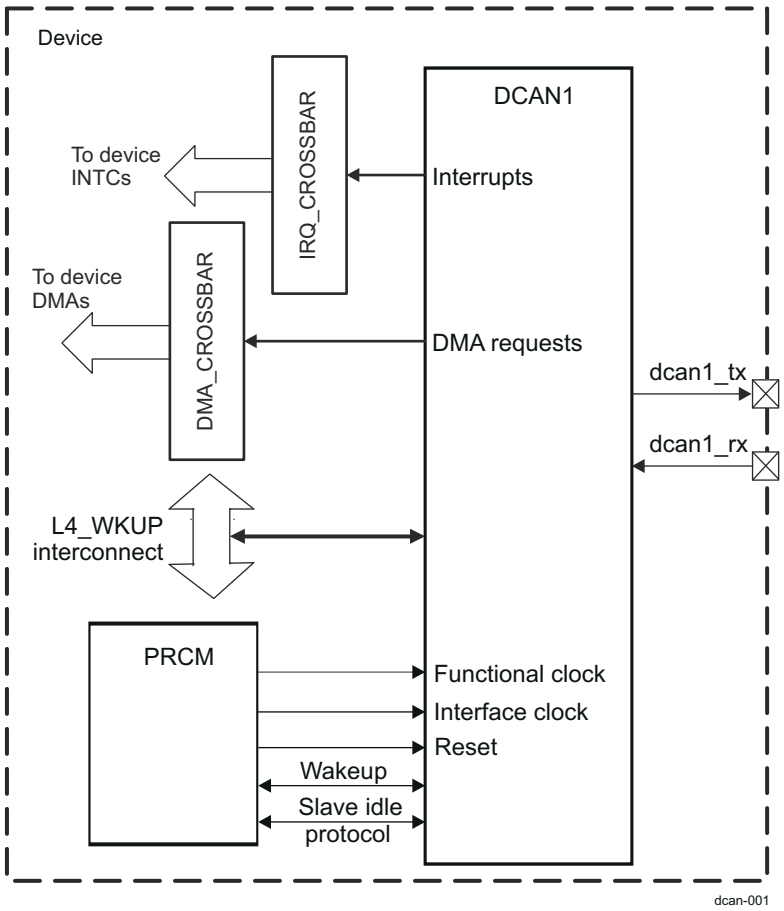

Figure 24-170. DCAN1 Overview

Figure 24-171 shows the DCAN2 module highlights .

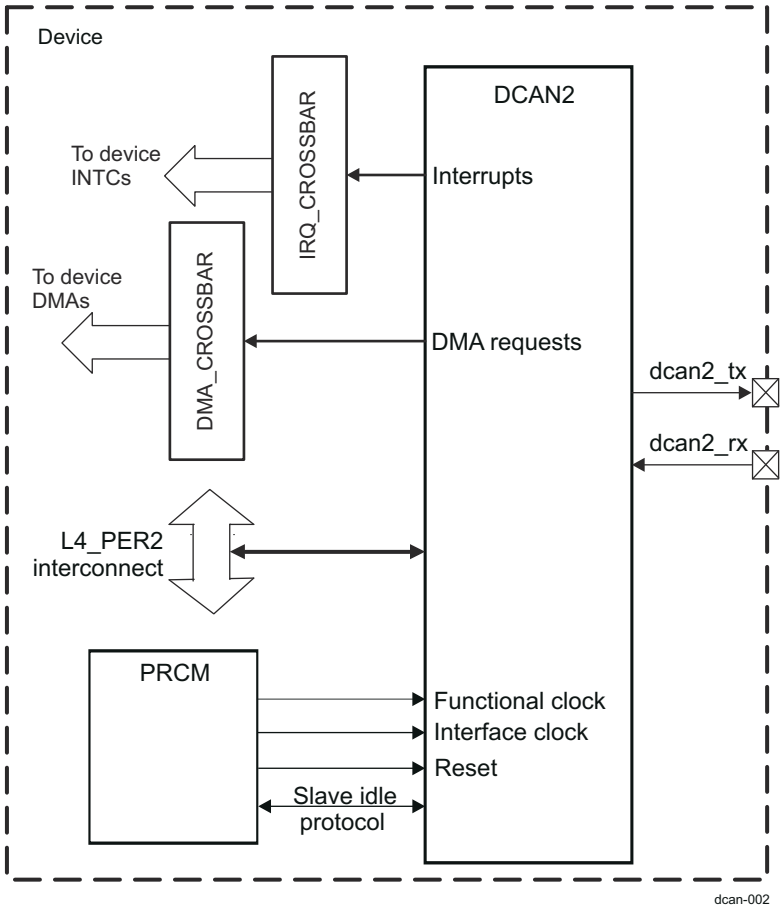

Figure 24-171. DCAN2 Overview

24.10.1.1 Features

The DCAN module implements the following features:

- Support for CAN protocol version 2.0 part A, B
- Bit rates up to 1 Mbit/s
- 64 message objects in a dedicated message RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM parity check mechanism
- Direct access to message RAM during test mode
- Support for two interrupt lines: Level 0 and Level 1, plus separate parity error interrupt line
- Local power down and wakeup support
- Automatic message RAM initialization
- Support for DMA access

24.10.2 DCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the DCAN.

Figure 24-172 shows an overview of a typical DCAN application.

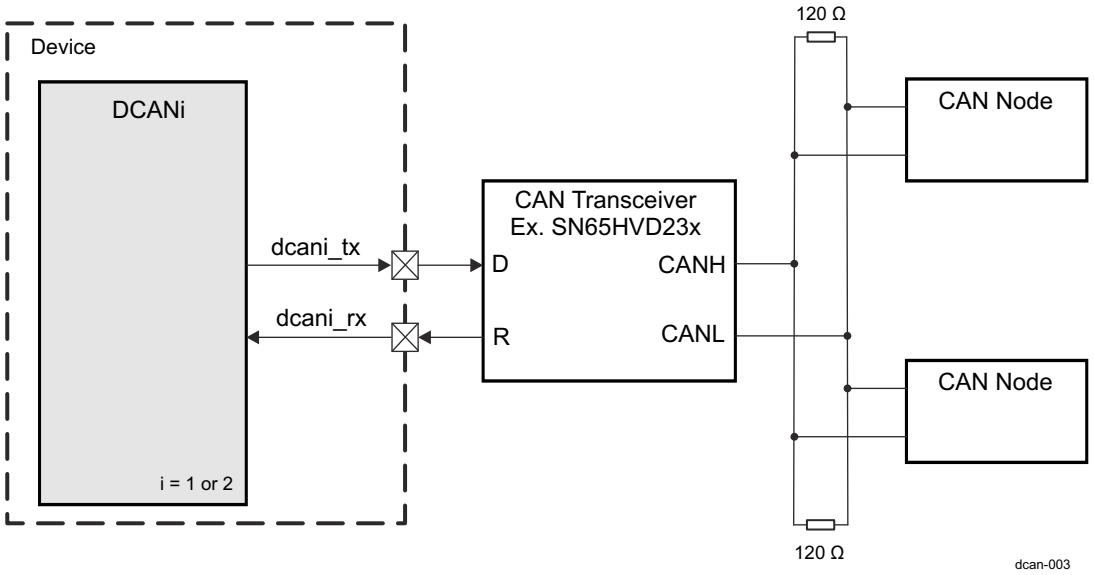

Figure 24-172. DCAN Typical Application

Table 24-713 describes the external signals of the DCAN1 module .

Table 24-713. DCAN2 I/O Description

Module Signal	Device Signal	I/O(1)	Description	Value at Reset
CAN_RX	dcan2_rx	I	Serial data input from external CAN tranceiver	HiZ
CAN_TX	dcan2_tx	O	Serial data output to external CAN tranceiver	1

(1) I = Input; O = Output

Table 24-714 describes the external signals of the DCAN2 module .

Table 24-714. DCAN1 I/O Description

Module Signal	Device Signal	I/O(1)	Description	Value at Reset
CAN_RX	dcan1_rx	I	Serial data input from external CAN tranceiver	HiZ
CAN_TX	dcan1_tx	O	Serial data output to external CAN tranceiver	1

(1) I = Input; O = Output

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers* of *Control Module*.

24.10.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using NRZ encoding and has two states:
  - Recessive state (logic 1)

  - Dominant state (logic 0)
- The network is multimaster. When two or more nodes attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost
- The message transmission is multicast. Data messages transmitted are identifier based, not address based
- Content of message is labeled by the identifier that is unique throughout the network (for example, rpm, temperature, position, pressure, etc.)
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is)
- Data is transmitted and received using message frames, consisting of:
  - Arbitration field
  - Control field
  - Data field (0 ÷ 8 bytes)
  - CRC field
  - ACK field.

24.10.3 DCAN Integration

Figure 24-173 shows the integration of the DCAN1 module in the device.

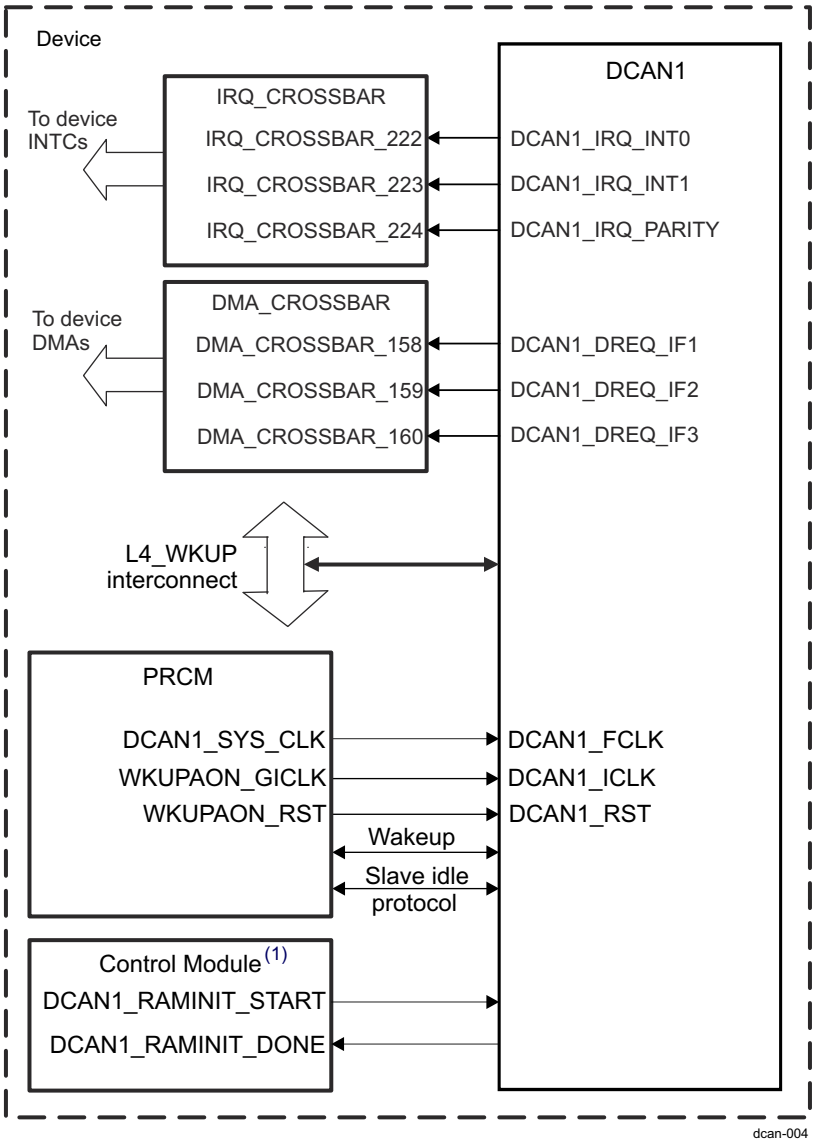

Figure 24-173. DCAN1 Integration

(1) For more information on DCAN RAM Initialization see Section 24.10.4.12.1.3, *DCAN RAM Hardware Initialization*

Figure 24-174 shows the integration of the DCAN2 module in the device .

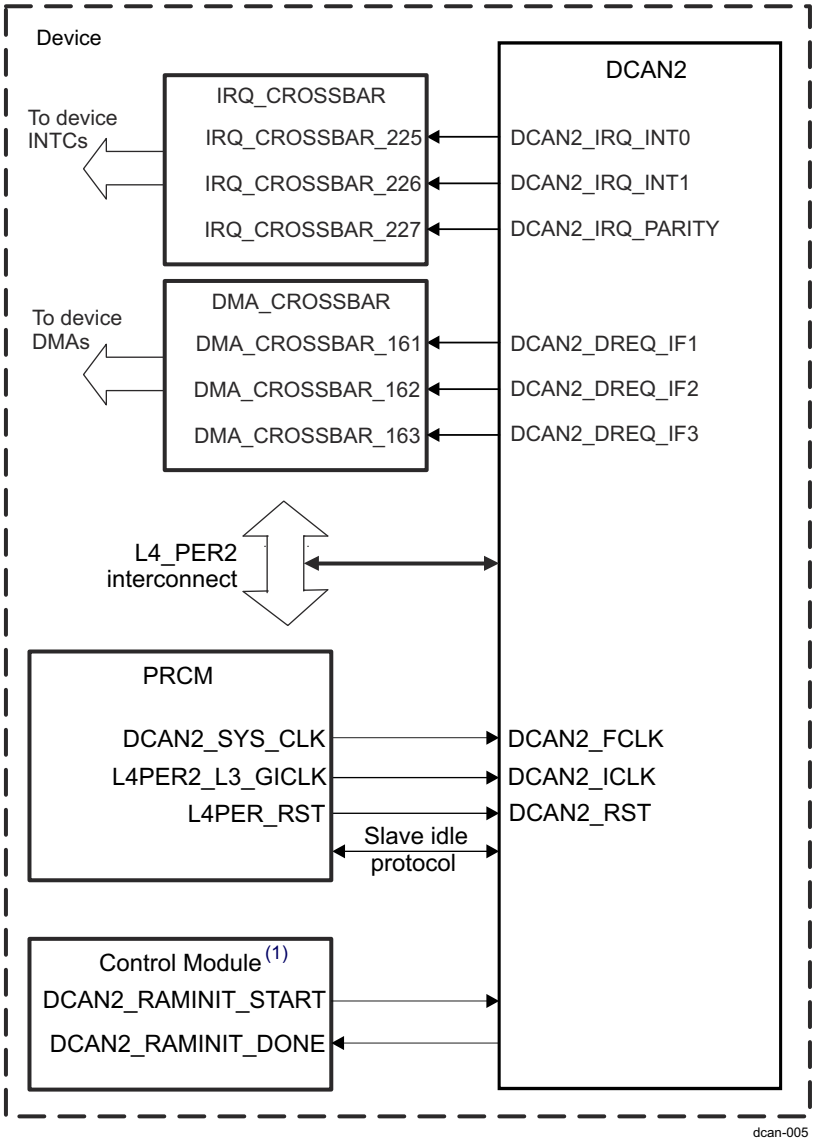

Figure 24-174. DCAN2 Integration

(1) For more information on DCAN RAM Initialization see Section 24.10.4.12.1.3, *DCAN RAM Hardware Initialization*

Table 24-715 through Table 24-717 summarize the integration of the DCAN modules in the device.

Table 24-715. DCAN Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
DCAN1	PD_WKUPAON	Yes	L4_WKUP
DCAN2	PD_COREAON	No	L4_PER2

Table 24-716. DCAN Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DCAN1	DCAN1_ICLK	WKUPAON_GICLK	PRCM	Interface clock for the DCAN1 module

Table 24-716. DCAN Clocks and Resets (continued)

	DCAN1_FCLK	DCAN1_SYS_CLK	PRCM	Functional clock for the DCAN1 core (CAN_CLK). Gated SYS_CLK1 or SYS_CLK2 version.
DCAN2	DCAN2_ICLK	L4PER2_L3_GICLK	PRCM	Interface clock for the DCAN2 module
	DCAN2_FCLK	DCAN2_SYS_CLK	PRCM	Functional clock for the DCAN2 core (CAN_CLK). Gated SYS_CLK1 version.

Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DCAN1	DCAN1_RST	WKUPAON_RST	PRCM	Asynchronous reset signal to the DCAN1 module
DCAN2	DCAN2_RST	L4PER_RST	PRCM	Asynchronous reset signal to the DCAN2 module

Table 24-717. DCAN Hardware Requests

Interrupt Requests

Module Instance	Source Signal Name	IRQ_CROSSBAR Input	Default Mapping	Description
DCAN1	DCAN1_IRQ_INT0	IRQ_CROSSBAR_222	-	Error, Status, and Message Objects interrupt
	DCAN1_IRQ_INT1	IRQ_CROSSBAR_223	-	Message Objects interrupt
	DCAN1_IRQ_PARITY	IRQ_CROSSBAR_224	-	Parity error interrupt
DCAN2	DCAN2_IRQ_INT0	IRQ_CROSSBAR_225	-	Error, Status, and Message Objects interrupt
	DCAN2_IRQ_INT1	IRQ_CROSSBAR_226	-	Message Objects interrupt
	DCAN2_IRQ_PARITY	IRQ_CROSSBAR_227	-	Parity error interrupt

DMA Requests

Module Instance	Source Signal Name	DMA_CROSSBAR Input	Default Mapping	Description
DCAN1	DCAN1_DREQ_IF1	DMA_CROSSBAR_158	-	DMA request for IF1 register set
	DCAN1_DREQ_IF2	DMA_CROSSBAR_159	-	DMA request for IF2 register set
	DCAN1_DREQ_IF3	DMA_CROSSBAR_160	-	DMA request for IF3 register set
DCAN2	DCAN2_DREQ_IF1	DMA_CROSSBAR_161	-	DMA request for IF1 register set
	DCAN2_DREQ_IF2	DMA_CROSSBAR_162	-	DMA request for IF2 register set
	DCAN2_DREQ_IF3	DMA_CROSSBAR_163	-	DMA request for IF3 register set

Note

DCAN has no default IRQ mappings through the IRQ_CROSSBAR. For DCAN, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.

Note

For the description of the interrupt source, see Section 24.10.4.2, *Interrupt Functionality*.

24.10.4 DCAN Functional Description

The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 24-175 shows the DCAN block diagram and its features are described below.

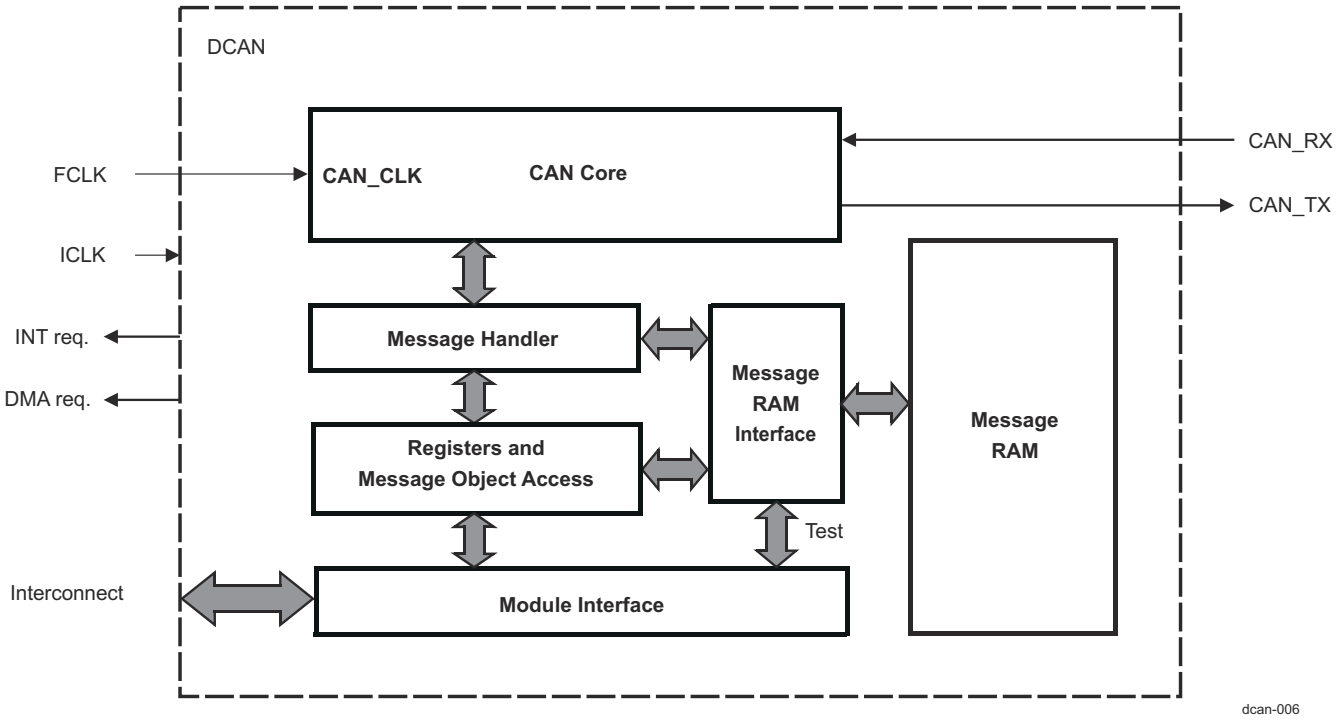

Figure 24-175. DCAN Block Diagram

CAN Core: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

Message Handler: The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

Message RAM: The DCAN enables a storage of 64 CAN messages.

Message RAM Interface: Three interface register sets control the MPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in Section 24.10.4.8.12, *Reading From a FIFO Buffer*.

The interface registers have the same word-length as the message RAM.

Registers and Message Object Access: Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either MPU or DMA.

Module Interface: The DCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.

Clocking: Two clocks are provided to the DCAN module: the peripheral synchronous clock (interface clock [ICLK]) and the peripheral asynchronous clock (functional clock [FCLK]) .

24.10.4.1 Module Clocking Requirements

Two clocks are provided to the DCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

Note

ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the DCAN. Here, also the frequency shift of the modulated ICLK has to be considered:

$f_{0,ICLK}(OCP) \pm \Delta f_{FM,ICLK}(OCP) \geq f_{FCLK}$

For more information on how to configure the relevant clock source registers, see *PRCM* and the device data manual.

24.10.4.2 Interrupt Functionality

Interrupts can be generated on two interrupt lines: INT0 and INT1. These lines can be enabled by setting the DCAN_CTL[1] IE0 and [17] IE1 bits, respectively. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see Figure 24-176, *Error and Status Change Interrupts* and Figure 24-177, *Message Objects Interrupts*).

The source of an interrupt can be determined by the interrupt identifiers DCAN_INT[15:0] INT0ID/[23:16] INT1ID. When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register DCAN_INT[15:0] INT0ID/[23:16] INT1ID again reach zero (this means the cause of the interrupt is reset), or until IE0/IE1 are reset.

The value 0x8000 in the INT0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register (DCAN_ES). This interrupt has the highest priority. The software can update (reset) the status bits [9] WAKEUPPND, [4] RXOK, [3] TXOK and [2:0] LEC by reading DCAN_ES, but a write access of the software will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, INT0ID resp. INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time (DCAN_IF1CMD/DCAN_IF2CMD[19] CLRINTPND bit). When IntPnd is cleared, DCAN_INT will point to the next message object with a pending interrupt.

24.10.4.2.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPnd, TxIE and RxIE that are described in Section 24.10.4.11.1, *Structure of Message Objects*.

Message object interrupts can be routed to either INT0 or INT1 line, controlled by the interrupt multiplexer registers (DCAN_INTMUX12 to DCAN_INTMUX78).

24.10.4.2.2 Status Change Interrupts

The events WAKEUPPND, RXOK, TXOK and LEC in the error and status register (DCAN_ES) belong to the status change interrupts. The status change interrupt group can be enabled by DCAN_CTL[2] SIE bit.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

Note

Reading DCAN_ES will clear the WAKEUPPND flag. If in global power-down mode, the WAKEUPPND flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WAKEUPPND flag, and a second interrupt may occur.

24.10.4.2.3 Error Interrupts

The events PER, BOFF and EWARN, monitored in the DCAN_ES register belong to the error interrupts. The error interrupt group can be enabled by setting bit DCAN_CTL[3] EIE = 1.

Error interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

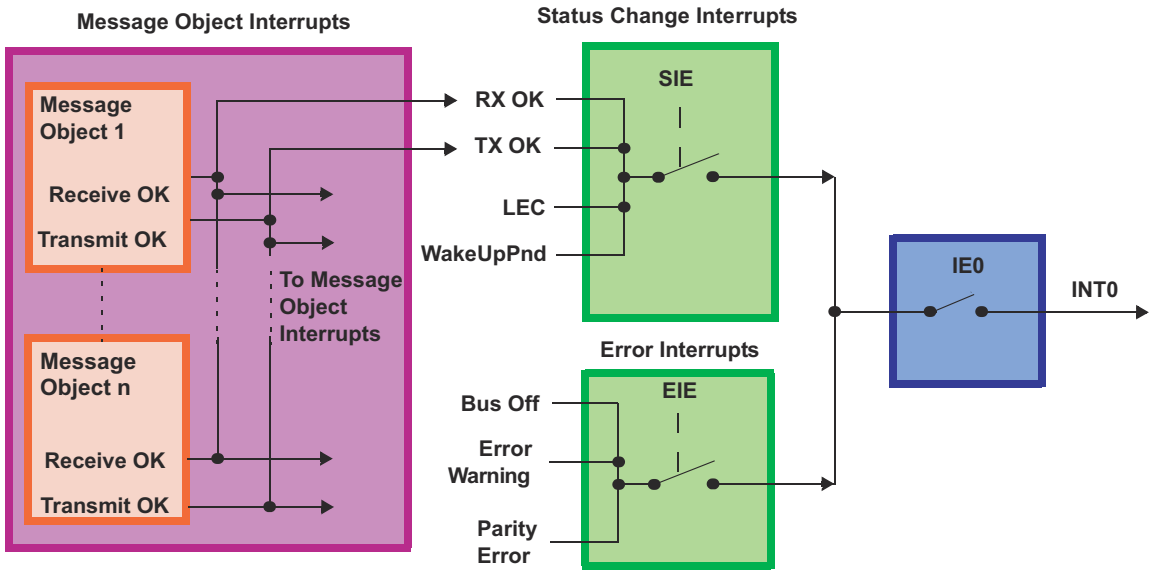

Figure 24-176. Error and Status Change Interrupts

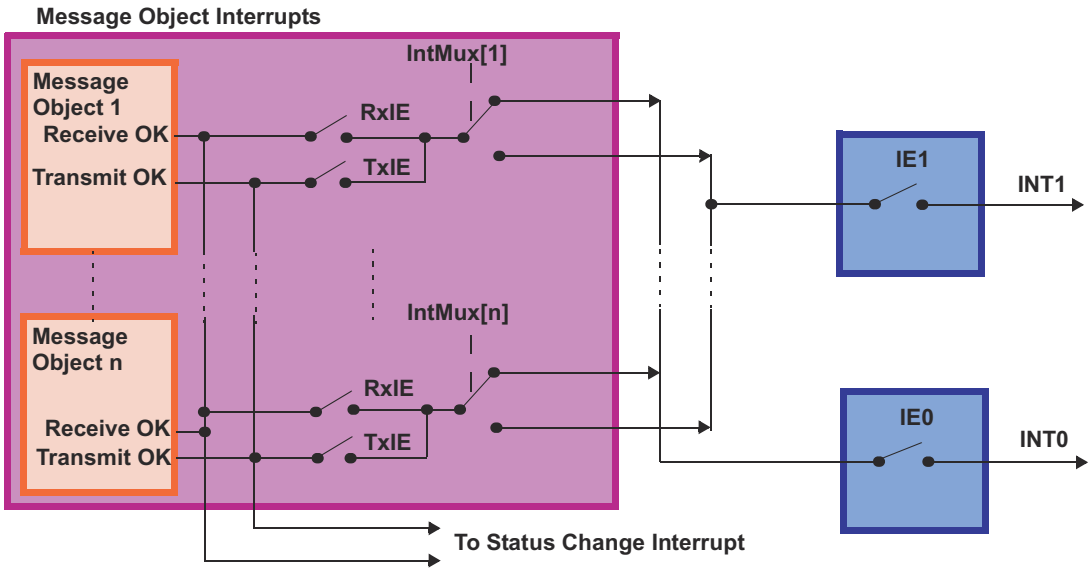

Figure 24-177. Message Objects Interrupts

24.10.4.3 DMA Functionality

The DCAN provides three DMA request lines, each indicating new data in one of the three interface register sets IF1, IF2 and IF3.

The update of IF1 and IF2 registers will be initiated by a write access to the IF1 respective IF2 Command Registers (DCAN_IF1CMD, DCAN_IF2CMD).

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update, see Section 24.10.4.10.2, *IF3 Register Set*.

When a DCAN internal IFx (x = 1 to 3) update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers. The DMA functionality has to be enabled by setting bit [18] DE0/[19] DE1/[20] DE3 in DCAN_CTL.

24.10.4.4 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the DCAN registers.

24.10.4.4.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the DCAN_CTL[24] PDR bit (=1).

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the DCAN_CTL[0] INIT bit to prevent any further CAN transfers, and it will also set the DCAN_ES[10] PDA bit. With setting the PDA bit, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see Section 24.10.4.4.2, *Wakeup From Local Power Down*) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

Note

In local low-power mode, the software must not clear the INIT bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the INIT bit, these messages may get sent.

24.10.4.4.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

- The application could wake up the DCAN module manually by clearing the DCAN_CTL[24] PDR bit and then clearing the DCAN_CTL[0] INIT.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity bit (DCAN_CTL[25] WUBA). If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the DCAN_CTL[24] PDR bit and also clear the DCAN_ES[10] PDA bit. The DCAN_ES[10] WAKEUPPND bit will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the DCAN_CTL[0] INIT bit will be cleared.

After the INIT bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

Note

The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 24-178 shows a flow diagram about entering and leaving local power-down mode.

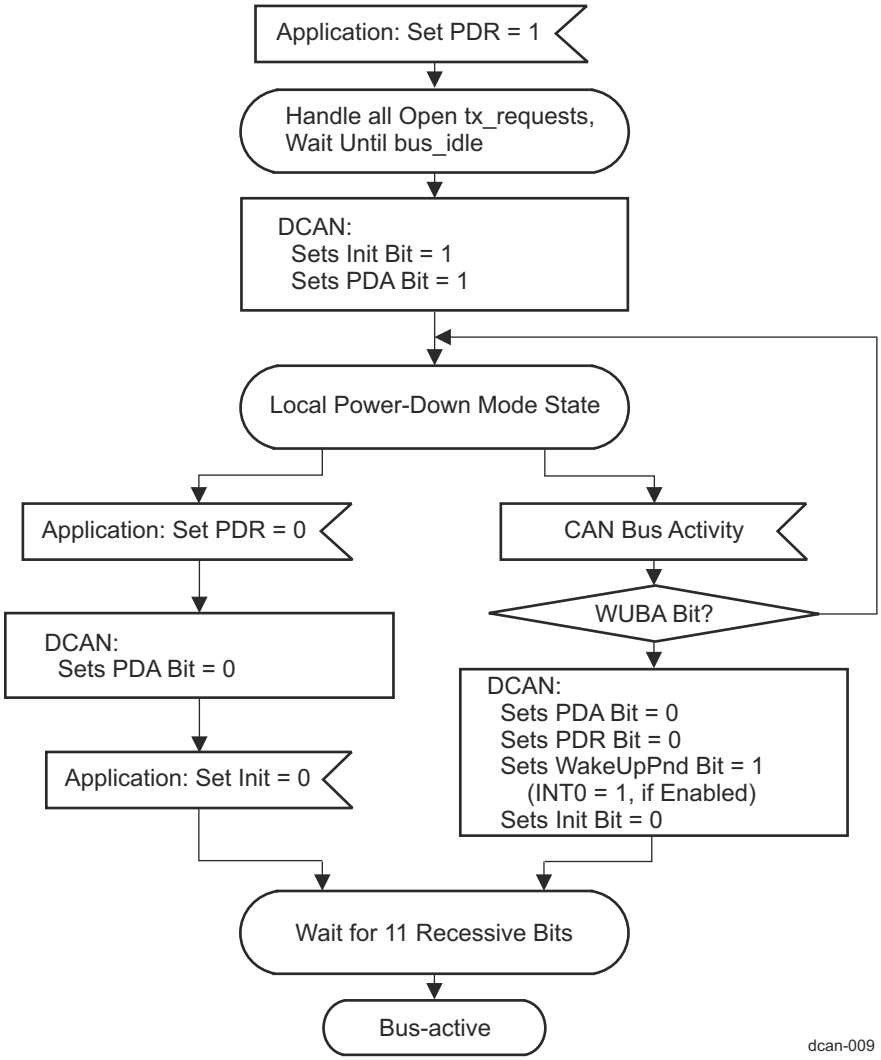

Figure 24-178. Local Power-Down Mode Flow Diagram

24.10.4.5 Parity Check Mechanism

The DCAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in message RAM, one parity bit will be calculated. The formation of the different words is according to the message RAM representation in RDA mode, see Section 24.10.4.11.4, *Message RAM Representation in Direct Access Mode*.

Parity information is stored in the message RAM on write accesses and will be checked against the stored parity bit from message RAM on read accesses.

The Parity check functionality can be enabled or disabled by DCAN_CTL[13:10] PMD bit field.

In case of disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the DCAN. The parity bits could be read in debug/suspend mode (see Section 24.10.4.11.3, *Message RAM Representation in Debug/ Suspend Mode*) or in RDA mode (see Section 24.10.4.11.4, *Message RAM Representation in Direct Access Mode*). However, direct write access to the parity bits is only possible in this two modes with parity check disabled.

A parity bit will be set, if the modulo-2-sum of the data bits is 1. This definition is equivalent to: The parity bit will be set, if the number of 1 bits in the data is odd.

Note

DCAN is configured to even parity by the design.

24.10.4.5.1 Behavior on Parity Error

On any read access to message RAM (e.g., during start of a CAN frame transmission), the parity of the message object will be checked. If a parity error is detected, the DCAN_ES[8] PER bit will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset to 0.

The message object data can be read by the software, independently of parity errors. Thus, the software has to ensure that the read data is valid, for example, by immediately checking the parity error code register (DCAN_PERR) on parity error interrupt.

Note

During RAM initialization, no parity check is done, but if the PMD bit is set, the parity bits will be generated.

24.10.4.5.2 Parity Testing

Testing the parity mechanism can be done by enabling the bit RamDirectAccess (DCAN_TEST[9] RDA) and manually writing the parity bits directly to the dedicated RAM locations. With this, data and parity bits could be checked when reading directly from RAM.

Note

If parity check is disabled, the software has to ensure correct parity bit handling in order to prevent parity errors later on when parity check is enabled.

24.10.4.6 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via interconnect interface.

Before entering debug/suspend mode, the DCAN will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit DCAN_CTL[8] IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by DCAN_CTL [16] INITDBG flag.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return ‘0’. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see Section 24.10.4.11.3, *Message RAM Representation in Debug/Suspend Mode*.

Note

During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

Note

Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- DCAN_ES register (clear of status flags by read)
- DCAN_IF1CMD/DCAN_IF2CMD command registers (clear of [14] DMAACTIVE flag by read/write)

24.10.4.7 Configuration of Message Objects Description

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver must offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = '1')

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.

In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

24.10.4.7.1 Configuration of a Transmit Object for Data Frames

Table 24-718 shows how a transmit object can be initialized.

Table 24-718. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data length and data itself (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TXIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 24.10.4.8.8, *Reception of Remote Frames*.

Identifier masking must be disabled (UMask = ‘0’) if no remote frames are allowed to set the TxRqst bit (RmtEn = ‘0’).

24.10.4.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data rrame for which this receive object is configured.

24.10.4.7.3 Configuration of a Single Receive Object for Data Frames

Table 24-719 shows how a receive object for data frames can be initialized.

Table 24-719. Initialization of a single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to ‘0’.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = ’1’) to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to “don’t care,” the corresponding bits of the arbitration register (DCAN_IF1ARB, DCAN_IF2ARB, DCAN_IF3ARB) will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = ’1’) for acceptance filtering.

24.10.4.7.4 Configuration of a Single Receive Object for Remote Frames

Table 24-720 shows how a receive object for remote frames can be initialized.

Table 24-720. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 24.10.4.7.5, *Configuration of a FIFO Buffer*).

UMask must be set to ‘1.’ The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to “must-match” or to “don’t care,” to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 24.10.4.8.8, *Reception of Remote Frames*.

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to “don’t care,” the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to ‘0.’

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

24.10.4.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

24.10.4.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

24.10.4.8.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same or higher as the message the object found by last scanning
- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

24.10.4.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the

lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

24.10.4.8.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the MSGVAL bits in the Message Valid register (DCAN_MSGVAL12 to DCAN_MSGVAL78) and the TXRQST bits in the transmission request register (DCAN_TXRQ12 to DCAN_TXRQ78) are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DCAN_CTL[5] DAR bit, the behavior of bits TXRQST and NEWDAT in the DCAN_IF1CMD/DCAN_IF2CMD register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error), bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

24.10.4.8.4 Updating a Transmit Object

The software may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MSGVAL, nor TXRQST have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register (DCAN_IF1DATA/DCAN_IF2DATA) or IF1/IF2 Data B register (DCAN_IF1DATB/DCAN_IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the software has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the software writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1/IF2 Command register (DCAN_IF1CMD/DCAN_IF2CMD) and then the number of the message object is written to bits [7:0] MESSAGE_NUMBER of the command register, concurrently updating the data bytes and setting TXRQST with NEWDAT.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 24.10.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

24.10.4.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The software can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD) can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither Dir, nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD) should be set to 0x87.

Note

After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

24.10.4.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

24.10.4.8.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the software) has been received. The software should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the software) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the DCAN_INT to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

24.10.4.8.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = ‘1’ (direction = transmit), RmtEn = ‘1’, UMask = ‘1’ or ‘0’

  The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘0’

  The remote frame is ignored, this message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘1’

The remote frame is treated similar to a received data frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

24.10.4.8.9 Reading Received Messages

The software may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the software will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] MESSAGE_NUMBER of the command register (DCAN_IF1CMD/ DCAN_IF2CMD). That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register (DCAN_IF1MCTL/DCAN_IF2MCTL/DCAN_IF3MCTL) always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

24.10.4.8.10 Requesting New Data for a Receive Object

By means of a remote frame, the software may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD).

24.10.4.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the software has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

24.10.4.8.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

A FIFO buffer of length N will store N–1, plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 24-179.

Note

All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

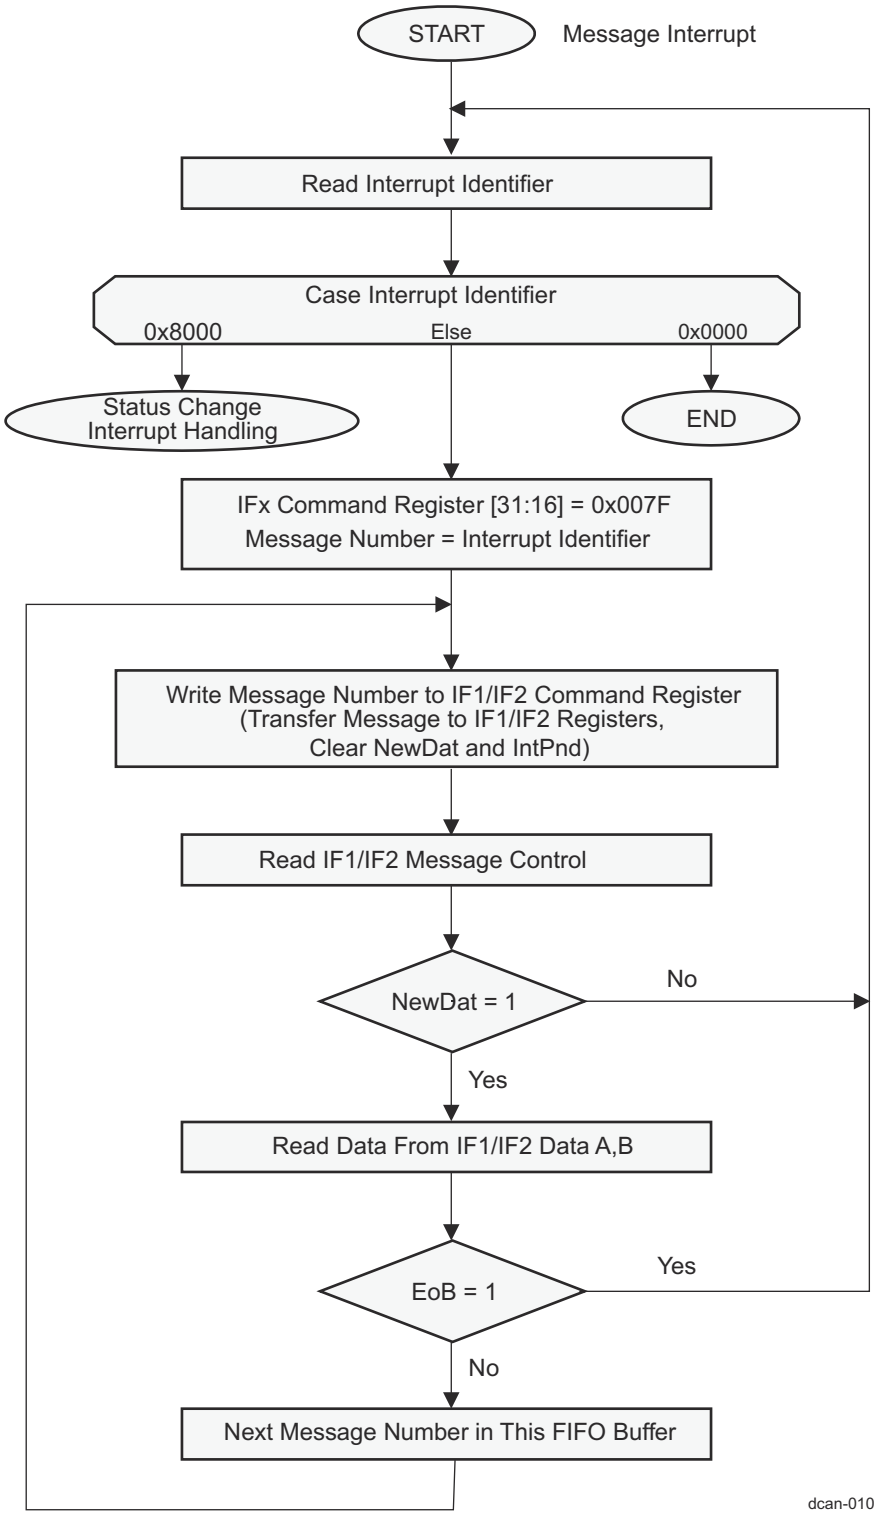

Figure 24-179. Software Handling of a FIFO Buffer (Interrupt Driven)

24.10.4.9 CAN Bit Timing

The DCAN supports bit rates between < 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

24.10.4.9.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 24-180):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

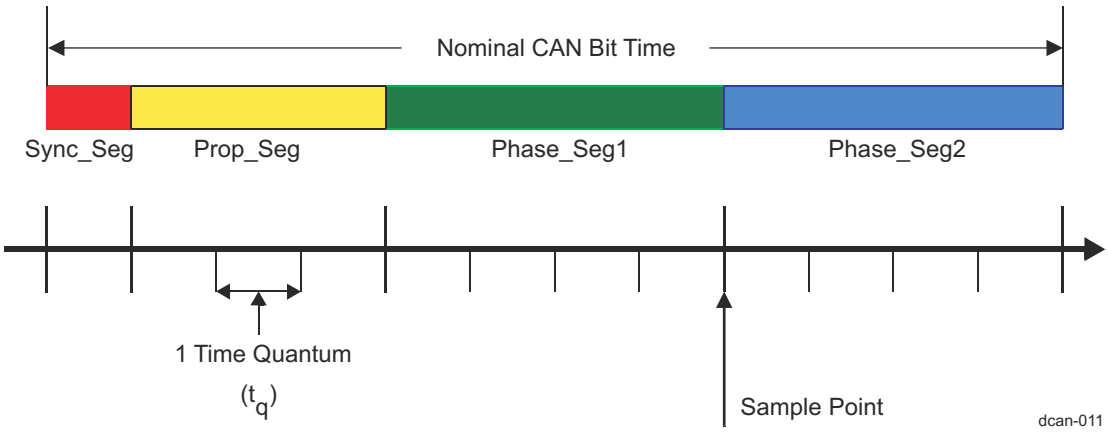

Figure 24-180. Bit Timing

Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the FCLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / FCLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 24-721 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Table 24-721. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to FCLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times

Table 24-721. Parameters of the CAN Bit Time (continued)

Parameter	Range	Remark
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

Note

For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

24.10.4.9.1.1 Synchronization Segment

The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

24.10.4.9.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 24-181 shows the phase shift and propagation times between two CAN nodes.

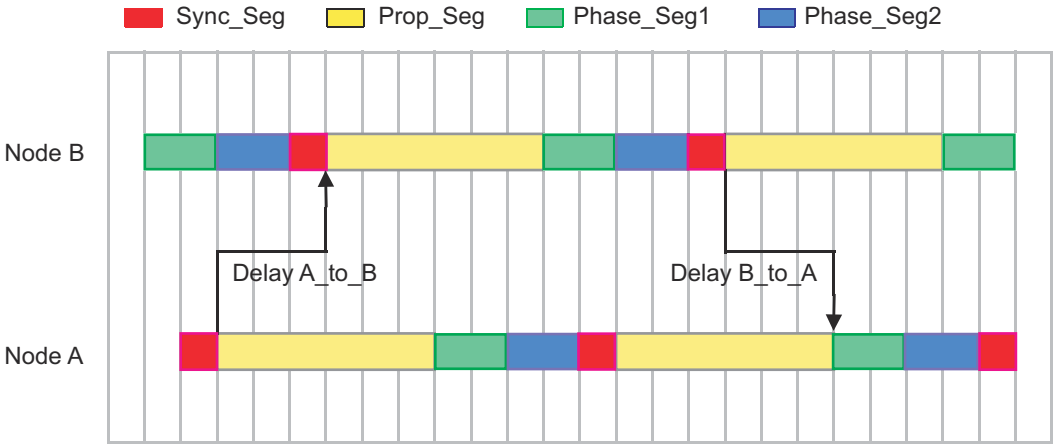

Figure 24-181. The Propagation Time Segment

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while

node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

24.10.4.9.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.
- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than

SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 24-182 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

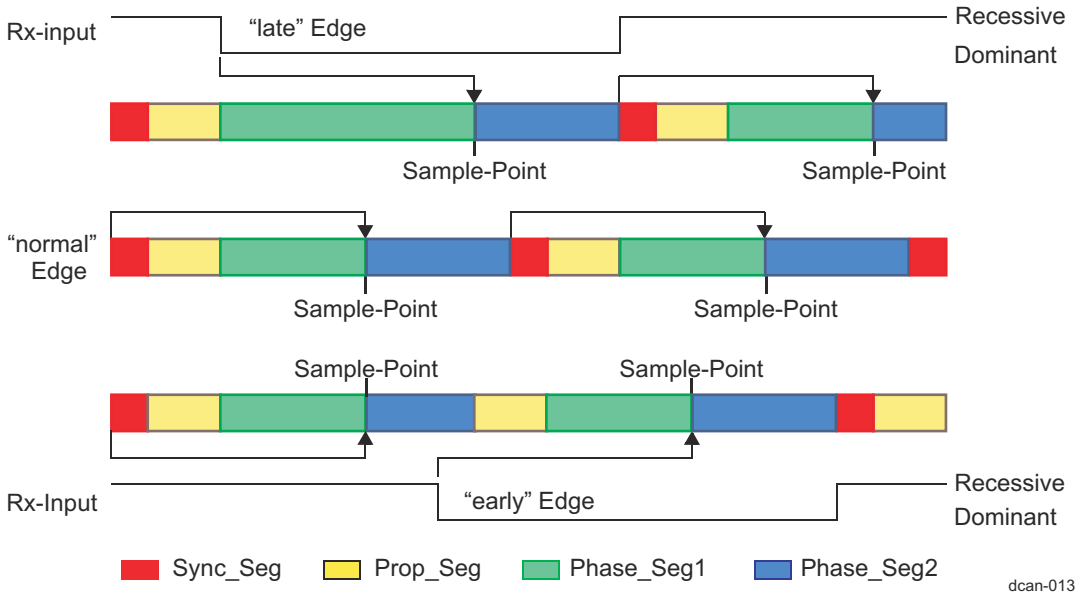

Figure 24-182. Synchronization on Late and Early Edges

In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

Figure 24-183 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

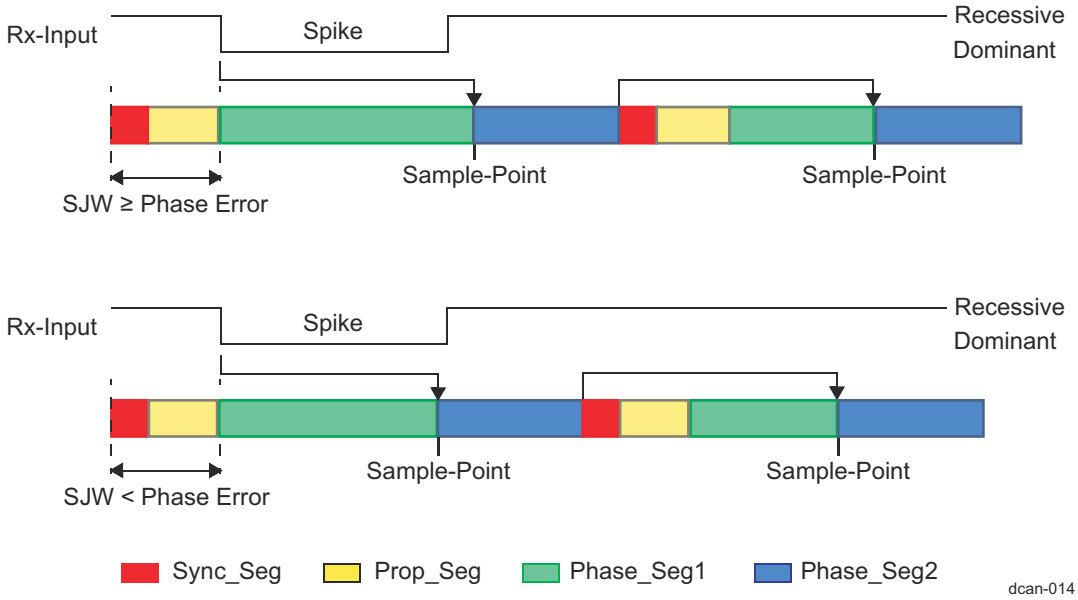

Figure 24-183. Filtering of Short Dominant Spikes

24.10.4.9.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) \bullet f_{nom} \le f_{osc} \le (1 + df) \bullet f_{nom}$$

dcan-e015

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \le \frac{\min(TSeg1, TSeg2)}{2x\left(13x\left(bit\_time - TSeg2\right)\right)}$$

$$\text{II:} \quad df \le \frac{SJW}{20xbit\_time}$$

dcan-e016

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 µs) with a bus length of 40 m.

24.10.4.9.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in DCAN_BTR[14:0], additionally a baud rate prescaler extension of four bits (DCAN_BTR[19:16] BRPE) is provided.

- The sum of Prop_Seg and Phase_Seg1 is set in [11:8] TSEG1
- Phase_Seg2 in [14:12] TSEG2
- SynchronizationJumpWidth in [7:6] SJW
- and baud rate prescaler [5:0] BRP (plus [19:16] BRPE)

Figure 24-184 shows the CAN protocol controller.

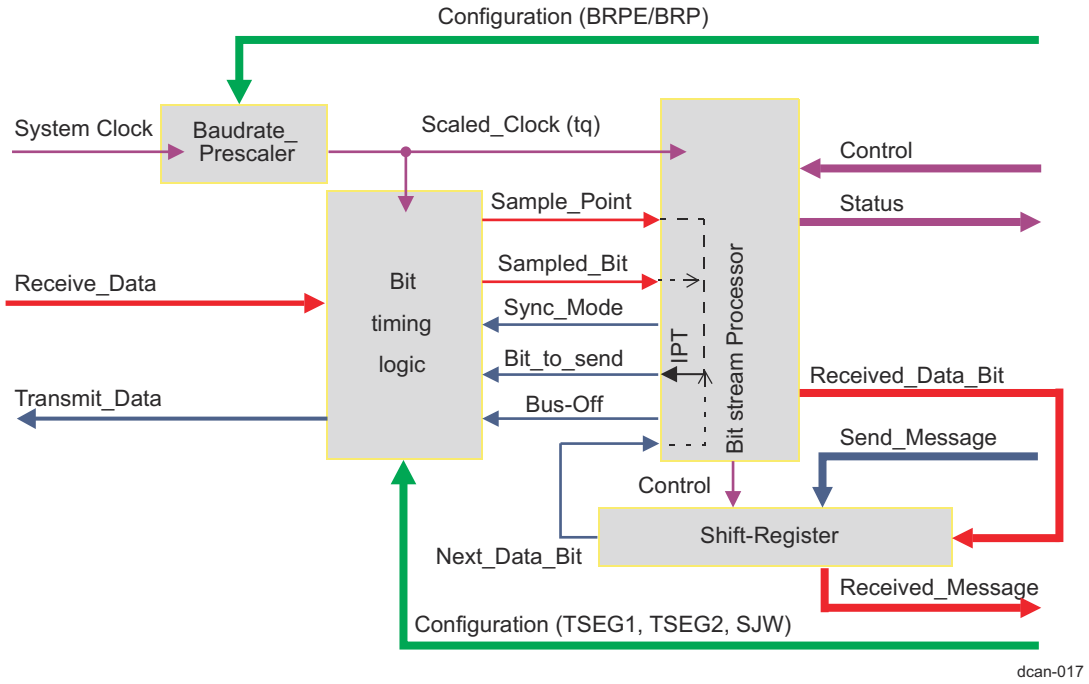

Figure 24-184. Structure of the CAN Core's CAN Protocol Controller

In DCAN_BTR register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1…n], values in the range of [0…n–1] are programmed. That way, e.g., SJW (functional range of [1…4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the bit timing register (DCAN_BTR) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (e.g., data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is 0 tq for the DCAN.

Generally, the IPT is CAN controller-specific, but may not be longer than 2 tq. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

24.10.4.9.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the baud rate prescaler with t_q = (Baud Rate Prescaler) / FCLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0…2] t_q.

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Table 24-722.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register (DCAN_BTR):

[14:12] TSEG2 = Phase_Seg2 - 1

[11:8] TSEG1 = Phase_Seg1+ Prop_Seg - 1

[7:6] SJW = SynchronizationJumpWidth - 1

[5:0] BRP = Prescaler - 1

24.10.4.9.2.2 Example for Bit Timing Calculation

In this example, the frequency of FCLK is 20 MHz, BRP is 2, the bit rate is 500 KBit/s.

Table 24-722. Example For Bit Timing

Parameter	Formula	Value	t_q
bit time (500 KBit/s)	1/bit rate, consists of $t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$	2000 ns	20
delay of bus driver		280 ns	-
delay of receiver circuit		29 ns	-
delay of bus line (16 m)	16 × 5.5 ns/m	88 ns	-
t_q	BRP/FCLK	100 ns	1
t_{Sync_Seg}	1 × t_q (fixed)	100 ns	1
t_{Prop_Seg}	INT (2×delays + 1) = 8 × t_q	800 ns	8
t_{Seg1}	$t_{Prop\_Seg} + t_{Phase\_Seg1}$	1400 ns	14
t_{Seg2}	bit time - ($_{Sync\_Seg} + t_{Seg1}$)	500 ns	5
t_{SJWmax}	MIN (4 × t_q, t_{Phase_Seg1})	400 ns	4

In this example, the bit timing register DCAN_BTR is programmed to:

- BRP = 2 - 1 = 1
- BRPE = 0
- TSEG1 = 14 - 1 = 13 (0xC)
- TSEG2 = 5 - 1 = 4
- SJW = 4 - 1 = 3

24.10.4.10 Message Interface Register Sets

The interface register sets control the software read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be left unchanged.

By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent software accesses to the message RAM and CAN message reception and transmission. A complete message object (see Section 24.10.4.11.1, *Structure of Message Objects*) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see Section 24.10.5, *DCAN Register Manual*) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

24.10.4.10.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. DCAN_IF1CMD/ DCAN_IF2CMD address the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] MESSAGE_NUMBER.

When the software initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the [15] BUSY bit in respective DCAN_IF1CMD/DCAN_IF2CMD to 1. After the transfer has completed, the BUSY bit is set back to 0 (see Figure 24-185).

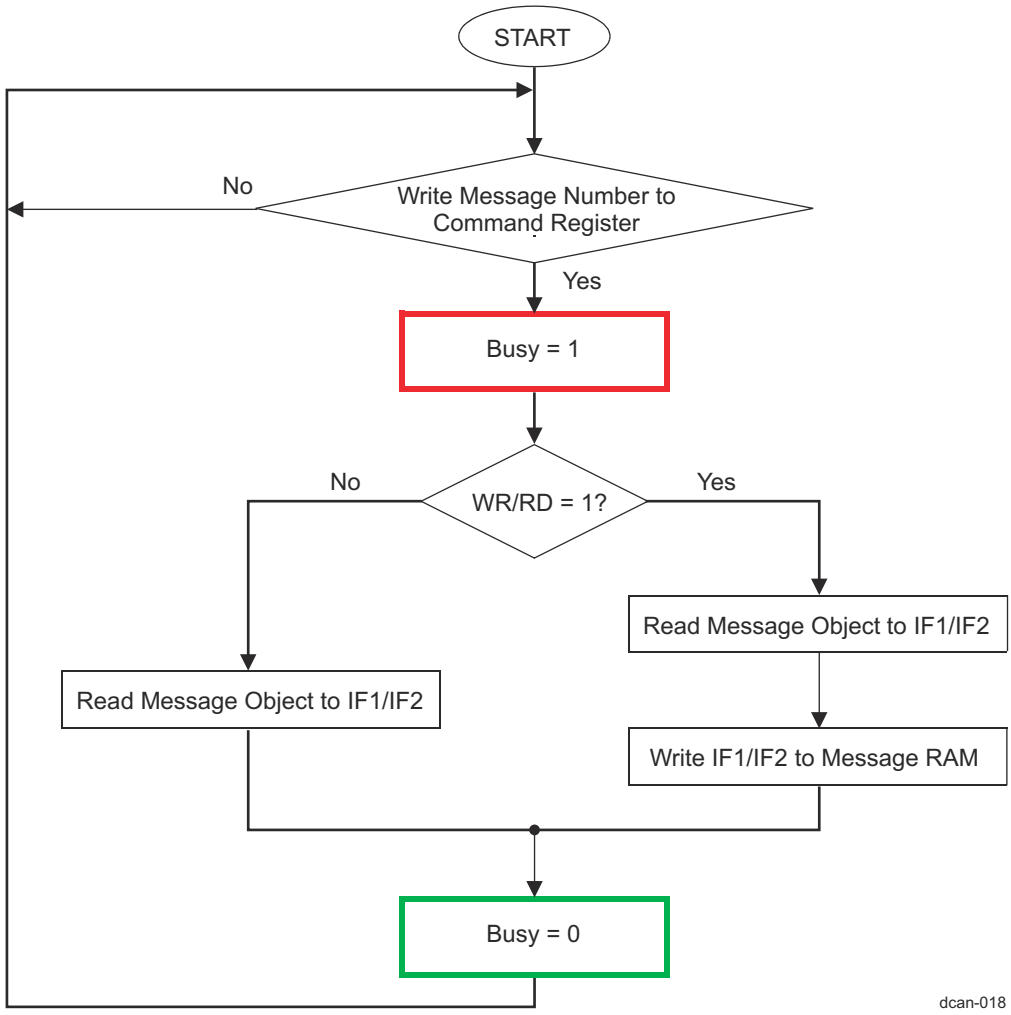

Figure 24-185. Data Transfer Between IF1/IF2 Registers and Message RAM

24.10.4.10.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object (DCAN_IF3UPD12 to DCAN_IF3UPD78).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register (DCAN_IF3OBS). If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DCAN_CTL[20] DE3 = 1.

Note

The IF3 register set cannot be used for transferring data into message objects.

24.10.4.11 Message RAM

The DCAN message RAM contains message objects and parity bits for the message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the software cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the software to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The software does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the software:

- Debug/Suspend mode (see Section 24.10.4.11.3, *Message RAM Representation in Debug/Suspend Mode*)
- RAM Direct Access (RDA) mode (see Section 24.10.4.11.4, *Message RAM Representation in Direct Access Mode*)

CAUTION

Writes to the DCAN RAM must not be done while it is in low-power mode. If such writes occur, the behavior is undefined and RAM content is corrupted. It has to be ensured in software that the low-power mode is removed from the DCAN RAM before writing to it.

24.10.4.11.1 Structure of Message Objects

Table 24-723 shows the structure of a message object.

The highlighted fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Table 24-723. Structure of a Message Object

UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 24-724. Message Object Field Descriptions

Field Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required. The software must reset the MsgVal bit of all unused Messages Objects during the initialization before it resets the INIT bit in the DCAN_CTL register.

Table 24-724. Message Object Field Descriptions (continued)

Field Name	Value	Description
UMask		Use acceptance mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the software.
	1	The message handler or the software has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the software.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register (DCAN_INT) will point to this message object if there is no other interrupt source with higher priority.

Table 24-724. Message Object Field Descriptions (continued)

Field Name	Value	Description
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0 - 8	Data frame has 0 - 8 data bytes.
	9 - 15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

24.10.4.11.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
Message RAM base address + (message object number) × 0x20

That is, message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

Note

Because 0 is not a valid message object number, at offset 0x0000 is not located message object 0, but the last implemented: 64.

The base address for DCAN1 RAM is 0x4AE3 D000 and DCAN2 RAM is 0x4848 1000.

Message object number 1 has the highest priority.

Table 24-725. Message RAM Addressing in Debug/Suspend and RDA Modes

Message Object Number	Offset	Word Number	Debug/Suspend Mode, see Section 24.10.4.11.3	RDA Mode, see Section 24.10.4.11.4
64 (last implemented)	0x0000	1	Parity	Data Bytes 4-7
	0x0004	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x0008	3	Xtd,Dir,ID	ID[27:0],DLC
	0x000C	4	Ctrl	Mask,Xtd,Dir,ID[28]

	0x0050	5	Data Bytes 3-0	Parity,Ctrl,MXtd,MDir
	0x0054	6	Data Bytes 7-4	-
…	…	…	…	…
63	0x07E0	1	Parity	Data Bytes 4-7
	0x07E4	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x07E8	3	Xtd,Dir,ID	ID[27:0],DLC
	0x07EC	4	Ctrl	Mask,Xtd,Dir,ID[28]
	0x07F0	5	Data Bytes 3-0	Parity,Ctrl,MXtd,MDir
	0x07F4	6	Data Bytes 7-4	-

24.10.4.11.3 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

Note

During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

Table 24-726. Message RAM Representation in Debug/Suspend Mode

24.10.4.11.4 Message RAM Representation in Direct Access Mode

When the DCAN_TEST[9] RDA bit is set while the DCAN module is in test mode (DCAN_CTL[7] TEST = 1), the software has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The software has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RAM Direct Access during normal operation mode (TEST bit or RDA bit not set) will be ignored.

24.10.4.12 CAN Operation

After device reset, the DCAN_CTL[0] INIT is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 24-186 illustrates the basic initialization flow for the CAN module.

24.10.4.12.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the software has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

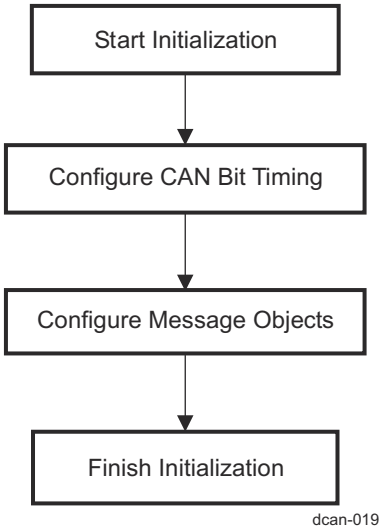

Figure 24-186. CAN Module General Initialization Flow

24.10.4.12.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see Figure 24-187, *CAN Bit-Timing Configuration*.

Step 1: Enter *initialization mode* (DCAN_CTL[0] INIT = 1).

While the INIT bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the INIT bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on device reset and during Bus-Off.

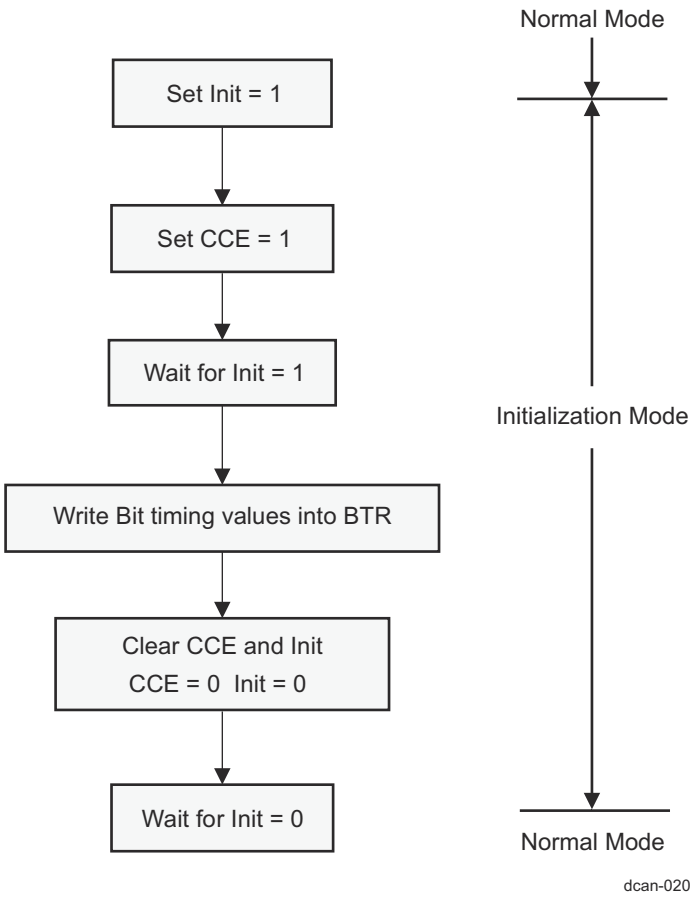

Figure 24-187. CAN Bit-Timing Configuration

Step 2: Set the Configure Change Enable bit (DCAN_CTL[6] CCE = 1).

The access to the Bit Timing register (DCAN_BTR) for the configuration of the bit timing is enabled when both INIT = 1 and CCE = 1.

Step 3: Wait for the INIT bit to get set (=1). This would make sure that the module has entered Initialization mode.

Step 4: Write the bit timing values into DCAN_BTR. See Section 24.10.4.9.2, *DCAN Bit Timing Registers* for the values calculation for a given bit timing.

Step 5: Clear the CCE and INIT bits (=0).

Step 6: Wait for the INIT bit to clear (=0). This would ensure that the module has come out of Initialization mode.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the DCAN_BTR is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

Note

The module will not come out of the Initialization mode if any incorrect DCAN_BTR values are written in step 4.

Note

The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in Section 24.10.4.12.1, *CAN Module Initialization*.

24.10.4.12.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the software does not have direct access to the message object (message RAM) . Familiarize yourself with the interface register set (IFx) usage (see Section 24.10.4.10, *Message Interface Register Sets*) and the message object structure (see Section 24.10.4.11, *Message RAM*) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see Section 24.10.4.7, *Configuration of Message Objects Description*. All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

Note

The message objects initialization is independent of the bit-timing configuration.

24.10.4.12.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control module. Setting RAMINIT_START to 1, causes RAM initialization with zeros and sets parity bits accordingly. Software must wait for the RAMINIT_DONE bit to be set to ensure successful RAM initialization.

For more details on CTRL_CORE_CONTROL_IO_2 register, see *Control Module Register Manual*.

24.10.4.12.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and DCAN_CTL[0] INIT bit is reset (=0), the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The software may enable the interrupt lines (DCAN_CTL[1] IE0 and [17] IE1 = 1) at the same time when it clears [0] INIT and [6] CCE = 0. The status interrupts [3] EIE and [2] SIE may be enabled (=1) simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The DCAN_INT register points to those message objects with IntPnd = 1. It is updated even if the interrupt lines to the host processor are disabled (DCAN_CTL[1] IE0 and [17] IE1 = 0).

The software may poll all MessageObject's NewDat and TxRqst bits in parallel from the DCAN_NWDAT_X and the DCAN_TXRQ_X registers respectively. Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to "don't care" may change in the message object when a received message is stored.

The software may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

24.10.4.12.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission (DCAN_CTL[5] DAR = 1). Further details to this mode are provided in Section 24.10.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

24.10.4.12.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the software can start a Bus-Off-Recovery sequence by resetting the DCAN_CTL[0] INIT bit to 0. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit DCAN_CTL[9] ABO. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of interface clock cycles which can be defined in the Auto-Bus-On Time register (DCAN_ABOTR).

Note

If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the INIT bit. Once the INIT bit has been reset by the software or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

24.10.4.12.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

For all test modes, the DCAN_CTL[7] TEST bit needs to be set to 1. This enables write access to the test register (DCAN_TEST).

Note

It must be ensured by software that all message transfers are completed before entering test mode.

24.10.4.12.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (e.g., acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Figure 24-188 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the DCAN_TEST[3] SILENT bit to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

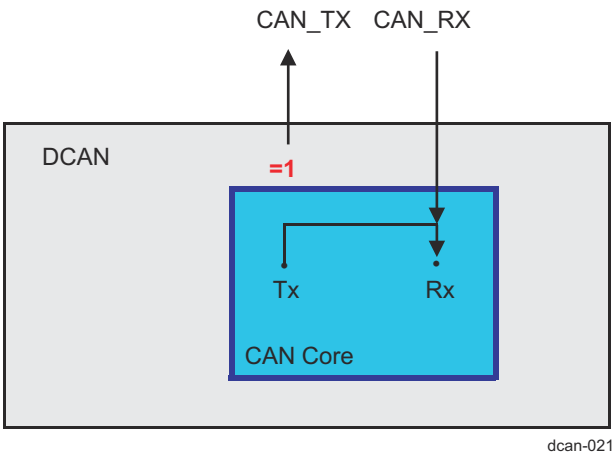

Figure 24-188. CAN Core in Silent Mode

24.10.4.12.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 24-189 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit DCAN_TEST[4] LBACK to 1.

Note

In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 24.10.4.12.3.3, *External Loopback Mode*.

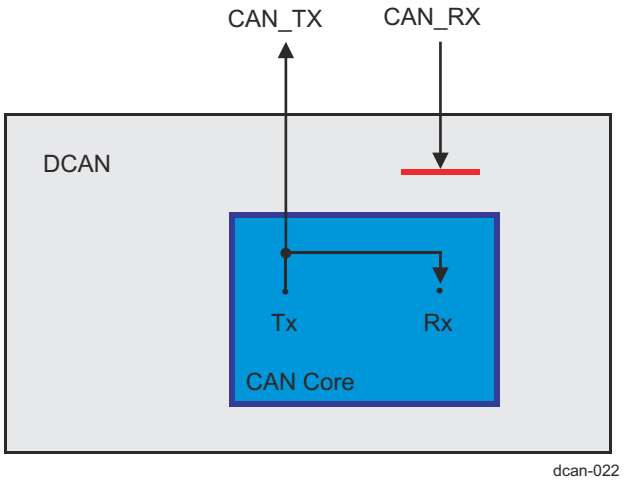

Figure 24-189. CAN Core in Loopback Mode

24.10.4.12.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit DCAN_TEST[8] EXL to 1.

Figure 24-190 shows the connection of signals CAN_TX and CAN_RX to the CAN core in external loopback mode.

Note

When loopback mode is active (LBACK bit set), the EXL bit will be ignored.

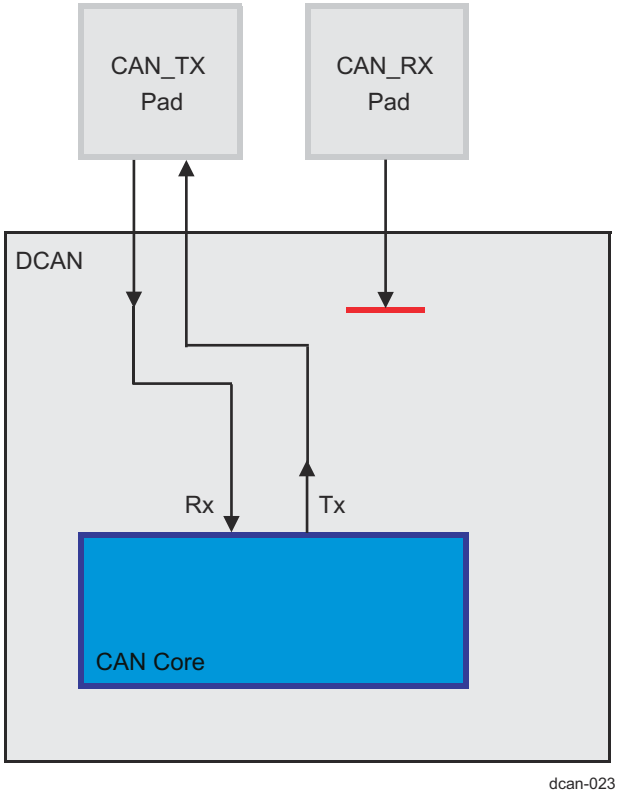

Figure 24-190. CAN Core in External Loopback Mode

24.10.4.12.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits DCAN_TEST[4] LBACK and [3] SILENT at the same time. This mode can be used for a "Hot Selftest", that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits will be sent on the CAN_TX pin.

Figure 24-191 shows the connection of the signals CAN_TX and CAN_RX to the CAN core in case of the combination of loopback mode with silent mode.

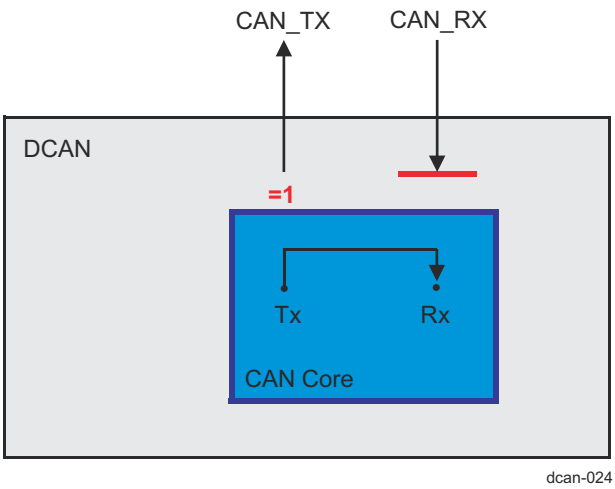

Figure 24-191. CAN Core in Loop Back Combined With Silent Mode

24.10.4.12.3.5 Software Control of CAN_TX Pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the DCAN_TEST[6:5] TX:

- 0x0: Normal operation, CAN_TX is controlled by the DCAN core
- 0x1: Sample point can be monitored at CAN_TX pin
- 0x2: CAN_TX pin drives a dominant value
- 0x3: CAN_TX pin drives a recessive value.

Note

The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

24.10.4.13 GPIO Support

The CAN_RX and CAN_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register (DCAN_TIOC) and the CAN RX IO control register (DCAN_RIOC).

24.10.5.1 DCAN Instance Summary

Table 24-728. DCAN Instance Summary

Module Name	Base Address	Size
DCAN1	0x4AE3 C000	8 KiB
DCAN2	0x4848 0000	8 KiB

24.10.5.2 DCAN Registers

Note

After device reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The INIT bit in the DCAN_CTL is set to enable the software initialization. The DCAN will not influence the CAN bus until the software resets INIT to 0.

24.10.5.2.2 DCAN Register Description

Table 24-730. DCAN_CTL

Address Offset	0x0000 0000		
Physical Address	0x4AE3 C000 0x4848 0000	**Instance**	DCAN1 DCAN2
Description	DCAN control register **NOTE**: The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting INIT bit. If the module goes Bus-Off, it will automatically set the INIT bit and stop all bus activities. When the INIT bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset. After the INIT bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to DCAN_ES, enabling the software to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.		

Table 24-730. DCAN_CTL (continued)

Type RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED						WUBA	PDR	RESERVED			DE3	DE2	DE1	IE1	INITDBG	SWR	RESERVED	PMD				ABO	IDS	TEST	CCE	DAR	RESERVED	EIE	SIE	IE0	INIT

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
25	WUBA	Automatic wake up on bus activity when in local power-down mode. Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost. 0: No detection of a dominant CAN bus level while in local power-down mode. 1: Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started (Additional information can be found in *Local Power-Down Mode*).	RW	0
24	PDR	Request for local low power-down mode 0: No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the INIT bit has to be cleared. 1: Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the DCAN_ES register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in *Local Power-Down Mode*).	RW	0
23:21	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0
20	DE3	Enable DMA request line for IF3. Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. 0: Disabled 1: Enabled	RW	0
19	DE2	Enable DMA request line for IF2. Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers. 0: Disabled 1: Enabled	RW	0
18	DE1	Enable DMA request line for IF1. Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. 0: Disabled 1: Enabled	RW	0
17	IE1	Interrupt line 1 enable 0: Disabled - Module interrupt INT1 is always low. 1: Enabled - interrupts will assert line INT1 to one; line remains active until pending interrupts are processed.	RW	0

Bits	Field Name	Description	Type	Reset
16	INITDBG	Internal init state while debug access 0: Not in debug mode, or debug mode requested but not entered. 1: Debug mode requested and internally entered; the DCAN is ready for debug accesses.	RW	0
15	SWR	Software reset enable. Note: To execute software reset, the following procedure is necessary: 1. Set INIT bit to shut down CAN communication. 2. Set SWR (this) bit additionally to INIT bit. 0: Normal Operation 1: Module is forced to reset state. This bit will automatically get cleared after execution of software reset after one OCP clock cycle.	RW	0
14	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
13:10	PMD	Parityon/off 0x5: function disabled Others: function enabled	RW	0x5
9	ABO	Auto-Bus-On enable 0: The Auto-Bus-On feature is disabled 1: The Auto-Bus-On feature is enabled	RW	0
8	IDS	Interruption debug support enable 0: When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode 1: When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.	RW	0
7	TEST	Test mode enable 0: Normal Operation 1: Test Mode	RW	0
6	CCE	Configuration change enable 0: The software has no write access to the configuration registers. 1: The software has write access to the configuration registers (when INIT bit is set).	RW	0
5	DAR	Disable automatic retransmission 0: Automatic retransmission of not successful messages enabled. 1: Automatic retransmission disabled.	RW	0
4	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
3	EIE	Error interrupt enable 0: Disabled - PER, BOFF and EWARN bits can not generate an interrupt. 1: Enabled - PER, BOFF and EWARN bits can generate an interrupt at INT0 line and affect the interrupt register.	RW	0
2	SIE	Status change interrupt enable 0: Disabled - WAKEUPPND, RXOK, TXOK and LEC bits can not generate an interrupt. 1: Enabled - WAKEUPPND, RXOK, TXOK and LEC can generate an interrupt at INT0 line and affect the interrupt register.	RW	0

Bits	Field Name	Description	Type	Reset
1	IE0	Interrupt line 0 enable 0: Disabled - Module interrupt INT0 is always low. 1: Enabled - interrupts will assert line INT0 to one; line remains active until pending interrupts are processed.	RW	0
0	INIT	Initialization 0: Normal operation 1: Initialization mode is entered	RW	1

Table 24-732. DCAN_ES

Address Offset	0x0000 0004		
Physical Address	0x4AE3 C004 0x4848 0004	**Instance**	DCAN1 DCAN2
Description	Error and Status Register Interrupts are generated by bits PER, BOFF and EWARN (if EIE bit in DCAN_CTL is 1) and by bits WAKEUPPND, RXOK, TXOK, and LEC (if SIE bit in DCAN_CTL is 1). A change of bit EPASS will not generate an interrupt. Reading the DCAN_ES clears the WAKEUPPND, PER, RXOK and TXOK bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the DCAN_INT will be replaced by the next lower priority interrupt value. For debug support, the auto clear functionality of DCAN_ES (clear of status flags by read) is disabled when in debug/suspend mode.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					PDA	WAKEUPPND	PER	BOFF	EWARN	EPASS	RXOK	TXOK	LEC		

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00 0000

Bits	Field Name	Description	Type	Reset
10	PDA	Local power-down mode acknowledge 0: DCAN is not in local power-down mode. 1: Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.	R	0
9	WAKEUPPND	Wake up pending. This bit can be used by the software to identify the DCAN as the source to wake up the system. This bit will be reset if DCAN_ES is read. 0: No Wake Up is requested by DCAN. 1: DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.	R	0
8	PER	Parity error detected. This bit will be reset if DCAN_ES register is read. Read 0: No parity error has been detected since last read access. Read 1: The parity check mechanism has detected a parity error in the Message RAM. Write 0: No effect Write 1: End of interrupt (EOI) for parity error on DCAN_PARITY interrupt line	RW	0
7	BOFF	Bus-Off state 0: The CAN module is not bus-off state. 1: The CAN module is in bus-off state.	R	0
6	EWARN	Warning state 0: Both error counters are below the error warning limit of 96. 1: At least one of the error counters has reached the error warning limit of 96.	R	0
5	EPASS	Error passive state 0: On CAN Bus error, the DCAN could send active error frames. 1: The CAN core is in the error passive state as defined in the CAN Specification.	R	0
4	RXOK	Received a message successfully. This bit will be reset if DCAN_ES register is read. 0: No message has been successfully received since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1: A message has been successfully received since the last time when this bit was reset by a read access of the software (independent of the result of acceptance filtering).	R	0
3	TXOK	Transmitted a message successfully. This bit will be reset if DCAN_ES register is read. 0: No message has been successfully transmitted since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1: A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the software.	R	0

Bits	Field Name	Description	Type	Reset
2:0	LEC	Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0x0: No error 0x1: Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed. 0x2: Form error: A fixed format part of a received frame has the wrong format. 0x3: Ack error: The message this CAN core transmitted was not acknowledged by another node. 0x4: Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 0x5: Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the software to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 0x6: CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). 0x7: No CAN bus event was detected since the last time the software read DCAN_ES. Any read access to DCAN_ES re-initializes the LEC to value '7.'	R	0x7

Table 24-736. DCAN_BTR

Address Offset	0x0000 000C		
Physical Address	0x4AE3 C00C 0x4848 000C	**Instance**	DCAN1 DCAN2
Description	Bit timing register This register is only writable if CCE and INIT bits in the DCAN_CTL are set. The CAN bit time may be programmed in the range of 8 to 25 time quanta The CAN time quantum may be programmed in the range of 1 to 1024 CAN_CLK periods.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												BRPE				RESERVED			TSEG2			TSEG1		SJW		BRP					

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x000
19:16	BRPE	Baud rate prescaler extension. Valid programmed values are 0 to 15. By programming BRPE the baud rate prescaler can be extended to values up to 1024.	RW	0x0
15	RESERVED	These bits are always read as 0. Writes have no effect.	R	0
14:12	TSEG2	Time segment after the sample point Valid programmed values are 0 to 7. The actual TSeg2 value which is interpreted for the bit timing will be the programmed TSeg2 value + 1.	RW	0x2
11:8	TSEG1	Time segment before the sample point Valid programmed values are 1 to15. The actual TSeg1 value interpreted for the bit timing will be the programmed TSeg1 value + 1.	RW	0x3
7:6	SJW	Synchronization Jump Width Valid programmed values are 0 to 3. The actual SJW value interpreted for the synchronization will be the programmed SJW value + 1.	RW	0x0

Bits	Field Name	Description	Type	Reset
5:0	BRP	Baud rate prescaler Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid programmed values are 0 to 63. The actual BRP value interpreted for the bit timing will be the programmed BRP value + 1.	RW	0x1

Table 24-738. DCAN_INT

Address Offset	0x0000 0010		
Physical Address	0x4AE3 C010 0x4848 0010	**Instance**	DCAN1 DCAN2
Description	Interrupt register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								INT1ID								INT0ID															

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
23:16	INT1ID	Interrupt 1 Identifier (indicates the message object with the highest pending interrupt) 0x00: No interrupt is pending 0x01-0x80: Number of message object which caused the interrupt. 0x81-0xFF: Unused If several interrupts are pending, DCAN_INT will point to the pending interrupt with the highest priority. The INT1 interrupt line remains active until INT1ID reaches value 0 (the cause of the interrupt is reset) or until IE1 is cleared. A message interrupt is cleared by clearing the message object's IntPnd bit. Among the message interrupts, the message object's interrupt priority decreases with increasing message number.	R	0x00

Bits	Field Name	Description	Type	Reset
15:0	INT0ID	Interrupt Identifier (the number here indicates the source of the interrupt) 0x0000: No interrupt is pending 0x0001-0x0080: Number of message object which caused the interrupt. 0x0081-0x7FFF: Unused 0x8000: DCAN_ES value is not 0x07. 0x8001-0xFFFF: Unused If several interrupts are pending,DCAN_INTwill point to the pending interrupt with the highest priority. The INT0 interrupt line remains active until INT0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. The Status interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number.	R	0x0000

Table 24-740. DCAN_TEST

Address Offset	0x0000 0014		
Physical Address	0x4AE3 C014 0x4848 0014	**Instance**	DCAN1 DCAN2
Description	Test Register For all test modes, the TEST bit in DCAN_CTL control register needs to be set to 1. If TEST bit is set, the RDA, EXL, TX1, TX0, LBACK and SILENT bits are writable. Bit RX monitors the state of pin CAN_RX and therefore is only readable. All test register functions are disabled when TEST bit is cleared.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						RDA	EXL	RX	TX			LBACK	SILENT	RESERVED	

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00 0000
9	RDA	RAM direct access enable 0: Normal operation 1: Direct access to the RAM is enabled while in test mode	RW	0
8	EXL	External loopback mode. When the internal loop-back mode is active (bit LBACK is set), bit EXL will be ignored. 0: Disabled 1: Enabled	RW	0

Bits	Field Name	Description	Type	Reset
7	RX	Receive pin. Monitors the actual value of the CAN_RX pin 0: The CAN bus is dominant 1: The CAN bus is recessive	R	-
6:5	TX	Control of CAN_TX pin. Setting Tx[1:0] other than '00' will disturb message transfer. 0x0: Normal operation, CAN_TX is controlled by the CAN core. 0x1: Sample point can be monitored at CAN_TX pin. 0x2: CAN_TX pin drives a dominant value. 0x3: CAN_TX pin drives a recessive value.	RW	0x0
4	LBACK	Loopback mode. When the internal loop-back mode is active (bit LBACK is set), bit EXL will be ignored. 0: Disabled 1: Enabled	RW	0
3	SILENT	Silent mode 0: Disabled 1: Enabled	RW	0
2:0	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0

Table 24-742. DCAN_PERR

Address Offset	0x0000 001C		
Physical Address	0x4AE3 C01C 0x4848 001C	**Instance**	DCAN1 DCAN2
Description	Parity Error Code Register If a parity error is detected, the PER flag will be set in the DCAN_ES. This bit is not reset by the parity check mechanism; it must be reset by reading DCAN_ES. In addition to the PER flag, the parity error code register will indicate the memory area where the parity error has been detected (message number and word number). If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

Table 24-766. DCAN_NWDAT78 (continued)

Description	New Data Register This register hold the NewDat bits of the implemented message objects. By reading out these bits, the software can check for new data in the message objects. The NewDat bit of a specific message object can be set/reset by the software via the IF1/IF2 interface register sets, or by the message handler after reception of a data frame or after a successful transmission.

Table 24-796. DCAN_IF1CMD (continued)

Description

IF1 Command Register
The IF1 Command Register (DCAN_IF1CMD) configure and initiate the transfer between the IF1 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.
While BUSY bit is one, IF1/IF2 register sets are write protected.
For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode.
If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.

Type RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
23	WR_RD	Write/Read 0: Direction = Read: Transfer direction is from the message object addressed by MESSAGE_NUMBER to the IF1 register set. 1: Direction = Write: Transfer direction is from the IF1 register set to the message object addressed by MESSAGE_NUMBER.	RW	0
22	MASK	Access mask bits 0: Mask bits will not be changed 1: Direction = Read: The mask bits (identifier mask + MDir + MXtd) will be transferred from the message object addressed by MESSAGE_NUMBER to the IF1 register set. 1: Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF1 register set to the message object addressed by MESSAGE_NUMBER.	RW	0
21	ARB	Access arbitration bits 0: Arbitration bits will not be changed 1: Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by MESSAGE_NUMBER to the corresponding IF1 register set. 1: Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF1 register set to the message object addressed by MESSAGE_NUMBER.	RW	0

Bits	Field Name	Description	Type	Reset
20	CONTROL	Access control bits 0: Control bits will not be changed 1: Direction = Read: The message control bits will be transferred from the message object addressed by MESSAGE_NUMBER to the IF1 register set. 1: Direction = Write: The message control bits will be transferred from the IF1 registerset to the message object addressed by MESSAGE_NUMBER. If the TXRQST_NEWDAT bit in this register(Bit [18]) is set, the TXRQST/ NEWDAT bits in the DCAN_IF1MCTL will be ignored.	RW	0
19	CLRINTPND	Clear interrupt pending bit 0: IntPnd bit will not be changed 1: Direction = Read: Clears IntPnd bit in the message object. 1: Direction = Write: This bit is ignored. Copying of IntPnd flag from IF1 Registers to message RAM can only be controlled by the CONTROL flag (Bit [20]).	RW	0
18	TXRQST_NEWDAT	Access transmission request bit 0: Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the CONTROL bit. 1: Direction = Read: Clears NewDat bit in the message object. 1: Direction = Write: Sets TxRqst/NewDat in message object. Note: If a CAN transmission is requested by setting TXRQST_NEWDAT in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in DCAN_IF1MCTL. Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the DCAN_IF1MCTL always reflect the status before resetting them.	RW	0
17	DATA_A	Access Data Bytes 0-3 0: Data Bytes 0-3 will not be changed. 1: Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the MESSAGE_NUMBER to the corresponding IF1 registerset. 1: Direction = Write: The data bytes 0-3 will be transferred from the IF1 registerset to the message object addressed by the MESSAGE_NUMBER. Note: The duration of the message transfer is independent of the number of bytes to be transferred.	RW	0
16	DATA_B	Access Data Bytes 4-7 0: Data Bytes 4-7 will not be changed. 1: Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by MESSAGE_NUMBER to the corresponding IF1 registerset. 1: Direction = Write: The data bytes 4-7 will be transferred from the IF1 registerset to the message object addressed by MESSAGE_NUMBER. Note: The duration of the message transfer is independent of the number of bytes to be transferred.	RW	0

Bits	Field Name	Description	Type	Reset
15	BUSY	Busy flag 0: No transfer between IF1 register set and message RAM is in progress. 1: Transfer between IF1 register set and message RAM is in progress. This bit is set to one after the message number has been written to bits [7:0] MESSAGE_NUMBER. IF1 register set will be write protected. The bit is cleared after read/write action has been finished.	RW	0
14	DMAACTIVE	Activation of DMA feature for subsequent internal IF1 update 0: DMA request line is independent of IF1 activities. 1: DMA is requested after completed transfer between IF1 register set and message RAM. The DMA request remains active until the first read or write to one of the IF1 registers; an exception is a write to MESSAGE_NUMBER when DMAACTIVE is one. Note: Due to the auto reset feature of the DMAACTIVE bit, this bit has to be set for each subsequent DMA cycle separately.	RW	0
13:8	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
7:0	MESSAGE_NUMBER	Number of message object in message RAM which is used for data transfer 0x00: Invalid message number 0x01-0x80: Valid message numbers 0x81-0xFF: Invalid message numbers	RW	0x1

RESERVED																NEWDAT	MSGLST	INTPND	UMASK	TXIE	RXIE	RMTEN	TXRQST	EOB	RESERVED			DLC			

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0000

Bits	Field Name	Description	Type	Reset
15	NEWDAT	New data 0: No new data has been written into the data portion of this message object by the message handler since the last time when this flag was cleared by the software. 1: The message handler or the software has written new data into the data portion of this message object.	RW	0
14	MSGLST	Message lost (only valid for message objects with direction = receive) 0: No message lost since the last time when this bit was reset by the software. 1: The message handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten.	RW	0
13	INTPND	Interrupt pending 0: This message object is not the source of an interrupt. 1: This message object is the source of an interrupt. The Interrupt Identifier in DCAN_INT will point to this message object if there is no other interrupt source with higher priority.	RW	0
12	UMASK	Use acceptance mask 0: Mask ignored 1: Use mask (Msk[28:0], MXtd, and MDir) for acceptance filtering If the UMASK bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.	RW	0
11	TXIE	Transmit interrupt enable 0: IntPnd will not be triggered after the successful transmission of a frame. 1: IntPnd will be triggered after the successful transmission of a frame.	RW	0
10	RXIE	Receive interrupt enable 0: IntPnd will not be triggered after the successful reception of a frame. 1: IntPnd will be triggered after the successful reception of a frame.	RW	0
9	RMTEN	Remote enable 0: At the reception of a remote frame, TxRqst is not changed. 1: At the reception of a remote frame, TxRqst is set.	RW	0
8	TXRQST	Transmit request 0: This message object is not waiting for a transmission. 1: The transmission of this message object is requested and is not yet done.	RW	0
7	EOB	End of Block 0: The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block. 1: The message object is a single message object or the last message object in a FIFO Buffer Block. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to 1.	RW	0
6:4	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0

Bits	Field Name	Description	Type	Reset
3:0	DLC	Data length code 0-8: Data frame has 0-8 data bytes. 9-15 Data frame has 8 data bytes. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.	RW	0x0

Description

IF2 Command Register
The IF2 Command Register (DCAN_IF2CMD) configure and initiate the transfer between the IF2 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.
While BUSY bit is one, IF1/IF2 register sets are write protected.
For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode.
If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.

Type RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								WR_RD	MASK	ARB	CONTROL	CLRINTPND	TXRQST_NEWDAT	DATA_A	DATA_B	BUSY	DMAACTIVE	RESERVED						MESSAGE_NUMBER							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
23	WR_RD	Write/Read 0: Direction = Read: Transfer direction is from the message object addressed by MESSAGE_NUMBER to the IF2 register set. 1: Direction = Write: Transfer direction is from the IF2 register set to the message object addressed by MESSAGE_NUMBER.	RW	0

Bits	Field Name	Description	Type	Reset
22	MASK	Access mask bits 0: Mask bits will not be changed 1: Direction = Read: The mask bits (identifier mask + MDir + MXtd) will be transferred from the message object addressed by MESSAGE_NUMBER to the IF2 register set. 1: Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF2 register set to the message object addressed by MESSAGE_NUMBER.	RW	0
21	ARB	Access arbitration bits 0: Arbitration bits will not be changed 1: Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by MESSAGE_NUMBER to the corresponding IF2 register set. 1: Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF2 register set to the message object addressed by MESSAGE_NUMBER.	RW	0
20	CONTROL	Access control bits 0: Control bits will not be changed 1: Direction = Read: The message control bits will be transferred from the message object addressed by MESSAGE_NUMBER to the IF2 register set. 1: Direction = Write: The message control bits will be transferred from the IF2 registerset to the message object addressed by MESSAGE_NUMBER. If the TXRQST_NEWDAT bit in this register(Bit [18]) is set, the TXRQST/ NEWDAT bits in the DCAN_IF1MCTL/ DCAN_IF2MCTL will be ignored.	RW	0
19	CLRINTPND	Clear interrupt pending bit 0: IntPnd bit will not be changed 1: Direction = Read: Clears IntPnd bit in the message object. 1: Direction = Write: This bit is ignored. Copying of IntPnd flag from IF2 Registers to message RAM can only be controlled by the CONTROL flag (Bit [20]).	RW	0
18	TXRQST_NEWDAT	Access transmission request bit 0: Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the CONTROL bit. 1: Direction = Read: Clears NewDat bit in the message object. 1: Direction = Write: Sets TxRqst/NewDat in message object. Note: If a CAN transmission is requested by setting TXRQST_NEWDAT in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in DCAN_IF1MCTL/DCAN_IF2MCTL. Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the DCAN_IF1MCTL/DCAN_IF2MCTL always reflect the status before resetting them.	RW	0

Bits	Field Name	Description	Type	Reset
17	DATA_A	Access Data Bytes 0-3 0: Data Bytes 0-3 will not be changed. 1: Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the MESSAGE_NUMBER to the corresponding IF2 registerset. 1: Direction = Write: The data bytes 0-3 will be transferred from the IF2 registerset to the message object addressed by the MESSAGE_NUMBER. Note: The duration of the message transfer is independent of the number of bytes to be transferred.	RW	0
16	DATA_B	Access Data Bytes 4-7 0: Data Bytes 4-7 will not be changed. 1: Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by MESSAGE_NUMBER to the corresponding IF2 registerset. 1: Direction = Write: The data bytes 4-7 will be transferred from the IF2 registerset to the message object addressed by MESSAGE_NUMBER. Note: The duration of the message transfer is independent of the number of bytes to be transferred.	RW	0
15	BUSY	Busy flag 0: No transfer between IF2 register set and message RAM is in progress. 1: Transfer between IF2 register set and message RAM is in progress. This bit is set to one after the message number has been written to bits [7:0] MESSAGE_NUMBER. IF2 register set will be write protected. The bit is cleared after read/write action has been finished.	RW	0
14	DMAACTIVE	Activation of DMA feature for subsequent internal IF2 update 0: DMA request line is independent of IF2 activities. 1: DMA is requested after completed transfer between IF2 register set and message RAM. The DMA request remains active until the first read or write to one of the IF2 registers; an exception is a write to MESSAGE_NUMBER when DMAACTIVE is one. Note: Due to the auto reset feature of the DMAACTIVE bit, this bit has to be set for each subsequent DMA cycle separately.	RW	0
13:8	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
7:0	MESSAGE_NUMBER	Number of message object in message RAM which is used for data transfer 0x00: Invalid message number 0x01-0x80: Valid message numbers 0x81-0xFF: Invalid message numbers	RW	0x1

Table 24-820. DCAN_IF3OBS (continued)

Description IF3 Observation Register

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software (Additional information can be found in Section 24.10.4.11.1 *Structure of Message Objects*). The observation flags (Bits [4:0]) are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data. Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses. A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).

24.11 Gigabit Ethernet Switch (GMAC_SW)

This chapter describes the three-port gigabit switch ethernet subsystem in the device.

24.11.1 GMAC_SW Overview

The three-port gigabit ethernet switch subsystem (GMAC_SW) provides ethernet packet communication and can be configured as an ethernet switch. It provides the gigabit media independent interface (G/MII) in MII mode, reduced gigabit media independent interface (RGMII), reduced media independent interface (RMII), and the management data input output (MDIO) for physical layer device (PHY) management.

Figure 24-192 shows the GMAC_SW subsystem overview.

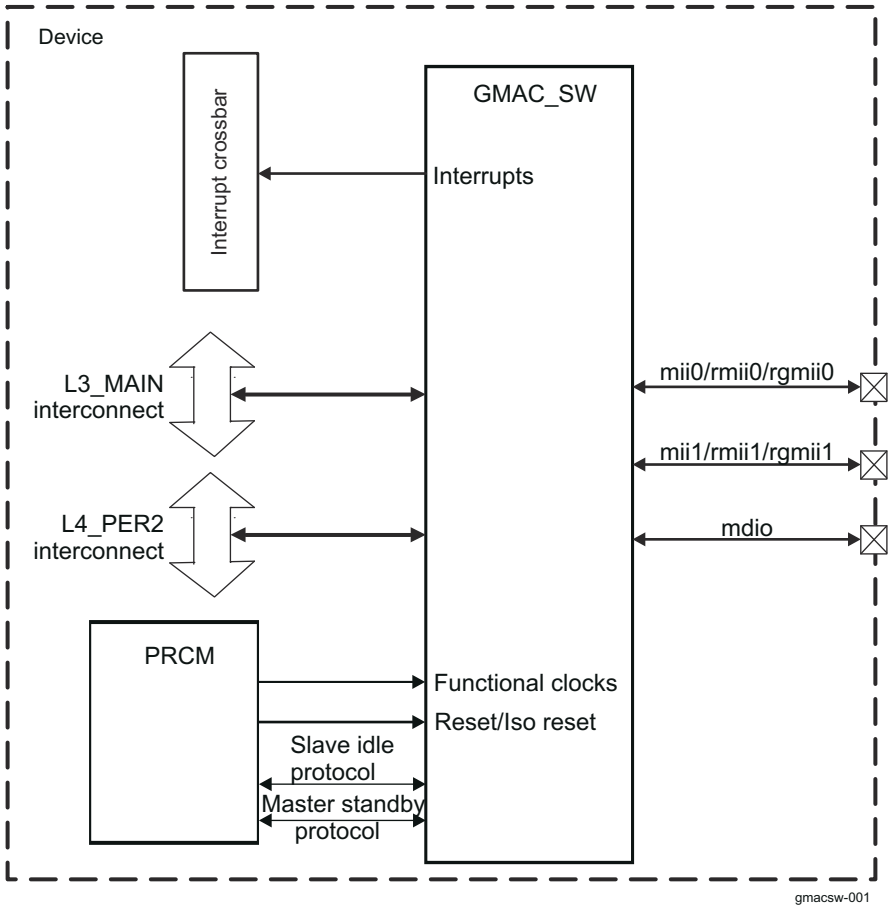

Figure 24-192. GMAC_SW Overview

24.11.1.1 Features

The GMAC_SW subsystem provides the following features:

- Two Ethernet ports (port 1 and port 2) with selectable RGMII, RMII, and G/MII (in MII mode only) interfaces plus internal Communications Port Programming Interface (CPPI 3.1) on port 0
- Synchronous 10/100/1000 Mbit operation
- Wire rate switching (802.1d)
- Non-blocking switch fabric
- Flexible logical FIFO-based packet buffer structure
- Four priority level Quality Of Service (QOS) support (802.1p)
- CPPI 3.1 compliant DMA controllers
- Support for Audio/Video Bridging (P802.1Qav/D6.0)

- Support for IEEE 1588 Clock Synchronization (2008 Annex D and Annex F)
  - Timing FIFO and time stamping logic embedded in the subsystem
- Device Level Ring (DLR) Support
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control Support (802.3x)
- Address Lookup Engine (ALE)
  - 1024 total address entries plus VLANs
  - Wire rate lookup
  - Host controlled time-based aging
  - Multiple spanning tree support (spanning tree per VLAN)
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive-based or destination-based multicast and broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
  - Remapping of priority level of VLAN or ports
- VLAN support
  - 802.1Q compliant
    - Auto add port VLAN for untagged frames on ingress
    - Auto VLAN removal on egress and auto pad to minimum frame size
- Ethernet Statistics:
  - EtherStats and 802.3Stats Remote network Monitoring (RMON) statistics gathering (shared)
  - Programmable statistics interrupt mask when a statistic is above one half its 32-bit value
- Flow Control Support (802.3x)
- Digital loopback and FIFO loopback modes supported
- Maximum frame size 2016 bytes (2020 with VLAN)
- 8k (2048 × 32) internal CPPI buffer descriptor memory
- Management Data Input/Output (MDIO) module for PHY Management
- Programmable interrupt control with selected interrupt pacing
- Emulation support
- Programmable Transmit Inter Packet Gap (IPG)
- Reset isolation (switch function remains active even in case of all device resets except for POR pin reset and ICEPICK cold reset)
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps.
- IEEE 802.3 gigabit Ethernet conformant

Note

G/MII interface is functional in MII mode only.

24.11.1.2

Terminology:

AVB	Audio Video Bridging
AVBTP	Audio Video Bridging Trasport Protocol
BMCA	Best Master Clock Algorithm
CFI	Canonical Format Indicator
CPPI	Communications Port Programming Interface
DLR	Device Level Ring
DSCP	Differentiated Services Code Point
EEE	Energy Efficient Ethernet
EMAC	Ethernet Media Access Control
EOP	End of Packet
EOQ	End of Queue
IPG	Inter-Packet Gap
LPI	Low Power Indicator
MDIO	Management Data Input/Output
MOF	Middle of Frame
PTP	Precision Time Protocol
RMON	Remote Monitoring
RTCP	RTP Control Protocol
RTP	Real-time Transport Protocol
SCR	Switched Central Resource
SRP	Stream Reservation Protocol
TOS	Type of Service
VLAN	Virtual Local Area Network

24.11.2 GMAC_SW Environment

24.11.2.1 G/MII Interface

G/MII Interface can operate only in MII Mode.

- In MII Mode (100/10 Mbps): GMAC_SW operates in full-duplex and half-duplex.

The pin connections of the G/MII Interface is shown in Figure 24-193. The detailed description of the signals are listed in the following tables.

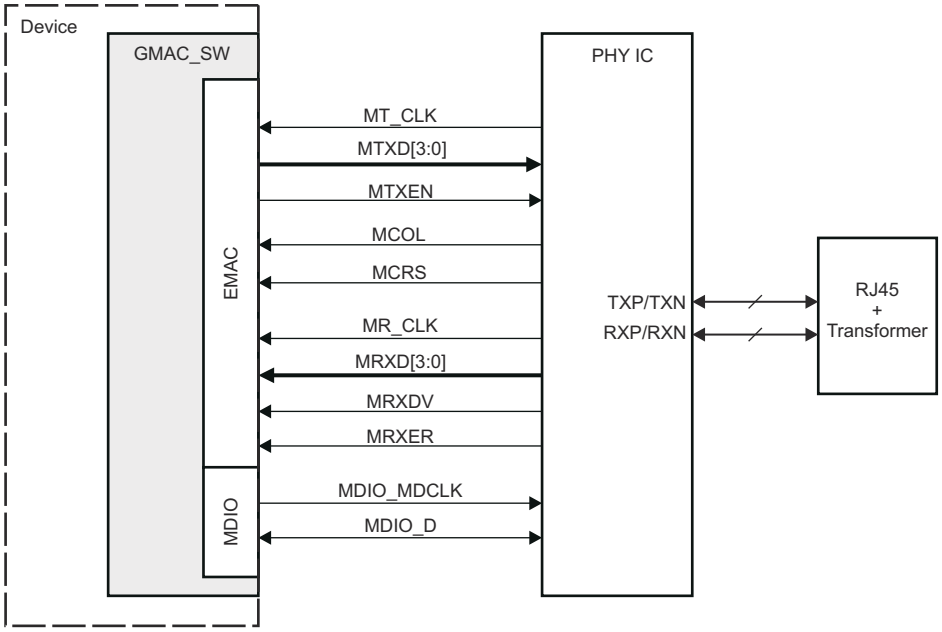

Figure 24-193. MII Interface Typical Application

Table 24-844. MII I/O Description

Signal	Device Pin(s)	I/O[1]	Description
MT_CLK	mii0_txclk mii1_txclk	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MTXD and MTXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MTXD[3:0]	mii0_txd[3:0] mii1_txd[3:0]	O	The transmit data pins are a collection of 4 data signals MTXD[3:0] comprising 4 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by MT_CLK and valid only when MTXEN is asserted.
MTXEN	mii0_txen mii1_txen	O	The transmit enable signal indicates that the MTXD pins are generating 4bit data for use by the PHY. It is driven synchronously by MT_CLK.
MTXER	mii0_txer mii1_txer	O	Transmit data error. Used only for EEE to request PHY for low power transition.
MCOL	mii0_col mii1_col	I	In half-duplex operation, the MCOL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used.
MCRS	mii0_crs mii1_crs	I	In half-duplex operation, the MCRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is de-asserted when both transmit and receive are idle. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCRS pin should be held low.

Table 24-844. MII I/O Description (continued)

Signal	Device Pin(s)	I/O(1)	Description
MR_CLK	mii0_rxclk mii1_rxclk	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MRXD	mii0_rxd[0:3] mii1_rxd[0:3]	I	The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRXD0 is the least-significant bit (LSB).The signals are synchronized by MR_CLK and valid only when MRXDV is asserted.
MRXDV	mii0_rxdv mii1_rxdv	I	The receive data valid signal indicates that the MRXD pins are generating nibble data for use by the GMAC_SW. It is driven synchronously to MR_CLK.
MRXER	mii0_rxer mii1_rxer	I	Receive Data Error input
MDIO_MDCLK	mdio_mclk	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

24.11.2.2 RMII Interface

Figure 24-194 shows a device with integrated GMAC_SW and MDIO interfaced via a RMII connection in a typical system. The individual CPSW and MDIO signals for the RMII interface are summarized in Table 24-845.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

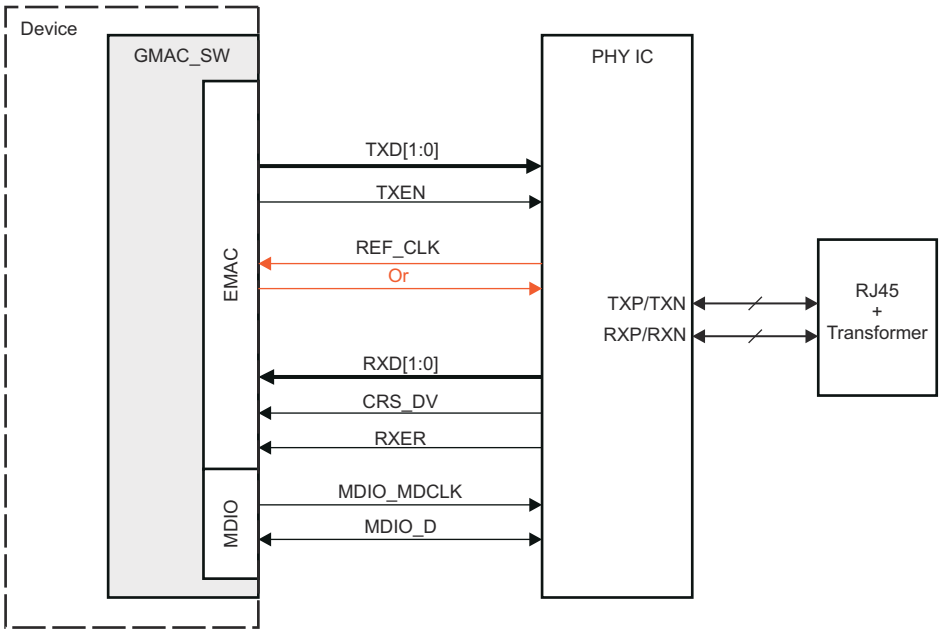

Figure 24-194. RMII Interface Typical Application

Table 24-845. RMII I/O Description

Signal	Device Pin(s)	I/O(1)	Description
TXD[1:0]	rmii0_txd[1:0] rmii1_txd[1:0]	O	Transmit data . The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when TXEN is asserted.

Table 24-845. RMII I/O Description (continued)

Signal	Device Pin(s)	I/O[1]	Description
TXEN	rmii0_txen rmii1_txen	O	Transmit enable. The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK
RMII0_MHZ_50_CLK RMII1_MHZ_50_CLK	RMII_MHZ_50_CLK	I/O	RMII reference clock. The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RXD[1:0]	rmii0_rxd[1:0] rmii1_rxd[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when CRS_DV is asserted and RXER is de-asserted.
CRS_DV	rmii0_crs rmii1_crs	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RXER	rmii0_rxer rmii1_rxer	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MDCLK	mdio_mclk	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

24.11.2.3 RGMII Interface

Figure 24-195 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW and MDIO signals for the RGMII interface are summarized in Table 24-846.

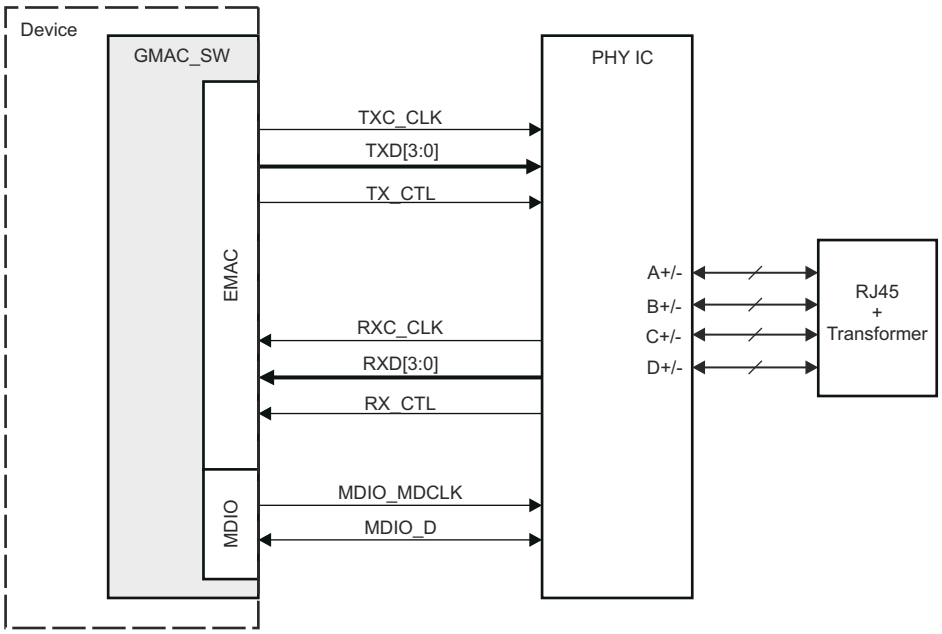

Figure 24-195. RGMII Interface Typical Application

Table 24-846. RGMII I/O Description

Signal	Device Pin(s)	I/O[1]	Description
TXD[3:0]	rgmii0_txd[3:0] rgmii1_txd[3:0]	O	The transmit data pins are a collection of 4 bits of data. TXD0 is the least-significant bit (LSB). The signals are valid only when TX_CTL is asserted.

Table 24-846. RGMII I/O Description (continued)

Signal	Device Pin(s)	I/O[1]	Description
TX_CTL	rgmii0_rxctl rgmii1_rxctl	O	Transmit Control/enable. The transmit enable signal indicates that the TXD pins are generating data for use by the PHY.
TXC_CLK	rgmii0_txc rgmii1_txc	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RXD[3:0]	rgmii0_rxd[3:0] rgmii1_rxd[3:0]	I	The receive data pins are a collection of 4 bits of data. RXD0 is the least-significant bit (LSB). The signals are valid only when RX_CTL is asserted
RX_CTL	rgmii0_rxctl rgmii1_rxctl	I	The receive data valid/control signal indicates that the RXD pins are nibble data for use by the GMAC_SW.
RXC_CLK	rgmii0_rxc rgmii1_rxc	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MDCLK	mdio_mclk	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

Note

The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see *Pad Configuration Registers* in *Control Module*.

24.11.3 GMAC_SW Integration

Figure 24-196 shows the integration of the GMAC_SW module in the device.

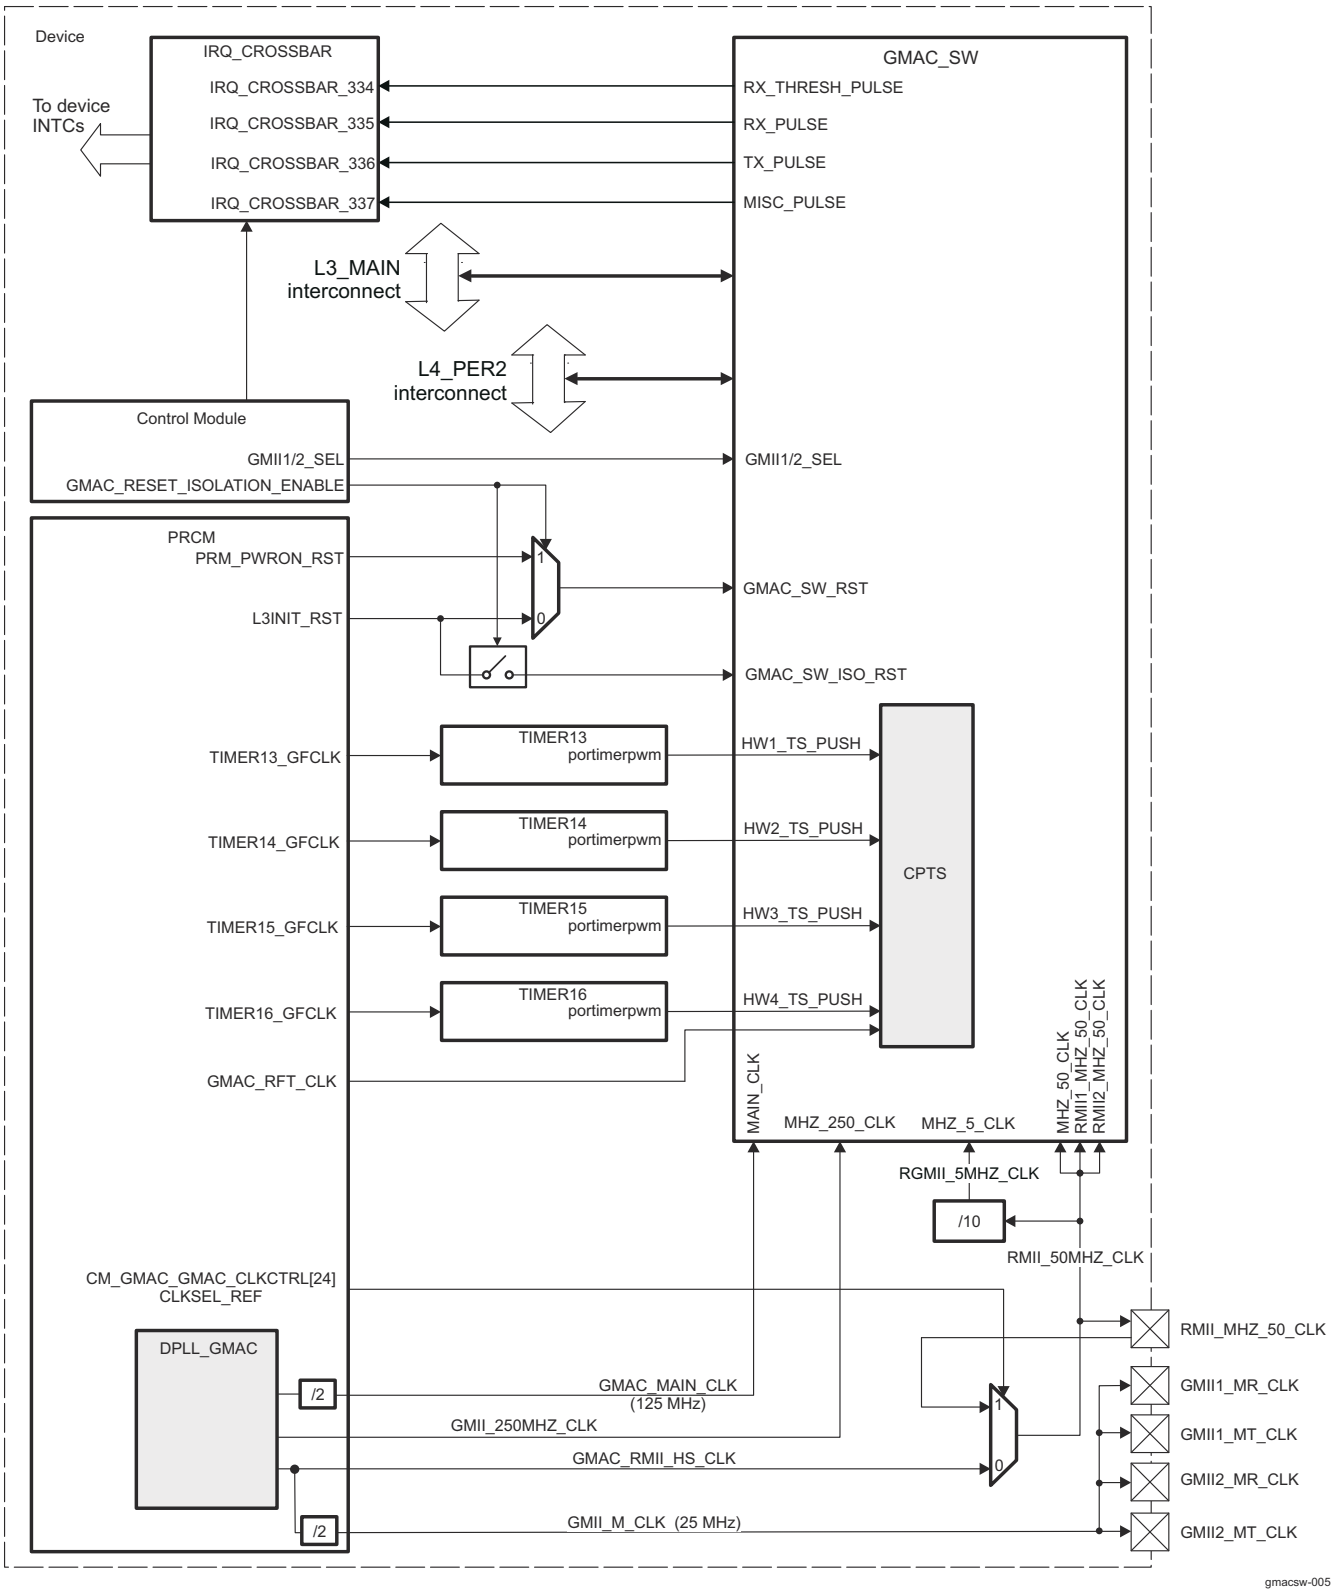

Figure 24-196. GMAC_SW Integration

Note

The device provides the option to receive or output the RMII reference clock (RMII_50MHZ_CLK) from/to external pin as shown in Figure 24-196. See the RMII_CLK_SETTING register bit in the *Control Module Register Manual*, and CLKSEL_REF in *, PRCM Register Manual* to configure the clocking option of RMII.

See *PRCM* for details about power, clock and reset options for GMAC_SW.

Table 24-847 through Table 24-849 summarize the integration of the GMAC_SW module in the device.

Table 24-847. GMAC_SW Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
GMAC_SW	PD_COREAON	Yes	L3_MAIN L4_PER2

Table 24-848. GMAC_SW Clocks and Resets

Clocks

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GMAC_SW	MAIN_CLK	GMAC_MAIN_CLK	PRCM	Interface clock for the GMAC_SW module (125 MHz)
	MHZ_5_CLK	RGMII_5MHZ_CLK	PRCM	5-MHz RGMII clock
	MHZ_50_CLK	RMII_50MHZ_CLK	PRCM or RMII_MHZ_50_CLK pin	50-MHz RGMII clock
	MHZ_250_CLK	GMII_250MHZ_CLK	PRCM	250-MHz RGMII clock
	RMII1_MHZ_50_CLK	RMII_50MHZ_CLK	PRCM or RMII_MHZ_50_CLK pin	50-MHz RMII1 clock
	RMII2_MHZ_50_CLK	RMII_50MHZ_CLK	PRCM or RMII_MHZ_50_CLK pin	50-MHz RMII2 clock
	CPTS_RFT_CLK	GMAC_RFT_CLK	PRCM	IEEE 1588 clock
	GMII1_MR_CLK	GMII_M_CLK	PRCM or the external pin	MII1 receive clock
	GMII1_MT_CLK	GMII_M_CLK	PRCM or the external pin	MII1 transmit clock
	GMII2_MR_CLK	GMII_M_CLK	PRCM or the external pin	MII2 receive clock
	GMII2_MT_CLK	GMII_M_CLK	PRCM or the external pin	MII2 transmit clock

Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GMAC_SW	GMAC_SW_RST	L3INIT_RST/ PRM_PWRON_RST	PRCM	GMAC_SW main reset
	GMAC_SW_ISO_RST	tied off/L3INIT_RST	PRCM	GMAC_SW isolate reset (must be enabled in Control module)

Table 24-849. GMAC_SW Hardware Requests

Interrupt Requests

Module Instance	Source Signal Name	IRQ_CROSSBAR Input	Default Mapping	Description
GMAC_SW	RX_THRESH_PULSE	IRQ_CROSSBAR_334	-	Receive threshold interrupt
	RX_PULSE	IRQ_CROSSBAR_335	-	Receive packet completion interrupt
	TX_PULSE	IRQ_CROSSBAR_336	-	Transmit packet completion interrupt

Table 24-849. GMAC_SW Hardware Requests (continued)

MISC_PULSE	IRQ_CROSSBAR_337	-	Miscellaneous interrupt (SPF2_PEND, SPF1_PEND, EVNT_PEND,STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT)

Note

GMAC_SW has no default IRQ mappings through the IRQ_CROSSBAR. For GMAC_SW, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s). For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For the description of the interrupt source, see Section 24.11.4.5, *Interrupt Functionality*.

24.11.4 GMAC_SW Functional Description

The 3-port switch (GMAC_SW) Ethernet subsystem modules are compliant to the IEEE Std 802.3 Specification.GMAC_SW is shown in Figure 24-197.

24.11.4.1 Functional Block Diagram

The GMAC_SW subsystem consists of:

- CPSW_3G which contains two G/MII interfaces
- Two RGMII interface modules
- Two RMII interface modules
- One MDIO interface module
- One Interrupt Controller module
- One CPPI interface
- Local CPPI memory of size 8 KiB
- Two Static Packet Filters

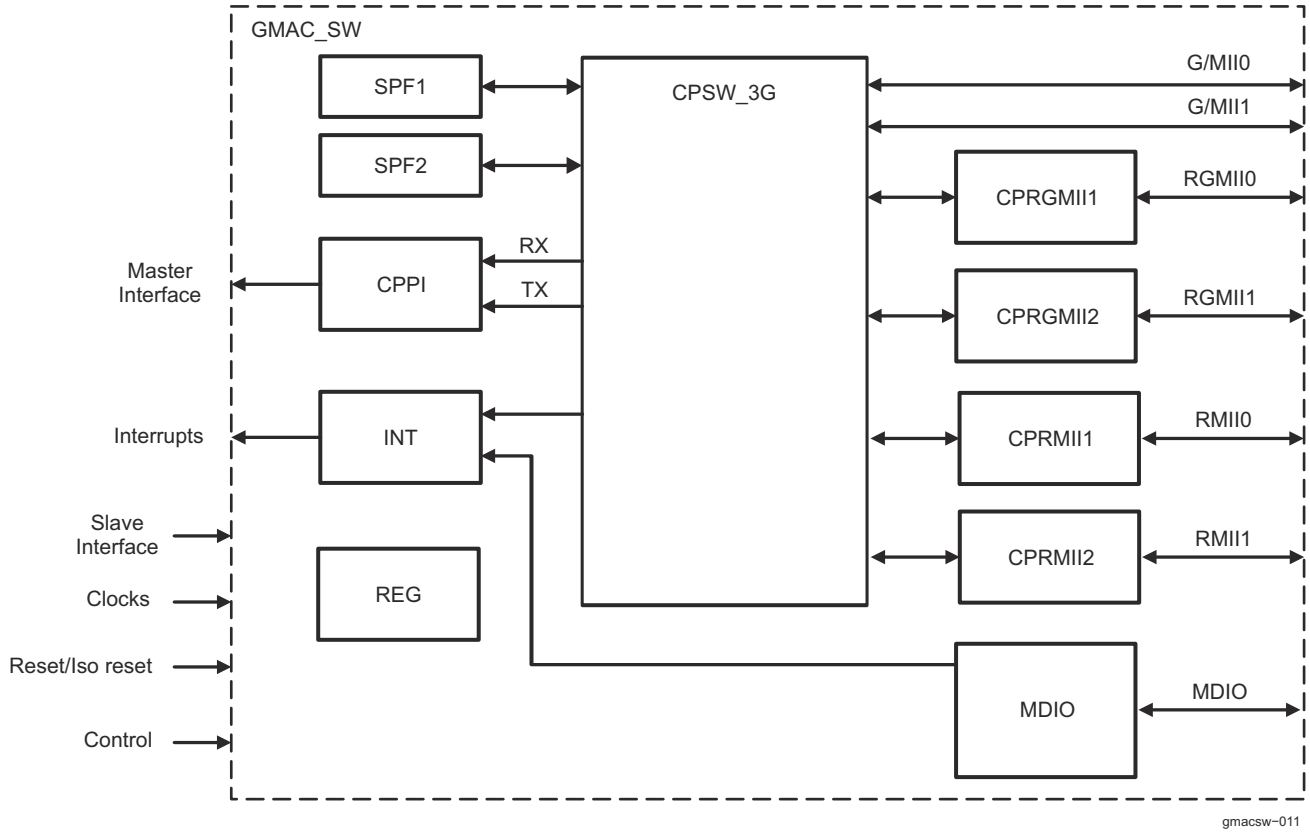

Figure 24-197. GMAC_SW Top Level Block Diagram

24.11.4.2 GMAC_SW Ports

Ethernet Subsystem has three Ports. Port 0 is the Host port (internal to the Subsystem). Ports 1 and 2 are the external ports connected to G/MII, RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the Host Port
- Port1 is referred to the interfaces GMII0/RGMII0/RMII0
- Port2 is referred to the interfaces GMII1/RGMII1/RMII1

24.11.4.2.1 Interface Mode Selection

The 3-port switch (GMAC_SW) Ethernet Subsystem has two 10/100/1000 Ethernet ports with selectable MII, RMII, and RGMII interfaces.

The interface mode is selected by configuring the MII mode selection register bitfields (GMII1_SEL and GMII2_SEL) in the control module. See *Control Module Register Manual* for details.

See device data manual for configuring the pin mux mode as per the interface selected.

24.11.4.3 Clocking

24.11.4.3.1 Subsystem Clocking

GMAC_SW clocking summary is shown in Section 24.11.3, *GMAC_SW Integration*.

24.11.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

24.11.4.3.2.1 G/MII Interface Clocking

GMII1_MR_CLK, GMII1_MT_CLK, GMII2_MR_CLK, GMII2_MT_CLK frequencies are fixed by the 802.3 specification.

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

24.11.4.3.2.2 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

24.11.4.3.2.3 RMII Interface Clocking

RMII interface clock RMII_50MHZ_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

See the RMII_CLK_SETTING bit in the device Control Module and CLKSEL_REF in PRCM to configure the clocking option of RMII (external pin or PRCM).

24.11.4.3.2.4 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (MAIN_CLK) clock, running at 125 MHz.The application software or driver must control the divide-down value.

See the MDIO_CONTROL register for configuring the Clock Divider (CLKDIV) value.

24.11.4.4 Software IDLE

The submodule software idle register bits enable CPSW_3G operation to be completely or partially suspended by software control. There are three CPSW_3G submodules that contain software idle register bits (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW_3G module enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW_3G is in the idle state when all three submodules are in the idle state. The CPSW_SOFT_IDLE[0] SOFT_IDLE bit may be set if desired after the submodules are in the idle state. The CPSW SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

24.11.4.5 Interrupt Functionality

GMAC_SW Ethernet Subsystem has four Interrupt outputs:

- RX_PULSE - Receive Interrupt
- TX_PULSE - Transmit Interrupt
- RX_THRESH_PULSE - Receive Threshold Interrupt
- MISC_PULSE - Miscellaneous Interrupt.

24.11.4.5.1 Receive Packet Completion Pulse Interrupt (RX_PULSE)

The RX_PULSE interrupt is a pulse interrupt selected from the GMAC_SW RX_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX_PEND[7:0]).

The following steps will enable the receive packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the CPDMA_RX_INTMASK_SET register.
2. The receive completion interrupt(s) to be routed to RX_PULSE is selected by setting one or more bits in the receive interrupt enable register (WR_C0_RX_EN) . The masked interrupt status can be read in the address location of RX_STAT bit in the WR_C0_RX_STAT register.

When the GMAC_SW completes a packet reception, the subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the software processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RX *n*_CP) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

1. Read the WR_C0_RX_STAT[7:0] RX_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process received packets for the interrupting channel(s).
3. Write the GMAC_SW completion pointer(s) (RX *n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the GMAC_SW has received more packets than the software has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the GMAC_SW is expecting is found by reading the receive channel *n* completion pointer register (RX *n*_CP).
4. Write the value 1h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the CPDMA_RX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the WR_C0_RX_EN register.

The software could still poll for the CPDMA_RX_INTSTAT_RAW and CPDMA_RX_INTSTAT_MASKED registers if the corresponding interrupts are enabled.

24.11.4.5.2 Transmit Packet Completion Pulse Interrupt (TX_PULSE)

The TX_PULSE interrupt is a pulse interrupt selected from the GMAC_SW TX_PEND[7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX_PEND[7:0]).

To enable the transmit packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the CPDMA_TX_INTMASK_SET register.
2. The transmit completion interrupt(s) to be routed to TX_PULSE is selected by setting one or more bits in the transmit interrupt enable register WR_C0_TX_EN .The masked interrupt status can be read in the address location of TX_STAT bit in the WR_C0_TX_STAT register.

When the GMAC_SW completes the transmission of a packet, the GMAC_SW subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon reception of an interrupt, software should perform the following:

1. Read the TX_STAT bit address location to determine which channel(s) caused the interrupt
2. Process received packets for the interrupting channel(s).
3. Write the GMAC_SW completion pointer(s) (TX *n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the GMAC_SW (address of last buffer descriptor used by the GMAC_SW). If the two values are not equal (which means that the GMAC_SW has transmitted more packets than the software has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the GMAC_SW is expecting is found by reading the transmit channel *n*completion pointer register (TX *n*_CP).
4. Write the 2h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the CPDMA_TX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the WR_C0_TX_EN register.

The software could still poll for the CPDMA_TX_INTSTAT_RAW and CPDMA_TX_INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

24.11.4.5.3 Receive Threshold Pulse Interrupt (RX_THRESH_PULSE)

The RX_THRESH_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW_3G RX_THRESH_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX_THRESH_PEND[7:0]).

To enable the receive threshold pulse Interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the CPDMA_RX_INTMASK_SET register.
2. The receive threshold interrupt(s) to be routed to RX_THRESH_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register WR_C0_RX_THRESH_EN. The masked interrupt status can be read in the address location of RX_THRESH_STAT bit in the WR_C0_RX_THRESH_STAT register.

The RX_THRESH_PULSE is asserted when enabled when the channel's associated free buffer count RX *n*_FREEBUFFER is less than or equal to the corresponding RX *n*_PENDTHRESH register.

Upon reception of an interrupt, software should perform the following:

1. Read the RX_THRESH_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process the received packets in order to add more buffers to any channel that is below the threshold value.
3. Write the CPSW_3G completion pointer(s).
4. Write the value 0h to the CPDMA_EOI_VECTOR register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

1. The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the CPDMA_RX_INTMASK_CLEAR register.
2. The receive threshold pulse interrupt could be disabled by clearing to 0 the corresponding bits in the WR_C0_RX_THRESH_EN register.

The software could still poll for the CPDMA_RX_INTSTAT_RAW and CPDMA_RX_INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

24.11.4.5.4 Miscellaneous Pulse Interrupt (MISC_PULSE)

The MISC_PULSE interrupt is an immediate pulse interrupt selected from the miscellaneous interrupts (SPF2_PEND, SPF1_PEND, EVNT_PEND,STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT).

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register (WR_C0_MISC_EN).

Upon reception of an interrupt, software should perform the following:

- Read the MISC_STAT bit address location to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the CPDMA_EOI_VECTOR register.

Note

The WR_C0_MISC_STAT register's MDIO_LINKINT and MDIO_USERINT bitfields represent the Port0/Phy0 status. MDIO_LINKINT[1] and MDIO_USERINT[1] are not provided in WR_C0_MISC_STAT register. As such, MDIO Link and User interrupts can only be generated for Port0. For Port1, software must poll the status, visible in the MDIO_LINKINTMASKED or MDIO_USERINTMASKED registers.

24.11.4.5.4.1 EVNT_PEND(CPTS_PEND) Interrupt

See Section 24.11.4.10, *Common Platform Time Sync (CPTS)* for more details on this interrupt.

24.11.4.5.4.2 Statistics Interrupt

The statistics level interrupt (STAT_PEND) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement all statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The raw and masked statistics interrupt status may be read by reading the CPDMA_TX_INTSTAT_RAW and CPDMA_TX_INTSTAT_MASKED registers, respectively.

The Statistics interrupt is enabled by setting to 1 the STAT_INT_MASK bit in the CPDMA_DMA_INTMASK_SET register

24.11.4.5.4.3 Host Error interrupt

The host error interrupt (HOST_PEND) will be asserted, if enabled when a host error is detected during transmit or receive CPDMA transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked host interrupt status can be read by reading the CPDMA_DMA_INTSTAT_RAW and CPDMA_DMA_INTSTAT_MASKED registers, respectively.

The transmit host error conditions are:

- SOP error
- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP cleared to 0
- buffer pointer cleared to 0

- buffer length cleared to 0
- packet length error

The receive host error conditions are:

- OWNERSHIP bit not set in input buffer
- Zero buffer pointer
- Zero buffer Length on non-SOP descriptor
- SOP buffer length not greater than offset

The HOST_PEND is enabled by setting to 1 the HOST_ERR_INTMASK in the CPDMA_DMA_INTMASK_SET register. The host error interrupt is disabled by setting to 1 the appropriate bit in the CPDMA_DMA_INTMASK_CLEAR register.

24.11.4.5.4.4 MDIO Interrupts

MDIO_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR_MON field of the MDIO_USERPHYSEL*n* register and the corresponding LINKINT_ENABLE bit is set. The MDIO_LINKINT event is also captured in the MDIO_LINKINTMASKED register. When the GO bit in the MDIO_USERACCESS*n* register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the MDIO_USERINTMASKSET register is set, the MDIO_USERINT signal is asserted. The MDIO_USERINT event is also captured in the MDIO_USERINTMASKED register.

24.11.4.5.5 Interrupt Pacing

RX_PULSE and TX_PULSE interrupts can be paced. The RX_THRESH_PULSE and MISC_PULSE interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (for example, 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the processor cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the processor instruction cache.

Each RX_PULSE and TX_PULSE interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1 ms interval of time. At the end of each 1 ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1 ms interval is derived from a 4 µs pulse that is created from a prescale counter whose value is set in the INT_PRESCALE field in the WR_INT_CONTROL register. The INT_PRESCALE value should be written with the number of ICLK periods in 4 µs. The pacing timer determines the interval during which interrupts are blocked and decrements every 4 µs. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1 ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
    pace_timer = 255;
  else if (intr_count > 1.5*intr_max)
    pace_timer = last_pace_timer*2 + 1;
  else if (intr_count > 1.0*intr_max)
    pace_timer = last_pace_timer + 1;
  else if (intr_count > 0.5*intr_max)
    pace_timer = last_pace_timer - 1;
  else if (intr_count != 0)
    pace_timer = last_pace_timer/2;
else
pace_timer = 0;
```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be "paced" at the rate specified in the interrupt maximum register. The WR_C0_RX_IMAX/ WR_C0_TX_IMAX register should be written with a value between 2 and 63 inclusive, indicating the target number of interrupts per millisecond.

24.11.4.6 Reset Isolation

Reset isolation for the GMAC_SW allows the switch function to remain active in during all device resets except for POR pin reset and ICEPICK COLD reset. Packet traffic to/from the GMAC_SW host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is undergoing a device reset. Pin mux configuration for ethernet related I/O and reference clocks needed by the GMAC_SW to be active is controlled by a protected control module bit.

24.11.4.6.1 Reset Isolation Functional Description

The device has two modes of operation concerning the reset of the GMAC_SW Ethernet switch. The mode is controlled by the GMAC_RESET_ISOLATION_ENABLE bit in the Control Module. This bit defaults to 0. Any modification of this bit first requires writing an unlock pattern to lock register in device control module. After modification, the bit should again be locked by writing appropriate value to the lock register. Writes to the GMAC_RESET_ISOLATION_ENABLE bit and to the lock register must all be supervisor mode writes.

GMAC_RESET_ISOLATION_ENABLE = 0 (disabled)

1. This is the default state of the bit after control module reset.
2. Upon any device level resets, the entire GMAC_SW, DPLL_GMAC, L3/L4 interconnect, control module (including all pin mux control and the GMAC_RESET_ISOLATION_ENABLE bit itself) are immediately reset.

GMAC_RESET_ISOLATION_ENABLE = 1 (enabled)

1. This mode is selected when the GMAC_RESET_ISOLATION_ENABLE bit is set to 1 by software.
2. Upon any device reset source other than porz pin or ICEPICK cold (that is, this includes software global cold, any watchdog reset, warm resetn pin, ICEPICK warm, software global warm or security violation), the following is true:
   a. The CPSW_3GSS_R is put into "isolate" mode and non-switch related portions of the subsystem are reset.
   b. The 50 MHz and 125 MHz reference clocks to the GMAC_SW Ethernet Subsystem remain active throughout the entire reset condition.
   c. The control for pin multiplexing for all of the signals maintain their current configuration throughout the entire reset condition.
   d. The reset-isolated logic inside GMAC_SW Ethernet Subsystem maintains the switch functionality
3. Upon any cold reset sources, the entire GMAC_SW Ethernet Subsystem, DPLL_GMAC, control module (including all pin mux control and the GMAC_RESET_ISOLATION_ENABLE bit itself) are reset.

For more details on the register configuration, see the Control Module CTRL_CORE_CONTROL_IO_2 register in *Control Module Register Manual*.

24.11.4.7 Software Reset

The CPSW_3G software reset register (CPSW_SOFT_RESET), CPSW_3GSS software reset register (WR_SOFT_RESET) and the three submodule software reset registers enable the CPSW_3GSS to be reset by software.

There are three CPSW_3G submodules that contain software reset registers (CPGMAC_SL1, CPGMAC_SL2 (SL_SOFT_RESET), and CPDMA (CPDMA_SOFT_RESET)). Each of the three submodules may be individually commanded to be reset by software.

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW_3G software reset register bit may be written to complete the CPSW_3G module software reset operation. The CPSW_3G software reset bit controls the reset of the FIFO's,

the statistics submodule, and the address lookup engine (ALE). The CPSW_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

The CPSW_3GSS software reset bit controls the reset of the INT, REGS, and CPPI. The CPSW_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

24.11.4.8 CPSW_3G

The CPSW_3G G/MII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW_3G contains two CPGMAC_SL interfaces (ports 1 and 2), one CPPI interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA. A top-level block diagram of the CPSW_3G is shown in Figure 24-198.

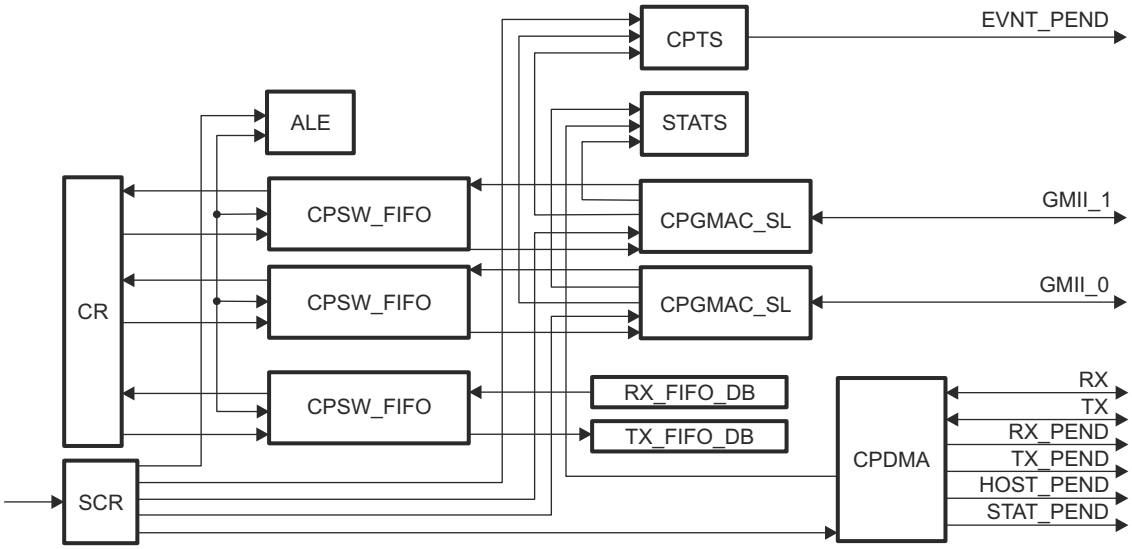

Figure 24-198. CPSW_3G Block Diagram

24.11.4.8.1 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI compliant packet DMA transfer controller. The CPPI interface is port 0.

24.11.4.8.1.1 Functional Operation

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI protocol. For a detailed description of buffer descriptors, see Section 24.11.4.11, *CPPI Buffer Descriptors*.

24.11.4.8.1.2 Receive DMA Interface

The receive DMA is an eight channel CPPI compliant interface. Each channel has a single queue for frame reception.

24.11.4.8.1.2.1 Receive DMA Host Configuration

To configure the RX DMA for operation the software must perform the following:

1. Initialize the receive addresses.
2. Initialize the RX_HDP registers to 0.

3. Enable the desired receive interrupts in the CPDMA_RX_INTMASK_SET register.
4. Write the CPDMA_RX_BUFFER_OFFSET register value.
5. Setup the receive channel(s) buffer descriptors in host memory as required by CPPI
6. Enable the RX DMA controller by setting the RX_EN bit in the CPDMA_RX_CONTROL register.

24.11.4.8.1.2.2 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the CPDMA_RX_TEARDOWN register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown_complete bit will be set in the next buffer descriptor in the chain (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- A receive interrupt for the channel will be issued to the host.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh Acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by a set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

24.11.4.8.1.3 Transmit DMA Interface

The tranmsit DMA is an eight channel CPPI compliant interface. Priority between the eight queues may be either fixed or round robin as selected by the TX_PTYPE bit in the CPDMA_DMACONTROL register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7.

24.11.4.8.1.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the software must do the following:

1. Initialize the TX_HDP registers to 0.
2. Enable the desired transmit interrupts in the CPDMA_TX_INTMASK_SET register.
3. Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI.
4. Configure and enable the transmit operation as desired in the CPDMA_TX_CONTROL register.
5. Write the appropriate TX_HDP registers with the appropriate values to start transmit operations.

24.11.4.8.1.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the CPDMA_TX_TEARDOWN register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- An interrupt will be issued to inform the host of the channel teardown.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

24.11.4.8.1.4 Transmit Rate Limiting

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the TX_RLIM bit associated with that channel is set in the CPDMA_DMACONTROL register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then TX_RLIM should be set to 11000000b with the MSB corresponding to channel 7. When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (TX_PRI(0..7)_RATE) when the channel is rate-limiting. Each priority has a send count (PRI(0..7)_SEND_CNT) and an idle count (PRI(0..7)_IDLE_CNT). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the equation:

Priority Transfer rate in Mbit/s = ((PRI_IDLE_CNT/(PRI_IDLE_CNT + PRI_SEND_CNT)) × frequency × 32

Where *frequency* is the CPDMA interface clock (MAIN_CLK) frequency.

24.11.4.8.1.5 Command IDLE

The CMD_IDLE bit in the CPDMA_DMACONTROL register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

24.11.4.8.2 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should the forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE_ALE bit in the ALE_CONTROL register is set. All packets are dropped when the ENABLE_ALE bit is cleared to 0.

In normal operation, the CPGMAC_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the SL_MACCONTROL configuration bit(s) RX_CEF_EN, RX_CSF_EN, or RX_CMF_EN are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

The ALE may be configured to operate in bypass mode by setting the ALE_BYPASS bit in the ALE_CONTROL register. When in bypass mode, all CPGMAC_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate RX DMA channels by configuring the P0_CPDMA_RX_CH_MAP register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the ENABLE_OUI_DENY bit in the ALE_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

24.11.4.8.2.1 Address Table Entry

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 24-850. Learned Address Control Bits

Bit(s)	Value
unicast_type	11
Block	0
Secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40.**

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40.**

24.11.4.8.2.1.1 Free Table Entry

Table 24-851. Free (Unused) Address Table Entry Bit Values

71:62	61:60	59:0
Reserved	ENTRY_TYPE(00)	Reserved

24.11.4.8.2.1.2 Multicast Address Table Entry

Table 24-852. Multicast Address Table Entry Bit Values

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE(01)	Reserved	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

24.11.4.8.2.1.3 VLAN/Multicast Address Table Entry

Table 24-853. VLAN/Multicast Address Table Entry Bit Values

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE(11)	VLAN_ID	MULTICAST_ADDRESS

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASk has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

24.11.4.8.2.1.4 Unicast Address Table Entry

Table 24-854. Unicast Address Table Entry Bit Values

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE(01)	Reserved	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure

must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/ Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

24.11.4.8.2.1.5 OUI Unicast Address Table Entry

Table 24-855. OUI Unicast Address Table Entry Bit Values

71:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE(10)	ENTRY_TYPE(01)	Reserved	UNICAST_OUI	Reserved

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

24.11.4.8.2.1.6 VLAN/Unicast Address Table Entry

Table 24-856. Unicast Address Table Entry Bit Values

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE(11)	VLAN_ID	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast

forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/ Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

24.11.4.8.2.1.7 VLAN Table Entry

Table 24-857. VLAN Table Entry

71:62	61:60	59:48	47:27	26:24	23:19	18:16	15:11	10:8	7:3	2:0
Reserved	ENTRY_TYPE(10)	VLAN_ID	Reserved	FORCE_UNTAGGED_EGRESS	Reserved	REG_MCAST_FLOOD_MASK	Reserved	UNREG_MCAST_FLOOD_MASK	Reserved	VLAN_MEMBER_LIST

Table Entry Type (ENTRY_TYPE)

10: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

Registered Multicast Flood Mask (REG_MCAST_FLOOD_MASK)

Mask [port 2-1-0] used for multicast when the multicast address is found.

Unregistered Multicast Flood Mask (UNREG_MCAST_FLOOD_MASK)

Mask [port 2-1-0] used for multicast when the multicast address is not found.

VLAN Member List (VLAN_MEMBER_LIST)

This 3-bit field indicates which port(s) are members of the associated VLAN.

24.11.4.8.2.2 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN_Aware Lookup, VLAN_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The mcast_fwd_state indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the CPGMAC_SL to the ALE. Packets with errors may be passed to the host (not aborted) by a CPGMAC_SL port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set. Error packets that are passed to the host by the CPGMAC_SL are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the SL_MACCONTROL register:

- [22] RX_CEF_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX_CSF_EN - enables short frames to be forwarded
- [24] RX_CMF_EN - enables MAC control frames to be forwarded.

24.11.4.8.2.3 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

24.11.4.8.2.4 VLAN Aware Mode

The CPSW_3G is in VLAN aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL register. In VLAN aware mode, ports 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set rx_vlan_encap bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (pkt_type), packet priority (pkt_pri), and VLAN information.

24.11.4.8.2.5 VLAN Unaware Mode

The CPSW_3G is in VLAN unaware mode when the VLAN_AWARE bit is cleared to 0 in the CPSW_CONTROL register. Port 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 transmit packets are never VLAN encapsulated.

24.11.4.8.3 Packet Priority Handling

Packets are received on three ports, two are CPGMAC_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is the port priority for untagged packets, and the actual packet priority for priority tagged and VLAN tagged packets. The received packet priority is mapped through the receive ports associated packet priority to header packet priority mapping register to obtain the header packet priority (the CPDMA RX and TX nomenclature is reversed from the CPGMAC_SL nomenclature).

The header packet priority is mapped through the header priority to switch priority mapping register to obtain the hardware switch priority (0 to 3, with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

24.11.4.8.4 FIFO Memory Control

Each of the three CPSW_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX_MAX_BLKS field in the FIFOs associated Px_MAX_BLKS register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total). The RX_MAX_BLKS field in the FIFO's associated Px_MAX_BLKS register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX_MAX_BLKS value plus the RX_MAX_BLKS value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports are Port1 and Port2.

24.11.4.8.5 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC_SL nomenclature due to legacy reasons.

24.11.4.8.5.1 Normal Priority Mode

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used. For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting TX_IN_SEL = 00 for all ports (default value in P0/1/2_TX_IN_CTL)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to Section 24.11.4.8.3, *Packet Priority Handling*.

24.11.4.8.5.2 Dual MAC Mode

When operating in dual MAC mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each CPGMAC_SL appears as a single MAC with no bridging between MAC's. Each CPGMAC_SL has at least one unique (not the same) mac address.

Dual MAC mode is configured as described below:

- Set the ALE_VLAN_AWARE bit in the ALE_CONTROL register. This bit configures the ALE to process in VLAN aware mode. The CPSW_3G VLAN aware bit (VLAN_AWARE in CPSW_CONTROL) determines how packets VLAN's are processed on CPGMAC_SL egress and does not affect how the ALE processes packets or the packet destination. The CPSW_3G VLAN aware bit may be set or not as required (must be set, if VLAN's are to exit the switch).
- Configure the Port 1 to Port 0 VLAN
  - Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).
  - Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Configure the Port 2 to Port 0 VLAN
  - Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).
  - Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting TX_IN_SEL = 01 in P0_TX_IN_CTL. The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

24.11.4.8.5.3 Rate Limit Mode

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some CPGMAC_SL FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown below:

1. Set TX_IN_SEL = 10 in P1/2_TX_IN_CTL to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
2. Configure the number of rate-limited queues for port 1 and 2 transmit FIFO's by setting the TX_RATE_EN field in P1/2_TX_IN_CTL. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
3. Set P1_PRIN_SHAPE_EN and P2_PRIN_SHAPE_EN in the CPSW_PTYPE register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in TX_RATE_EN are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired. When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on a single queue then it must

be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).

4. P0_TX_IN_CTL[17:16] TX_IN_SEL should be set to 00, so Port 0 egress (CPDMA RX) is not rate-limited.
5. The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the TX_RLIM field in the CPDMA_DMACONTROL register. If there are two rate-limited channels, then TX_RLIM = 11000000 (the rate limited channels must be the highest priorities). Also, the TX_PTYPE bit in the CPDMA_DMACONTROL register must be set (fixed priority mode). Rate-limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

24.11.4.8.6 Audio Video Bridging

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks.* "a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks:* Forwarding and Queuing for Time-Sensitive Streams."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9:* Stream Reservation Protocol (SRP)."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

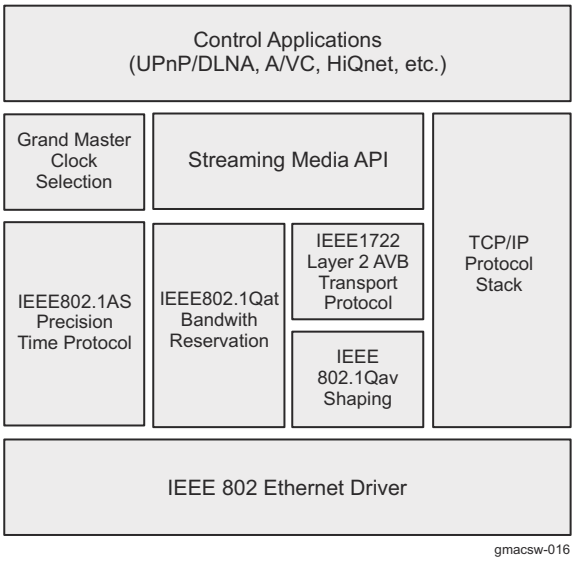

Figure 24-199. The Network Static with AVB

The following sections describe the media transport protocols that work within the AVB framework.

24.11.4.8.6.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))

The protocol defined by 802.1AS automatically selects a device to be the master clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

Note

The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

Based on IEEE 1588:2002,Â PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock master selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2--in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock master, the Best Master Clock Algorithm (BMCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandmaster. Once a Grandmaster has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Slave nodes compare the value of their RTC against the PTP Grandmaster and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1-µs accuracy over seven network hops.

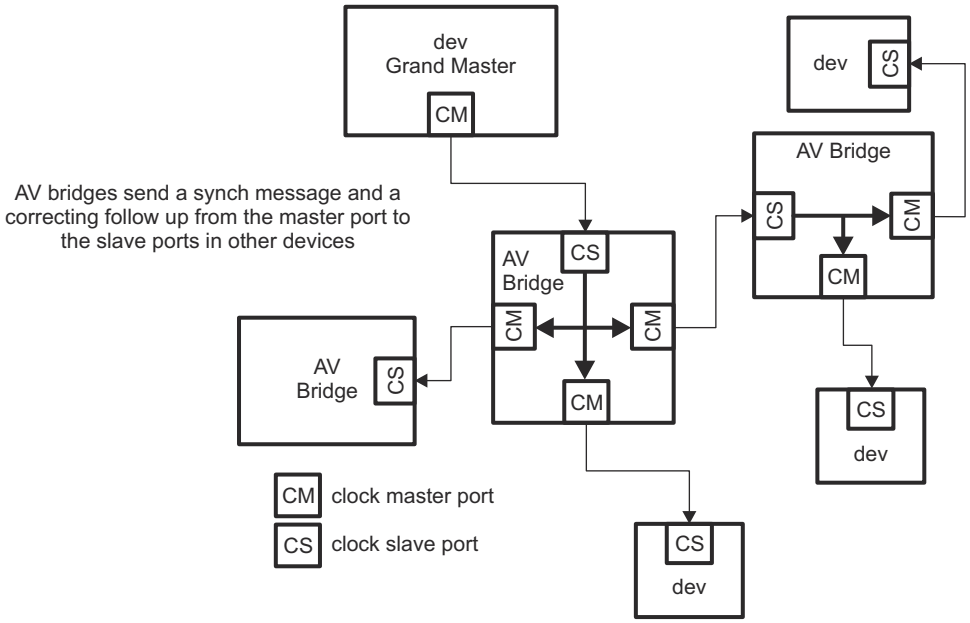

Figure 24-200. AVB Network & PTP Clock Entities

The media transport protocols that work within the AVB framework are:

24.11.4.8.6.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in Figure 24-201 and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

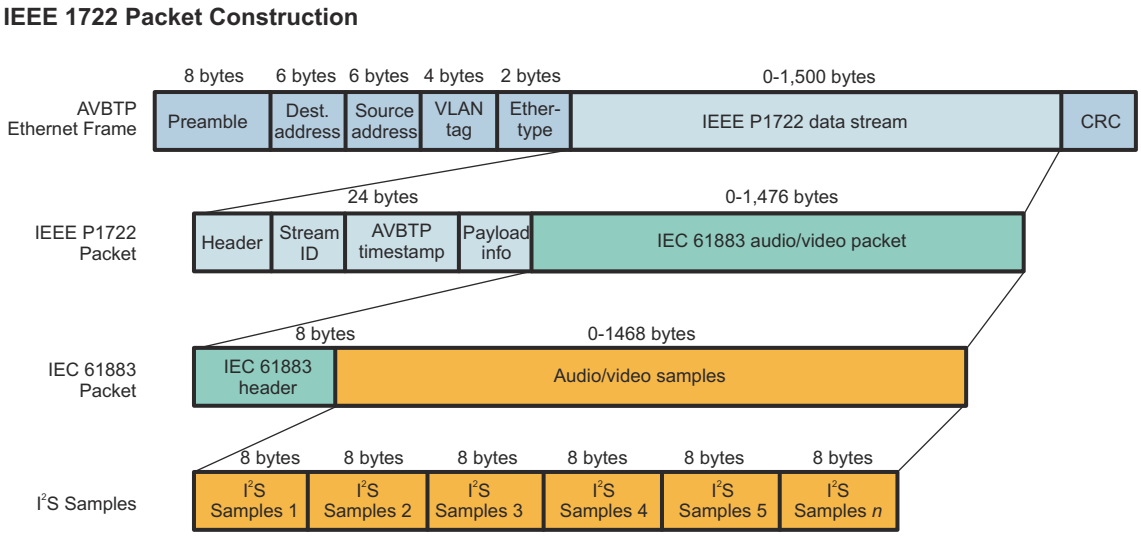

Figure 24-201. IEEE 1722 Packets

1722 or AVBTP Presentation Time and Synchronization:

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for

synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandmaster. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. Figure 24-202 illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

24.11.4.8.6.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/ Video Bridging (AVB) protocols.

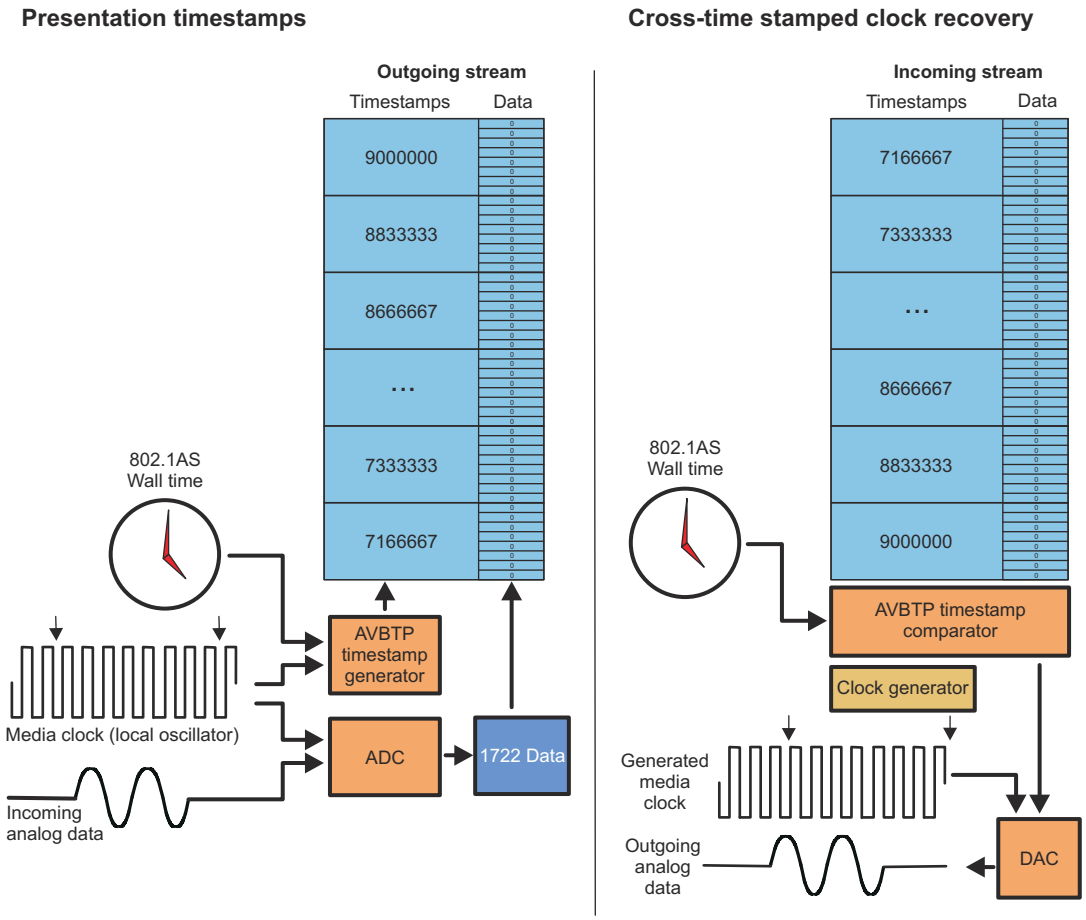

Figure 24-202. Cross Time Stamping and Presentation Timestamps

24.11.4.8.6.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in

aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
  - Receive policing and
  - Transmit rate control.

End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like Figure 24-203.

Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

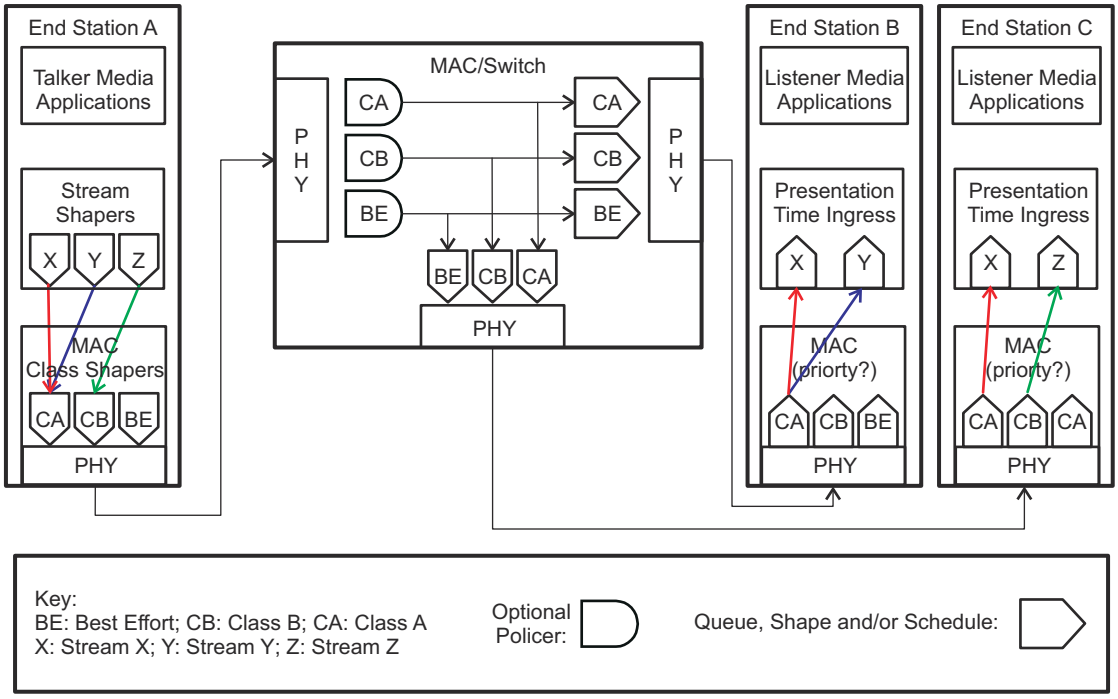

Figure 24-203. AV Stream Queuing/Policing

24.11.4.8.6.2.1 Configuring the Device for 802.1Qav Operation:

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW_3G that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
  - CPPI TX and RX descriptors
  - VLAN and Priority tags

Table 24-858. Example of TX Configuration

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

Table 24-859. Example of RX Configuration

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
  - ALE in VLAN-ware mode, Non-ALE in bypass mode.

Table 24-860. Example of Rate-limit Configurations

Register	Value	Description
CPSW_PTYPE	0x0006 0000	For Port1 -- 2 highest priority channels.

Table 24-860. Example of Rate-limit Configurations (continued)

Register	Value	Description
P1_TX_IN_CTL[23:20] TX_RATE_EN	0b1100	2 highest priority channels are rate limited
P1_TX_IN_CTL[17:16] TX_IN_SEL	0b10	Rate limit mode
P1_SEND_PERCENT	0x14 3E00	20% PRI7, 62% PRI5
CPDMA_DMACONTROL	0xC001	Chan7, Chan6 are Rate Limited. Round-robin selection of DMA channel.
CPDMA_TX_PRI7_RATE	0x1 0013	200 Mbps
CPDMA_TX_PRI6_RATE	0x1 0005	~600 Mbps

24.11.4.8.7 Ethernet MAC Sliver (CPGMAC_SL)

The CPGMAC_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation
- G/MII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control
- Programmable Inter Packet Gap (IPG).

24.11.4.8.7.1 G/MII Media Independent Interface

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

24.11.4.8.7.1.1 Data Reception

24.11.4.8.7.1.1.1 Receive Control

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

24.11.4.8.7.1.1.2 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

24.11.4.8.7.1.2 Data Transmission

The Gigabit Ethernet Mac Sliver (GMII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

24.11.4.8.7.1.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

24.11.4.8.7.1.2.2 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS_CRC bit is 0. For the CPMAC_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS_CRC bit is set.

24.11.4.8.7.1.2.3 MTXER

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

24.11.4.8.7.1.2.4 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX_PACE bit in the SL_MACCONTROL register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

24.11.4.8.7.1.2.5 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRS is de-asserted within approximately 48 bit times of MTXEN being de-asserted, then 96 bit times is measured from MTXEN. If the frame suffered a collision, or if MCRS is not de-asserted until more than approximately 48 bit times after MTXEN is de-asserted, then 96 bit times (approximately, but not less) is measured from MCRS.

The transmit IPG can be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the SL_MACCONTROL register enables the TX_SHORT_GAP input to determine whether the transmit IPG is shorted by eight bit times.

24.11.4.8.7.1.2.6 Back Off

The Gigabit Ethernet Mac Sliver (GMII) implements the 802.3 binary exponential back-off algorithm.

24.11.4.8.7.1.2.7 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the SL_TX_GAP register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

24.11.4.8.7.1.2.8 Speed, Duplex and Pause Frame Support Negotiation

The CPMAC_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

24.11.4.8.7.2 RMII Interface

The CPRMII peripheral is compliant to the RMII specification document.

24.11.4.8.7.2.1 Features

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

24.11.4.8.7.2.2 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMRXER on any di-bit in the received packet will cause an MRXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMCRSDV toggle will issue an MRXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMCRSDV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

24.11.4.8.7.2.3 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the GMAC_SW MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The GMAC_SW does not source the transmit error (MII TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMTXD[1:0] for each clock that RMTXEN is de-asserted.

24.11.4.8.7.3 RGMII Interface

The CPRGMII peripheral is compliant to the RGMII specification document.

24.11.4.8.7.3.1 RGMII Features

- Supports 1000/100/10 Mbps speed
- In SR1.0, Internal TXC delay on transmit is always enabled. SR1.0 information is valid only for the AM571x family of devices.
- In SR2.x, Internal TXC delay on transmit can be enabled or disabled using bits [26] RGMII2_ID_MODE_N and [25] RGMII1_ID_MODE_N of the CTRL_CORE_SMA_SW_1 register.
- MII mode is not supported

24.11.4.8.7.3.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

24.11.4.8.7.3.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the EXT_EN bit of the SL_MACCONTROL register is set to 1. The link status, duplexity, and speed are determined from the RGMII input data stream RXD[3:0] when RX_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in Table 24-861.

Table 24-861. In-Band Data

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0: half-duplex	00: 10-Mbps mode	2.5 MHz	0: Link is down
1: full-duplex	01: 100-Mbps mode	25 MHz	1: Link is up
	10: 1000-Mbps mode	125 MHz	
	11: reserved	reserved	

24.11.4.8.7.3.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the EXT_EN bit of the SL_MACCONTROL register is set to 0. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the SL_MACCONTROL[0] FULLDUPLEX and [7] GIG bits. If GIG = 1, then operation is gigabit mode. If the GIG is 0, the operation is 100 Mbps mode.

24.11.4.8.7.3.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRGMII module.

The TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII_LINK. Packet transmission will begin on the first TX_CTL rising edge after the 4096 transmit clock count has expired.

24.11.4.8.7.4 Frame Classification

Received frames are proper (good) frames if they are between 64 and RX_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the SL_RX_MAXLEN register. The SL_RX_MAXLEN register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain RX_MAXLEN number of bytes transferred to memory (if RX_CEF_EN = 1). An example with RX_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.

- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

24.11.4.8.8 Embedded Memories

Table 24-862. Embedded Memories

Memory Type Description	Number of Instances	
Single-port 2560 × 64 RAM	3	(Packet FIFO's)
Single-port 64-word × 1152-bit RAM	1	(ALE)
Single-port 2048-word × 32-bit RAM	1	(CPPI)

24.11.4.8.9 Flow Control

There are two types of switch flow control: CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

24.11.4.8.9.1 CPPI Port Flow Control

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the P0_FLOW_EN bit in the CPSW_FLOW_CONTROL register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

24.11.4.8.9.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX_PKT_CNT = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX_FLOW_EN bit in the associated CPGMAC_SL be set to 1. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for G/MII ports, then any packets that are dropped are dropped on transmit and not on receive.

24.11.4.8.9.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control

appropriate for the current mode of operation. Receive flow control is enabled by the RX_FLOW_EN bit in the SL_MACCONTROL register. Receive flow control is triggered (when enabled) when the RX_FLOW_TRIGGER input is asserted. The CPGMAC_SL is configured for collision or IEEE 802.3X flow control via the FULLDUPLEX bit in the SL_MACCONTROL register.

24.11.4.8.9.2.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in SL_MACCONTROL). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

24.11.4.8.9.2.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX is set in SL_MACCONTROL). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC_SL will transmit pause frames as:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL_SA[47:0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX_FLOW_EN is cleared to 0 while the pause time is nonzero, then the pause time will be cleared to 0 and a zero count pause frame will be sent.

24.11.4.8.9.2.2 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC_SL from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TX_FLOW_EN bits in the SL_MACCONTROL register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the RX_CMF_EN (copy MAC frames) bit in the SL_MACCONTROL

register is set. The TX_FLOW_EN and FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- TX_FLOW_EN is set in SL_MACCONTROL register, and
- the frame's length is 64 to SL_RX_MAXLEN bytes inclusive, and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If TX_FLOW_EN in SL_MACCONTROL register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01
  - , or the CPGMAC_SL SL_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC_SL will recognize any pause frame between 64 bytes and RX_MAXLEN bytes in length.

24.11.4.8.10 Short Gap

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the SL_MACCONTROL register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The CPSW_GAP_THRESH register value determines the port 1 short gap threshold, and the CPSW_GAP_THRESH register value determines the port 2 short gap threshold.

24.11.4.8.11 Switch Latency

The CPSW_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

Table 24-863. Switch Latency

Mode	Latency
Gig (1000)	880 ns
100	1.3 µs
10	6.5 µs

24.11.4.8.12 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW_3G operation to be completely or partially suspended. There are three CPSW_3G submodules that contain emulation control registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW_3G emulation control. The CPSW_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

CPGMAC_SL Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the SL_EMCONTROL register) allow CPGMAC_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

CPDMA Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the CPDMA_EMCONTROL register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals

Table 24-864 shows the operations of the emulation control input and register bits.

Table 24-864. Emulation Control Input

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

24.11.4.8.13 FIFO Loopback

FIFO loopback mode is entered when the FIFO_LOOPBACK bit in the CPSW_CONTROL register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel 0 in FIFO loopback mode. The RXSOFOVERRUN statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in fullduplex mode only.

24.11.4.8.14 Device Level Ring (DLR) Support

Device Level Ring (DLR) support is enabled by setting the DLR_EN bit in the CPSW_CONTROL register. When enabled, incoming received DLR packets are detected and sent to queue 3 (highest priority) of the

egress port(s). If the host port is the egress port for a DLR packet then the packet is sent on the CPDMA Rx channel selected by the P0_DLR_CPDMA_CH field in the P0_CONTROL register. The supervisor node MAC address feature is supported with the dlr_unicast bit in the unicast address table entry. When set, the dlr_unicast bit causes a packet with the matching destination address to be flooded to the vlan_member_list minus the receive port and minus the host port (the port_number field in the unicast address table entry is a don't care). Matching dlr_unicast packets are flooded regardless of whether the packet is a DLR packet or not. The EN_P0_UNI_FLOOD bit in the ALE_CONTROL register has no effect on DLR unicast packets. Packets are determined to be DLR packets as shown below:

1. DLR is enabled (DLR_EN is set in the CPSW_CONTROL).
2. One of the sequences below are true.
   a. The first packet ltype matches CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1 and Px_CONTROL[20] Px_VLAN_LTYPE1_EN is set and the second packet ltype matches CPSW_DLR_LTYPE[15:0] DLR_LTYPE.
   b. The first packet ltype matches CPSW_VLAN_LTYPE[31:16] VLAN_LTYPE2 and Px_CONTROL[21] Px_VLAN_LTYPE2_EN is set and the second packet ltype matches CPSW_DLR_LTYPE[15:0] DLR_LTYPE.
   c. The first packet ltype matches CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1 and Px_CONTROL[20] Px_VLAN_LTYPE1_EN is set and the second packet ltype matches CPSW_VLAN_LTYPE[31:16] VLAN_LTYPE2 and Px_CONTROL[21] Px_VLAN_LTYPE2_EN is set and the third packet ltype matches CPSW_DLR_LTYPE[15:0] DLR_LTYPE.

24.11.4.8.15 Energy Efficient Ethernet Support (802.3az)

Note

CM_GMAC_CLKSTCTRL[1:0]CLKTRCTRL bit field must not be programmed for SW_SLEEP or HW_AUTO.

Energy Efficient Ethernet (EEE) allows the PRCM to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. EEE operations are configured as shown below:

1. The 10-bit EEE clock pre-scale value is written to the CPSW_EEE_PRESCALE register. The pre-scaler is used to clock all EEE-related counters
2. The port Idle to LPI count values (Px_IDLE2LPI) are written with the desired values
3. The port LPI to Wake count values (Px_LPI2WAKE) are written with the desired values
4. The EEE_EN bit is set in the switch CPSW_CONTROL register
5. Set the WR_CONTROL[8] SS_EEE_EN bit to enable energy efficient operations at subsystem level.

EEE operation can begin after configuration. The host allows (through PRCM) the CPSW_3G to enter a low power state by asserting the CLKSTOP_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert CLKSTOP_REQ to the CPSW_3G.

Each ethernet port has a transmit and a receive LPI (low power indicate) state. The receive LPI state is entered when the port's corresponding PHY indicates the LPI state via the CPSW_3G GMII interface. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the Px_IDLE2LPI value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPDMA LPI state includes transmit and receive. The CPDMA LPI state is entered when the CPDMA transmit and receive have both been idle for the Idle to LPI time (P0_IDLE2LPI). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

Note

The procedure above is described for the GMII interfaces at the CPSW_3G boundary. External PHY signaling has the following conditions:

- GMII interface is used only in MII mode. Therefore, only MRXD[3:0] and MTXD[3:0] are pinned out
- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX_CTL at the rising and the falling TXC_CLK edges, respectively. RXDV and RXER are the sampled values of RX_CTL at the rising and the falling RXC_CLK edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the CLKSTOP_ACK signal is asserted, and the PRCM is allowed to stop the module clock. When CLKSTOP_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the CPSW_3G memory address space, and then turn off the clock again while CLKSTOP_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting CLKSTOP_REQ. The host may queue transmit packets at any time including without regard to the CPSW_3G LPI state (the clock must be restarted in order to write the CPSW_3G slave address space as described above). Host writes to transmit head descriptor pointers will cause the CLKSTOP_WAKEUP signal to be asserted if the CPSW_3G is in the low power state (if CLKSTOP_ACK is asserted).

The external Ethernet PHY's can also wakeup the PRCM by removing the Ethernet receive LPI indication. If the module is in the CPSW Idle state with CLKSTOP_ACK asserted and the receive LPI indication is removed, the CLKSTOP_WAKEUP signal will be asynchronously asserted. On wakeup, the PRCM restarts the clock and de-assert the CLKSTOP_REQ signal. The CLKSTOP_WAKEUP signal will be synchronously deasserted with CLKSTOP_ACK. Upon the deassertion of CLKSTOP_REQ, the Ethernet ports will count the Px_LPI2WAKE time for each port at which time the port is available for transmit. Upon the de-assertion of CLKSTOP_REQ, the CPDMA transmit will count the P0_LPI2WAKE count at which time the CPDMA will begin to send any packets that the host has queued (switch ingress). The wait time on CPDMA transmit is included to preclude the host from filling up the Ethernet port transmit FIFO's while the Ethernet ports are in the LPI to wake time. There is no LPI to wake time on CPDMA receive (switch egress).

24.11.4.8.16 CPSW_3G Network Statistics

The CPSW_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of GMAC_RST. When one or more port enable (Pn_STAT_EN) bits in the CPSW_STAT_PORT_EN register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, "the port" refers to any enabled port (with a corresponding set Pn_STAT_EN bit).

The statistics interrupt (STAT_PEND) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

See *STATS Registers* for description of every network statistic.

Rx Statistics Summary and *Tx Statistics Summary* summarize network statistics.

24.11.4.8.16.1

Table 24-865. Rx Statistics Summary

Rx Statistic	Frame/ Oct	Rx/ Rx+ Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data[5]															
			Pause frame	Non-pause[4]	Multi cast	Broad cast	Uni cast	<64	64	65-127	128-255	256-511	512-1023	1024-rx_ maxlen	>rx_ maxlen	Flow Coll.[8]	CRC Error	Align/ Code	Overrun	Addr. Disc.
Good Rx Frames	F	R	(y|[1]	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-[2]	n	n	-	n
Broadcast Rx Frames	F	R	(%|[6]	%|	n	y)	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Multicast Rx Frames	F	R	(%|	%|	y)	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Pause Rx Frames	F	R	y	n	n	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	-
Rx CRC Errors	F	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	-	y	-	n
Oversized Rx Frames	F	R	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	R	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	(y|	y)	-	n
Undersized Rx Frames	F	R	n	n	(y|	y|	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	R	n	n	(y|	y|	y)	y^[7]	n	n	n	n	n	n	n	-	(y|	y)	-	-
Rx Overruns[9]	F	R	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	y	n
64octet Frames	F	R+T[3]	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	y	n	n	n	n	-	-	-	-	n
256-511octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Net Octets	O	R+T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	-

(1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
(2) "-" indicates conditions which are ignored in the formations of the statistic.
(3) Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.
(4) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
(5) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
(6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
(7) "y^" Frame fragments are not counted if less than 8 bytes.
(8) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
(9) The rx_overruns stat is for RX_MOF_OVERRUNS and RX_SOF_OVERRUNS added together.

Table 24-866. Tx Statistics Summary

Tx Statistic[9]	Frame/ Oct	Tx/ Rx +Tx	Frame Type					Frame Size (bytes)								Event								
			MAC control[4]	Data												Collision Type								
			Pause-MAC	Any-CPU	Multicast	Broadcast	Unicast	64	65-127	128-255	256-511	512-1023	1024-1535	>1535	CRC Error	Flow[8]	1	2-15	16	Late	No Carrier	Queued	Deferred	Underrun
Good Tx Frames	F	T	(y|[1]	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-[2]	-	-	-	n	n	n	-	-	n
Broadcast Tx Frames	F	T	n	(%|[5]	n	y)	n	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Multicast Tx Frames	F	T	(y|	%|	y)	n	n	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Pause Tx Frames	F	T	y	n	n	n	n	y	n	n	n	n	n	n	-	-	-	-	-	-	-	-	-	-
Collisions	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	(+[6]	+	+	+	+)	n	-	-	-
Single Collision Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	y	n	n	n	n	-	-	-
Multiple Collision Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	y	n	n	n	-	-	-
Excessive Collisions	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	y	n	n	-	-	-
Late Collisions	F	T	n	(y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	-	-	-	-	-	y	-	-	-	-
Deferred Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	n	n	n	-	y	n
Carrier Sense Errors	F	T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	-	-	y	-	-	-
64octet Frames	F	R+T[3]	(y|	y|	y|	y|	y)	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
65-127octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
128-255octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-
256-511octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-
512-1023octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-
1024-UPoctet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-
Tx Octets	O	T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Net Octets	O	R+T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	$[7]	$	$	$	$	-	-	-

(1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
(2) “-“ indicates conditions which are ignored in the formations of the statistic.
(3) Statistics marked “R+T” are formed by summing the Rx and Tx statistics, each of which is formed independently.
(4) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
(5) “%” If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.

(6) "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
(7) "$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
(8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See Table 24-865.)
(9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

24.11.4.9 Static Packet Filter (SPF)

24.11.4.9.1 SPF Overview

The Static Packet Filter (SPF) provides protection against some of the most common forms of Denial of Service (DoS) attacks that exploit the Layer 3 and Layer 4 functions of the network stack running on a system. The DoS attacks that are mitigated by the SPF module are:

- ARP Flood
- Fraggle
- Illegal Fragment Offset
- Illegal TCP Options
- Jolt2
- Jolt
- Land
- Micro Fragment
- Null Scan
- Ping Flood
- Short ICMP Packet
- Smurf
- SSPing
- SYN Fragment
- TCP SYN Flood
- Xmas Scan

24.11.4.9.2 SPF Functional Description

24.11.4.9.2.1 SPF Block Diagram

Figure 24-204 shows the block diagram of the Static Packet Filter module. There are three main components of the static packet filter – packet header extractor to decode packet formats, rule engine to check for malformed protocol header fields and a host interface to provide control and configuration access to a host processor and to keep a log of filtered packets in system memory.

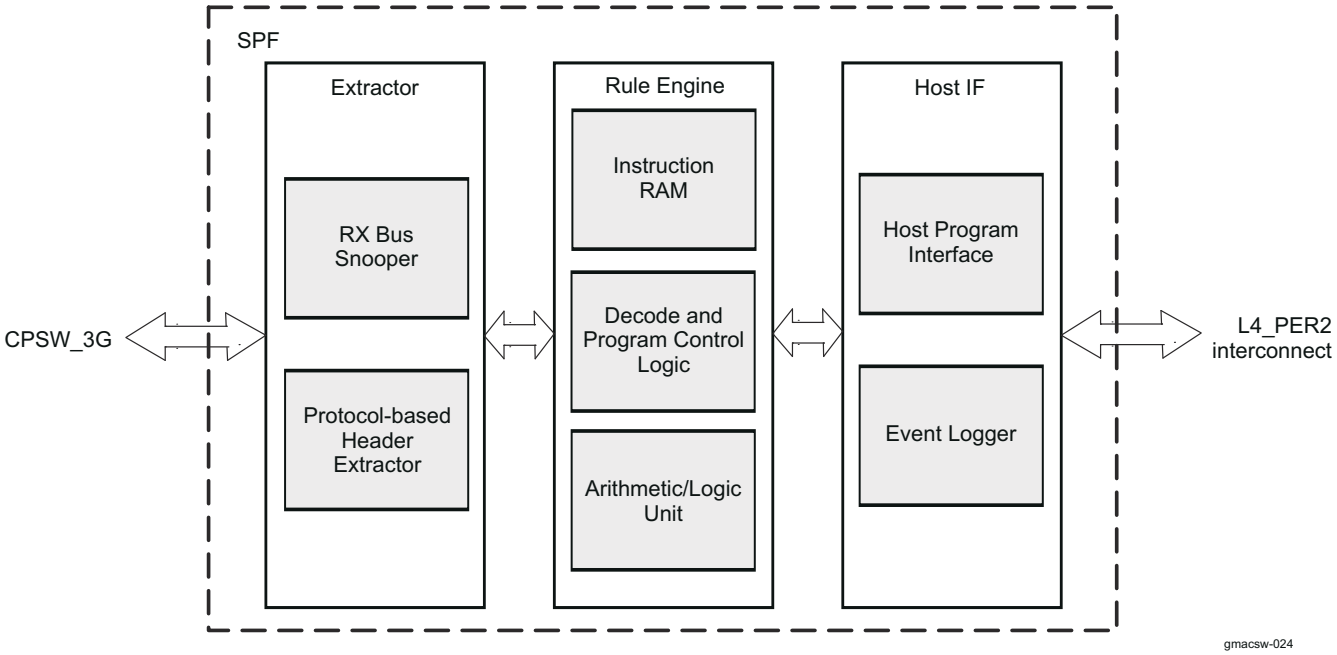

Figure 24-204. SPF Block Diagram

The packet parser interfaces to the three-port Ethernet switch (CPSW_3G). The CPSW_3G signals are snooped for receive traffic and the packet contents are provided to the packet header extractor. The parser can decode various network packet formats and determine the location of the header corresponding to each of the specified protocols and store the values in internal registers. The packet parser can decode VLAN, PPPoE, IP, TCP, UDP and ICMP frame formats and determine the location of each protocol header in a frame. The location of each of these headers is used by the rule engine for performing checks against preprogrammed conditions.

The rule engine monitors information in the header fields and upon detection of an abnormal combination of values in these packet header fields, issues an instruction to drop the packet to the external RFIFO interface. The rule engine can also monitor the receive rate of a particular class of packets and can limit the number of packets that actually pass through the system. The operation of rule engine is programmable and that gives flexibility to perform a range of different checks on the contents of packet to determine whether or not it should be accepted.

The event logger captures the activity in the packet filter. In addition, based upon the settings programmed by the host software, the event logger writes detailed information about any frames that have been dropped thus far. This information is written to a part of the system memory as configured by the host software.

24.11.4.9.2.2 Interrupts

The Static Packet Filter has one interrupt that is used to inform the host about excessive number of logged packet drops. The addresses of the instructions (or drop codes) in the instruction memory that cause packet to be dropped are associated with a threshold. When the threshold is met, the packet drop is logged. Each time a packet drop is logged, it is counted. When the number of logged records reaches the value specified by the SPF_INTCNT register, the host is interrupted. The threshold settings can be controlled by host software to limit the frequency of interrupts. Writing a zero to SPF_INTCNT disables the interrupt in this scenario. Whenever interrupt is enabled and is triggered, it can be cleared by writing one to either Raw register or Masked register.

Interrupts are controlled by the following registers:

1. Raw register SPF_INT_RAW: Holds the Raw state of interrupt, that is, without mask. The hardware interrupt is latched in this register and is only cleared when a one is written to either Raw register or Masked register. Writing a zero has no effect on this register.

2. Masked register SPF_INT_MASKED: This is the actual interrupt given to the system. It is the result of bitwise AND operation of Raw and Mask registers. Once the interrupt is sensed by the system, this register should be cleared by writing one to this register or to Raw register during ISR execution. Writing zero has no effect on this register
3. Mask set register SPF_MASK_SET: Writing one to this register enables the interrupt. By default, the interrupt is disabled and needs to be enabled by writing a one to this register. Writing a zero has no effect on this register. Writing to this register also set clear register.
4. Mask clear register SPF_MASK_CLR: Writing one to this register disables interrupt. Writing a zero has no effect on this register.

24.11.4.9.2.3 Protocol Header Extractor

The extractor module has a protocol aware state machine. It decodes the header field in the current protocol header to determine the encapsulating protocol type and extracts various parameters used for software logging. The extractor module also provides the offset to octets in the packet, where Layer 3 and Layer 4 protocol headers start, to the rule engine. These protocol headers correspond to the location of IP and TCP/UDP/ICMP headers from the beginning of the packet.

Ethernet packets with VLAN, PPPoE, IP, IP Options, and ICMP/TCP/UDP protocol are supported by the extractor. When unknown protocols are detected, the extractor skips any additional packet processing. Some examples of how packet parsing is done by the Extractor are given below.

- Ethernet – VLAN - PPPoE – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – IP options – Unknown – Payload
- Ethernet – VLAN – PPPoE – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – Unknown – Payload
- Ethernet – VLAN – PPPoE – Fragmented IP – Unknown – Payload
- Ethernet – VLAN – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – IP options – Unknown – Payload
- Ethernet – VLAN – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – Unknown – Payload
- Ethernet – VLAN – Fragmented IP – Unknown – Payload
- Ethernet – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – IP – IP options – Unknown – Payload
- Ethernet – IP – TCP/UDP/ICMP – Payload
- Ethernet – IP – Unknown – Payload
- Ethernet – Fragmented IP – Unknown – Payload
- Ethernet – Unknown

The flow of Extractor state machine flow is as follows.

1. Wait for start of packet and proceed to step 2 if start of packet detected.
2. Read Ethernet header Length/Type field (at offset 13). Go to step 3 if next header is VLAN, to step 4 if it is PPP header, to step 5 if it is IP header and to step 8 otherwise.
3. Allow VLAN header to pass and read the Length/Type field. Go to step 4 if next header is PPP, to step 5 if it is IP header and to step 8 otherwise.
4. Read the protocol type in PPP header. Go to step 5 if protocol is IP and to step 8 for unknown protocol
5. Extract source IP address and destination IP address from the IP header. Determine if the packet has IP options or if the packet is fragmented. Go to step 6 if the packet has IP options and to step 8 if the packet is fragmented. If there are no options and the next protocol header is TCP/UDP, go to step 7. Otherwise, skip processing and go to step 8 because the packet has unrecognized protocol header
6. Skip IP options and determines the next protocol header. Go to step 7 if next header is TCP/UDP/ICMP. In case the packet contains an IP fragment or if the protocol in the next header is unknown, skip processing and go to step 8.
7. The packet has TCP/UDP/ICMP header. Extract TCP/UDP source and destination port numbers for logging or ICMP type and code fields and go to step 8.
8. Wait for end of frame and go to step 1 at end of frame.

In case the packet is aborted (indicated by address 0x10 on VBUSP with request and write ready asserted), the extractor state machine flushes its current state, goes back to the idle state and waits for next packet.

The Extractor provides information to rule engine about location of Layer 3 and Layer 4 protocols. When this information is provided to rule engine, the Base Register 1 and Base register 2 are loaded with Layer 3 start offset and Layer 4 start offset respectively. Until the extractor completes decoding of these protocol headers and sends the offset values to rule engine, the rule engine does not execute any instruction that operates on fields in these protocol headers.

Extractor module extracts IP protocol, Source IP address, Destination IP address, TCP/UDP source port, TCP/UDP destination port and ICMP type/code from incoming packet and provides this information to the Host logger module for software reporting. In case IP header or TCP/UDP header does not contain the extractable fields then the corresponding field is logged as zero.

In case packet has unknown Layer 4 protocol or IP packet is fragmented such that the packet does not contain TCP/UDP/ICMP header then TCP/UDP source/destination ports or ICMP type/code fields are logged as zeros.

24.11.4.9.2.4 Programmable Rule Engine

The rule engine is a micro-coded machine that is programmed by the host software. The rule engine is programmed to evaluate various expressions involving the header fields of different protocols that the incoming packet belongs to. These expressions are coded into the instructions that are stored in an internal RAM and are used to check whether a packet is mal-formed or is potentially a DoS attack packet. The rule engine executes the instructions for each incoming packet and makes a decision about accepting or rejecting the packet.

Since each packet can have multiple distinct protocol headers, the location of the headers can be different from packet to packet. The rule engine gets information about the location of the protocol headers from the packet header extractor. The packet header extractor can decode several different protocol types. The octet number at which a particular protocol header is stored is loaded into SPF Base Registers. An application may require SPF to filter packets based on protocols that are not decoded by the extractor. In such cases, SPF allows bypassing the header extractor and then the rule engine can be programmed to analyze packets and figure out the location of each header.

The Rule Engine instructions are programmed before the SPF module is enabled. The instructions cannot be overwritten while the rule engine is processing packets. To modify the contents of code RAM during operation, SPF must be disabled temporarily and then new instructions can be loaded.

Once SPF is enabled, the rule engine starts to fetch instructions one at a time. For each instruction, the operands are obtained from either the packet octets that are being received, from internal registers or from the immediate values inside the instruction itself. If the octet that is needed for execution has not yet been received, then the execution stalls until the required octet is received. In case the operand specified in the instruction refers to a packet octet that has already gone by and is not available in the packet buffer, then the execution stalls until the end of packet. An instruction is executed only when all the required operands are available. Based on the instruction execution results, the packet may immediately be dropped or the results of the evaluated expressions may be stored for future use. In addition, the current instruction can also cause the rule engine to skip a specified number of instructions (immediately following the current instruction) and resume from another location in the instruction RAM.

The rule engine operates on multiple operands and performs multiple tasks in each clock cycle. In each cycle, it can perform one arithmetic and/or logical operation on two pairs of operands. The operands are masked with a 32-bit mask that is generated from the information provided in the instruction. The mask allows for operations that involve variable sized operands. Each operation generates a 32-bit number and a flag bit. The 32-bit number is typically either the sum or the output of bit-wise logical operation. The flag is a single bit result of a comparison operation. The result of each operation can be saved in the internal registers if a specified condition is satisfied. Similarly, depending on the result of the operation, the rule engine can jump to another location in the instruction memory. The program can instruct the rule engine to either perform two save operations, two conditional jumps or one jump and one save. The conditions must be mutually exclusive to prevent unspecified

operation. In addition to providing an alternate path for execution, the instruction can cause the rule engine to accept or reject the current packet and exit from the program until the next packet is received.

When the execution of an instruction does not result in a decision to accept or reject the packet, the rule engine progresses to the next instruction. Instructions are executed until a final decision is made. If a packet is aborted in the middle at the network interface, the rule engine aborts execution and clears all base registers, program counter, octet counter and packet buffer. It is then ready to process next packet.

From a hardware perspective, the rule engine contains a buffer to store packet octets, several internal registers for temporary storage, instruction decoding logic and control circuitry. A description of each of the hardware resources in the rule engine follows.

24.11.4.9.2.4.1 Internal Registers

Several different types of registers are provided in the rule engine. The description of each of theese is provided below.

- Base Registers (B0-B4): There are four hardware base registers (B1-B4) that store the location of various protocol headers. The B0 register is not a hardware register and it always means a reference to the first octet in a packet. Each base register is eight bits wide and is used to reference octets in a packet. The base registers can point to any octet in the packet upto 255 octets. These registers are readable and writable by the rule engine. In addition, base registers B1 and B2 are loaded with data provided by the extractor when the rule engine is not running in extractor bypass mode (SPF_CONTROL[2] SPF_EXT_BYPASS). The rule engine can write to base registers irrespective of whether extractor bypass is enabled. When an operand needs to use contents of B1-B4 registers, the instruction only executes if the specified base register was loaded at least once after the beginning of current packet. If the specified base register was not loaded during the current packet, then the operand referenced by this base register cannot be extracted from the packet and will cause the rule engine to stall.
- Constant Registers (C0-C7): The rule engine can refer to any of eight 32-bit constant values. These are programmed by the host (SPF_CONSTj, j = 0 to 7) and the rule engine only has read access to these registers. Each of these registers can be changed at any time by the host software. However, changing the value of these registers is not recommended as unpredictable behavior may occur if contents are changed while the rule engine is executing instructions that use the C0-C7 values.
- General Purpose 32-bit registers (R0-R7): There are eight 32-bit registers that can be read/written by the rule engine. These are general purpose registers and can be used as temporary storage. In addition, when the rule engine is required to provide logging information, R4-R7 are used to store information that will be written to memory.
- Rate limit registers (L0-L3): Four 8-bit rate limit registers are used by rule engine to count specific types of packets that are to be rate limited. These registers are counters that are loaded with programmed threshold values (SPF_RATELIMi, i = 0 to 3) at the end of time interval determined by the clock pre-scaler (SPF_PRESCALE)
- General Purpose 1-bit registers (T0-T3): Four 1-bit registers are provided to store comparison results by the rule engine. These registers can be used to store 1-bit output from ALUs. In addition, the logical OR and logical AND of the flags can also be stored in T0-T3 registers. The 32-bit ALU results may also be stored in T0-T3 registers but only the LSB will be stored.

The rule engine instructions refer to these internal registers during execution. More details about instruction encoding are in subsequent sections.

24.11.4.9.2.4.2 Packet Buffer

When the rule engine is processing a packet, it stored a snapshot of latest 32 octets in an internal buffer. This buffer allows evaluation of expressions on packet octets even after the packet octets have gone by on the external receive VBUSP network interface.

At the start of packet, the first eight octets received are loaded into the first eight locations of the packet buffer. When the next eight octets arrive, these are loaded into the first eight locations and the existing octets are moved to the following eight locations. This process is continued until the packet buffer is full. When packet

buffer is full and additional octets arrive, the oldest eight octets are shifted out and are no longer available to the rule engine. Thus, the packet buffer provides a snapshot of most recent octets received.

When the rule engine encounters instructions that reference packet octets which have not yet been received then the rule engine stalls until the required octets are available. Similarly, instructions which require octets that have already been shifted out of the packet buffer will cause rule engine to stall. And since these octets will never be available, the rule engine will not execute any further instructions for the current packet. It will return to the first instruction when the packet ends.

RFIFO VBUSP	63:56	55:48	47:40	39:32	31:24	23:16	15:8	7:0
Clock 0	8	7	6	5	4	3	2	1

gmacsw-025

Figure 24-205. Packet Octets as Stored in the Packet Buffer

The contents of a packet, when used as one or more operands in an instruction, are always fetched from the packet buffer. The Base registers (B0-B4) in conjunction with an offset and bits are used to specify which octets are to be used as operands.

24.11.4.9.2.5 Intrusion Event Logger

The activity of the static packet filter is logged by the intrusion event logger. Based on the configuration, the event logger writes specific fields of the incoming packet that violate a particular rule to the system memory for software diagnostics.

The logging module allows controlling the frequency at which events are logged to the memory. A set of nine counters are provided and, of these, eight can be mapped to any address of the rule engine's instruction RAM using map registers. This mapping logically associates the log information with the instruction that caused the packet to be dropped. The 9th counter is not associated with any particular instruction and it can be used to count the packets that were dropped at instructions not mapped to any of the other eight counters.

For each of the nine counters, there is a register to store the minimum number of attacks that must be detected before any information is logged to memory. Only when this threshold is met and logging is enabled, the host interface module writes log data in system memory. The memory area used to log is specified by the host in the SPF_LOG_BEGIN address and SPF_LOG_END address registers.

The event logger continues to write data to memory until it runs out of space and the log overwrite is disabled. With each update of the log, the SPF_LOG_HWPTR is updated. This information can be used by the host to determine how much data has been logged. The software in turn keeps the SPF_LOG_SWPTR updated to inform the SPF about the next address from where information will be read by the host software. It is required that software program correct value of SPF_LOG_END address to enable hardware to determine roll-over location. The SPF considers all space before the SPF_LOG_SWPTR as available for logging. In case SPF_CONTROL[9] SPF_LOGOW_EN control bit is set, SPF ignores SPF_LOG_SWPTR and logs data irrespective of software read log status. Note that the memory space allocated for logging is a multiple of four 32-bit words and end address SPF_LOG_END should be loaded with byte address of the next byte following the last log entry. For example if 16 bytes space is allocated for SPF logging from address 0x1400_0000, then SPF_LOG_BEGIN should be 0x1400_0000 and SPF_LOG_END should be 0x1400_0010.

The host software must set SPF_CONTROL[8] SPF_LOG_EN bit to activate logging. The setting of SPF_LOG_EN bit has no effect on the threshold based counters and they are always active. In addition to the log counters, SPF has one master drop count register (SPF_DROPCNT) which tracks the total number of packets dropped thus far. This counter does not roll over and must be cleared for re-run by the host processor once it reaches the maximum value.

The format in which packet information is written in the memory by the event logger is shown in Table 24-867 and Table 24-868.

Table 24-867. Format for TCP/UDP Packets

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Source TCP/UDP Port		Destination TCP/UDP Port	

Table 24-868. Format for ICMP Packets

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Type	Code	Checksum	

Each entry logged to memory has a drop code associated with it. The drop code is the address in instruction memory that actually triggered the drop. Up to eight drop codes can be monitored in this manner. In addition to drop code, the protocol, IP addresses and source/destination ports associated with the dropped packet are recorded.

Log data can be supplied by either Extractor module or by Rule engine. The SPF_CONTROL[3] SPF_RULE_LOG bit must be set to use log data from Rule Engine and cleared to use data supplied by the Extractor.

When logging is done through the Rule Engine, contents of internal registers R4-R7 are written to memory. The format of packet information stored can be programmed in the rule engine except for the drop code field which is static and cannot be changed. The format in which rule engine information is written in the memory by the event logger is shown in Table 24-869.

Table 24-869. Rule Engine Format

Drop Code	Register 4[23:0]
Register 5[31:0]	
Register 6[31:0]	
Register 7[31:0]	

The rule engine programming must ensure that these registers contain all required information that is to be recorded before the packet drop instruction is executed. As soon as the drop instruction is executed, the logging module starts to send data from the registers R4, R5, R6 and R7 to the system memory and is not possible to modify the contents of these registers.

24.11.4.9.2.6 Rate Limiter

The static packet filter provides a way to limit the rate of specific types of incoming packets. The SPF module provides four rate limit registers (L0-L3) that are used in conjunction with a clock prescaler (SPF_PRESCALE) and rule engine instructions. The clock prescaler is a clock divider and every count down to zero and the subsequent roll-over indicates end of a time interval. At every such event, each of the four rate limit registers is loaded with a preset value (SPF_RATELIMi, i= 0 to 3) that is programmable by the host processor. When packets are received, the rule engine can identify packets of particular types and execute a limit operation. The limit operation specifies a condition (described in Table 24-887) and a limit register. If the condition evaluates to true, the packet is dropped if the rate limit register is zero. If it is non-zero, then the rate limit register is decremented by one.

Thus, by using the prescaler and the limit registers, it is possible to control the rate of specific type of packets. By controlling the value of prescale counter (common to all rate limit registers) and the rate limit thresholds, the granularity of the rate can be modified. A lower value of prescale counter will cause frequent reloads of the rate limit registers and will allow rate control over small time intervals. Keeping the prescale counter at extremely small values may cause the rate limiter to be ineffective because the limit registers will be reloaded too frequently to count down to zero. Conversely, a higher value of prescale counter will cause less frequent reloads of the rate limit registers and the rate control will be over longer time intervals. The reload value of each 8-bit rate limit register and the prescale register are programmed by the host processor before SPF is enabled. A reload value of 0xFF can be used to disable any of the rate limiters at run-time without changing the firmware. Both the prescale and limit registers can be modified during run-time.

24.11.4.9.2.7 Rule Engine Instruction Set Architecture

24.11.4.9.2.7.1 Instruction Format

The design supports 64 deep instruction memory. Each of the instructions is 78 bit wide and is stored in a RAM internal to the SPF module. Each instruction can have up to four operands, two arithmetic/logical operations and two conditional jump/save actions based on the outcome of the operations.

The operand field is 52 bits wide and it can have up to four operands. The arithmetic and logical operation codes are four bits each. The operation codes are nine bits each.

Table 24-870. Instruction Format

Bits	Field Name	Description
77:26	OPERAND	Up to four operands are specified in this field. The source of the operands can be the packet that is being received at the network interface, one of the internal register values or an 8/16/32 bit operand specified within the instruction.
25:22	FUNCTION0	This field specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of first two operands specified in the instruction.
21:18	FUNCTION1	This field also specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of the third and fourth operands specified in the instruction.

Table 24-870. Instruction Format (continued)

Bits	Field Name	Description
17:9	OPERATION0	A Save/Jump/Limit/Nop operation is specified in this function. Save operation code includes the source and destination information. The save source is the output of functions and the destination is one of the internal registers where data should be saved. Jump operation code has information about a condition and a destination. The jump occurs when the condition, which is based on the result of function0 and function1, is true. The Jump destination controls the flow of instruction execution. Jump to location 1 results in the packet being dropped. Rule engine goes back to initial instruction and waits for next packet. The event logger writes information to memory. Jump to location zero results in the packet being accepted. The rule engine goes back to initial instruction and waits for next packet. Limit operation code has information about a condition and a rate limit register. The Limit operation either causes the packet to be dropped or results in the specified rate limit register to be decremented by one.
8:0	OPERATION1	This field specifies a second save/jump operation. The format for this field is same as for Operation0.

24.11.4.9.2.7.2 Operand Field

The operand field specifies up to four operands. Each operand is obtained from the incoming packet data, from an internal register or as an immediate value specified in the instruction itself. In addition, there is a bit mask associated with each operand. The mask values are encoded in the instruction itself and the mask for each operand is applied before it is used by the Arithmetic and Logic Unit.

The operands are input to the two 32-bit Arithmetic and Logic units. For all calculations, a mask is used with each operand. The mask is a 32-bit number that is generated from a 5-bit code provided in the instruction or from an immediate value in the instruction. The 5-bit mask code specifies how many bits (from the LSB side) will be input to the ALU. An immediate mask must be used when the mask is not a continuous sequence of 1's. Whenever an immediate mask value is specified, the mask value specified by the 'Bits' fields is ignored.

Each operand is at least 13-bits long and the encoding for each operand types is shown in Table 24-871 to Table 24-878.

Table 24-871. Packet Data Operand

Description	This type of operand is derived from the packet itself. The encoding specifies a number of bits (up to 32) to be extracted from a location in the packet indicated by the selected base register and offset. The format of 13-bit operand code is shown below. Internally, a 32-bit number is obtained from the packet. Then, a mask is created from the bits[4:0] field and bitwise ANDed with the 32- bits extracted from the packet.

12	11	10	9	8	7	6	5	4	3	2	1	0
Base[2:0]			Offset[4:0]					Bits[4:0]				

Bits	Field Name	Description
12:10	Base[2:0]	The Base field selects one of the Base registers B0, B1, B2, B3 or B4. The operand comprises of (Bits+1) bits extracted from the packet. The offset from where the operand octets are extracted is determined by the sum of the value of specified base register (Base 0 to Base 4) and the specified offset. Base 0 is start of packet.
9:5	Offset[4:0]	The value of the selected base register plus the specified offset is the octet location in the packet from where the specified number of bits will be picked.
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, only one bit is used as operand. When Bits[4:0] is 31, then 32 bits are used as operand.

Table 24-872. Constant Operand

Description	One of the eight constants programmed by the host software can be used as operand. The bits field specifies the mask to be applied to the selected 32-bit constant.

12	11	10	9	8	7	6	5	4	3	2	1	0

1	0	1	0	0	C[2:0]	Bits[4:0]

Bits	Field Name	Description
7:5	C[2:0]	This field selects one of the constants (C0-C7).
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.

Table 24-873. 32-bit Register Operand

Description	One of eight 32-bit registers is used as operand and bits[4:0] field specifies the bitmask to be applied to that register.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	0	1	R[2:0]			Bits[4:0]				

Bits	Field Name	Description
7:5	R[2:0]	This field selects one of the 32-bits registers (R0-R7).
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.

Table 24-874. 1-bit Register Operand

Description	One of the four 1-bit registers is used as operand.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	0	T[1:0]		0	0	0	0	0

Bits	Field Name	Description
6:5	T[1:0]	This field selects one of the four 1-bits registers (T0-T3).

Table 24-875. Base Register Operand

Description	One of the base registers is used. The 2-bit codes are 00, 01, 10 and 11 for B1 to B4 respectively.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	B[1:0]		0	0	Bits[2:0]		

Bits	Field Name	Description
6:5	B[1:0]	This field selects one of the four base registers (B1-B4). Note that B0 is a virtual register which is always zero and specifies the start of packet.
2:0	Bits[2:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.

Table 24-876. End of Packet Operand

Description	The End-of-Packet (EOP) operand can be used to detect the end of current packet. Use of this operand will stall the CPU until the end of packet is reached. The end of packet operand will always be equal to one when the CPU detects end of packet. It will be zero until packet data is being received and will also stall the CPU. The recommended use of this operand is in the last instruction where a check may be made for size of current packet. Note that this operand only tracks the end of a complete successfully received packet by the RFIFO. The EOP operand does not detect abort of a packet.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	0	1	0	Bits[4:0]				

Bits	Field Name	Description
4:0	Bits[4:0]	The number of bits specifies the mask. However, these bits are inconsequential for EOP operand. Irrespective of the mask specified by bits[4:0], the EOP operand is always equal to 0x1 in the execution cycle of the instruction it is used.

Table 24-877. Octet Count Operand

Description	The Octet count operand is used to determine the number of bytes that have been received by rule engine.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	0	0	1	1	1	Bits[4:0]				

Bits	Field Name	Description
4:0	Bits[4:0]	The number of bits specifies the mask that is applied to octet counter value. The recommend value for this field is 0x1F.

Table 24-878. Immediate Data Operands

Description	The immediate data operands can be bigger than 13 bits as shown in the codes below. Each of such operands is directly sent to the ALU without applying any addition bit mask. The immediate data operands can be 8, 16 or 32 bits wide.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	0	Data[7:0]							

20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	Data[15:0]															

36	35	34	33	32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	Data[31:0]																																	

Table 24-879. Immediate Operand Masks

Description	The operand fields can also be used to specify bit masks. These are used when only specific bits from an operand are to be extracted. There is provision for 8-bit and 16-bit masks that can be encoded into an instruction's operand field.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	Mask[7:0]							

20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	1	Mask[15:0]															

When the operand field is all-ones it does not specify any operand and is considered zero.

The tables below list the combinations in which operands may be programmed in an instruction. In this list, Pkt/Reg operand is an operand consisting of octets from the packet or the contents of one of the internal registers; mask specifies the value that is used as a mask instead of the mask generated from the Bits field in the instruction; immediate operand (immediate[7:0], immediate[15:0] and immediate[31:0]) is an 8/16/32 bit number that is used as an operand. The format of Pkt/Reg operand is as shown previously. The decoding of operands for each ALU is dependent upon the type of operation specified in the ALU and the format of the operand field. When there are four operands in the operand field, the first and second operands are used in ALU0 and the rest by ALU1. When ALU0 needs only one operand, then the remaining operands are fed to ALU1. The order of decoding operands is designed to first provide operands to ALU0 from the more significant side of operand field and then to ALU1. If the number of operands specified in instruction does not match with the number of operands required by the ALUs, unspecified behavior can occur. For an instruction to execute, both ALUs must have valid data. If any of the ALUs uses a packet data operand which is not yet available

then the rule engine stalls until data is available. During the stall phase, the instruction is decoded every cycle and all required operands must be available simultaneously for the instruction to be executed In addition, if an instruction refers to packet octets that are no longer available, the rule engine stalls until the end of packet.

Pkt/Reg Operand[12:0]	1101 Mask[15:0] 01 Immediate[15:0]		

Pkt / Reg / Imm[7:0] Operand[12:0]	11110 Immediate[31:0] 11

11110 Immediate[31:0] 11	Pkt / Reg / Imm[7:0] Operand[12:0]

Table 24-883. Operand Field With One Operand

Pkt / Reg / Imm[7:0] Operand[12:0]	Reserved	Reserved	Reserved
Pkt/Reg Operand[12:0]	11000 Mask[7:0]	Reserved	Reserved
Pkt/Reg Operand[12:0]	11001 Mask[15:0] 11111		Reserved
11101 Immediate[15:0] 11111		Reserved	Reserved
11110 Immediate[31:0] 11			Reserved

The formats in which operands are specified in the operand field have certain restrictions:

- a mask cannot follow an immediate value
- a mask cannot follow a previous mask
- a reserved field should have all following fields reserved as well
- the first field cannot be a mask

24.11.4.9.2.7.3 Arithmetic/Logical Function Field

There can be two codes for arithmetic and logical functions in each instruction. Each of the operations can involve one or two operands.

The location of each function field in an instruction is listed in Table 24-884.

Table 24-884. Arithmetic/Logical Instruction Field

Bits	Description
23:20	Single or Dual operand Arithmetic/Logic Function (function 0)
19:16	Single or Dual operand Arithmetic/Logic Function (function 1)

The bit codes for each arithmetic/logic function that can be performed on the operands of an instruction are listed in Table 24-885.

Table 24-885. Arithmetic/Logical Operation Codes

Code	Description	Operands Required	32-bit result	1-bit flag result
0x0	Less Than	2	0	Set if true
0x1	Less Than Equal To	2	0	Set if true
0x2	Greater Than	2	0	Set if true
0x3	Greater Than Equal To	2	0	Set if true
0x4	Equal to Zero	1	0	Set if true
0x5	Not Equal to Zero	1	0	Set if true
0x6	Equal to One	1	0	Set if true
0x7	Not Equal to One	1	0	Set if true
0x8	Equal	2	0	Set if true
0x9	Not Equal	2	0	Set if true
0xA	Add	2	Sum	Set if overflow
0xB	Subtract	2	Difference	Set if output is negative
0xC	Bitwise AND	2	Bitwise AND	0

Table 24-885. Arithmetic/Logical Operation Codes (continued)

Code	Description	Operands Required	32-bit result	1-bit flag result
0xD	Bitwise OR	2	Bitwise OR	0
0xE	Result is same as Operand	1	Same as operand	0
0xF	No Function (NOF)	0	0	0

The ALU0 and ALU1 are assigned function0 and function1 respectively. In case only one function is to be performed in an instruction, function0 field should be used to do that. An instruction with no function for ALU0 and a valid function for ALU1 will result in unspecified behavior.

The output of each function is in the form of a 32-bit number and a single bit value. The single bit value is either the carry bit from an add/subtract operation or the Boolean result from a comparison function. The single bit output from each function is referred as the flag0 or flag1 result. The 32-bit number is the outcome of arithmetic or a bitwise logical operation and it is referred to as the word0 or word1 result.

24.11.4.9.2.7.4 Operation Field

The operation field specifies a limit, save or a jump operation. All of these operations involve two arguments that are specified within the instruction.

In case of limit operation, one of the arguments is a condition and the other argument is a limit register. In case of save operation, one of the arguments is source data and the other argument is a destination where the data will be saved. In jump operation, the first argument is a condition that must be true for the jump to occur and the second argument is a destination to which the program control will be moved to. The destination argument in a jump operation also specifies specific destinations that lead to the current packet being immediately rejected or accepted.

The location of operation field in an instruction is shown in Table 24-886.

Table 24-886. Operation Fields

Bits	Description
17:9	Limit/Save/Jump Operation (operation 0) For limit operation, [17:16] is the operation field, [15:13] is the condition field and [12:9] is a limit register. For save operation, [17:16] is the operation field, [15:13] is the source field, and [12:9] is the destination field. For jump operation, [17:16] is the operation field, [15:13] is the condition field, and [12:9] is the destination field
8:0	Limit/Save/Jump Operation (operation 1) For limit operation, [8:7] is the operation field, [6:4] is the condition field and [3:0] is a limit register. For save operation, [8:7] is the operation field, [6:4] is the source field, and [3:0] is the destination field. For jump operation, [8:7] is the operation field, [6:4] is the condition field, and [3:0] is the destination field.

Table 24-887. Limit Operation

Description	In a limit operation, the condition argument specifies a condition that must be true for the specified limit register to be decremented if non-zero or the packet to be dropped if the limit register is zero.

8	7	6	5	4	3	2	1	0
0	0	Condition Code			Limit Register			

Bits	Field Name	Description
6:4	Condition Code	It is a 3-bit code that specifies the condition that must be true for the operation to be executed. 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 | flag1) 0x3: Logical NOR of flags (!(flag0 | flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Decrement/Limit

Bits	Field Name	Description
3:0	Limit Register	It is a 4-bit code that specifies the limit register that is to be decremented or checked for zero value. 0x0: Rate limit register L0 0x1: Rate limit register L1 0x2: Rate limit register L2 0x3: Rate limit register L3 0x4-0xF: Reserved

Table 24-888. Save Operation

Description	The arguments for a save operation include a code for source data and a code for the destination. The source is either a single bit data or a 32-bit word. The single bit data is either a flag from the functions or a logical OR/AND of the flags. The 32-bit word is the result of the ALU arithmetic/logical functions.

8	7	6	5	4	3	2	1	0
0	1	Source Data Code			Destination Register Code			

Bits	Field Name	Description
6:4	Source Data Code	It is a 3-bit code that specifies the source data which is to be save in another register 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 | flag1) 0x3: Logical AND of flags (flag0 & flag1) 0x4: Output of function (word0) 0x5: Output of function (word1) 0x6-0x7: Reserved
3:0	Destination Register Code	It is a 4-bit code that specified the register in which source data is to be stored 0x0-0x3: Single Bit register (T0-T3) 0x4-0x7: Base Register (B1-B3) 0x8-0xF: 32-bit Register (R0-R7)

For some instructions, the rule engine extracts the operand from the current packet. To determine the packet bits to be used as operands, it refers to one or more base registers. Whenever an instruction causes a change in value of any of the base registers, it cause the rule engine to wait for one clock cycle before executing the next instruction. The rule engine is a pipelined processor and change in the value of a base register causes the prefetched operand values to become stale and these need to be fetched again. The clock cycle inserted allows rule-engine to fetch the data again before the instruction using this data is executed. Only the instructions that use packet data will be delayed by a clock cycle if the previous instruction caused a change in the base register that is referenced in the current instruction.

Table 24-889. Jump Operation

Description	For jump operation, one of the operands is a condition that must evaluate to true for the jump operation to occur. The other operand is the destination to which the program counter will move to if the jump operation is executed. The condition in a jump operation is either one of the flags from the output of the arithmetic/logic unit or a logical AND/OR of the flags.

8	7	6	5	4	3	2	1	0
1	0	Condition Code			Destination Code			

Bits	Field Name	Description
6:4	Condition Code	Condition Code 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 | flag1) 0x3: Logical NOR of flags (!(flag0 | flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Jump

Bits	Field Name	Description
3:0	Destination Code	Destination Code 0x0: Accept packet, return to instruction zero and wait for the next packet. 0x1: Reject packet and return to instruction zero. 0x2-0xF: Go to instruction at offset +2 ...+15

The jump operation results in a change of program execution flow. The jump destination determines the next instruction that will be executed by the rule engine. The destination is only specified as a positive offset to the current value of the program counter. The program counter can result in the rule engine skipping a given number of instructions instead of executing the next instruction. In addition, the destination field can instruct the rule engine to immediately reject or accept the current packet without any further checks. The rule engine then goes back to the first instruction and waits for a new packet to arrive before it executes any further instructions.

The rule engine is a pipelined processor. When it executes a jump operation, there is a delay of one clock cycle before the next instruction is executed.

The operations specified in the two operation fields are independent of each other. However, it is possible that conflicting operations are specified in the operation fields of an instruction. When conflicting operations are specified and conditions of both operations evaluate to true; then the execution flow is determined as described below:

1. If one of the ALUs has a limit/jump operation that will cause the packet to be dropped, then the packet will be dropped irrespective of what the other ALU indicates.
2. If case 1 above is false and one of the ALUs has a jump operation that will cause the packet to be accepted, then the packet will be accepted and the rule engine will return to idle state.
3. If case 1 and 2 above are false and one of the ALUs has a jump to offset with the respective condition true, the jump will be executed. If there is conflicting jump to offset information in the two ALUs, ALU0 is given priority.

Table 24-890. No Operation

Description	If there is no Save, Jump or Limit operation specified in the operation field, it is interpreted as a no operation. There is no change in execution flow, no change in any register values or rate limit registers when a no operation is encountered.

8	7	6	5	4	3	2	1	0
1	1	Reserved			Reserved			

It is expected that the rule engine will be programmed such that a decision to accept or discard the current packet is made before all instructions have executed. If the rule engine reaches the last instruction and it does not result in a decision to accept/reject the packet, then the execution flow does not stop and all instructions from the first instruction are executed again until the end of packet is reached.

24.11.4.9.3 Programming Guide

24.11.4.9.3.1 Initialization Routine

The packet filter must be initialized in order for it to operate as specified. A typical order in which the module can be initialized is shown below:

1. Initialize the firmware by programming the internal memory and verify it (SPF_INSTR_W2, SPF_INSTR_W1, SPF_INSTR_W0, SPF_INSTR_CTL)
2. Allocate memory for logs written by SPF and initialized the log space parameters (SPF_LOG_BEGIN, SPF_LOG_END, SPF_SW_PTR)
3. Program the log map registers to associate drop codes with the log thresholds. (SPF_LOG_MAP0, SPF_LOG_MAP1)
4. Program log thresholds (SPF_LOG_THRESHk, where k = 0 to 8)
5. Program constant registers if required by the firmware (SPF_CONSTj, where j = 0 to 7)
6. Program clock prescale counters and rate limit registers if required by the firmware (SPF_PRESCALE, SPF_RATELIMi , where i = 0 to 3)

7. Program the interrupt frequency control register and interrupt mask register to setup interrupts (SPF_INTCNT, SPF_MASK_SET)
8. Program the control registers to enable SPF filter and logger (SPF_CONTROL).

24.11.4.9.3.2 Interrupt Service Routine

The interrupt service routine in SPF should be designed to process the data logs generated by SPF. It should trigger a higher layer application software that can analyze the data logs and determine if any remedial measures are required based on the information in the logs. At the minimum, the interrupt service routine must reprogram the software pointer for the logging machine to be able to continue logging.

The typical tasks performed following an interrupt are listed in the pseudo code below.

```
SPF_ISR {
read log hardware pointer
read log software pointer
determine how many log entries are to be read
read each log entry starting with the software pointer
update software pointer to reflect the next unread entry
clear interrupt
}
```

24.11.4.9.3.3 Rule Engine Example Program

Here is an example of how the rule engine can be programmed to detect packets that resemble Denial of Service traffic. The pseudo code is shown below.

```
IDLE:
jump to ICMP if start_of_packet
ICMP:
if (protocol==ICMP)
limit_ICMP
if (fragmented packet)
drop and jump to IDLE
accept and jump to IDLE
else
jump to IP
IP:
if (source_ip==dest_ip)
drop and jump to IDLE
if (fragmented and (fragment_offset+ip_size)>2^16)
drop and jump to IDLE
accept the packet and jump to IDLE
```

24.11.4.10 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

24.11.4.10.1 CPTS Architecture

Figure 24-206 shows the architecture of the CPTS module inside the GMAC_SW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the GMAC_SW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value though the Event FIFO

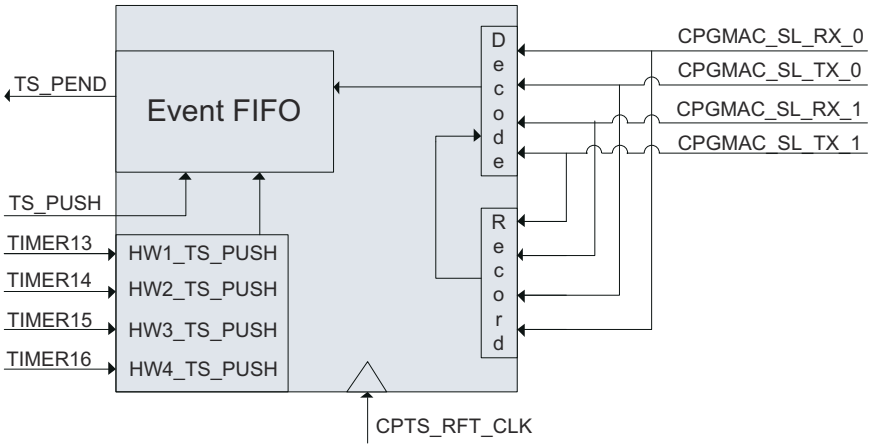

Figure 24-206. CPTS Block Diagram

The reference clock used for the time stamp (CPTS_RFT_CLK) can be derived from several sources. See *PRCM* for more details.

24.11.4.10.2 CPTS Initialization

The CPTS module should be configured as:

1. Reset the CPTS module.
2. Clear the CPTS_EN bit in the CPTS_CONTROL register.
3. Write the CLKSEL_RFT value in the CM_GMAC_GMAC_CLKCTRL register in the PRCM with the desired reference clock selection.
4. Set the CPTS_EN bit in the CPTS_CONTROL register.
5. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPTS_INT_ENABLE register.

24.11.4.10.3 Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS_RFT_CLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_VAL and CPTS_TS_LOAD_EN registers).

24.11.4.10.4 Event FIFO

All time sync events are push onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

24.11.4.10.5 Time Sync Events

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. Two 32-bit registers, CPTS_EVENT_HIGH and CPTS_EVENT_LOW hold the data of a time sync event. There are five types of sync events:

- Time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

24.11.4.10.5.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPTS_TS_PUSH register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

24.11.4.10.5.2 Time Stamp Counter Rollover Event

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from FFFF FFFFh to 0000 0000h, and the software maintained upper count value should be incremented.

24.11.4.10.5.3 Time Stamp Counter Half-rollover Event

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 7FFF FFFFh to 8000 0000h. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 24-207 shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0000 0000h through 7FFF FFFFh), then the event time stamp was taken after the rollover and no correction is required. If the value is high (8000 0000h through FFFF FFFFh), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

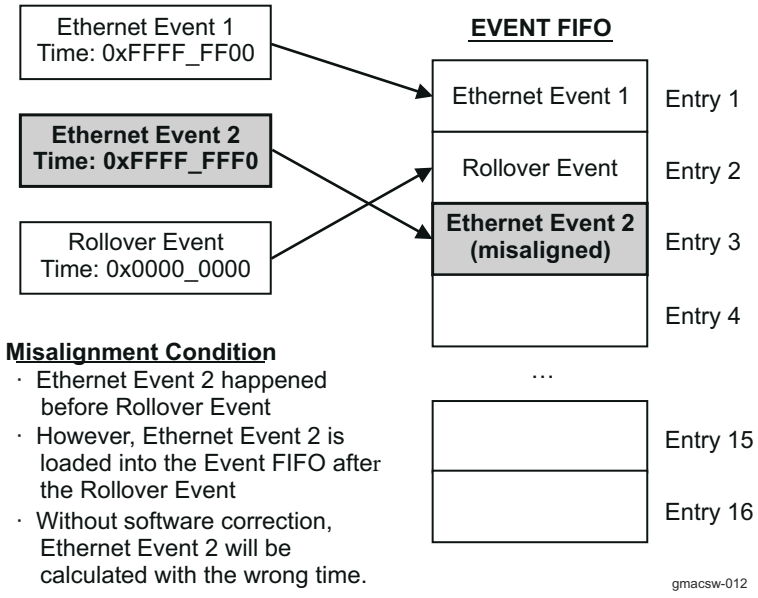

Figure 24-207. Event FIFO Misalignment Condition

24.11.4.10.5.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in Figure 24-208.

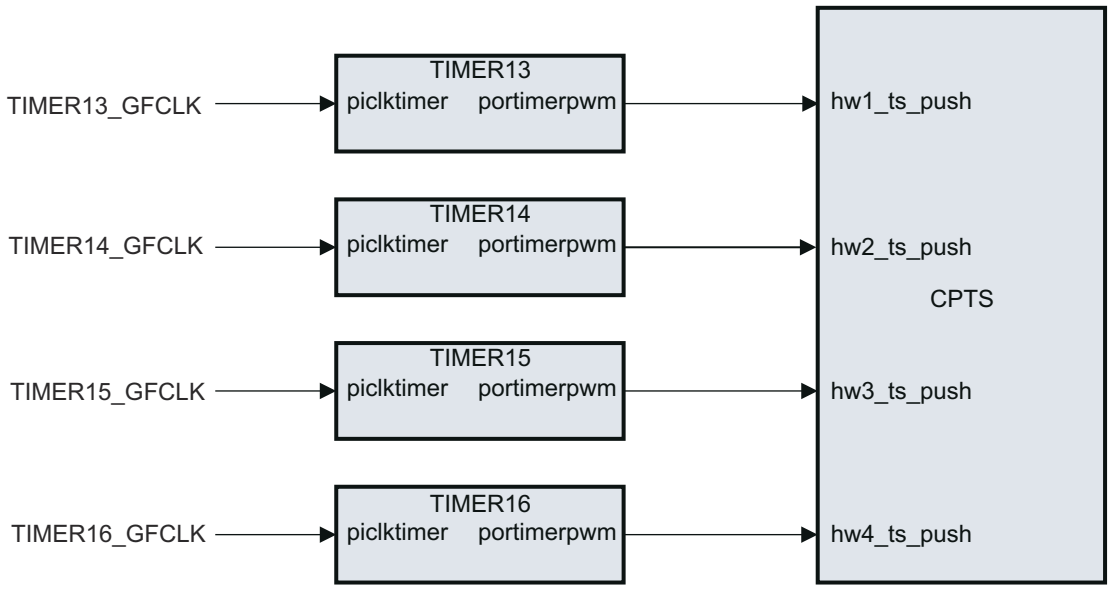

Figure 24-208. HW1/4_TSP_PUSH Connection

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPTS_EVENT_HIGH register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS_CONTROL register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

24.11.4.10.5.5 Ethernet Port Events

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in Figure 24-209. For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field or the TS_LTYPE2 field (depending on which enable bit was set) in the CPSW_TS_LTYPE register, which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in Figure 24-209. To indicate to the CPTS hardware that a virtual LAN is in use, the Pn_TS_VLAN_LTYPE1_EN (or Pn_TS_VLAN_LTYPE2_EN) enable bit must be set in the Pn_CONTROL register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the VLAN_LTYPE1 (or VLAN_LTYPE2 depending on which enable bit was set) field in the CPSW_VLAN_LTYPE register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 24-209. In this case, both VLAN_LTYPE1 and VLAN_LTYPE2 must be enabled. The outer tag must match the value of the VLAN_LTYPE1 field, and the inner tag must match the value of the VLAN_LTYPE2 field.

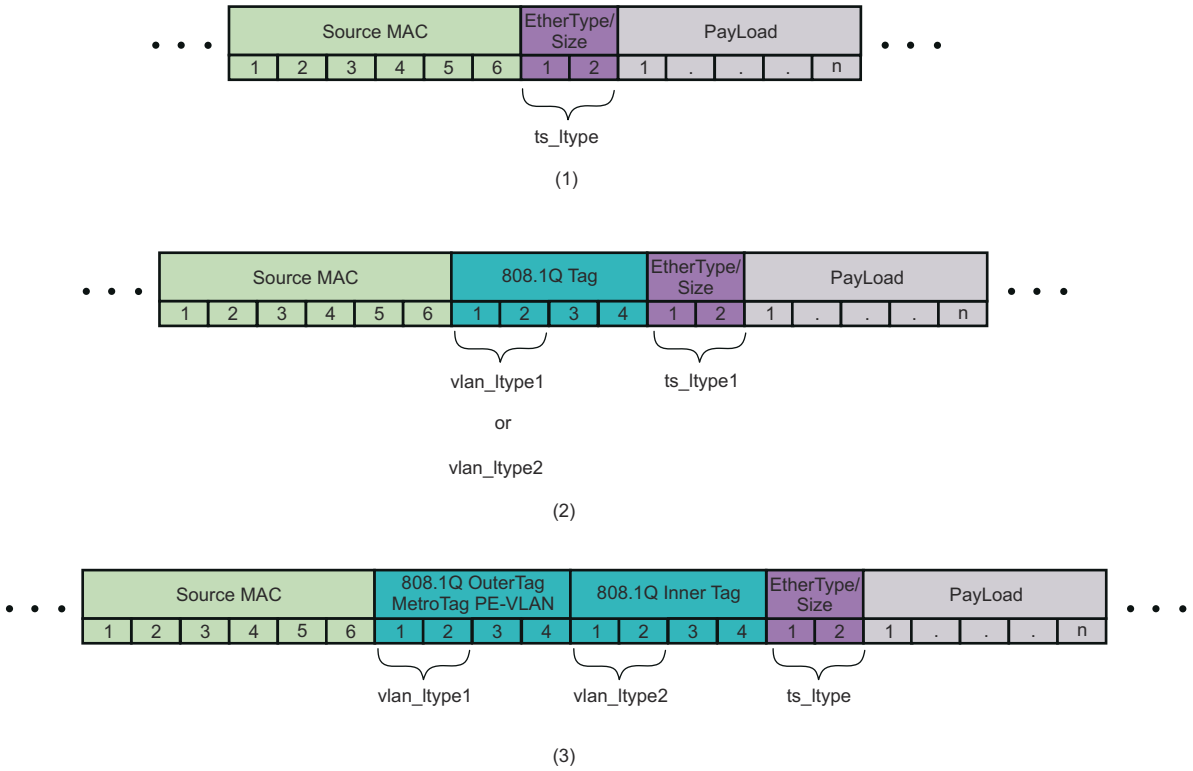

Figure 24-209. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)

To enable transmit/receive event packets on a given Ethernet port, perform the following steps, where n is the port number:

1. Set the [1] Pn_TS_TX_EN or the [0] Pn_TS_RX_EN bit in the Pn_CONTROL register to enable transmit/ receive event packets
2. Configure the register fields as follows:
   a. Set the Pn_CONTROL[2] Pn_TS_LTYPE1_EN or [3] Pn_TS_LTYPE2_EN bit to 1
   b. Set the CPSW_TS_LTYPE[15:0] TS_LTYPE1 or [31:16] TS_LTYPE2 (depending on which enable bit was set in 2(a)) field to 88F7h, which corresponds to the Precision Time Protocol (IEEE 1588) EtherType.
   c. Set the Pn_TS_SEQ_MTYPE[21:16] Pn_TS_SEQ_ID_OFFSET field to 1Eh, which is the sequence ID offset in the common message header given in the IEEE 1588 specification.
3. To enable support for VLAN tagging (IEEE 802.1Q):
   a. Set the [20] Pn_TS_VLAN_LTYPE1_EN or [21] Pn_TS_VLAN_LTYPE2_EN bit in the Pn_CONTROL register.
   b. Set the CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1 or [31:16] VLAN_LTYPE2 field (matching what was used in step 3a) to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType.
4. To enable support for up to two stacked VLANs (IEEE 802.1ad):
   a. Set the Pn_TS_VLAN_LTYPE1_EN and Pn_TS_VLAN_LTYPE2_EN bits in the Pn_CONTROL register.
   b. Set the VLAN_LTYPE1 field in the CPSW_VLAN_LTYPE register to match the EtherType of the outer tag.
   c. Set the VLAN_LTYPE2 field in the CPSW_VLAN_LTYPE register to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType of the inner tag.
5. Set the Pn_TS_SEQ_MTYPE[15:0] Pn_TS_MSG_TYPE_EN field to choose which types of time stamp messages will push events onto the Event FIFO. Table 9-20 lists the message types defined in the IEEE 1588-2008 specification. Table 24-891 lists the message types defined in the IEEE 1588-2008 specification.

Table 24-891. Values of Message Type Field

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4-7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E-F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO. The CPTS_EVENT_HIGH register contains the Message Type and Sequence ID values from the original time sync packet. The CPTS_EVENT_LOW register contains the time stamp value when the packet arrived at the corresponding port.

24.11.4.10.6 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP field (bit 0) of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP bit of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four CPTS_RFT_CLK periods plus four MAIN_CLK periods.
5. Read the TS_PEND_RAW bit in the CPTS_INTSTAT_RAW register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, go to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPTS_INTSTAT_RAW register to determine if a valid event is on the event FIFO.

24.11.4.11 CPPI Buffer Descriptors

The buffer descriptor is a central part of the GMAC_SW Ethernet Subsystem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

Host Software sends and receives network frames via the CPPI compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

Note

The 8K bytes of Ethernet Subsystem CPPI RAM begin at address 0x4848 6000 and end at 0x4848 7FFF from the GMAC_SW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use this address range.

24.11.4.11.1 TX Buffer Descriptors

A TX buffer descriptor () is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

24.11.4.11.1.1 CPPI TX Data Word 0

Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC. The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC

24.11.4.11.1.2 CPPI TX Data Word 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the buffer_pointer. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

24.11.4.11.1.3 CPPI TX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts

on byte 16 of the buffer. The host sets the Buffer_Offset value (which may be zero to the buffer length minus 1). Valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the Buffer_Length. The Buffer_Length must be greater than zero.

24.11.4.11.1.4 CPPI TX Data Word 3

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise,,the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer.

1 - Start of packet buffer.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

Ownership (OWNER) Flag

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

0 - The TX queue has more packets to transfer.

1 - The Descriptor buffer is the last buffer in the last packet in the queue.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

0 - The port has not completed the teardown process.

1 - The port has completed the commanded teardown process.

Pass CRC (PASSCRC) Flag

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC. When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

0 - The CRC is not included with the packet data and packet length.

1 - The CRC is included with the packet data and packet length.

TO_PORT

Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode.

1 - Send the packet to port 1 if TO_PORT_EN is asserted.

2 - Send the packet to port 2 if TO_PORT_EN is asserted.

TO_PORT_ENABLE

Indicates when set that the packet is a directed packet to be sent to the TO_PORT field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

0 - not a directed packet

1 - directed packet

24.11.4.11.2 RX Buffer Descriptors

A RX buffer descriptor () is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

24.11.4.11.2.1 CPPI RX Data Word 0

Next Descriptor Pointer

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the Next_Descriptor_Pointer.

24.11.4.11.2.2 CPPI RX Data Word 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the Buffer_Pointer.

24.11.4.11.2.3 CPPI RX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the Buffer_Offset with the value from the CPDMA_RX_BUFFER_OFFSET register value. The host initializes the Buffer_Offset to zero for free buffers. The Buffer_Length must be greater than the CPDMARX_BUFFER_OFFSET register value. The buffer offset is valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the Buffer_Length, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The Buffer_Length must be greater than zero.

24.11.4.11.2.4 CPPI RX Data Word 3

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by

the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

Long (Jabber) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX_CEF_EN bit was set in the SL_MACCONTROL register. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

Short (Fragment) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX_CSF_EN bit was set in the SL_MACCONTROL register.

Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX_CMF_EN bit was set in the SL_MACCONTROL register.

Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

Packet Error (PKT_ERR) Flag

Packet Contained Error on Ingress:

00 - no error

01 - CRC error on ingress

10 - Code error on ingress

11 - Align error on ingress

VLAN Encapsulated Packet (RX_VLAN_ENCAP)

Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the CPSW_CONTROL register RX_VLAN_ENCAP bit.

FROM_PORT

Indicates the port number that the packet was received on (ingress to the switch).

24.11.4.12 MDIO

The MII Management interface module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers (MDIO_USERACCESS0/MDIO_USERACCESS1) control and monitor up to two PHYs simultaneously.

24.11.4.12.1 MDIO Frame Formats

Table 24-892 shows the read format and Table 24-893 shows the write format of the 32-bit MII Management interface frames.

Table 24-892. MDIO Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 24-893. MDIO Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 01 pattern. The pattern assures transitions from the default logic 1 state to logic 0, and back to logic 1.

Operation Code

The operation code for a read is 10, while the operation code for a write is a 01.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

24.11.4.12.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the MDIO_CONTROL register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO_LINK register. The LINKSEL bit in the MDIO_USERPHYSEL0/1 register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO_LINKINTRAW register and the MDIO_LINKINTMASKED register, if enabled by the LINKINT_ENABLE bit in the MDIO_USERPHYSEL0/1 register.

The MDIO_ALIVE register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO_ALIVE register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a MDIO_USERACCESS0/1 register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW bit in the MDIO_USERINTRAW register corresponding to the MDIO_USERACCESS0/1 register being used. The corresponding bit in the MDIO_USERINTMASKED register may also be set depending on the mask setting in the MDIO_USERINTMASKSET and MDIO_USERINTMASKCLR registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different MDIO_USERACCESS0/1 registers. The host should check the status of the GO bit in the MDIO_USERACCESS0/1 register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO_USERACCESS0/1 register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the SL_MACCONTROL register in the corresponding MAC.

24.11.5 GMAC_SW Programming Guide

24.11.5.1 Transmit Operation

After reset, the host must write zeroes to all TX DMA State head descriptor pointers. The TX port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate TX DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the TX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Write the Buffer Length with the number of bytes in the buffer
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only)
5. Set the SOP, EOP, and Ownership bits as appropriate
6. Clear the End Of Queue bit

The port begins TX packet transmission on a given channel when the host writes the channel's TX queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each TX packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each TX packet must have the End of Packet (EOP) bit set to one by the host. The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's TX DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written. When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a TX interrupt to the host by writing to the queue's associated TX completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete. The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated TX Completion Pointer in the TX DMA State. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is de-asserted. The port write to the completion pointer actually stores the value in the state register (RAM). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

A mis-queued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The mis-queued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the mis-queued packet condition by initiating a new packet transfer for the mis-queued packet by writing the mis-queued packet's SOP buffer descriptor address to the appropriate DMA State TX Queue head Descriptor Pointer.

The host may add packets to the tail end of an active TX queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a TX queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate TX DMA State head descriptor pointer. The host software should always check for and reinitiate transmission for mis-queued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any TX packet that is not complete and ready for transmission.

The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

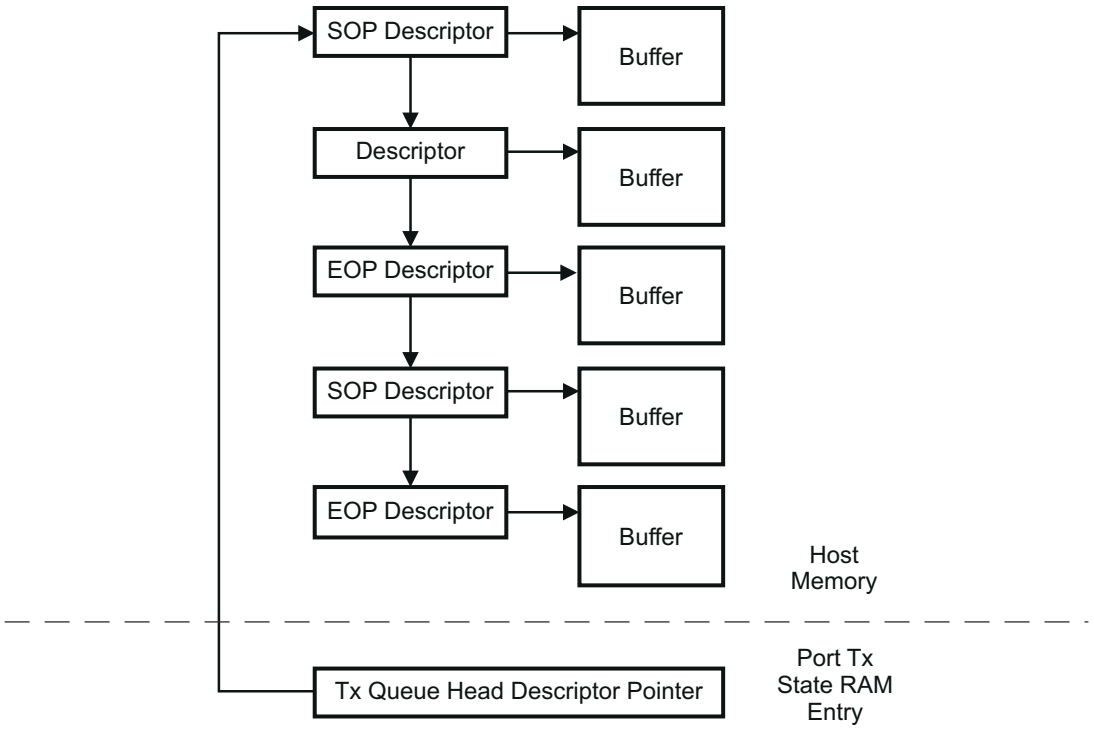

Figure 24-210. TX Queue Head Descriptor

24.11.5.2 Receive Operation

After reset, the host must write zeroes to all RX DMA State head descriptor pointers. The RX port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate RX DMA state head descriptor pointer. For each RX buffer descriptor added to the queue, the host must initialize the RX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Clear the Offset field
4. Write the Buffer Length with the number of bytes in the buffer
5. Clear the SOP, EOP, and EOQ bits
6. Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's RX DMA state. When packet reception begins on a given channel, the port fills each RX buffer with data in order starting with the first buffer and proceeding through the RX queue. If the Buffer Offset in the RX DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

1. Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value will be less than or equal to the host initialized value.
2. Set the EOP bit in the packet's EOP buffer descriptor.
3. Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
4. Overwrite the packet's SOP buffer descriptor Buffer Offset with the RX DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.

5. Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
6. Set the SOP bit in the packet's SOP buffer descriptor.
7. Write the SOP buffer descriptor Packet Length field.
8. Clear the Ownership bit in the packet's SOP buffer descriptor.
9. Issue an RX host interrupt by writing the address of the packet's last buffer descriptor to the queue's RX DMA State Completion Pointer. The interrupt is generated by the write to the RX DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the RX buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host. The host may continue RX queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the RX queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A mis-queued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The mis-queued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the mis-queued buffer case. If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start of packet overrun). If the mis-queued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the mis-queued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the mis-queued buffer condition by writing the added buffer descriptor address to the appropriate RX DMA State Head Descriptor Pointer.

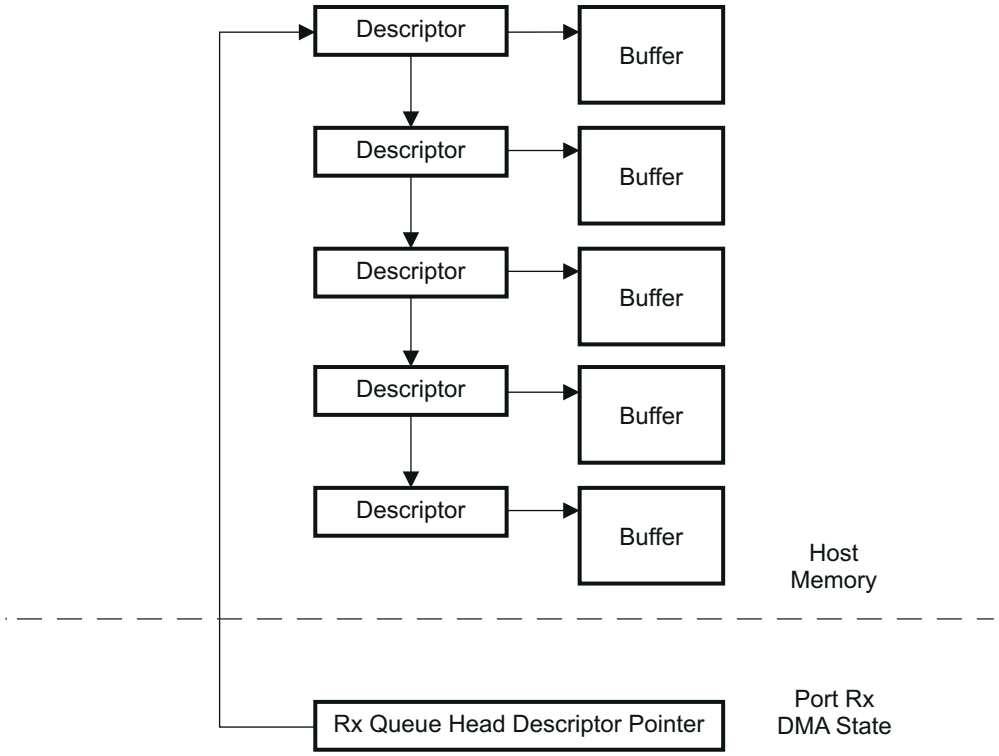

Figure 24-211. RX Queue Head Descriptor

24.11.5.3 MDIO Software Interface

24.11.5.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (MDIO_CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in MDIO_CONTROL.
3. The MDIO PHY alive status register (MDIO_ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO_LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (MDIO_USERPHYSEL0/1), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO_USERINTMASKSET) to use the MDIO user access register (MDIO_USERACCESS0/1). Since only one PHY is used in this device, the application software can use one MDIO_USERACCESS0/1 to trigger a completion interrupt; the other MDIO_USERACCESS0/1 is not setup.

24.11.5.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO_USERACCESS0/1) to directly access a specified PHY device.To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO_USERACCESS0/1) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO_USERACCESS0/1 corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO_USERACCESS0/1 for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIO_USERINTRAW) corresponding to MDIO_USERACCESS0/1 used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register

(MDIO_USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIO_USERINTMASKED) and an interrupt is triggered on the host processor.

24.11.5.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO_USERACCESS0/1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO_USERACCESS*n*) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in MDIO_USERACCESS0/1 corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in MDIO_USERACCESS0/1 after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in MDIO_USERACCESS0/1. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIO_USERINTRAW) corresponding to MDIO_USERACCESS0/1 used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIO_USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIO_USERINTMASKED) and an interrupt is triggered on the host processor.

24.11.5.4 Initialization and Configuration of CPSW

To configure the GMAC_SW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (G/MII, RGMII, RMII) Mode
2. Configure pads (PIN muxing), as per the interface selected.
3. Enable the GMAC_SW Ethernet Subsystem Clocks
4. Configure the PRCM registers CM_GMAC_CLKSTCTRL and CM_GMAC_GMAC_CLKCTRL to enable power and clocks to GMAC_SW Ethernet Subsystem.
5. Apply Soft Reset to GMAC_SW Subsystem, CPSW_3G, CPGMAC_SL1/2, and CPDMA
6. Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL
7. Configure the Interrupts
8. Configure the CPSW_CONTROL register
9. Configure the CPSW_STAT_PORT_EN register
10. Configure the ALE
11. Configure the MDIO
12. Configure the CPDMA receive DMA controller
13. Configure the CPDMA transmit DMA controller
14. Configure the CPPI TX and RX Descriptors
15. Configure CPGMAC_SL1 and CPGMAC_SL2, as per the desired mode of operations.
16. Start up RX and TX DMA (Write to HDP of RX and TX)
17. Wait for the completion of Transfer (HDP cleared to 0)

24.11.6 GMAC_SW Register Manual

24.11.6.1 GMAC_SW Instance Summary

Table 24-894. GMAC_SW Instance Summary

Module Name	Module Base Address	Size
SS	0x4848 4000	80 Bytes
PORT	0x4848 4100	1792 Bytes
CPDMA	0x4848 4800	256 Bytes
STATS	0x4848 4900	128 Bytes

Table 24-896. CPSW_ID_VER

Address Offset	0x0000 0000		
Physical Address	0x4848 4000	**Instance**	SS
Description	CPSW_3G ID version register		

Table 24-896. CPSW_ID_VER (continued)

Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	CPSW_3G Revision Value	R	0x-

Table 24-897. CPSW_CONTROL

Address Offset	0x0000 0004		
Physical Address	0x4848 4004	Instance	SS
Description	Switch control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											EEE_EN	DLR_EN	RX_VLAN_ENCAP	VLAN_AWARE	FIFO_LOOPBACK

Bits	Field Name	Description	Type	Reset
31:5	RESERVED		R	0x0
4	EEE_EN	EEE (Energy Efficient Ethernet) enable 0 – EEE is disabled. 1 – EEE is enabled	RW	0x0
3	DLR_EN	DLR enable 0 - DLR is disabled. DLR packets will not be moved to queue priority 3 and will not be separated out onto dlr_cpdma_ch. 1 - DLR is disabled. DLR packets be moved to destination port transmit queue priority 3 and will be separated out onto dlr_cpdma_ch when packet is to egress on port 0.	RW	0x0
2	RX_VLAN_ENCAP	Port 0 VLAN Encapsulation (egress): 0 - Port 0 receive packets (from CPSW_3G) are not VLAN encapsulated. 1 - Port 0 receive packets (from CPSW_3G) are VLAN encapsulated.	RW	0x0
1	VLAN_AWARE	VLAN Aware Mode: 0 - CPSW_3G is in the VLAN unaware mode. 1 - CPSW_3G is in the VLAN aware mode.	RW	0x0
0	FIFO_LOOPBACK	FIFO Loopback Mode 0 - Loopback is disabled 1 - FIFO Loopback mode enabled. Each packet received is turned around and sent out on the same port's transmit path. Port 2 receive is fixed on channel zero. The RXSOFOVERRUN statistic will increment for every packet sent in FIFO loopback mode.	RW	0x0

Table 24-898. CPSW_SOFT_RESET

Address Offset	0x0000 0008		
Physical Address	0x4848 4008	Instance	SS
Description	Soft reset register		

Table 24-898. CPSW_SOFT_RESET (continued)

Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															SOFT_RESET

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	SOFT_RESET	Software reset - Writing a one to this bit causes the 3G logic (INT, REGS, CPPI, and SPF modules) to be reset. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.	RW	0x0

Table 24-899. CPSW_STAT_PORT_EN

Address Offset	0x0000 000C		
Physical Address	0x4848 400C	Instance	SS
Description	Statistics port enable register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																													P2_STAT_EN	P1_STAT_EN	P0_STAT_EN

Bits	Field Name	Description	Type	Reset
31:3	RESERVED		R	0x0
2	P2_STAT_EN	Port 2 (GMII2 and Port 2 FIFO) Statistics Enable 0 - Port 2 statistics are not enabled. 1 - Port 2 statistics are enabled.	RW	0x0
1	P1_STAT_EN	Port 1 (GMII1 and Port 1 FIFO) Statistics Enable 0 - Port 1 statistics are not enabled. 1 - Port 1 statistics are enabled.	RW	0x0
0	P0_STAT_EN	Port 0 Statistics Enable 0 - Port 0 statistics are not enabled 1 - Port 0 statistics are enabled. FIFO overruns (SOFOVERRUNS) are the only port 0 statistics that are enabled to be kept.	RW	0x0

Table 24-900. CPSW_PTYPE

Table 24-965. P1_SEND_PERCENT

Address Offset	0x0000 0128		
Physical Address	0x4848 4228	**Instance**	PORT
Description	CPSW PORT 1 transmit queue send percentages		

Table 24-965. P1_SEND_PERCENT (continued)

Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								PRI3_SEND_PERCENT								RESERVED	PRI2_SEND_PERCENT							RESERVED	PRI1_SEND_PERCENT						

Bits	Field Name	Description	Type	Reset
31:23	RESERVED		R	0x0
22:16	PRI3_SEND_PERCENT	Priority 3 Transmit Percentage - This percentage value is sent from FIFO priority 3 (maximum) when CPSW_PTYPE[18] P1_PRI3_SHAPE_EN is set (queue shaping enabled). This is the percentage of the wire that packets from priority 3 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).	RW	0x0
15	RESERVED		R	0x0
14:8	PRI2_SEND_PERCENT	Priority 2 Transmit Percentage - This percentage value is sent from FIFO priority 2 (maximum) when CPSW_PTYPE[17] P1_PRI2_SHAPE_EN is set (queue shaping enabled). This is the percentage of the wire that packets from priority 2 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).	RW	0x0
7	RESERVED		R	0x0
6:0	PRI1_SEND_PERCENT	Priority 1 Transmit Percentage - This percentage value is sent from FIFO priority 1 (maximum) when the CPSW_PTYPE[16] P1_PRI1_SHAPE_EN is set (queue shaping enabled). This is the percentage of the wire that packets from priority 1 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).	RW	0x0

RESERVED																								P2_TX_MAX_BLKS				P2_RX_MAX_BLKS			

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x0
8:4	P2_TX_MAX_BLKS	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of P2_TX_MAX_BLKS unless the port is in fullduplex flow control mode. In flow control mode, the P2_RX_MAX_BLKS will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in P2_RX_MAX_BLKS. 0xE is the minimum value P2_TX_MAX_BLKS.	RW	0x11
3:0	P2_RX_MAX_BLKS	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In fullduplex flow control mode to 0x5 or 0x6 depending on the required runout space. The P2_TX_MAX_BLKS value must be decreased by the amount of increase in P2_RX_MAX_BLKS. 0x3 is the minimum value P2_RX_MAX_BLKS and 0x6 is the maximum value.	RW	0x3

RESERVED																															SOFT_RESET

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	SOFT_RESET	Software reset - Writing a one to this bit causes the CPDMA logic to be reset. Software reset occurs when the RX and TX DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.	RW	0x0

TX_PTYPE must be set if any TX_RLIM bit is set for fixed priority.	RW	0x0
7:5	RESERVED		R	0x0
4	RX_CEF	RX Copy Error Frames Enable - Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when RX_CEF is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. 0 - Frames containing overrun errors are filtered. 1 - Frames containing overrun errors are transferred to memory.	RW	0x0
3	CMD_IDLE	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read IDLE in CPDMA_DMASTATUS)	RW	0x0
2	RX_OFFLEN_BLOCK	Receive Offset/Length word write block. 0 - Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0. 1 - Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor.	RW	0x0
1	RX_OWNERSHIP	Receive Ownership Write Bit Value. 0 - The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0. 1 - The CPDMA writes the receive ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.	RW	0x0
0	TX_PTYPE	Transmit Queue Priority Type 0 - The queue uses a round robin scheme to select the next channel for transmission. 1 - The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission	RW	0x0

IDLE	RESERVED							TX_HOST_ERR_CODE				RESERVED	TX_ERR_CH			RX_HOST_ERR_CODE				RESERVED	RX_ERR_CH			RESERVED							

Bits	Field Name	Description	Type	Reset
31	IDLE	Idle Status Bit - Indicates when set that the CPDMA is not transferring a packet on transmit or receive.	R	0x0
30:24	RESERVED		R	0x0
23:20	TX_HOST_ERR_CODE	TX Host Error Code - This field is set to indicate CPDMA detected TX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. A zero packet length is an error, but it is not detected. 0x0 - No error 0x1 - SOP error. 0x2 - Ownership bit not set in SOP buffer. 0x3 - Zero Next Buffer Descriptor Pointer Without EOP 0x4 - Zero Buffer Pointer. 0x5 - Zero Buffer Length 0x6 - Packet Length Error (sum of buffers is less than packet length) 0x7 - 1xF - reserved	R	0x0
19	RESERVED		R	0x0
18:16	TX_ERR_CH	TX Host Error Channel - This field indicates which TX channel (if applicable) the host error occurred on. This field is cleared to zero on a host read.	R	0x0
15:12	RX_HOST_ERR_CODE	RX Host Error Code - This field is set to indicate CPDMA detected RX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. 0x0 - No error 0x1 - reserved 0x2 - Ownership bit not set in input buffer. 0x3 - reserved 0x4 - Zero Buffer Pointer. 0x5 - Zero buffer length on non-SOP descriptor 0x6 - SOP buffer length not greater than offset 0x7 - 1xF - reserved	R	0x0
11	RESERVED		R	0x0
10:8	RX_ERR_CH	RX Host Error Channel - This field indicates which RX channel the host error occurred on. This field is cleared to zero on a host read.	R	0x0
7:0	RESERVED		R	0x0

RESERVED																RX_BUFFER_OFFSET															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_BUFFER_OFFSET	Receive Buffer Offset Value - The RX_BUFFER_OFFSET will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the rx_buffer_offset value of bytes. A value of 0x0000 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.	RW	0x0

RESERVED																RX_FREEBUFFER															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_FREEBUFFER	Rx Free Buffer Count - This field contains the count of free buffers available. The CPDMA_RX0_PENDTHRESH[7:0] RX_PENDTHRESH value is compared with this field to determine if the receive threshold pending interrupt should be asseted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If receive threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the received frame) the associated channel register for each received frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.	W	0x0

RESERVED	RX_FREEBUFFER

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_FREEBUFFER	Rx Free Buffer Count - This field contains the count of free buffers available. The CPDMA_RX3_PENDTHRESH[7:0] RX_PENDTHRESH value is compared with this field to determine if the receive threshold pending interrupt should be asseted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If receive threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the received frame) the associated channel register for each received frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.	W	0x0

24.11.6.5.2 STATS Register Description

Table 24-1127. GOOD_RX_FRAMES

Address Offset	0x0000 0000		
Physical Address	0x4848 4900	**Instance**	STATS
Description	The total number of good frames received on the port. A good frame is defined to be: - Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode - Had a length of 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had no CRC error, alignment error or code error. See the RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

Table 24-1131. MULTICAST_RX_FRAMES

Address Offset	0x0000 0008		
Physical Address	0x4848 4908	Instance	STATS
Description	The total number of good multicast frames received on the port. A good multicast frame is defined to be: - Any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFFFFFF - Had a length of SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had no CRC error, alignment error or code error. See the RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

Table 24-1133. PAUSE_RX_FRAMES

Address Offset	0x0000 000C		
Physical Address	0x4848 490C	Instance	STATS
Description	The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame: - Contained any unicast, broadcast, or multicast address - Contained the length/type field value 88.08 (hex) and the opcode 0x0001 - Was of length 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had no CRC error, alignment error or code error - Pause-frames had been enabled on the port (SL_MACCONTROL[4] TX_FLOW_EN = 1). The port could have been in either half or full-duplex mode. See the RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 24-1135. RX_CRC_ERRORS

Address Offset	0x0000 0010		
Physical Address	0x4848 4910	**Instance**	STATS
Description	The total number of frames received on the port that experienced a CRC error. Such a frame: - Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode - Was of length 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had no code/align error, - Had a CRC error Overruns have no effect upon this statistic. A CRC error is defined to be: - A frame containing an even number of nibbles - Failing the Frame Check Sequence test		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 24-1137. RX_ALIGN_CODE_ERRORS

Address Offset	0x0000 0014		
Physical Address	0x4848 4914	**Instance**	STATS
Description	The total number of frames received on the port that experienced an alignment error or code error. Such a frame: - Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode - Was of length 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had either an alignment error or a code error Overruns have no effect upon this statistic. An alignment error is defined to be: - A frame containing an odd number of nibbles - Failing the Frame Check Sequence test if the final nibble is ignored A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception. Note: RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS.

Table 24-1155. PAUSE_TX_FRAMES

Address Offset	0x0000 0040		
Physical Address	0x4848 4940	**Instance**	STATS
Description	This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count. Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic. Transmitted pause frames are always 64 byte multicast frames so will appear in the MULTICAST_TX_FRAMES and RX_TX_64_OCTET_FRAMES statistics.		
Type	RW

Table 24-1159. COLLISIONS

Address Offset 0x0000 0048

Physical Address 0x4848 4948 **Instance** STATS

Description This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.
1. When a transmit data or MAC control frame:
- Was destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions) CRC errors have no effect upon this statistic.
2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

Type RW

Table 24-1167. LATE_COLLISIONS

Address Offset	0x0000 0058		
Physical Address	0x4848 4958	**Instance**	STATS
Description	The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame: - Was any data or MAC control frame destined for any unicast, broadcast or multicast address - Was any size - Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The Late Collisions statistic dominates over the single, multiple and excessive Collisions statistics - if a late collision occurs the frame will not be counted in any of these other three statistics. CRC errors have no effect upon this statistic.

Table 24-1187. NET_OCTETS (continued)

Description	The total number of bytes of frame data received and transmitted on the port. Each frame counted: - was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter) - Any length (including less than 64 bytes and greater than SL_RX_MAXLEN[13:0] RX_MAXLEN bytes) Also counted in this statistic is: - Every byte transmitted before a carrier- loss was experienced - Every byte transmitted before each collision was experienced, (i.e. multiple retries are counted each time) - Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting) Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic. The objective of this statistic is to give a reasonable indication of ethernet utilization

24.11.6.6.2 STATERAM Register Description

Table 24-1196. TX0_HDP

Address Offset	0x0000 0000		
Physical Address	0x4848 4A00	**Instance**	STATERAM
Description	CPDMA_STATERAM TX channel 0 head descriptor pointer		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TX_HDP																															

Bits	Field Name	Description	Type	Reset
31:0	TX_HDP	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.	RW	0x0

Physical Address	0x4848 4C0C	**Instance**	CPTS
Description	Time stamp event push register		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															TS_PUSH

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	TS_PUSH	Time stamp event push - When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.	W	0x0

TS_LOAD_VAL																															

Bits	Field Name	Description	Type	Reset
31:0	TS_LOAD_VAL	Time Stamp Load Value - Writing the CPTS_TS_LOAD_EN[0] TS_LOAD_EN bit causes the value contained in this register to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register.	RW	0x0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENABLE_ALE	CLEAR_TABLE	AGE_OUT_NOW	RESERVED																				EN_P0_UNI_FLOOD	LEARN_NO_VID	EN_VID0_MODE	ENABLE_OUI_DENY	BYPASS	RATE_LIMIT_TX	VLAN_AWARE	ENABLE_AUTH_MODE	ENABLE_RATE_LIMIT	

Bits	Field Name	Description	Type	Reset
31	ENABLE_ALE	Enable ALE - 0 - Drop all packets 1 - Enable ALE packet processing	RW	0x0

Bits	Field Name	Description	Type	Reset
30	CLEAR_TABLE	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.	RW	0x0
29	AGE_OUT_NOW	Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case.	RW	0x0
28:9	RESERVED		R	0x0
8	EN_P0_UNI_FLOOD	Enable Port 0 (Host Port) unicast flood 0 - do not flood unknown unicast packets to host port (p0) 1 - flood unknown unicast packets to host port (p0)	RW	0x0
7	LEARN_NO_VID	Learn No VID - 0 - VID is learned with the source address 1 - VID is not learned with the source address (source address is not tied to VID).	RW	0x0
6	EN_VID0_MODE	Enable VLAN ID = 0 Mode 0 - Process the packet with VID = PORT_VLAN[11:0]. 1 - Process the packet with VID = 0.	RW	0x0
5	ENABLE_OUI_DENY	Enable OUI Deny Mode - When set this bit indicates that a packet with a non OUI table entry matching source address will be dropped to the host unless the destination address matches a multicast table entry with the super bit set.	RW	0x0
4	BYPASS	ALE Bypass - When set, all packets received on ports 0 and 1 are sent to the host (only to the host).	RW	0x0
3	RATE_LIMIT_TX	Rate Limit Transmit mode - 0 - Broadcast and multicast rate limit counters are received port based 1 - Broadcast and multicast rate limit counters are transmit port based.	RW	0x0
2	VLAN_AWARE	ALE VLAN Aware - Determines what is done if VLAN not found. 0 - Flood if VLAN not found 1 - Drop packet if VLAN not found	RW	0x0
1	ENABLE_AUTH_MODE	Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). 0 - The ALE is not in MAC authorization mode 1 - The ALE is in MAC authorization mode	RW	0x0
0	ENABLE_RATE_LIMIT	Enable Broadcast and Multicast Rate Limit 0 - Broadcast/Multicast rates not limited 1 - Broadcast/Multicast packet reception limited to the port control register rate limit fields.	RW	0x0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RX_CMF_EN	RX_CSF_EN	RX_CEF_EN	TX_SHORT_GAP_LIM_EN	RESERVED		EXT_EN	GIG_FORCE	IFCTL_B	IFCTL_A	RESERVED		CMD_IDLE	TX_SHORT_GAP_EN	RESERVED		GIG	TX_PACE	GMII_EN	TX_FLOW_EN	RX_FLOW_EN	MTEST	LOOPBACK	FULLDUPLEX

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
24	RX_CMF_EN	RX Copy MAC Control Frames Enable - Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the SL_MACCONTROL register, regardless of the value of RX_CMF_EN. Frames transferred to memory due to RX_CMF_EN will have the control bit set in their EOP buffer descriptor. 0 - MAC control frames are filtered (but acted upon if enabled). 1 - MAC control frames are transferred to memory.	RW	0x0
23	RX_CSF_EN	RX Copy Short Frames Enable - Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RX_CSF_EN will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. 0 - Short frames are filtered 1 - Short frames are transferred to memory.	RW	0x0
22	RX_CEF_EN	RX Copy Error Frames Enable - Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when RX_CEF _EN is not set. 0 - Frames containing errors are filtered. 1 - Frames containing errors are transferred to memory.	RW	0x0
21	TX_SHORT_GAP_LIM_EN	Transmit Short Gap Limit Enable When set this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed.	RW	0x0
20:19	RESERVED		R	0x0
18	EXT_EN	Control Enable - Enables the fullduplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the FULLDUPLEX and GIG bits in this register. The FULLDUPLEX_MODE bit reflects the actual fullduplex mode selected 0 - Use this setting for RMII/GMII mode . 1 - Use this setting for RGMII mode	RW	0x0
17	GIG_FORCE	Gigabit Mode Force - This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.	RW	0x0
16	IFCTL_B	Interface Control B (NOT FUNCTIONAL) 0 - 10Mbps operation 1 - 100Mbps operation	RW	0x0
15	IFCTL_A	Interface Control A 0 - 10Mbps operation 1 - 100Mbps operation	RW	0x0
14:12	RESERVED		R	0x0
11	CMD_IDLE	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read IDLE in SL_MACSTATUS)	RW	0x0

Bits	Field Name	Description	Type	Reset
10	TX_SHORT_GAP_EN	Transmit Short Gap Enable 0 - Transmit with a short IPG is disabled 1 - Transmit with a short IPG (when TX_SHORT_GAP input is asserted) is enabled.	RW	0x0
9:8	RESERVED		R	0x0
7	GIG	Gigabit Mode - 0 - 10/100 mode 1 - Gigabit mode (full duplex only) The GIG_OUT output is the value of this bit.	RW	0x0
6	TX_PACE	Transmit Pacing Enable 0 - Transmit Pacing Disabled 1 - Transmit Pacing Enabled	RW	0x0
5	GMII_EN	GMII Enable - 0 - GMII RX and TX held in reset. 1 - GMII RX and TX released from reset.	RW	0x0
4	TX_FLOW_EN	Transmit Flow Control Enable - Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_MBP_Enable bits determine whether or not received pause frames are transferred to memory. 0 - Transmit Flow Control Disabled. Full-duplex mode - Incoming pause frames are not acted upon. 1 - Transmit Flow Control Enabled . Full-duplex mode - Incoming pause frames are acted upon.	RW	0x0
3	RX_FLOW_EN	Receive Flow Control Enable - 0 - Receive Flow Control Disabled Half-duplex mode - No flow control generated collisions are sent. Full-duplex mode - No outgoing pause frames are sent. 1 - Receive Flow Control Enabled Half-duplex mode - Collisions are initiated when receive flow control is triggered. Full-duplex mode - Outgoing pause frames are sent when receive flow control is triggered.	RW	0x0
2	MTEST	Manufacturing Test mode - This bit must be set to allow writes to the SL_BOFFTEST and SL_RX_PAUSE/ SL_TX_PAUSE registers.	RW	0x0
1	LOOPBACK	Loop Back Mode - Loopback mode forces internal fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The LOOPBACK bit should be changed only when GMII_EN is deasserted. 0 - Not looped back 1 - Loop Back Mode enabled	RW	0x0
0	FULLDUPLEX	Full Duplex mode - Gigabit mode forces fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit 0 - half duplex mode 1 - full duplex mode	RW	0x0

RESERVED																								RX_MAXLEN							

Bits	Field Name	Description	Type	Reset
31:14	RESERVED		R	0x0
13:0	RX_MAXLEN	RX Maximum Frame Length - This field determines the maximum length of a received frame. The reset value is 1518 (dec). Frames with byte counts greater than rx_maxlen are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. The maximum value is 16,383.	RW	0x5EE

Table 24-1309. SL_BOFFTEST

Address Offset	0x0000 0014

Table 24-1309. SL_BOFFTEST (continued)

Physical Address	0x4848 4D94 0x4848 4DD4	**Instance**	SL1 SL2
Description	CPGMAC_SL backoff test register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								PACEVAL								RNDNUM								COLL_COUNT				RESERVED			
																								TX_BACKOFF						

Bits	Field Name	Description	Type	Reset
31	RESERVED		R	0x0
30:26	PACEVAL	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to zero. When PACEVAL is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce 'capture' effects improving overall network bandwidth.	RW	0x0
25:16	RNDNUM	Backoff Random Number Generator - This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when mtest has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset.	RW	0x0
15:12	COLL_COUNT	Collision Count - The number of collisions the current frame has experienced.	R	0x0
11:10	RESERVED		R	0x0
9:0	TX_BACKOFF	Backoff Count - This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.	R	0x0

Table 24-1324. MDIO_CONTROL

Address Offset	0x0000 0004		
Physical Address	0x4848 5004	**Instance**	MDIO
Description	MDIO Control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDLE	ENABLE	RESERVED	HIGHEST_USER_CHANNEL					RESERVED			PREAMBLE	FAULT	FAULTENB	INTTESTENB	RESERVED	CLKDIV																

Bits	Field Name	Description	Type	Reset
31	IDLE	MDIO state machine IDLE. Set to 1 when the state machine is in the idle state. 0: State machine is not in idle state. 1: State machine is in idle state.	R	0x0
30	ENABLE	Enable control. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the IDLE bit. If using byte access, the ENABLE bit has to be the last bit written in this register. 0: Disables the MDIO state machine. 1: Enable the MDIO state machine.	RW	0x0
29	RESERVED		R	0x0
28:24	HIGHEST_USER_CHANNEL	Highest user channel. This field specifies the highest user access channel that is available in the module and is currently set to 1. This implies that the MDIO_USERACCESS1 register is the highest available user access channel.	R	0x0
23:21	RESERVED		R	0x0
20	PREAMBLE	Preamble disable. 0: Standard MDIO preamble is used. 1: Disables this device from sending MDIO frame preambles.	RW	0x0
19	FAULT	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. 0: No failure. 1: Physical layer fault; the MDIO state machine is reset.	RW	0x0
18	FAULTENB	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. 0: Disables the physical layer fault detection. 1: Enables the physical layer fault detection.	RW	0x0

Bits	Field Name	Description	Type	Reset
17	INTTESTENB	Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes. 0: Interrupt bits are not set. 1: Enables the host to set the USERINT and LINKINT bits for test purposes.	RW	0x0
16	RESERVED		R	0x0
15:0	CLKDIV	Clock divider. This field specifies the division ratio between ICLK and the frequency of MDCLK. MDCLK is disabled when CLKDIV is set to 0. MDCLK frequency = ICLK frequency/(CLKDIV+1).	RW	0x0

ALIVE																															

Bits	Field Name	Description	Type	Reset
31:0	ALIVE	MDIO alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.	RW	0x0

LINK

Bits	Field Name	Description	Type	Reset
31:0	LINK	MDIO link state. This register is updated after a read of the Generic Status Register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. In addition, the status of the two PHYs specified in the MDIO_USERPHYSEL registers can be determined using the MLINK input pins (NOT PINNED OUT). This is determined by the LINKSEL bit in the MDIO_USERPHYSEL register.	R	0x0

RESERVED																														LINKINTMASKED	

Bits	Field Name	Description	Type	Reset
31:2	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
1:0	LINKINTMASKED	MDIO link change interrupt, masked value. When asserted 1, a bit indicates that there was an MDIO link change event (i.e. change in the MDIO Link register) corresponding to the PHY address in the MDIO_USERPHYSEL register and the corresponding LINKINTENB bit was set. LINKINTMASKED[0] and LINKINTMASKED[1] correspond to MDIO_USERPHYSEL0 and MDIO_USERPHYSEL1, respectively. Writing a 1 will clear the interrupt and writing 0 has no effect. If the INTTESTENB bit in the MDIO_CONTROL register is set, the host may set the LINKINT bits to a 1. This mode may be used for test purposes.	RW	0x0

Gigabit Ethernet Switch (GMAC_SW)

- SPF Register Summary: [0]

Table 24-1388. SPF_CONTROL

Address Offset	0x0000 0008		
Physical Address	0x4848 5C08 0x4848 5E08	**Instance**	SPF1 SPF2
Description	SPF control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						SPF_LOGOW_EN	SPF_LOG_EN	RESERVED				SPF_RULE_LOG	SPF_EXT_BYPASS	SPF_DROP	SPF_ENABLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED		R	0x0
9	SPF_LOGOW_EN	SPF Log Overwrite Enable. Setting this bit will cause SPF to overwrite previously logged data whether or not software has updated the software_working_pointer. Overwriting only occurs if there is new data but no space to write it in the space indicated by log_start_address and log_end_address.	RW	0x0
8	SPF_LOG_EN	SPF Log Enable. Setting this bit will allow SPF to log information about dropped packets to memory.	RW	0x0
7:4	RESERVED		R	0x0
3	SPF_RULE_LOG	SPF Rule Engine Log Enable. Setting this bit will allow SPF to log data from rule engine. The default is log data from extractor.	RW	0x0
2	SPF_EXT_BYPASS	SPF Extractor Bypass Enable. The extractor will not provide any offset information to rule engine if this bit is set. The rule engine must load each of the base registers it intends to use to determine if the packet should be discarded.	RW	0x0
1	SPF_DROP	SPF Drop Enable. This bit must be set to activate packet drops.	RW	0x0
0	SPF_ENABLE	SPF Enable. This bit must be set to enable any operation in SPF. The SPF instruction memory can only be accessed by host processor when the spf_enable is deasserted. Once spf_enable is set, writing a zero to this bit will only take effect when spf_busy signal is low. This ensures that spf stops only on packet boundaries.	RW	0x0

Table 24-1406. SPF_INSTR_CTL

Address Offset	0x0000 005C		
Physical Address	0x4848 5C5C 0x4848 5E5C	**Instance**	SPF1 SPF2
Description	Instruction Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SPF_INSTR_WEN	SPF_INSTR_REN	RESERVED																						SPF_INSTR_PTR							

Bits	Field Name	Description	Type	Reset
31	SPF_INSTR_WEN	SPF Write enable bit specifies whether a write operation is to be performed. To read or write instructions, spf processing must be stopped. When the rule engine is processing instructions, the instruction memory cannot be accessed. This bit is set to perform a write and the data in the SPF_INSTR_W2, SPF_INSTR_W1 and SPF_INSTR_W0 registers is written to the instruction RAM at address specified in the SPF_INSTR_PTR field. This bit is always read as zero.	W	0x0
30	SPF_INSTR_REN	SPF Read enable bit specifies whether a read operation is to be performed. This bit is set to perform a read and read data is available in the SPF_INSTR_W2, SPF_INSTR_W1 and SPF_INSTR_W0 registers once read operation has completed. This bit is always read as zero.	W	0x0
29:6	RESERVED		R	0x0
5:0	SPF_INSTR_PTR	The address in the instruction memory that is to be accessed.	RW	0x0

24.12 Media Local Bus (MLB)

Note

Media Local Bus (MLB) is not supported on the AM571x / AM570x family of devices.

Chapter 25

eMMC/SD/SDIO

This chapter describes the features and functions of the eMMC/SD/SDIO interface of the device.

25.1 eMMC/SD/SDIO Overview

The eMMC/SD/SDIO host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either eMMC, SD® memory cards, or SDIO cards and handles eMMC/SD/SDIO transactions with minimal LH intervention.

Optionally, the controller is connected to the L3_MAIN interconnect to have a direct access to system memory. It also supports two direct memory access (DMA) slave channels or a DMA master access (in this case, slave DMA channels are deactivated) depending on its integration.

The eMMC/SD/SDIO host controller deals with eMMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit, and checking for syntactical correctness.

The application interface can send every eMMC/SD/SDIO command and poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The eMMC/SD/SDIO host controller also supports two DMA channels.

There are four eMMC/SD/SDIO host controllers inside the device. Figure 25-1 gives an overview of the eMMC/SD/SDIOi (i = 1 to 4) controllers.

Each controller has the following data width:

- eMMC/SD/SDIO1 - 4-bit wide data bus
- eMMC/SD/SDIO2 - 8-bit wide data bus
- eMMC/SD/SDIO3 - 8-bit wide data bus
- eMMC/SD/SDIO4 - 4-bit wide data bus

The eMMC/SD/SDIOi controller is also referred to as MMCi.

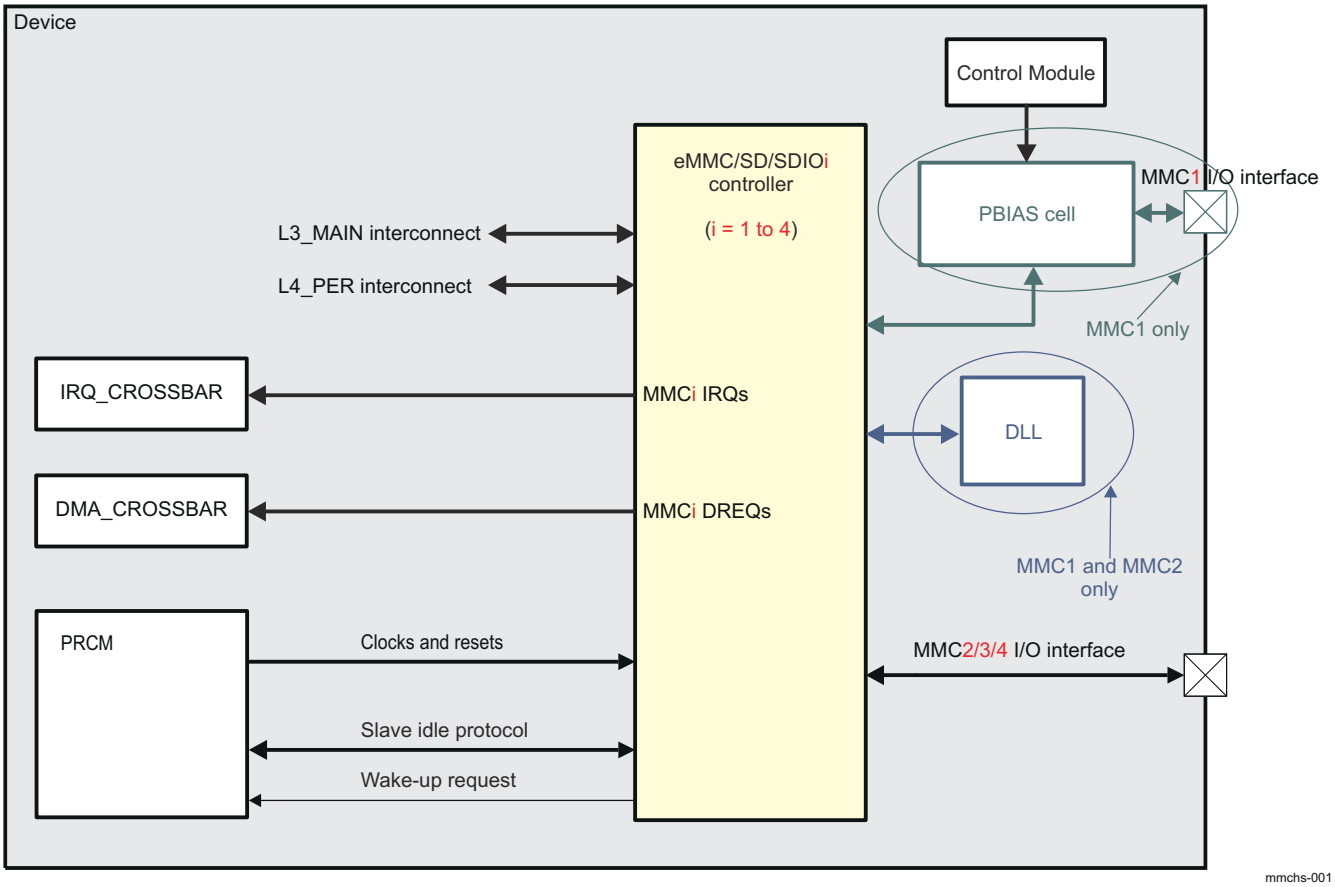

Figure 25-1. eMMC/SD/SDIOi Overview (i = 1 to 4)

25.1.1 eMMC/SD/SDIO Features

This section describes the features supplied by the eMMC/SD/SDIO controllers.

Compliance with standards:

- Full compliance with MMC/eMMC command/response sets as defined in the JC64 MMC/eMMC standard specification, v4.5.
- Full compliance with SD command/response sets as defined in the SD Physical Layer specification v3.01
- Full compliance with SDIO command/response sets and interrupt/read-wait suspend-resume operations as defined in the SD part E1 specification v3.00
- Full compliance with SD Host Controller Standard Specification sets as defined in the SD card specification Part A2 v3.00

Main features of the eMMC/SD/SDIO host controllers:

- Flexible architecture allowing support for new command structure
- 32-bit wide access bus to maximize bus throughput
- Designed for low power
- Programmable clock generation
- Dedicated DLL to support SDR104 mode (MMC1 only)
- Dedicated DLL to support HS200 mode (MMC2 only)
- Card insertion/removal detection and write protect detection
- L4 slave interface supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 9-bit address bus width

  - Streaming burst supported only with burst length up to 7
  - WNP supported
- L3 initiator interface Supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 32-bit address bus width
  - Burst supported
- Built-in 1024-byte buffer for read or write
- Two DMA channels, one interrupt line
- Support JC 64 v4.4.1 boot mode operations
- Support SDA 3.00 Part A2 programming model
- Support SDA 3.00 Part A2 DMA feature (ADMA2)
- Supported data transfer rates:
  - MMCi supports the following SD v3.0 data transfer rates:
    - DS mode (3.3V IOs): up to 12 MBps (24 MHz clock)
    - HS mode (3.3V IOs): up to 24 MBps (48 MHz clock)
    - SDR12 (1.8V IOs): up to 12 MBps (24 MHz clock)
    - SDR25 (1.8V IOs): up to 24 MBps (48 MHz clock)
    - SDR50 (1.8V IOs): up to 48 MBps (96 MHz clock) - MMC1 and MMC3 only
    - DDR50 (1.8V IOs): up to 48 MBps (48 MHz clock) - MMC1 only
    - SDR104 (1.8V IOs) cards can be supported up to 192 MHz clock (96 MBps max) - MMC1 only
  - MMCi supports the Default SD mode 1-bit data transfer up to 24Mbps (3MBps)
  - Only MMC2 supports also the following JC64 v4.5 data transfer rates:
    - Up to 192 MBps in eMMC mode, 8-bit SDR mode (192 MHz clock frequency)
    - Up to 96 MBps in eMMC mode, 8-bit DDR mode (48 MHz clock frequency)
- All eMMC/SD/SDIO controllers are connected to 1,8V/3.3V compatible I/Os to support 1,8V/3.3V signaling

Note

eMMC functionality is supported fully by MMC2 only. The other MMC modules are capable of eMMC functionality, but are not timing-optimized for eMMC. For more information about timing limitations, see the data manual of the device.

The differences between the eMMC/SD/SDIO host controllers and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v3.00 are:

- The clock divider in the eMMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v3.0. The eMMC/SD/SDIO host controller supports odd and even clock ratio.
- The eMMC/SD/SDIO host controller supports configurable busy time-out.
- ADMA2 64-bit mode is not supported.
- There is no external LED control.

Note

Only even ratios are supported in DDR mode.

Table 25-1 lists the features supported in the 4.5 standard.

Table 25-1. Standard 4.5 Supported Features

Feature	Support	Limitation	Comment
Bus width	1-bit mode		x 1, 4, 8 bits
	4-bit mode		
	8-bit mode		

Table 25-1. Standard 4.5 Supported Features (continued)

Feature	Support	Limitation	Comment
Support density	No hardware limitation for density support	Limitation can come from file system (32 GiB).	
Simple boot (CMD, alternate boot)	Yes		Device ROM code supports the following boot modes: 1. Alternate Boot 2. Raw (UDA) Boot 3. File System For more information about boot modes, see *Memory Booting*. in *Initialization.*
Sleep mode	Yes		
Reliable write	Yes		
Secure write protection	Yes		
Hardware reset	No		Use the reset command if hardware reset is needed.
Secure memory block (RPMB)	Yes		
Partition feature	Yes		
Secure erase	Yes		
DDR interface (bandwidth)	Up to 96 MBps in DDR mode – 8-bit		
High-priority interrupt (read while write)	Yes		
Background operation	Yes		
Enhanced reliable write	Yes		
HS200 mode	Yes		

Table 25-2 shows the supported by each MMCi host controller transfer rates and functionalities (SD, eMMC and SDIO).

Table 25-2. MMCi Supported Transfer Rates and Functionalities

	SD[1]	eMMC	SDIO
MMC1	Yes (Up to SDR104 mode)	Yes (Up to High Speed DDR mode; timings optimized for SD)	Yes (timings optimized for SD)
MMC2	Yes (Up to SDR25 mode; timings optimized for eMMC)	Yes (Up to HS200 mode)	Yes (timings optimized for eMMC)
MMC3	Yes (Up to SDR50 mode)	Yes (Up to High Speed SDR mode; timings optimized for SD/ SDIO)	Yes (Up to SDR50 mode)
MMC4	Yes (Up to SDR25 mode)	Yes (Up to High Speed SDR mode; timings optimized for SD/ SDIO)	Yes (Up to SDR25 mode)

(1) 3.3V IO required for initial SD Card communication.

25.2 eMMC/SD/SDIO Environment

One eMMC/SD/SDIO host controller can support one eMMC memory card, one SD memory card, or one SDIO card.

Other combinations (for example, two SD cards, one eMMC, and one SD card) are not supported through a single controller. The following is supported:

- The MMC1 instance supports 1- and 4-bit data transfers. (mainly used for connection with SD cards)
- The MMC2 instance supports 1-, 4-, and 8-bit data transfers. (mainly used for connection with eMMC cards)
- The MMC3 instance supports 1-, 4-, and 8-bit data transfers. (mainly used for connection with SDIO cards)
- The MMC4 instance supports 1- and 4-bit data transfers. (mainly used for connection with SDIO cards)

25.2.1 eMMC/SD/SDIO Functional Modes

25.2.1.1 eMMC/SD/SDIO Connected to an eMMC, SD, or SDIO Card

Figure 25-2 shows the eMMC/SD/SDIOi host controller (where i = 1 to 4) connected to an eMMC, SD, or SDIO card and its related external connections.

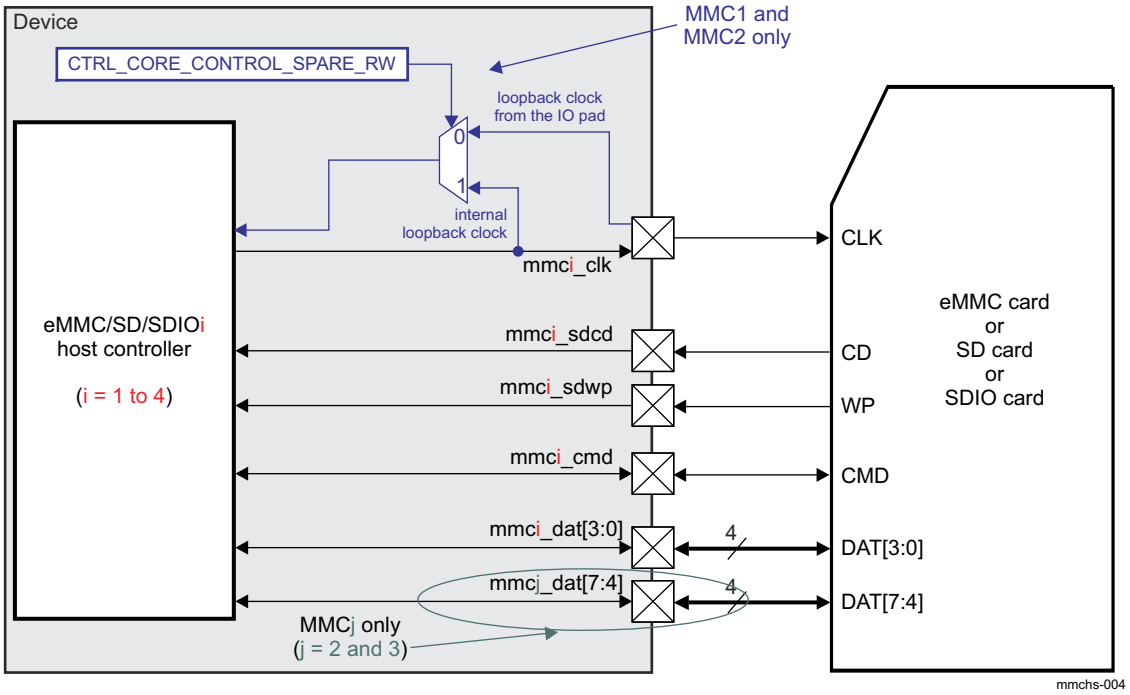

Figure 25-2. eMMC/SD/SDIOi Controller Connected to an eMMC, SD, or SDIO Card (where i = 1 to 4)

Table 25-3 describes the eMMC/SD/SDIOi host controller I/O's (where i = 1 to 4).

Table 25-3. Description of eMMC/SD/SDIOi host controller I/O's (where i = 1 to 4)

Instance	Signal name	I/O[1]	Description	Reset Value[2]
MMC1	mmc1_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc1_cmd	I/O	Command line	Hi-Z[3]
	mmc1_dat[3:0]	I/O	Data signals	Hi-Z[3]
	mmc1_sdcd	I	Card insertion/removal detection signal	Hi-Z
	mmc1_sdwp	I	Write protect detection signal	Hi-Z

Table 25-3. Description of eMMC/SD/SDIOi host controller I/O's (where i = 1 to 4) (continued)

Instance	Signal name	I/O[1]	Description	Reset Value[2]
MMC2	mmc2_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc2_cmd	I/O	Command line	Hi-Z[3]
	mmc2_dat[7:0]	I/O	Data signals	Hi-Z[3]
	mmc2_cd	I	Card insertion/removal detection signal	Hi-Z
	mmc2_wp	I	Write protect detection signal	Hi-Z
MMC3	mmc3_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc3_cmd	I/O	Command line	Hi-Z[3]
	mmc3_dat[7:0]	I/O	Data signals	Hi-Z[3]
	mmc3_cd	I	Card insertion/removal detection signal	Hi-Z
	mmc3_wp	I	Write protect detection signal	Hi-Z
MMC4	mmc4_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc4_cmd	I/O	Command line	Hi-Z[3]
	mmc4_dat[3:0]	I/O	Data signals	Hi-Z[3]
	mmc4_cd	I	Card insertion/removal detection signal	Hi-Z
	mmc4_wp	I	Write protect detection signal	Hi-Z

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High Impedance
(3) Initialized as input upon reset

Note

For mmc2_clk, mmc3_clk and mmc4_clk signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers must be set to 0x1 by software. This is because the eMMC/SD/SDIO controller uses the input from the pad as loopback clock, which the controller can use for read capture depending on the mode it is in.

Note

On SR2.x devices the internal PU/PD resistors on pads mmc2_dat[7:0] can be permanently disabled. For more information, see *Permanent PU/PD disabling (SR 2.x only)* in *Control Module*.

25.2.2 Protocol and Data Format

The bus protocol between the eMMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

- Command: A command starts an operation. The command is transferred serially from the eMMC/SD/SDIO host controller to the card on the CMD line.
- Response: A response is an answer to a command. The response is sent from the card to the eMMC/SD/SDIO host controller. It is transferred serially on the CMD line.
- Data: Data are transferred from the eMMC/SD/SDIO host controller to the card or from a card to the eMMC/SD/SDIO host controller using the data lines.
- Busy: The DAT[0] signal is maintained low by the card as far as it is programming the data received.

- CRC status: The CRC result is sent by the card through the DAT[0] line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on DAT[0]. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on DAT[0] and starts the data programming procedure.

25.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO cards, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1*).

Figure 25-3 and Figure 25-4 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmci_cmd line.

Note

Stream commands are supported only by MMC cards.

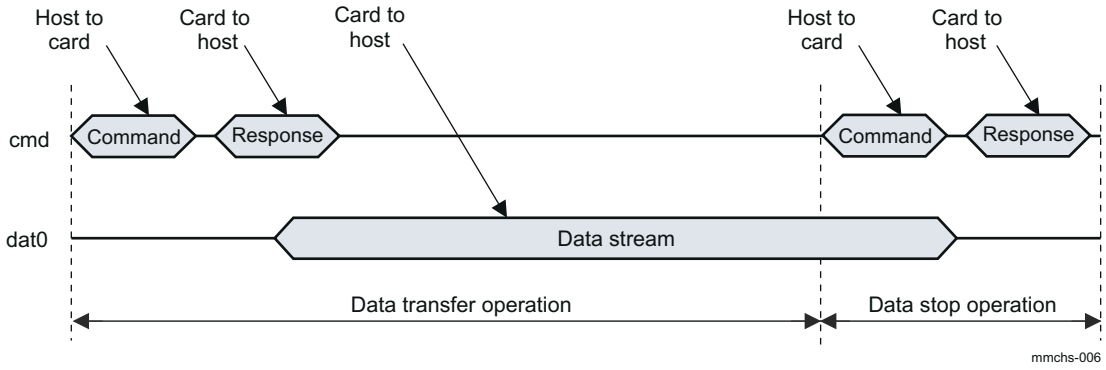

Figure 25-3. Sequential Read Operation (MMC Cards Only)

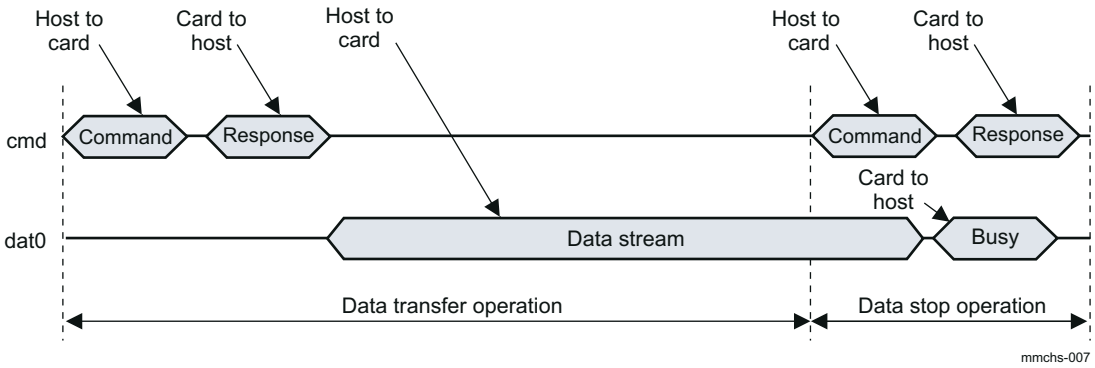

Figure 25-4. Sequential Write Operation (MMC Cards Only)

Figure 25-5 and Figure 25-6 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmci_cmd line. These operations are available for all kinds of cards.

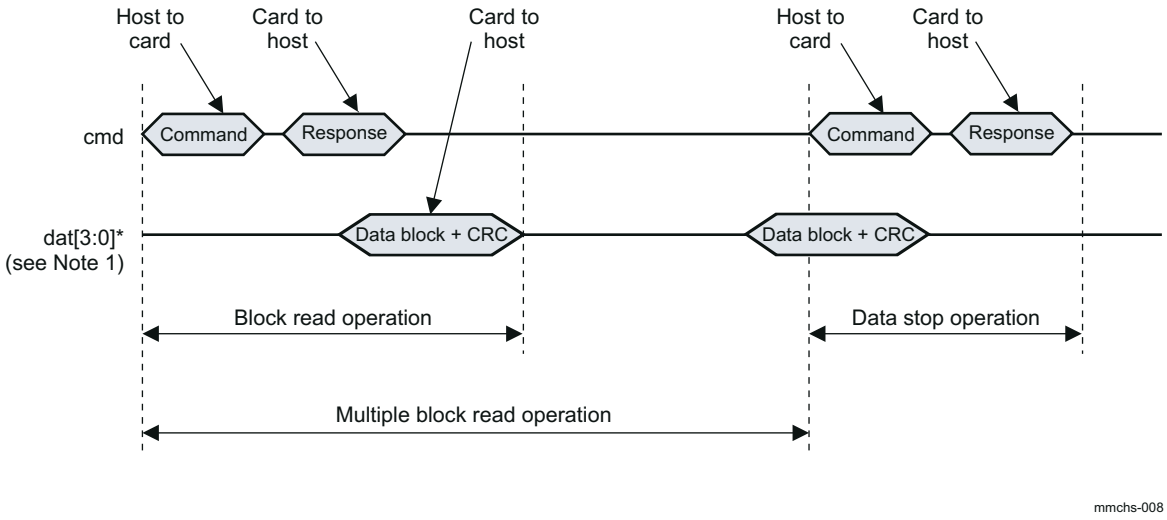

Figure 25-5. Multiple Block Read Operation

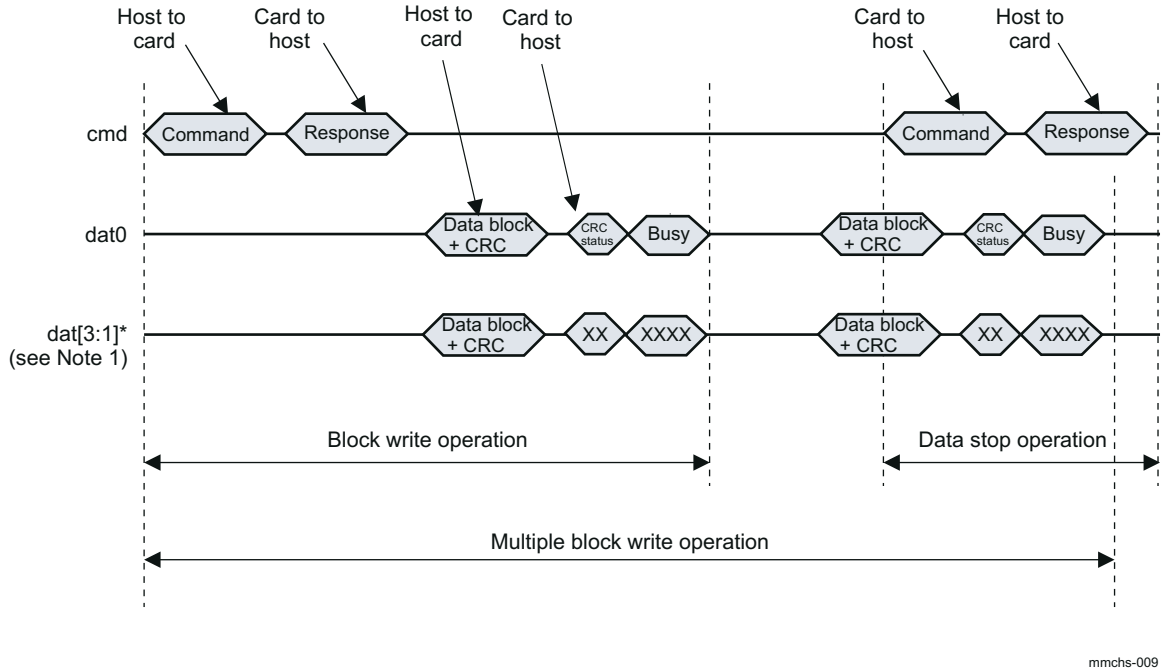

Figure 25-6. Multiple Block Write Operation With Card Busy Signal

Note

- The card busy signal is not always generated by the card; refer to Figure 25-5 and Figure 25-6, that show a particular case.
- Software must perform a software reset (set the MMCi.MMCHS_SYSCTL[26] SRD bit to 0x1) after a data time-out to ensure that CLK is stopped.
- For multiblock transfer, and especially for MMC cards, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

25.2.2.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 25-7).

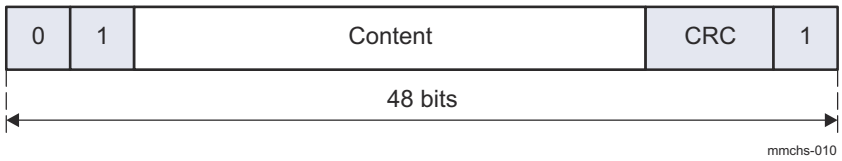

Figure 25-7. Command Token Format

Coding Scheme for Response Token

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SD]) and the content is protected by 7-bit CRC checksum (see Figure 25-8 and Figure 25-9). Depending on the type of commands sent to the card, the MMCHS_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see Table 25-4). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification*.

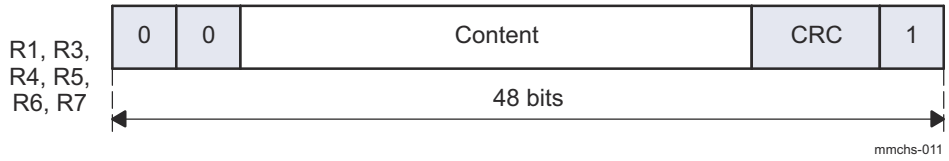

Figure 25-8. Response Token Format (R1, R3, R4, R5, R6, R7)

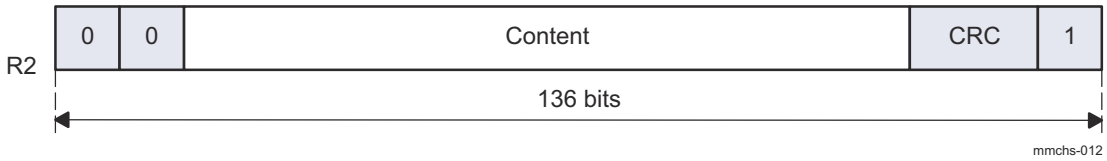

Figure 25-9. Response Token Format (R2)

Table 25-4. Relationship Between Configuration and Name of Response Type

Response Type MMCi.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCi.MMCHS_CMD[20] CICE	CRC Check Enable MMCi.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5, (R7 for SD cards)
11	1	1	R1b, R5b

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 25-10 through Figure 25-12).

25.3 eMMC/SD/SDIO Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 25-13 shows the integration of the MMC1 and MMC2 controllers which are connected to both L3_MAIN and L4_PER1 interconnects and are able to act as master or slave. In master mode the L3_MAIN interconnect is used. In slave mode the L4_PER1 interconnect is used.

Figure 25-14 shows the integration of the MMC3 and MMC4 controllers which are connected to the L4_PER1 interconnect and act as a slave only.

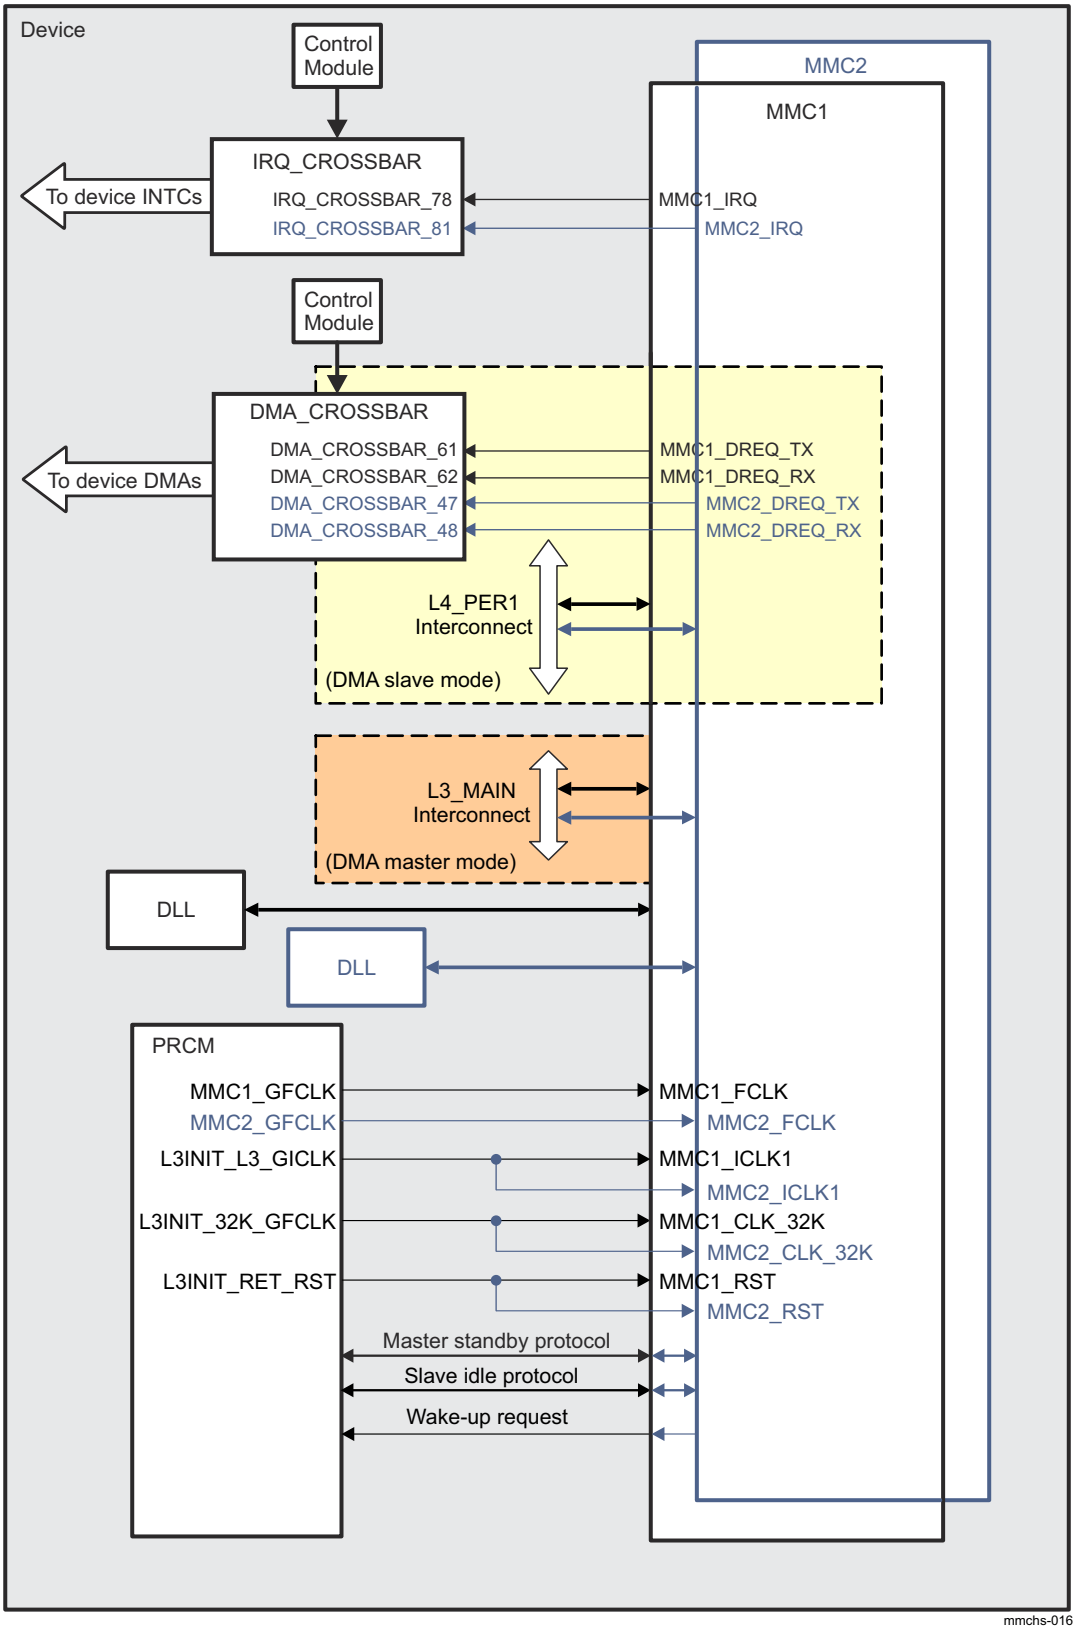

Figure 25-13. Integration of MMC1 and MMC2 Controllers – Master and Slave Capable

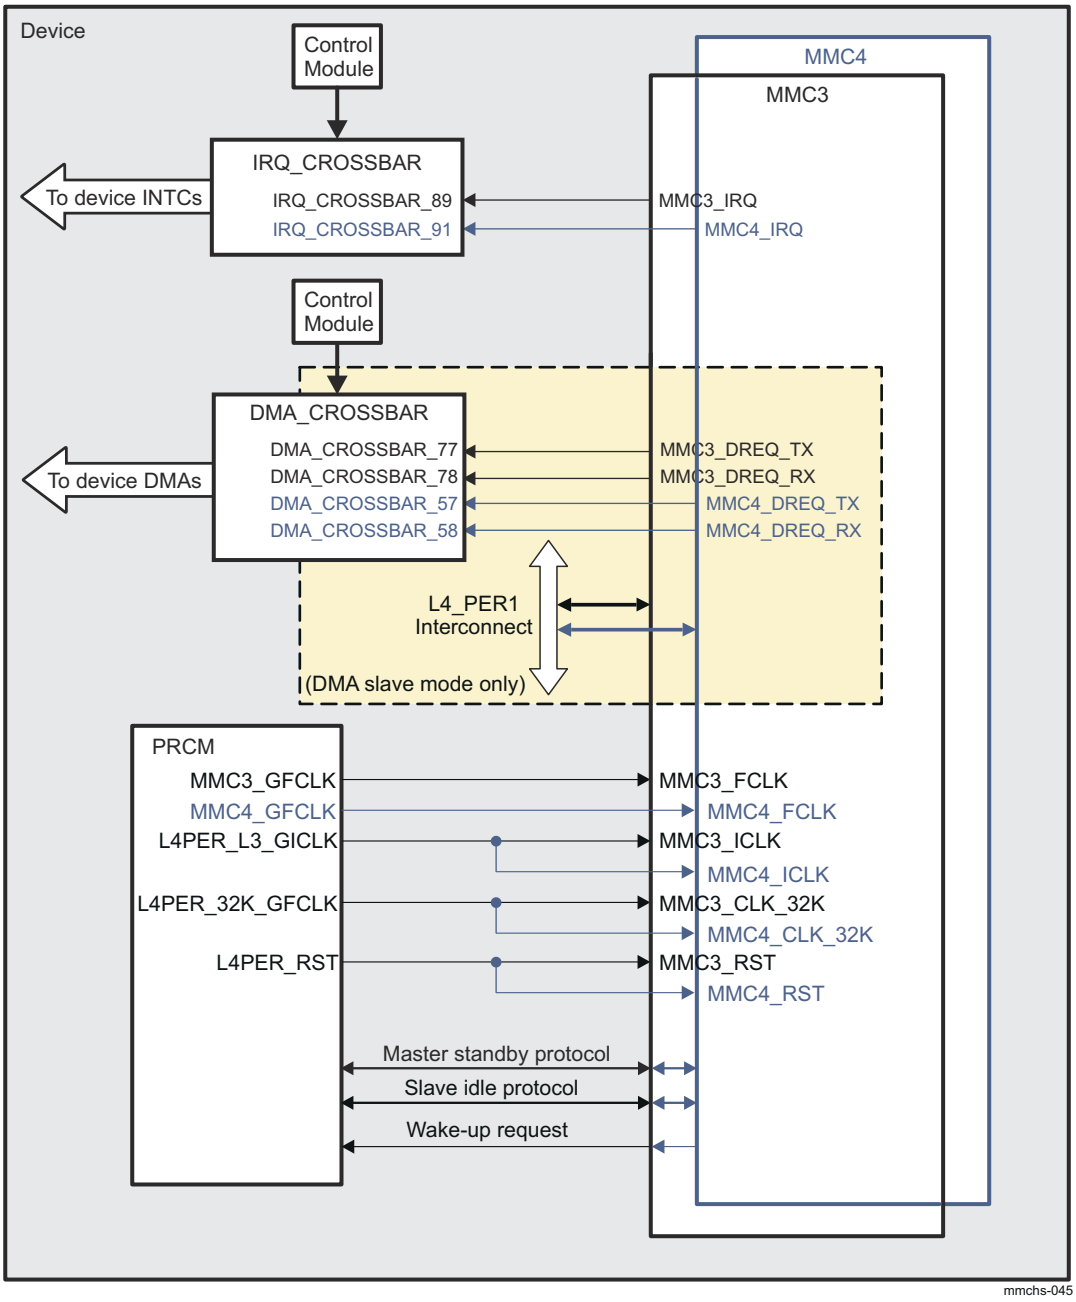

Figure 25-14. Integration of MMC3 and MMC4 Controllers – Slave Capable Only

Note

For more information about the slave idle protocol and the wake-up request, see *Device Power-Management Architecture Building Blocks*, in *Power, Reset, and Clock Management*.

Table 25-5 through Table 25-7 summarize the integration of the module in the device.

Table 25-5. MMC Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
MMC1	PD_COREAON	L3_MAIN L4_PER1

MMC2	MMC2_DREQ_TX	DMA_CROSSBAR_47	DMA_SYSTEM_DREQ_46 DMA_EDMA_DREQ_46	MMC2 DMA TX
	MMC2_DREQ_RX	DMA_CROSSBAR_48	DMA_SYSTEM_DREQ_47 DMA_EDMA_DREQ_47	MMC2 DMA RX
MMC3	MMC3_DREQ_TX	DMA_CROSSBAR_77	DMA_SYSTEM_DREQ_76	MMC3 DMA TX
	MMC3_DREQ_RX	DMA_CROSSBAR_78	DMA_SYSTEM_DREQ_77	MMC3 DMA RX
MMC4	MMC4_DREQ_TX	DMA_CROSSBAR_57	DMA_SYSTEM_DREQ_56 DMA_EDMA_DREQ_56	MMC4 DMA TX
	MMC4_DREQ_RX	DMA_CROSSBAR_58	DMA_SYSTEM_DREQ_57 DMA_EDMA_DREQ_57	MMC4 DMA RX

Note

The “**Default Mapping**” column in Table 25-7 *MMC Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.
For more information about the device DMA_SYSTEM module, see *System DMA*.
For more information about the device EDMA module, see *Enhanced DMA*.

Note

- For a description of the interrupt source, see *Interrupt Requests*.
- For a description of the DMA source, see *DMA Modes*.

25.4 eMMC/SD/SDIO Functional Description

25.4.1 Block Diagram

Figure 25-15 is a block diagram of the eMMC/SD/SDIOi host controller.

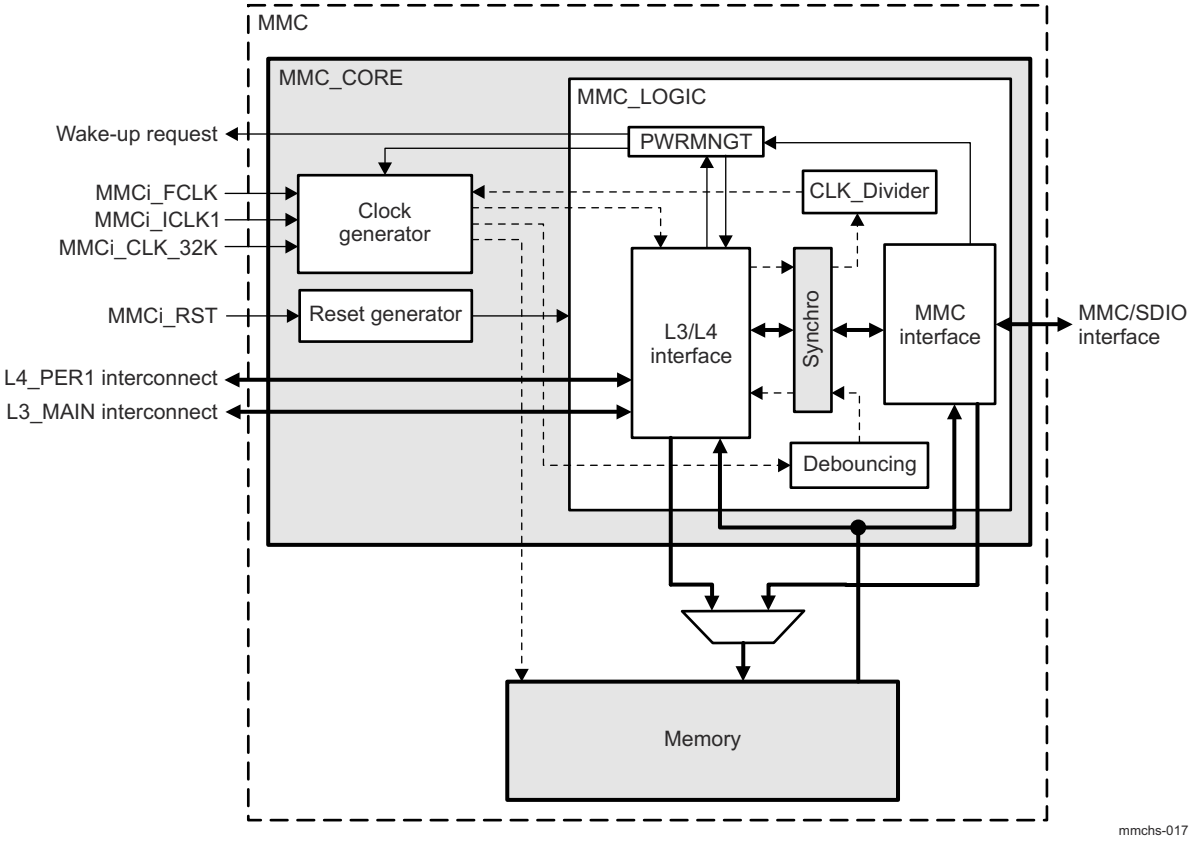

Figure 25-15. eMMC/SD/SDIO Diagram

25.4.2 Resets

25.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see Table 25-6 for more information about reset signals).

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a hardware reset.

Note

The functional clock (MMCi_FCLK) and interface clock (MMCi_ICLK) must be provided to the module to allow the RESETDONE status bit to be set.

The debounce clock (MMCi_32K) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

25.4.2.2 Software Reset

The module is reinitialized by software through the MMCi.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same effect on the module logic as the hardware signal (MMCi_RST), with the following exceptions:

- Debounce logic

- MMCi.MMCHS_PSTATE, MMCi.MMCHS_CAPA, and MMCi.MMCHS_CUR_CAPA registers (see the corresponding register description)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by hardware. The MMCi.MMCHS_SYSCTL[24] SRA bit has the same action on the design as the SOFTRESET bit.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS_SYSCTL[26] SRD
- MMCi.MMCHS_SYSCTL[25] SRC

These 2 reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When these bits are set to 1, a reset process is automatically released when the reset completes:

- The MMCi.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines (FSMs) and status management that handle data transfers on the interface and functional sides.
- The MMCi.MMCHS_SYSCTL[25] SRC bit resets all FSMs and status management that handle command transfers on the interface and functional sides.

25.4.3 Power Management

The eMMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The eMMC/SD/SDIO host controller is compliant with the handshake protocol of the power, reset, and clock management (PRCM) module.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (card insertion, card removal, an interrupt from a SDIO card).
- A transaction on the MMC/SD/SDIO interface starts.

When a card removal event is detected the eMMC/SD/SDIO host controller automatically clears MMCHS_HCTL[8] SDBP and MMCHS_SYSCTL[2] CEN bits. Then it enters into low power state with auto gated interface clock even if MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 0. The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCi_ICLK and MMCi_FCLK clocks provided to the eMMC/SD/SDIO host controller are switched off upon a PRCM module request. They are switched back upon module request.

The eMMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- IDLE request from the system power manager
- Idle acknowledgment from the eMMC/SD/SDIO host controller
- Wake-up request from the eMMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The eMMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.

- 0x1: No-idle mode. The eMMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The eMMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.
- 0x3: Smart-idle wake-up-capable mode. The eMMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when it is in IDLE state (related to IRQ or DMA requests)

During the smart-idle mode period, the eMMC/SD/SDIO host controller acknowledges that the MMCi_ICLK and MMCi_FCLK clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

The debounce clock is used to debounce the signals related to the card insertion and the card removal that are also sources of wake-up in idle mode. The debounce clock must never be switched off by the system power manager in order to detect card removal in functional mode, and detect wake-up in idle mode.

Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2 or 0x3.

The eMMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an IDLE request, according to its internal activity.

The eMMC/SD/SDIO host controller acknowledges the IDLE request from the PRCM after ensuring the following:

- The current multi- or single-block transfer is complete.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the DATA[1] signal.

As long as the eMMC/SD/SDIOi controller does not acknowledge the IDLE request, if an event occurs, the eMMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the IDLE request from the PRCM module.

As soon as the eMMC/SD/SDIOi controller acknowledges the IDLE request from the PRCM module:

- If smart-idle mode: The module does not assert any new interrupt or DMA request.
- If smart-idle wake-up-capable mode: The module may generate wake-up events related to an interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when both the MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit and one of the three bits MMCi.MMCHS_HCTL[26] REM, MMCi.MMCHS_HCTL[25] INS, MMCi.MMCHS_HCTL[24] IWE are set to 0x1.

The corresponding interrupt status enable bits must also be set before going in idle mode. Setting one of the following bits:

- MMCi.MMCHS_IE[8] CIRQ_ENABLE
- MMCi.MMCHS_IE[7] CREM_ENABLE
- MMCi.MMCHS_IE[6] CINS_ENABLE

to 0x1 enables the wakeup event detection. The source of wakeup can be identified after idle mode exiting by reading one of the corresponding MMCHS_STAT bits.

The wakeup is generated only in smart-idle mode, when the module is in idle mode.

Table 25-8 lists the supported cases in smart-idle mode.

Table 25-8. Smart-Idle Mode and Wake-Up Capabilities

Mode	MMCi_ICLK Clock	MMCi_FCLK Clock	Wake-Up Event
Card interrupt	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request when a card interrupt on the DATA[1] signal is detected.
Card insertion	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request when card insertion is detected.
Card removal	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request when card removal is detected.

(1) The eMMC/SD/SDIOi host controller assumes that both clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

Transition From Smart-Idle Mode to Normal Mode

The eMMC/SD/SDIO host controller detects the end of the idle period when the PRCM module deasserts the IDLE request.

For the wake-up event, there is a corresponding interrupt status in the MMCi.MMCHS_STAT register. The eMMC/SD/SDIOi host controller operates the conversion between the wake-up and interrupt (or DMA request) upon exit from smart-idle mode, if the associated enable bit is set in the MMCi.MMCHS_ISE register.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MMCi.MMCHS_HCTL and MMCi.MMCHS_ISE registers. The overall consistency must be ensured by software.

One of the bits MMCHS_STAT[8] CIRQ, MMCHS_STAT[7] CREM, MMCHS_STAT[6] CINS in the interrupt status register is updated with the event that caused the wake-up when one of the bits MMCHS_IE[8] CIRQ_ENABLE, MMCHS_IE[7] CREM_ENABLE, MMCHS_IE[6] CINS_ENABLE is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCi.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the IDLE request from the PRCM module is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode in which the eMMC/SD/SDIOi host controller responds unconditionally to the IDLE request from the PRCM module. Moreover, in this mode, the eMMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines if they are asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCi.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCi_ICLK and MMCi_FCLK can be switched off.

CAUTION

In force-idle mode, an IDLE request from the PRCM module during a command or a data transfer can lead to an unexpected and unpredictable result.
When the module is idle, any access to the module generates an error as long as the MMCi_ICLK clock is alive.

The module exits force-idle mode when the PRCM module deasserts the IDLE request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

Standby Mode

The eMMC/SD/SDIO host controller also provides standby information to the system power manager if the generic parameter MMCHS_HL_HWINFO[0] MADMA_EN is set to 1.

The eMMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- Standby request from the eMMC/SD/SDIO host controller
- Wait acknowledgement from the PRCM module

The standby request varies according to the MMCi.MMCHS_SYSCONFIG[13:12] STANDBYMODE bit field:

- 0x0: Force-standby. The eMMC/SD/SDIO host controller sends the standby request to the system power manager unconditionally.
- 0x1: No-standby. The eMMC/SD/SDIO host controller does not generate any standby request to the system power manager and behaves normally
- 0x2: Smart-standby. The eMMC/SD/SDIO host controller sends the standby request to the system power manager according to the master L3 interface state.

Power Pad Control

The eMMC/SD/SDIO host controller has the ability to reduce the pad power leakage when no transfer is sent through the pad. According to the MMCHS_CON[15] PADEN there are two different pad power management modes: automatic and manual.

If MMCHS_CON[15] PADEN is set to 1, pads CLK, CMD, DAT[0] and DATA[i] (where i = 2 through 7) are always powerd on.

If MMCHS_CON[15] PADEN is set to 0, the power for pads CLK, CMD, DAT[0] and DATA[i] (where i = 2 through 7) is "ON" only when there is a transfer on going. This is automatically managed by an internal state machine of the eMMC/SD/SDIO host controller.

The DATA[1] pad active state is controlled through MMCHS_CON[11] CTPL in order to detect SDIO asynchronous interrupt when there is no transaction.

The delay between pad power "ON" and the command transmission is controlled through the MMCHS_PWCNT register which act as a programmable counter. It is also used to delay the pad power "OFF" after the end of transmission. By default this counter is reset which means that no additional delay is added. But there is approximately 6-7 clock cycles margin between pad power "ON" and real start of the command due to an internal state machine of the eMMC/SD/SDIO host controller.

Note

The MMCHS_PWCNT register is considered as static. No dynamic configuration during the transfer is supported. This results in an unpredictable behavior.

Local Power Management

Table 25-9 describes the power-management features available for the eMMC/SD/SDIOi modules.

Note

For information about source clock gating and a description of the sleep/wake-up transitions, see *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.

Table 25-9. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	MMCHS_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module by gating the MMCi_ICLK clock upon the interface activity, or gating the MMCi_FCLK clock upon the internal activity.

Table 25-9. Local Power-Management Features (continued)

Feature	Registers	Description
Slave-idle modes	MMCHS_SYSCONFIG[3:4] SIDLEMODE	Force-idle, No-idle, Smart-idle and Smart-idle wake-up-capable modes are available.
Clock activity	MMCHS_SYSCONFIG[8:9] CLOCKACTIVITY	For configuration details, see Table 25-10.
Master standby modes	MMCHS_SYSCONFIG[12:13] STANDBYMODE	Force-standby, No-standby and Smart-standby modes are available.
Global wake-up enable	MMCHS_SYSCONFIG[2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	MMCHS_HCTL register	This register holds one active-high enable bit per event source that is able to generate a wake-up signal.

Table 25-10. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State	Wake-Up Events
	MMCi_ICLK	MMCi_ FCLK		
00	OFF	OFF	None	Card interrupt, Card insertion, Card removal
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMCi clock PRCM control bits. For a description of the Clock activity feature, see *Module-Level Clock Management*, in *Power, Reset, and Clock Management*.

25.4.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS_IE register enable or disable the automatic update of the MMCi.MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS_ISE register enable or disable the transmission of an interrupt request on the interrupt line MMCi_IRQ on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the eMMC/SD/SDIOi host controller updates the status bit) in the MMCi.MMCHS_STAT register. If a mask is later applied on the interrupt in the MMCi.MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS_STAT register and the corresponding mask is removed from the MMCi.MMCHS_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS_STAT register and the eMMC/SD/SDIOi host controller does not transmit an interrupt request.

Note

If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the eMMC/SD/SDIOi host controller waits for the service of the interrupt without updating the status MMCi.MMCHS_STAT register or transmitting an interrupt request.

Table 25-11 lists the event flags, and their mask, that can cause module interrupts.

Table 25-11. Events

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[29] BADA	MMCHS_IE[29] BADA_ENABLE	MMCi_IRQ	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE = 0). This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_PSTATE[10] BWE = 0).
MMCHS_STAT[28] CERR	MMCHS_IE[28] CERR_ENABLE	MMCi_IRQ	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the auto CMD12 command.
MMCHS_STAT[26] TE	MMCHS_IE[26] TE_ENABLE	MMCi_IRQ	Tuning Error. This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure. The Tuning Error is with higher priority than the other error interrupts generated during data transfer.
MMCHS_STAT[25] ADMAE	MMCHS_IE[25] ADMAE_ENABLE	MMCi_IRQ	ADMA error. This bit is set when the host controller detects errors during an ADMA-based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA error status register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.
MMCHS_STAT[24] ACE	MMCHS_IE[24] ACE_ENABLE	MMCi_IRQ	Auto CMD12 error and Auto CMD23 error. This bit is set automatically when one of the bits MMCHS_AC12[4:0] changes from 0 to 1.
MMCHS_STAT[22] DEB	MMCHS_IE[22] DEB_ENABLE	MMCi_IRQ	Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode.
MMCHS_STAT[21] DCRC	MMCHS_IE[21] DCRC_ENABLE	MMCi_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position 010 token during a block write command.
MMCHS_STAT[20] DTO	MMCHS_IE[20] DTO_ENABLE	MMCi_IRQ	Data time-out error. This bit is set automatically according to the following conditions: • Busy time-out for R1b, R5b response type • Busy time-out after write CRC status • Write CRC status time-out • Read data time-out

Table 25-11. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[19] CIE	MMCHS_IE[19] CIE_ENABLE	MMCi_IRQ	Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD[20] CICE bit.
MMCHS_STAT[18] CEB	MMCHS_IE[18] CEB_ENABLE	MMCi_IRQ	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
MMCHS_STAT[17] CCRC	MMCHS_IE[17] CCRC_ENABLE	MMCi_IRQ	Command CRC error. This bit is set automatically when a CRC7 error occurs in the command response. CRC check is enabled through the MMCHS_CMD[19] CCCE bit.
MMCHS_STAT[16] CTO	MMCHS_IE[16] CTO_ENABLE	MMCi_IRQ	Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles.
MMCHS_STAT[15] ERRI	MMCHS_IE[15] ERRI_ENABLE	MMCi_IRQ	Error interrupt. If any of the bits in the error interrupt status register (MMCHS_STAT[31:16]) are set, this bit is set to 1.
MMCHS_STAT[10] BSR	MMCHS_IE[10] BSR_ENABLE	MMCi_IRQ	Boot status received interrupt. This bit is set automatically when the MMCHS_CON[18] BOOT_CF0 bit is set to 0x1 or 0x2 and a boot status is received on the dat0 line. This interrupt is useful only for the MMC card.
MMCHS_STAT[8] CIRQ	MMCHS_IE[8] CIRQ_ENABLE	MMCi_IRQ	Card interrupt. This bit is used only for SD, SDIO, and CE-ATA cards. In 1-bit mode, the interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, the interrupt source is sampled during the interrupt cycle. In CE-ATA mode, the interrupt source is detected when the card drives the CMD line to 0 during one cycle after data transmission end.
MMCHS_STAT[7] CREM	MMCHS_IE[7] CREM_ENABLE	MMCi_IRQ	Card removal. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 1 to 0.
MMCHS_STAT[6] CINS	MMCHS_IE[6] CINS_ENABLE	MMCi_IRQ	Card insertion. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 0 to 1.
MMCHS_STAT[5] BRR	MMCHS_IE[5] BRR_ENABLE	MMCi_IRQ	Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH must empty the buffer by reading it.
MMCHS_STAT[4] BWR	MMCHS_IE[4] BWR_ENABLE	MMCi_IRQ	Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the MMCHS_BLK[10:0] BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer.
MMCHS_STAT[3] DMA	MMCHS_IE[3] DMA_ENABLE	MMCi_IRQ	DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completes.
MMCHS_STAT[2] BGE	MMCHS_IE[2] BGE_ENABLE	MMCi_IRQ	Block gap event. When a stop at the block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.

Table 25-11. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[1] TC	MMCHS_IE[1] TC_ENABLE	MMCi_IRQ	Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request (MMCHS_HCTL[16] SBGR). • In read mode: This bit is automatically set when a read transfer completes (MMCHS_PSTATE[9] RTA). • In write mode: This bit is automatically set when the DAT line use completes (MMCHS_PSTATE[2] DLA).
MMCHS_STAT[0] CC	MMCHS_IE[0] CC_ENABLE	MMCi_IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt.

Note

To send an interrupt request to the MMCi_IRQ line, the mask/unmask bit must be set in the MMCi.MMCHS_IE and MMCi.MMCHS_ISE registers.

The eMMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

25.4.4.1 Interrupt-Driven Operation

An interrupt-enable bit must be set in the MMCi.MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the MMCi.MMCHS_STAT register to identify which event occurred.
2. Write 1 into the corresponding bit of the MMCi.MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

Note

In the MMCi.MMCHS_STAT register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The MMCi.MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS_IE[8] CIRQ_ENABLE bit (set to 0x0), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The MMCi.MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in the MMCi.MMCHS_STATregister (bits 31 through 16) are cleared.

25.4.4.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

Note

See the previous note concerning clearing of the CIRQ and ERRI bits.

25.4.4.3 Asynchronous Interrupt

Asynchronous interrupt is defined in *SDIO Card Specification version 3.00, part E*. This interrupt is effective in 4-bit mode and is generated without SD clock. Asynchronous interrupt period is defined in the synchronous interrupt period after the last data block and until a next command is received.

Asynchronous interrupt period in a multiple block write operation.

If MMCHS_CAPA[29] AIS is set to 0, writing to MMCHS_AC12[30] AI_ENABLE is ignored. This bit is set to 0. A synchronous interrupt period starts two clocks after the last data block. If MMCHS_AC12[30] AI_ENABLE is set to 1, the asynchronous interrupt period starts four clocks after the start of the synchronous interrupt period. Four clocks after the start bit of the next command, the asynchronous interrupt period ends and goes back to the synchronous interrupt period.

25.4.5 DMA Modes

Two DMA management modes can be used to load data from memory to the internal buffer of the controller (or vice versa). These modes are exclusive and depend on the module integration.

- DMA master mode:

  DMA master mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 1. In this case, the controller has direct access to data using a specific algorithm called ADMA2 (prevents the system from being interrupted). Data are exchanged using the L3_MAIN master interface, which supports burst accesses to maximize throughput.

  Note

  This mode is supported only by modules connected to the L3_MAIN interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.1, *eMMC/SD/SDIO Overview*.

  This mode is available for modules MMC1 and MMC2.

- DMA slave mode:

  DMA slave mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMCi_DMA_TX and MMCi_DMA_RX).

  Note

  This mode is the only mode supported by modules that are not connected to the L3_MAIN interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.1, *eMMC/SD/SDIO Overview*.

  This mode is available for all MMC modules.

25.4.5.1 Master DMA Operations

The eMMC/SD/SDIOi host controller has direct access to the internal data. This feature is called advanced DMA (ADMA). It follows a specific algorithm (ADMA2) defined by an instruction in memory that starts at an address

previously loaded in the MMCHS_ADMASAL register before any data command issued to the MMC card. Only 32-bit address spacing is supported by the controller for data storage.

Note

This mode is supported only by modules connected to the L3_MAIN interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.1, *eMMC/SD/SDIO Overview*.

These instructions must be loaded by software in a 32-bit-addressed descriptor table in system memory, as shown in Figure 25-16. In this case the MMCHS_ADMASAL register is used as the program address pointer

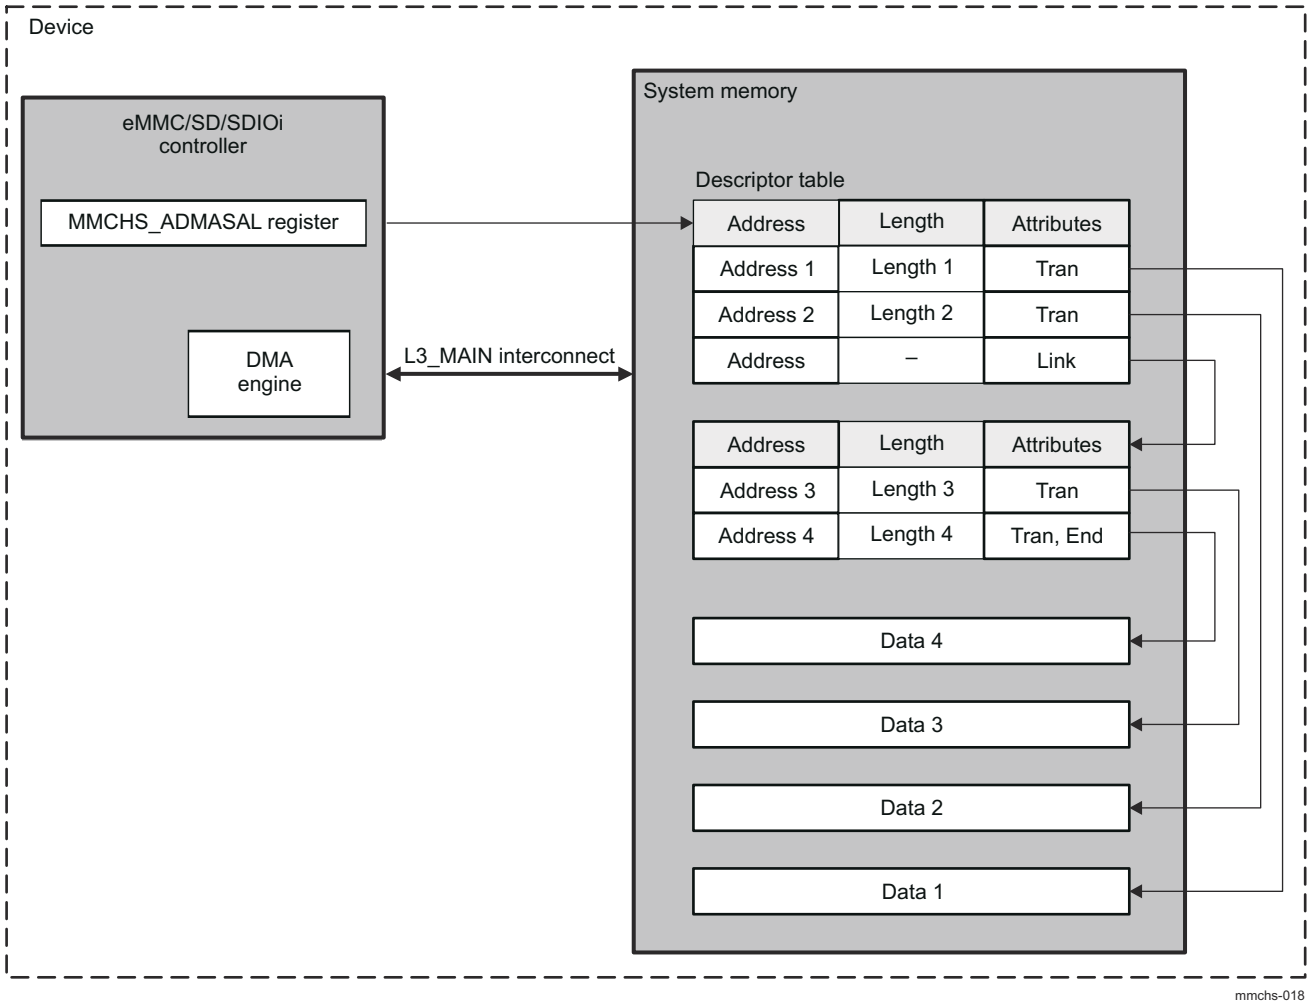

Figure 25-16. ADMA Block Diagram Overview

25.4.5.1.1 Descriptor Table Description

Each descriptor line contains an address, a length, and attributes fields. The attributes define which operation will be processed. Every descriptor line is a 64-bit-wide register that is fetched in the controller using the L3_MAIN master interface, and requires two 32-bit accesses to memory.

Table 25-12 shows the structure of a descriptor line.

Table 25-12. Descriptor Line Overview

Address Field		Length		Reserved		Attributes					
63	32	31	16	15	6	5	4	3	2	1	0
32-bit address		16-bit length		0x0		Act2	Act1	0	Int	Ent	Valid

The attribute of the descriptor line is divided into two parts:

- Attributes[5:4]: The action to be processed by the ADMA engine
- Attributes[3:0]: Additional parameters characterizing the behavior of the ADMA engine

Table 25-13 describes the available actions of a descriptor line.

Table 25-13. Available Actions of a Descriptor Line

Act2	Act1	Symbol	Comment	Operation
0	0	Nop	No operation	Do not execute the current line and go to the next line.
0	1	Rsv	Reserved	Reserved action. Behaves the same as the Nop command.
1	0	Tran	Transfer data	Transfer data of one descriptor line.
1	1	Link	Link descriptor	Link to another descriptor.

Table 25-14 describes the additional parameters of a descriptor line.

Table 25-14. Additional Parameters of a Descriptor Line

Bit	Description
Valid	Valid = 1 indicates that this descriptor line is effective. If Valid = 0, an ADMA error interrupt is generated and the ADMA is stopped. This prevents runaways.
End	End = 1 indicates the end of a descriptor. The transfer-complete interrupt is generated when the operation of the descriptor line is complete.
Int	Int = 1 generates a DMA interrupt when the operation of the descriptor line is complete.

25.4.5.1.2 Requirements for Descriptors

The following sections discuss restrictions and tips on how to correctly configure the descriptors to be used by the ADMA engine.

25.4.5.1.2.1 Data Length

There are three requirements to program descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64 KiB.
- Total length = $Length_1$ + $Length_2$+ $Length_3$ + ... + $Length_n$ must be a multiple of the block size.

If the total length of a descriptor is not a multiple of the block size, data transfer with the ADMA engine may not have been terminated. In this case, the controller returns a data time-out event and the transfer is aborted.

The block count register (the MMCHS_BLK[31:16] NBLK bit field) is defined as 16 bits and limits data transfers to a maximum of 65,535 blocks. If the ADMA data transfer size is less than or equal to the 65,535-block transfer, the block count register can be used. In this case, the total length of the descriptor table must be equivalent to "block size" by "block count." If the ADMA data transfer is greater than 65,535 blocks, the block count register must be disabled by setting the block count enable bit (MMCHS_CMD[1] BCE) to 0. In this case, the length of the data transfer is not designated by the block count but by the descriptor table.

Note

The timing for detecting the last block on the SD bus may differ, which affects control of the read transfer active (MMCHS_PSTATE[9] RTA), write transfer active (MMCHS_PSTATE[8] WTA), and DAT line active (MMCHS_PSTATE[2] DLA) bits. In case of a read operation, more blocks than required may be read from the card. The host driver must ignore an out-of-range error if the read operation is for the last block of the memory area.

25.4.5.1.2.2 Supported Features

The ADMA engine does not support the suspend/resume function. However, the stop and continue functions are available.

When the stop-at-block-gap request (the MMCHS_HCTL[16] SBGR bit) is set during the ADMA operation, the block gap event interrupt is generated when the ADMA is stopped at block gap (the MMCHS_STAT[2] BGE bit). The host controller must stop the ADMA read operation by using read wait or by stopping the SD clock. While stopping ADMA, SD commands cannot be issued.

25.4.5.1.2.3 Error Generation

When an error occurs during an ADMA transfer, the ADMA operation is stopped and the ADMA error interrupt is generated. The ADMA error state field (the MMCHS_ADMAES[1:0] AES bit field) holds the state of the ADMA when it is stopped. Software can identify the erroneous descriptor line by using the following method:

- If the ADMA stopped at ST_FDS state, the ADMA system address register (MMCHS_ADMASAL) points to the erroneous descriptor line.
- If the ADMA stopped at ST_TFR or ST_STOP state, the ADMA system address register points to the descriptor line following the erroneous one.

25.4.5.1.3 Advanced DMA Description

The ADMA is a DMA controller embedded in each eMMC controller. It can be seen as a small sequencer that fetches a descriptor line and executes the corresponding action. The base address of the descriptor table is stored in the MMCHS_ADMASAL register.

Note

Software must write the base address of the descriptor table in the MMCHS_ADMASAL register before the first use of the ADMA engine.

The ADMA program is executed according to descriptor attributes (see Section 25.4.5.1.1, *Descriptor Table Description*) and an FSM, as shown in Figure 25-17.

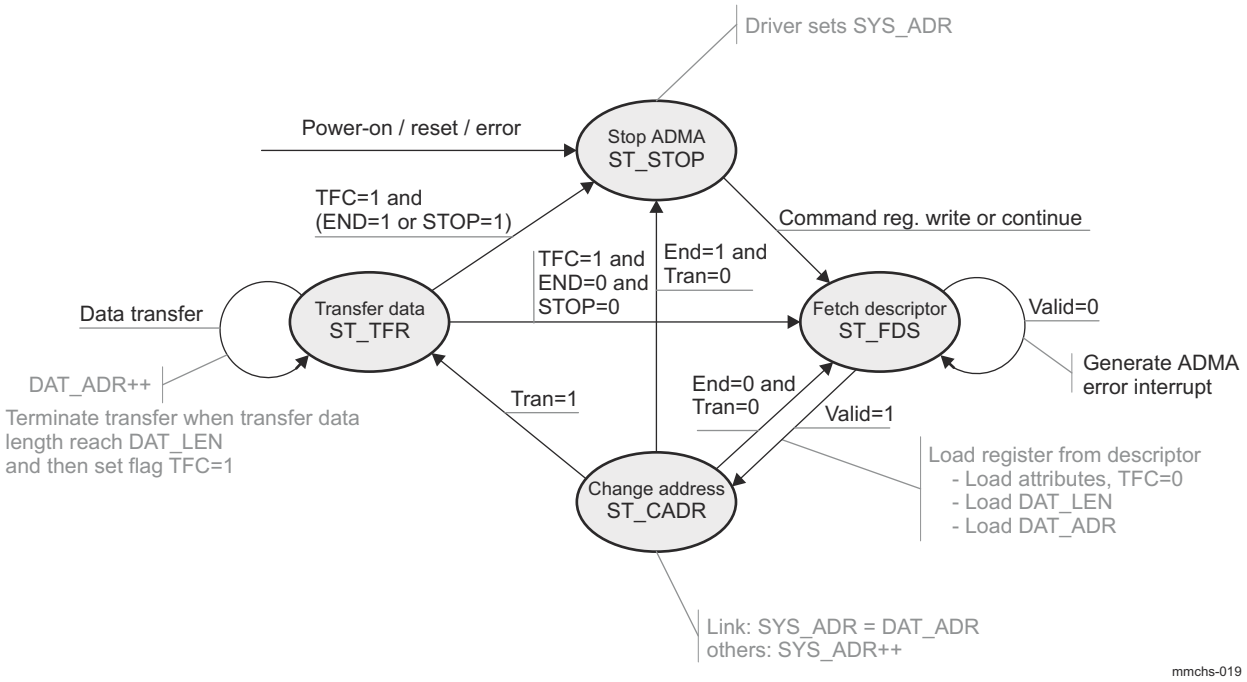

Figure 25-17. ADMA Finite State-Machine

Table 25-15 describes each state of the ADMA FSM.

Table 25-15. ADMA2 States Description

State Name	Operation
ST_FDS (fetch descriptor)	ADMA2 fetches a descriptor line and sets parameters in internal registers. It then goes to ST_CADR state.
ST_CADR (change address)	Link operation loads another descriptor address to the ADMA system address register (MMCHS_ADMASAL). In other operations, the ADMA system address register is incremented to point to the next descriptor line. If End = 0, go to ST_FDS state. **NOTE**: ADMA2 does not stop at this state if some errors occur.
ST_TFR (transfer data)	Data transfer of one descriptor line is executed between system memory and the SD card: • If data transfer continues (End = 0), go to ST_FDS state. • If data transfer completes, go to ST_STOP state.
ST_STOP (stop DMA)	ADMA2 stays in this state in the following cases: • After power-on reset (POR) or software reset • All descriptor data transfers are complete. If a new ADMA operation is stated by writing the command register, go to ST_FDS state.

Table 25-16 gives the description of each symbol used in the ADMA FSM (see Figure 25-17).

Table 25-16. ADMA FSM Symbol Definition

Symbol	Definition
SYS_ADR	ADMA system address register
SYS_ADR++	Point to next descriptor line
DAT_ADR	Data address register (internal)
DAT_LEN	Data length register (internal)
TFC	Transfer complete flag (internal)
STOP	Stop-at-block-gap request

25.4.5.2 Slave DMA Operations

The eMMC/SD/SDIOi host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (more than 1024 bytes) for SD cards, as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

Note

This mode is implied by modules that are not connected to the L3_MAIN interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.4.5.1, *Master DMA Operations*.

The DMA request is issued if the following conditions are met:

- The MMCi.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the CMD line.
- There is enough space in the buffer of the eMMC/SD/SDIOi host controller to write an entire block (BLEN writes).

25.4.5.2.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCi_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN bit field.

MMCi_DMA_RX is deasserted to its inactive level when the a certain device DMA module reads one word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

New DMA requests are internally masked if the DMA has not read exactly BLEN bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of DMA reads is Integer(BLEN / 4) + 1.

The receive buffer never overflows. In multiple block transfers for block sizes larger than 512 bytes, when the buffer becomes full, the mmci_clk clock signal (provided to the card) is momentarily stopped until a certain device DMA or the MPU performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 25-18 shows DMA receive mode.

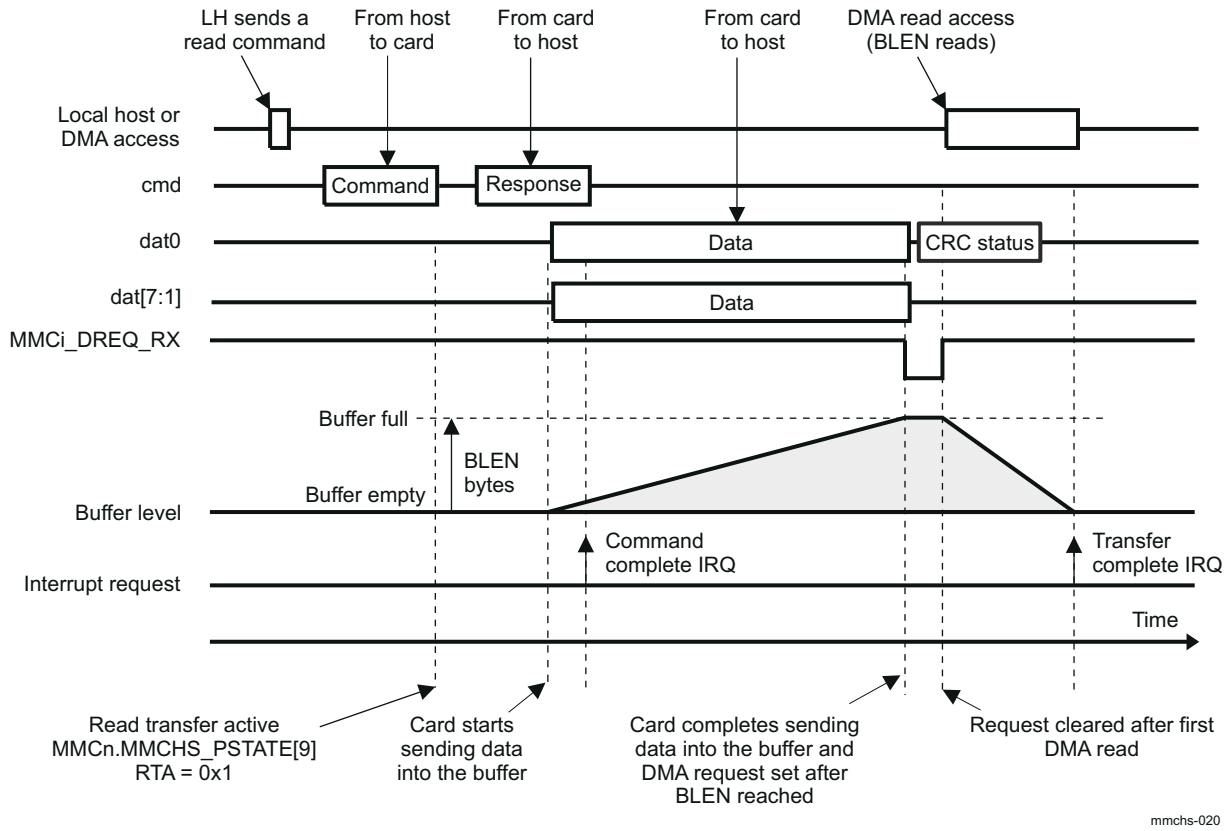

Figure 25-18. DMA Receive Mode

25.4.5.2.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMCi_DMA_TX is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN bit field.

MMCi_DMA_TX is deasserted to its inactive level when a certain device DMA writes one word to the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

New DMA requests are internally masked if the DMA has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of DMA reads is Integer(BLEN / 4) + 1) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 25-19 shows DMA transmit mode.

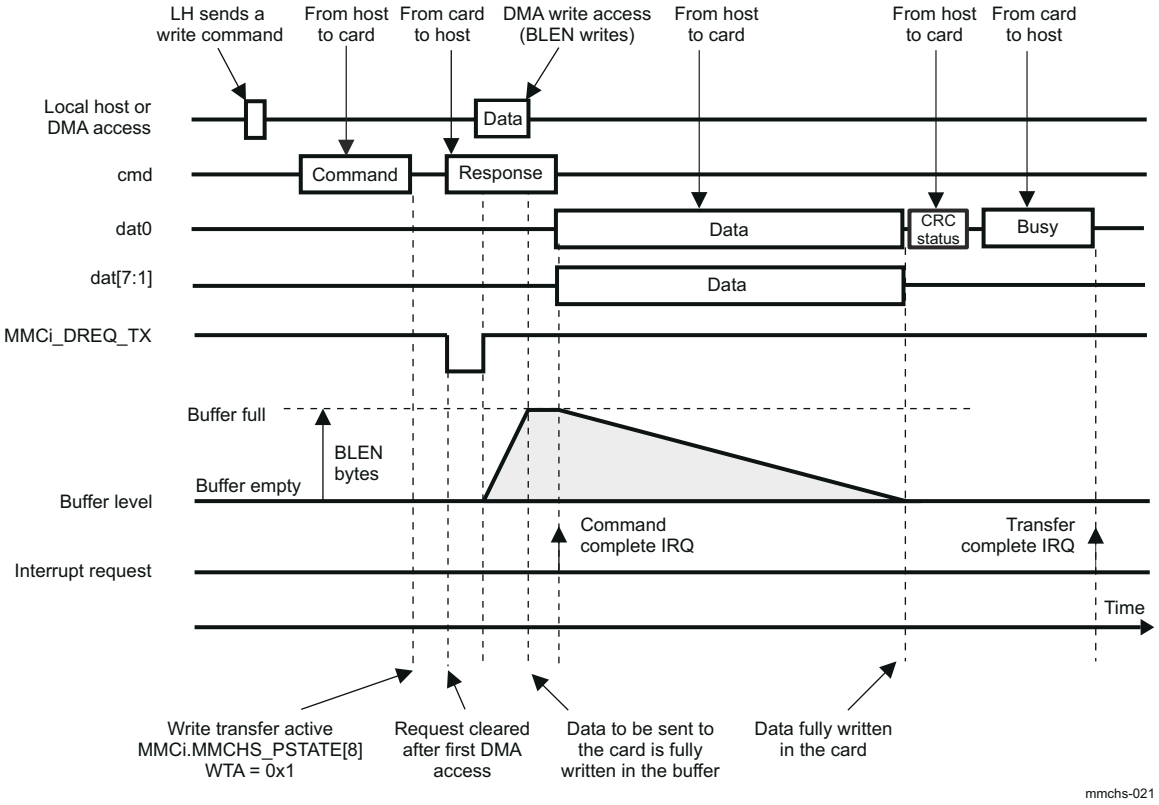

Figure 25-19. DMA Transmit Mode

25.4.6 Mode Selection

The eMMC/SD/SDIO host controller can be used in two modes: MMC and SD/SDIO. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification, Part E1*.

The purpose of the module is to transfer commands and data to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

25.4.7 Buffer Management

25.4.7.1 Data Buffer

The eMMC/SD/SDIOi host controller uses a data buffer. This buffer transfers data from one data bus (interconnect) to another data bus (SD/SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the prefetch buffer and the post-write buffer is the 32-bit MMCi.MMCHS_DATA register. A write access to the MMCi.MMCHS_DATA register followed by a read access from the MMCi.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCi.MMCHS_DATA register and the data of the read access to the MMCi.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCi.MMCHS_DATA register that are needed to read (or write) a data block with a size of the MMCi.MMCHS_BLK[11:0] BLEN bit field is equal to the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is hard-coded in the MMCi.MMCHS_CAPA[17:16] MBL bit field and cannot be changed.

A read access to the MMCi.MMCHS_DATA register is allowed only when the buffer read-enable status is set to 1 (the MMCi.MMCHS_PSTATE[11] BRE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled.

A write access to the MMCi.MMCHS_DATA register is allowed only when the buffer write-enable status is set to 1 (the MMCi.MMCHS_PSTATE[10] BWE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled and the data are not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus, and vice versa. The eMMC/SD/SDIOi host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time. In this way, data can be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) are being stored into the other portion, and vice versa. When BLEN is less than or equal to 0x200 (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits × BLEN divided by 4). No more than this total size of 2 × 32 bits × BLEN divided by 4 can be used.

CAUTION

The MMCi.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 25-20 and Figure 25-21 show the buffer management for a write and a read, respectively.

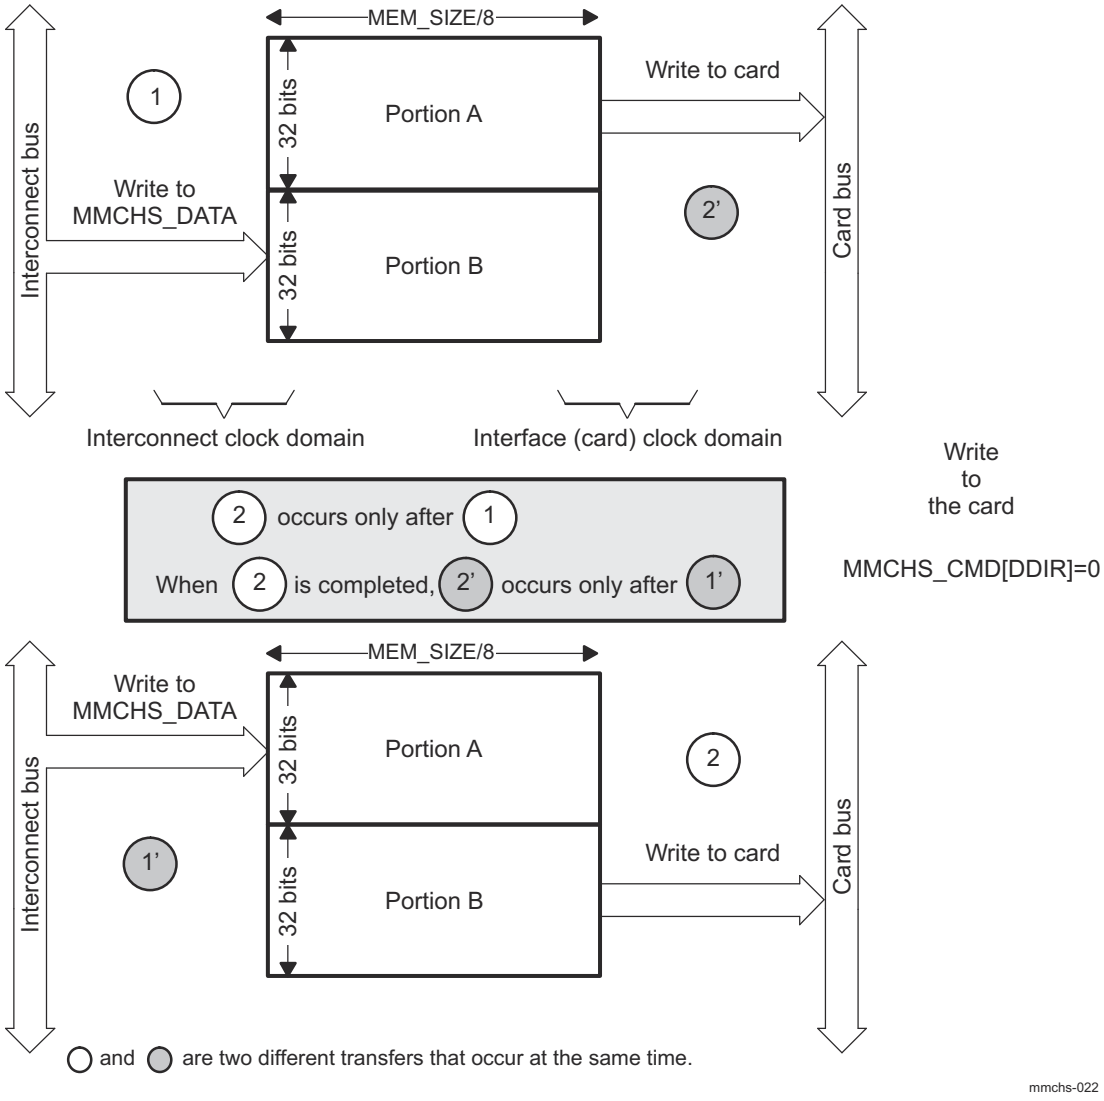

Figure 25-20. Buffer Management for a Write

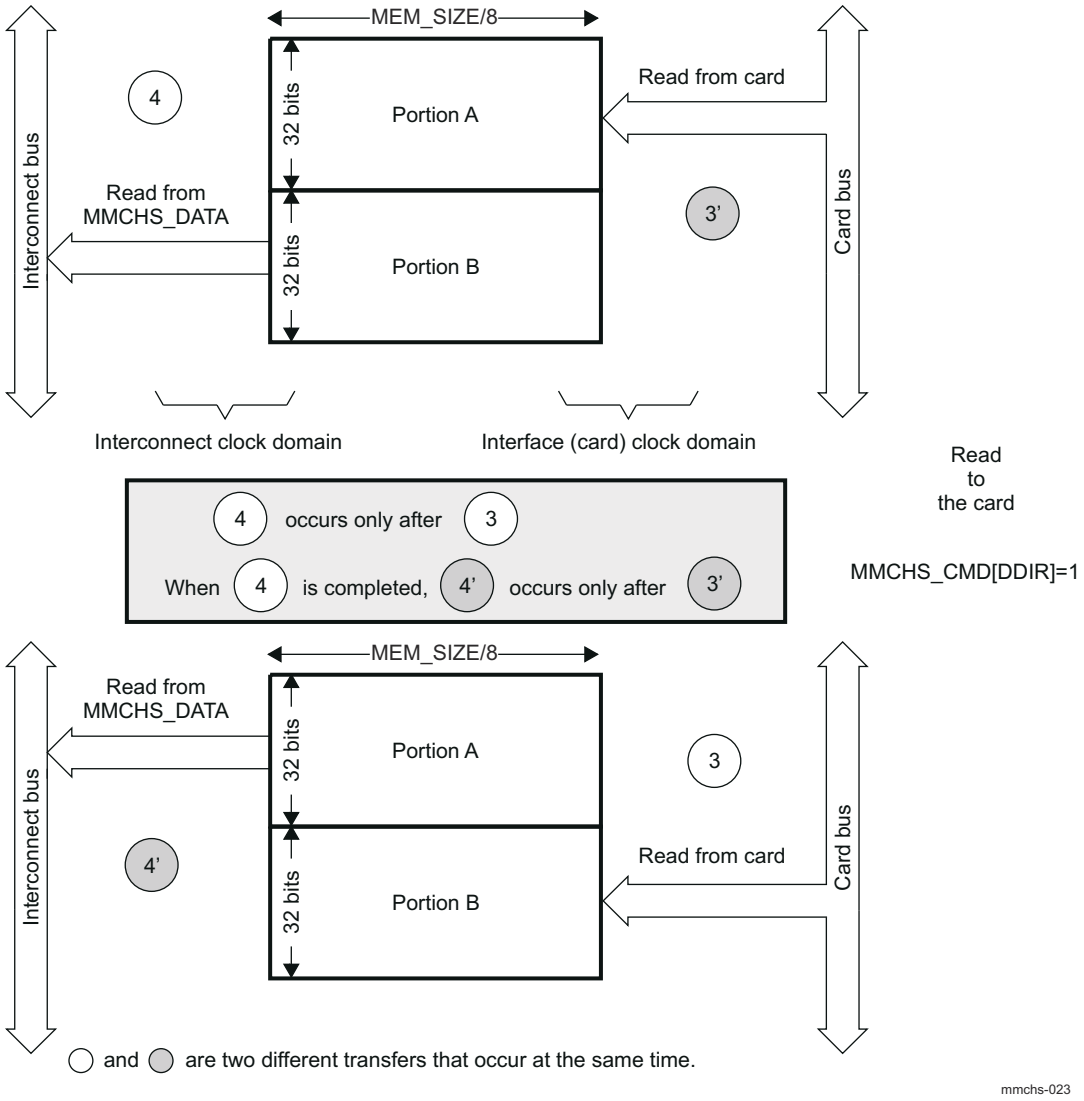

Figure 25-21. Buffer Management for a Read

- When the size of the data block to transfer is larger than MEM_SIZE / 2, only one data transfer at a time can occur from one data bus to the other data bus. The eMMC/SD/SDIOi host controller uses the entire data buffer as a single portion.

  In this mode, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

25.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see Table 25-17).

Note

Double-buffering is always the buffer management for large memory depth.

Table 25-17. Memory Size, BLEN, and Buffer Relationship

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	**512**	**1024**
Maximum block length supported	512	1024

Table 25-17. Memory Size, BLEN, and Buffer Relationship (continued)

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024
Double-buffering for maximum block length	N/A	BLEN <= 512
Single-buffering for block length	BLEN <= 512	512 < BLEN <= 1024

Note

For single-buffering management, throughput on the MMC bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the MMC bus. The clock is maintained on write MMC transfers (the MMCHS_CMD[4] DDIR bit is 0) and halted on read MMC transfers (the MMCHS_CMD[4] DDIR bit is 1).

25.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
  - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
  - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
  - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers:
  - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
  - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

25.4.8 Transfer Process

The process of a transfer depends on the type of command. It can be with or without a response, and with or without data.

25.4.8.1 Different Types of Commands

Different types of commands are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*; or *the SD Card Specification, Part A2, SD Host Controller Standard Specification*.

25.4.8.2 Different Types of Responses

Different types of responses are specific to the eMMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*; *SD Memory Card Specifications*; *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*.

Table 25-18 describes how the eMMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 25-18. MMC, SD, SDIO Responses in the MMCHS_RSPxx Registers

Type of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8](1)	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response), R1(Auto CMD23 response)	RESP[39:8](1)	MMCHS_RSP76[31:0]
R2	RESP[127:0](1)	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

(1) RESP refers to the command response format described in the specifications mentioned.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the host controller may execute multiple block data transfers on the DATA line concurrently with a command. This allows the host controller to avoid overwriting the response of Auto CMD12 with the command response stored in the MMCHS_RSP10 register, and vice versa.

While executing Auto CMD23 the response of CMD23 is saved in the MMCHS_RSP76[31:0] register and the response of multiple-block read and write command is saved in the MMCHS_RSP10 register. The response error of CMD23 is indicated in the MMCHS_AC12 register, bits [7:0].

25.4.9 Transfer or Command Status and Errors Reporting

Flags in the eMMC/SD/SDIOi host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see Table 25-19 and the register description.

Table 25-19. CC and TC Values Upon Error Detected

Error Hold in MMCi.MMCHS_STAT		CC	TC	Comments
29	BADA			No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion does not depend on the ongoing transfer.
28	CERR	1		CC is set upon CERR.
22	DEB		1	TC is set upon DEB.
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC. See CTO comment.
16	CTO			CTO and CC are mutually exclusive. CIE, CEB, and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears.

A MMCHS_STAT[20] DTO event can be asserted in the following conditions:

- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out
- Boot acknowledge time-out

25.4.9.1 Busy Time-Out for R1b, R5b Response Type

Figure 25-22 shows the DTO event condition asserted when there is a busy time-out for Rb1, R5b response.

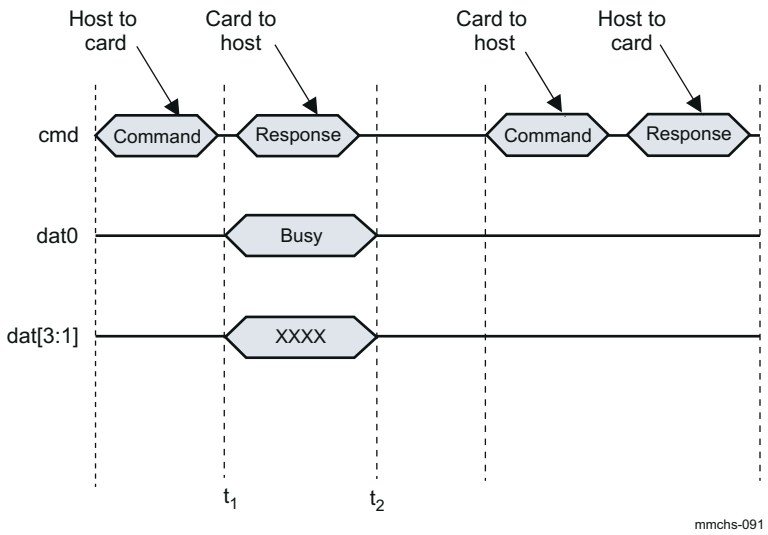

Figure 25-22. Busy Time-Out for R1b, R5b Response Type

t_1 – Data time-out counter is loaded and starts after R1b, R5b response type.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.2 Busy Time-Out After Write CRC Status

Figure 25-23 shows the DTO event condition asserted when there is a busy time-out after write CRC status.

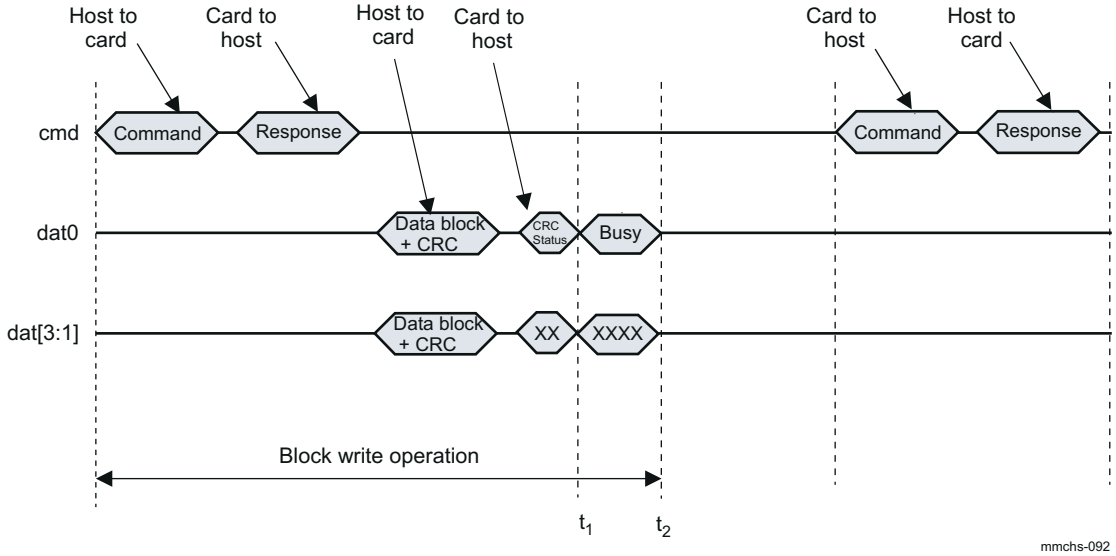

Figure 25-23. Busy Time-Out After Write CRC Status

t_1 – Data time-out counter is loaded and starts after CRC status.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.3 Write CRC Status Time-Out

Figure 25-24 shows the DTO event condition asserted when there is a write CRC status time-out.

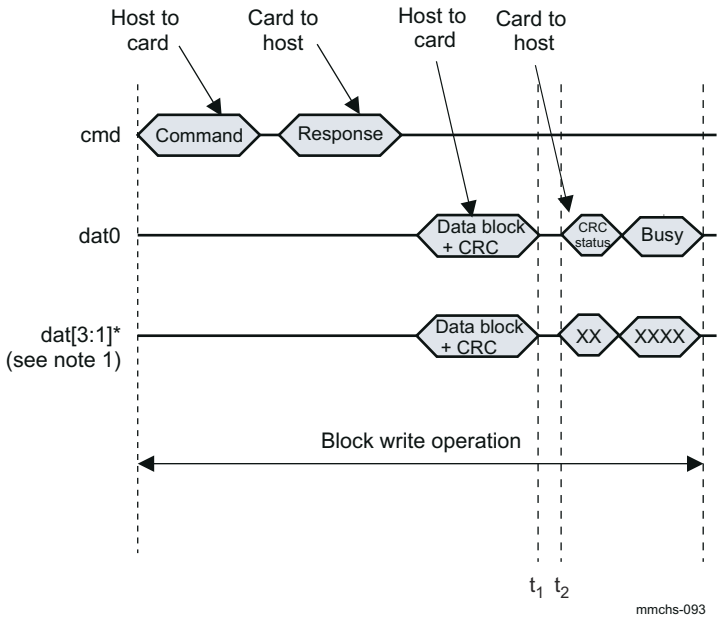

Figure 25-24. Write CRC Status Time-Out

t_1 – Data time-out counter is loaded and starts after data block + CRC.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.4 Read Data Time-Out

Figure 25-25 shows the DTO event condition asserted when there is a read data time-out.

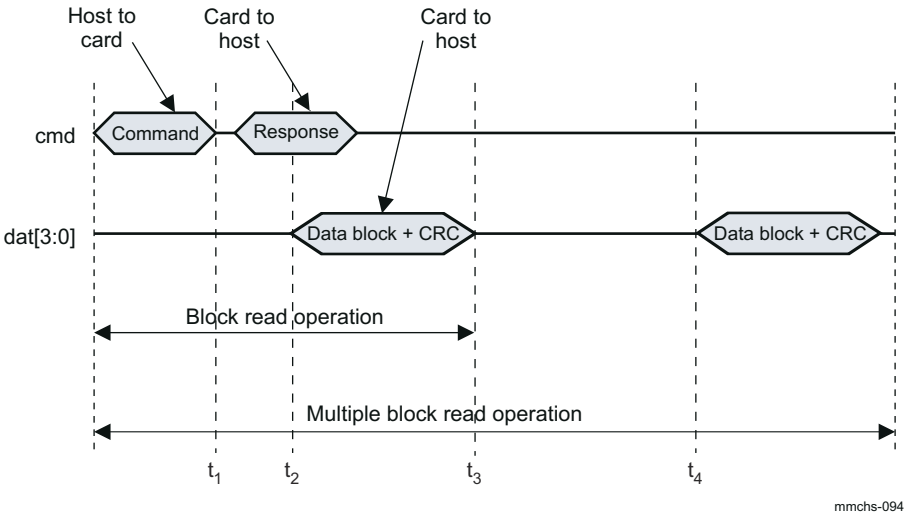

Figure 25-25. Read Data Time-Out

t_1 – Data time-out counter is loaded and starts after command transmission.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts after data block + CRC transmission.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.5 Boot Acknowledge Time-Out

Figure 25-26 shows the DTO event condition asserted when there is a boot acknowledge time-out and CMD0 is used.

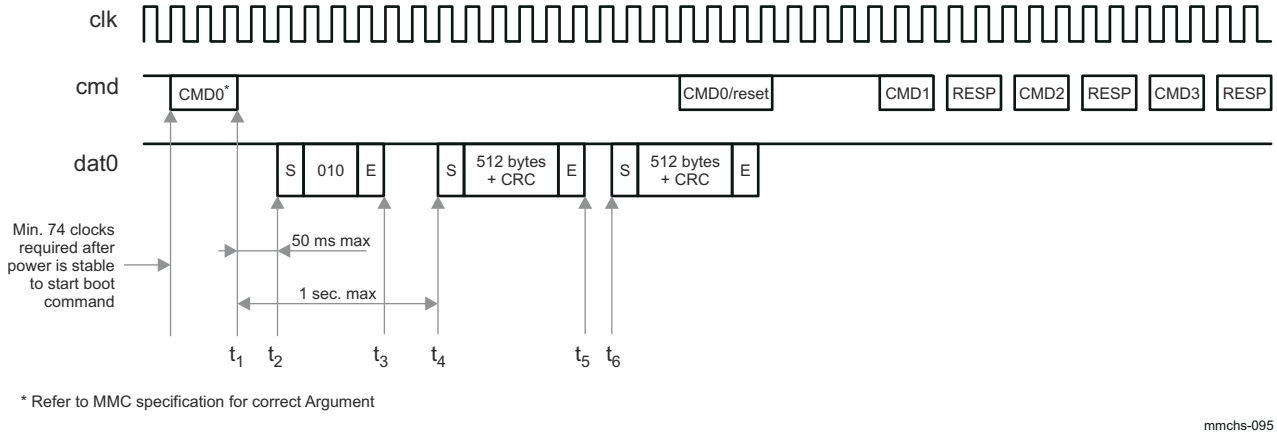

Figure 25-26. Boot Acknowledge Time-Out When Using CMD0

t_1 – Data time-out counter is loaded and starts after CMD0.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_5 – Data time-out counter is loaded and starts after data + CRC transmission.

t_6 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

Figure 25-27 shows the DTO event condition asserted when there is a boot acknowledge time-out when the CMD line is tied to 0.

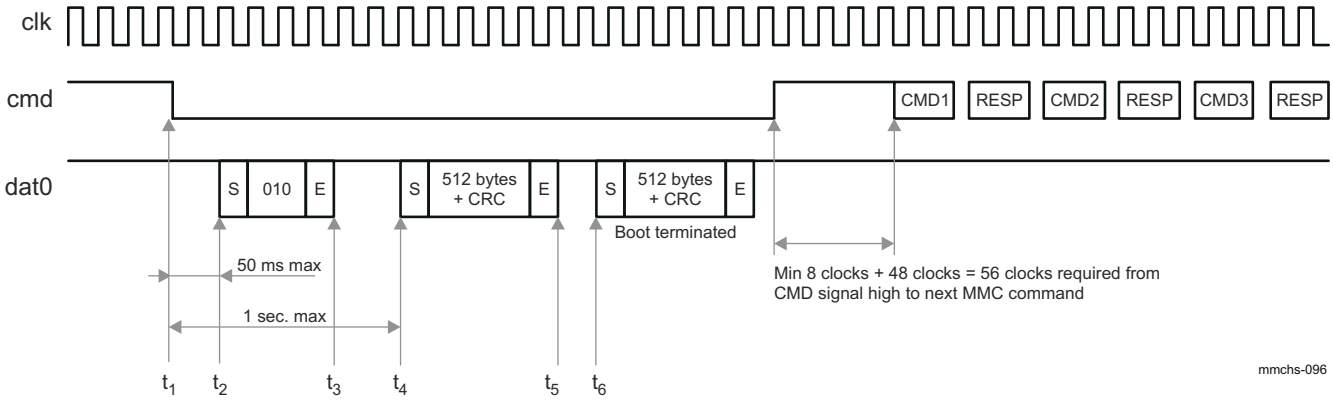

Figure 25-27. Boot Acknowledge Time-Out When CMD Line Tied to 0

t_1 – Data time-out counter is loaded and starts after the CMD line is tied to 0.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_5 – Data time-out counter is loaded and starts after data + CRC transmission.

t_6 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.10 Auto Command 12 Timings

With the UHS definition of SD cards with higher frequency for MMC clock up to 208, the SD standard imposes a specific timing for the arrival of the auto command 12 (Auto CMD12) end bit.

25.4.10.1 Auto CMD12 Timings During Write Transfer

A margin named Ncrc in the range of two to eight cycles has been defined for SDR50 and SDR104 card components for write data transfers, because the Auto CMD12 end bit must arrive after the CRC status end bit.

Figure 25-28 shows the Auto CMD12 timings during write transfer.

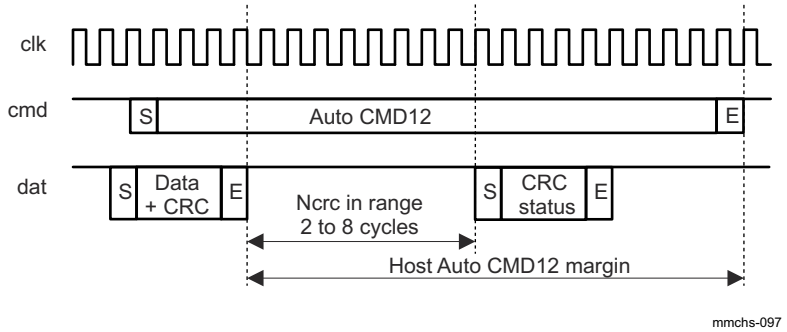

Figure 25-28. Auto CMD12 Timings During Write Transfer

The host controller has a margin of 18 clock cycles to enure that the Auto CMD12 end bit arrives after the CRC status. This margin does not depend on the MMC/SD bus configuration, DDR, or standard transfer, 1-, 4-, or 8-bit bus width.

25.4.10.2 Auto CMD12 Timings During Read Transfer

With UHS cards, the gap timing between two successive cards is extended from two cycles to four cycles. It provides more flexibility for the host Auto CMD12 arrival to receive the last complete and reliable block. The MMCHS controller follows only the left border case defined by the SD UHS specification.

Figure 25-29 shows Auto CMD12 timings during read transfer.

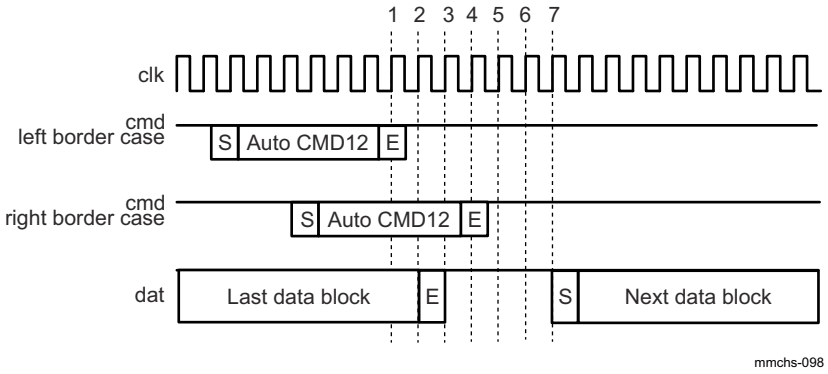

Figure 25-29. Auto CMD12 Timings During Read Transfer

The Auto CMD12 arrival sent by the host controller is not sensitive to the MMC/SD bus configuration, whether it is a DDR or standard transfer and whether it is a 1-, 4-, or 8-bit bus width transfer.

25.4.11 Transfer Stop

Whenever a transfer is initiated, the transmission can be stopped before it finishes. Several cases are possible, depending on the transfer type:

- Multiple-block-oriented transfers (transfer length is known)
- Continuous stream transfers (transfer has an infinite length)

Note

Because the eMMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

The eMMC/SD/SDIOi controller includes three features that make a transfer stop more convenient and easier to manage:

- Auto CMD12/Auto CMD23 (for eMMC and SD only):

  Auto CMD12/Auto CMD23 feature is enabled by setting the MMCi.MMCHS_CMD[3:2] ACEN bit field to 0x1 or to 0x2 respectively (this setting is relevant for an MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12/Auto CMD23 feature is enabled, the eMMC/SD/SDIOi controller automatically issues a CMD12/CMD23 command when the expected number of blocks is exchanged.
- Stop at block gap:

  This feature is enabled by setting the MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.
- ADMA mode:

  For ADMA-capable modules (MMC1 and MMC2) (for more information, see Section 25.4.5, *DMA Modes*), the last instruction can stop the transfer (the END bit is enabled in the descriptor line).

Note

For eMMC and SD cards, the stop-at-block-gap feature is not supported in read mode.

For SDIO cards, this setting can be supported in read mode if the card has read-wait capability.

Note

In SDR104 mode Auto CMD23 is used to stop multiple block read/write operation instead of Auto CMD12. In the other bus speed modes, if the card supports CMD23, Auto CMD23 is used instead of Auto CMD12.

Table 25-20 shows the common way to stop a transfer, indicating the command to send and the features to enable.

Table 25-20. eMMC/SD/SDIOi Controller Transfer Stop Command Summary

	Write Transfer		Read Transfer	
	SD/MMC	SDIO	SD/MMC	SDIO
Single block	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.

Table 25-20. eMMC/SD/SDIOi Controller Transfer Stop Command Summary (continued)

		Write Transfer		Read Transfer	
Multiblocks (finite or infinite)	Before the programmed block boundary	Send CMD12/ CMD23. Wait TC.	Send CMD52. Wait TC.	Send CMD12/ CMD23. Wait TC.	Send CMD52. Wait TC.
	Stop at the end of the transfer (finite transfer only)	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.	Set MMCi.MMCHS_HCTL [16] SBGR bit to 0x1. Send CMD52. Wait TC.	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.	**If READ_WAIT supported** Stop at block gap. Wait TC.
					If READ_WAIT not supported Send CMD52. Wait TC.

Note

The eMMC/SD/SDIOi controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

25.4.12 Output Signals Generation

The eMMC/SD/SDIO output signals can be driven on the falling edge or rising edge, depending on the MMCHS_HCTL[2] HSPE bit.

25.4.12.1 Generation on Falling Edge of MMC Clock

The controller defaults to this mode to maximize hold timings. In this case, the MMCHS_HCTL[2] HSPE bit is set to 0.

Figure 25-30 shows the output signals of the module when generating from the falling edge of the MMC clock.

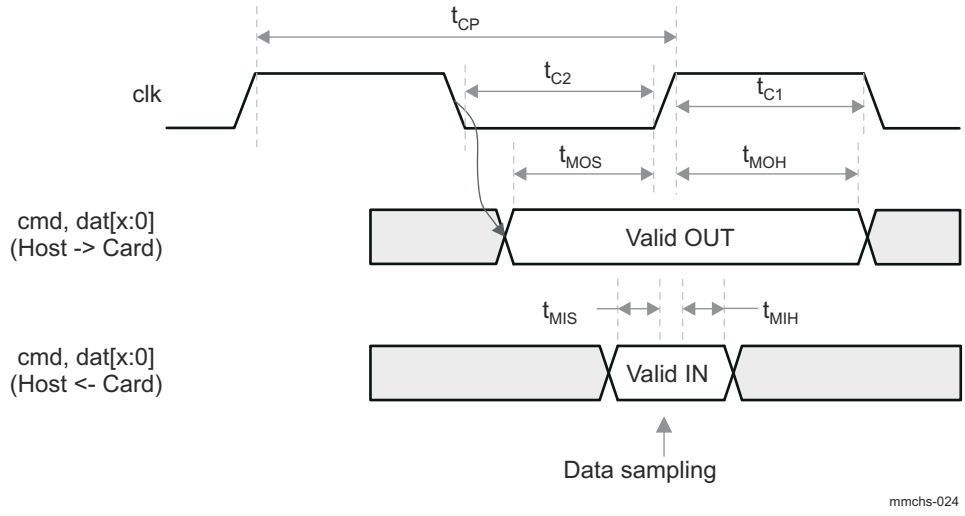

Figure 25-30. Output Driven on Falling Edge

25.4.12.2 Generation on Rising Edge of MMC Clock

This mode is intended to increase setup timings. This feature is activated by setting the MMCHS_HCTL[2] HSPE bit to 1.

Note

Do not use this feature in DDR mode (when the MMCHS_CON[19] DDR bit is set to 1).

Figure 25-31 shows the output signals of the module when generating from the rising edge of the MMC clock.

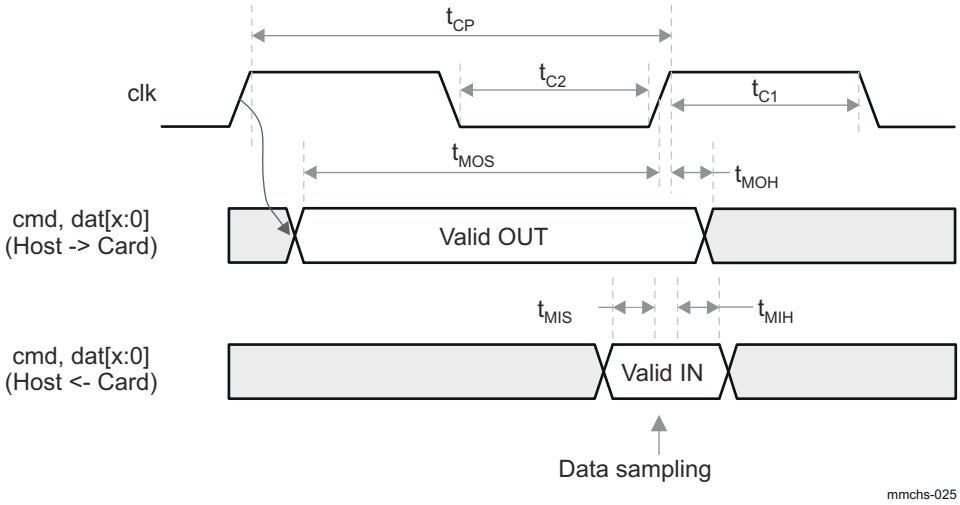

Figure 25-31. Output Driven on Rising Edge

25.4.13 Sampling Clock Tuning

In UHS-I mode the SD bus operates in high clock frequency mode and the data window from the card on CMD and DAT lines get smaller. The position of the data window varies depending on the card and the host system. To adjust the sampling clock when SDR104/HS200 operation mode is used the eMMC/SD/SDIOi host controller supports a tuning circuit. This tuning circuit is a dedicated DLL which delays the clock signal used for data sampling. The DLL is not part of the eMMC/SD/SDIOi host controller. It is instantiated at top level between the IOs and the host controller. There are two DLLs. One for MMC1 when SDR104 mode is used and one for MMC2 when HS200 mode is used.

In the default, lower frequency operation, a fixed sampling clock is used to receive signals on CMD and DAT lines. Before using the SDR104/HS200 or SDR50 (if MMCHS_CAPA2[13] TSDR50 = 0x1) modes software must execute the tuning procedure at the initialization sequence regardless of MMCHS_CAPA2[15:14] RTM value.

The software starts the tuning sequence by setting MMCHS_DLL[20] SWT to 1. Then it issues CMD19 for a SD card or CMD21 for an eMMC device repeatedly while cycling through 32 DLL ratios and recording pass/fail results for each. Thereafter the MMCHS_AC12[23] SCLK_SEL bit is checked and if it is set to 0 this indicates that the tuning procedure has failed. When MMCHS_AC12[23] SCLK_SEL is set to 1, this indicates that the tuning procedure has completed successfully. For more information about the DLL tuning procedure, see Section 25.5.1.2.4 , *SDR104/HS200 DLL Tuning Procedure*.

Note

The eMMC/SD/SDIO controller supports a Conflict Error (CFT Error) on the CMD line. This error detection logic must be disabled for SDR104/HS200 mode by setting the MMCHS_DLL[20] SWT bit to 0x1 during the DLL tuning procedure. This value (0x1) must be kept while SDR104/HS200 mode is used.

The eMMC/SD/SDIO controller generates a CFT error when it detects that the value sent on the CMD line is not the same as the value returned, indicating an external source is overriding the value.

25.4.14 Card Boot Mode Management

Boot operation mode lets the eMMC/SD/SDIOi host controller read boot data from the connected slave (MMC device) by keeping the CMD line low after power on (or sending CMD0 with a specific argument) before issuing CMD1. The data can be read from the boot area or user area, depending on the register setting.

Power-on boot defines a way for the boot code to be accessed by the eMMC/SD/SDIOi host controller without an upper-level software driver, thus speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

25.4.14.1 Boot Mode Using CMD0

Figure 25-32 shows the timing diagram of a boot sequence using CMD0.

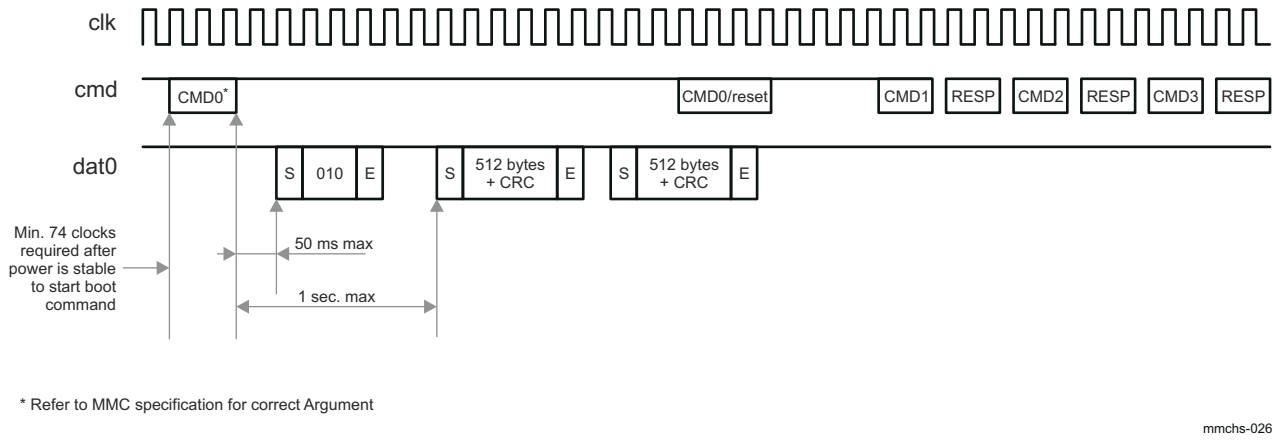

Figure 25-32. Boot Mode Using the CMD0 Timing Diagram

Note

Refer to MMC specification for correct Argument.

For more information about how to configure the eMMC/SD/SDIO host controller, see Section 25.5.1.2.3.1, *Boot Using the CMD0*.

25.4.14.2 Boot Mode With CMD Line Tied to 0

Figure 25-33 shows the timing diagram of a boot sequence with CMD line tied to 0.

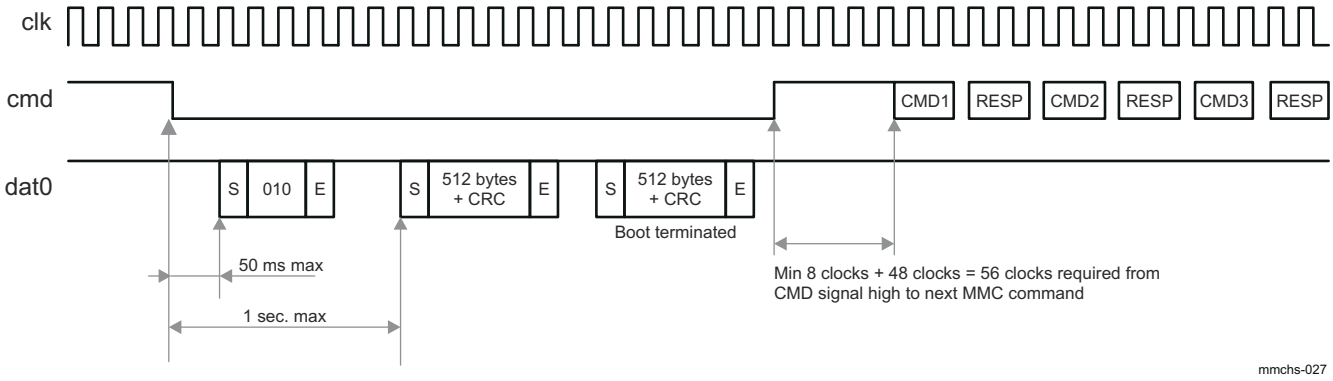

Figure 25-33. Boot Mode With CMD Line Tied to 0 Timing Diagram

For more information about how to configure the eMMC/SD/SDIO host controller, see Section 25.5.1.2.3.2, *Boot With CMD Line Tied to 0*.

25.4.15 MMC CE-ATA Command Completion Disable Management

The eMMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of the command completion token. When a command that requires a CCS (the MMCHS_CON[12] CEATA bit is set to 1 and the

MMCHS_CMD[3:2] ACEN bit field is set to 0x1) is launched, the host system is no longer allowed to emit a new command in parallel to the data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token are:

- Set the MMCHS_CON[12] CEATA bit to 1.
- Set the MMCHS_CON[2] HR bit to 1.
- Clear the MMCHS_ARG register.
- Write into the MMCHS_CMD register with the value 0x00000000.

When a command completion disable token was emitted (that is, the MMCHS_STAT[0] CC bit is received), the host system is again allowed to emit another type of command (for example, a CMD12 to abort transfer).

A critical case can be encountered when CCSD is emitted during the last data block transfer, and the sequence on the command line is sent close to the CCS token sent by the card.

Three possible cases are:

- CCS is received immediately before CCSD is emitted:

  An interrupt CIRQ is generated when CCS is detected, CCSD is transmitted to the card, and then an interrupt CC is generated when CCSD ends. In this case, the card considers the CCSD sequence.
- CCS is not generated or is generated during the CCSD transfer:

  The CCS bit cannot be detected (conflict is not possible because they drive the same level on the command line, and no CIRQ interrupt is generated; a CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

  Only the interrupt CIRQ is generated when CCS is detected.

25.4.16 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register (MMCHS_FE) is used to control the error status and error interrupt status for Auto CMD12 and Auto CMD23.

The system test register (MMCHS_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the MMCHS_CON[4] MODE bit = 1) for boundary connectivity verification.

The MMCHS_HCTL[7] CDSS and MMCHS_HCTL[6] CDTL bits enable manual control of MMCHS_PSTATE[16] CINS and interrupt generating indicated in MMCHS_STAT[7] CREM and MMCHS_STAT[6] CINS.

25.4.17 eMMC/SD/SDIO Hardware Status Features

Table 25-21 describes the eMMC/SD/SDIO hardware status features.

Table 25-21. eMMC/SD/SDIO Hardware Status Features

Feature	Type	Register/Bit Field	Description
Interrupt flags		See Section 25.4.4, *Interrupt Requests.*	
CMD line signal level	Status	MMCHS_PSTATE[24] CLEV	Indicates the level of the command line
DAT lines signal level	Status	MMCHS_PSTATE[23:20] DLEV	Indicates the level of the data lines
Write protect switch pin level	Status	MMCHS_PSTATE[19] WP	Indicates whether the SD card is write protected or not.
Card detect pin level	Status	MMCHS_PSTATE[18] CDPL	Indicates the level of the mmci_sdcd signal/pad

Table 25-21. eMMC/SD/SDIO Hardware Status Features (continued)

Feature	Type	Register/Bit Field	Description
Card State Stable	Status	MMCHS_PSTATE[17] CSS	Used for testing. Indicates mmci_sdcd stable state
Card inserted	Status	MMCHS_PSTATE[16] CINS	Indicates whether the SD card is inserted
Buffer read enable	Status	MMCHS_PSTATE[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	MMCHS_PSTATE[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	MMCHS_PSTATE[9] RTA	Used to detect completion of a read transfer.
Write transfer active	Status	MMCHS_PSTATE[8] WTA	Indicates a write transfer active
Re - Tuning Request	Status	MMCHS_PSTATE[3] RTR	Indicates whether the sampling clock needs re - tuning or not.
Data line active	Status	MMCHS_PSTATE[2] DLA	Indicates whether the data lines are active
Command Inhibit (DAT lines)	Status	MMCHS_PSTATE[1] DATI	Indicates whether issuing of command using data lines is allowed. For example, commands with busy mechanism (that is, R1b response), data transfer commands.
Command inhibit (CMD line)	Status	MMCHS_PSTATE[0] CMDI	Indicates whether issuing of command using command line is allowed

Table 25-22 describes the eMMC/SD/SDIO preset value features.

Table 25-22. eMMC/SD/SDIO Preset Value Registers

Feature	Type	Register	Description
Preset value register	Status	MMCHS_PVINITSD	Preset Values for Initialization and Default Speed modes
Preset value register	Status	MMCHS_PVHSSDR12	Preset Values for High Speed and SDR12 speed modes
Preset value register	Status	MMCHS_PVSDR25SDR50	Preset Values for SDR25 and SDR50 speed modes
Preset value register	Status	MMCHS_PVSDR104DDR50	Preset Values for SDR104 and DDR50 speed modes

25.5 eMMC/SD/SDIO Programming Guide

25.5.1 Low-Level Programming Models

25.5.1.1 Global Initialization

25.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module must be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the eMMC/SD/SDIO modules. For more information, see Section 25.3, *eMMC/SD/SDIO Integration*, and Section 25.2, *eMMC/SD/SDIO Environment*.Table 25-23 shows the global initialization of surrounding modules.

Table 25-23. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing and configuration must be set in the control module. See *Control Module* .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
Device DMAs	Device DMAs configuration must be done to enable the module DMA channel requests.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see *Interrupt Controllers*

25.5.1.1.2 eMMC/SD/SDIO Host Controller Initialization Flow

Table 25-24 shows the general boot process.

Table 25-24. eMMC/SD/SDIO Controller Meta Initialization Steps

Step	Access Type	Register/Bit Field/Programming Model	Value
Initialize clocks.		See Section 25.5.1.1.2.1, *Enable Interface and Functional Clock for MMC Controller*.	
Software reset of the controller.		See Section 25.5.1.1.2.2, *MMCHS Soft Reset Flow*.	
Set module hardware capabilities.		See Section 25.5.1.1.2.3,*Set MMCHS Default Capabilities*.	
Set module idle and wake-up modes.		See Section 25.5.1.1.2.4, *Wake-Up Configuration*.	

25.5.1.1.2.1 Enable Interface and Functional Clock for MMC Controller

Before any MMCHS register access, the MMCHS interface clock and functional clock in the PRCM module registers must be enabled. See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.

25.5.1.1.2.2 MMCHS Soft Reset Flow

Figure 25-34 shows the soft reset process of the MMCHS controller.

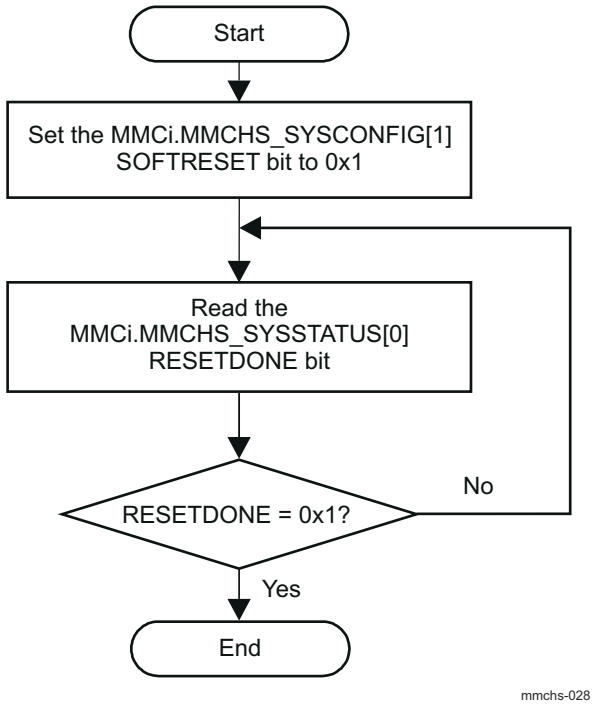

Figure 25-34. eMMC/SD/SDIO Controller Software Reset Flow

Table 25-25. Register Call Summary for Main Sequence – Software Reset Flow

Register Name	Register Name
MMCHS_SYSCONFIG	MMCHS_SYSSTATUS

25.5.1.1.2.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM, for example) and is allowed to set (write) the MMCi.MMCHS_CAPA[26:24] and MMCi.MMCHS_CUR_CAPA[23:0] bit fields before the eMMC/SD/SDIO host driver is started.

25.5.1.1.2.4 Wake-Up Configuration

Table 25-26 describes the MMCHS controller wake-up configuration.

Table 25-26. eMMC/SD/SDIO Controller Wake-Up Configuration

Step	Access Type	Register/Bit Field/Programming Model	Value
Configure wake-up bit (if necessary).	W	MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP	0x1
Enable wake-up events on SD card interrupt (if necessary).	W	MMCi.MMCHS_HCTL[24] IWE	0x1
SDIO card only: Enable card interrupt (if necessary).	W	MMCi.MMCHS_IE[8] CIRQ_ENABLE	0x1

25.5.1.1.2.5 MMC Host and Bus Configuration

Figure 25-35 shows the MMC bus configuration process.

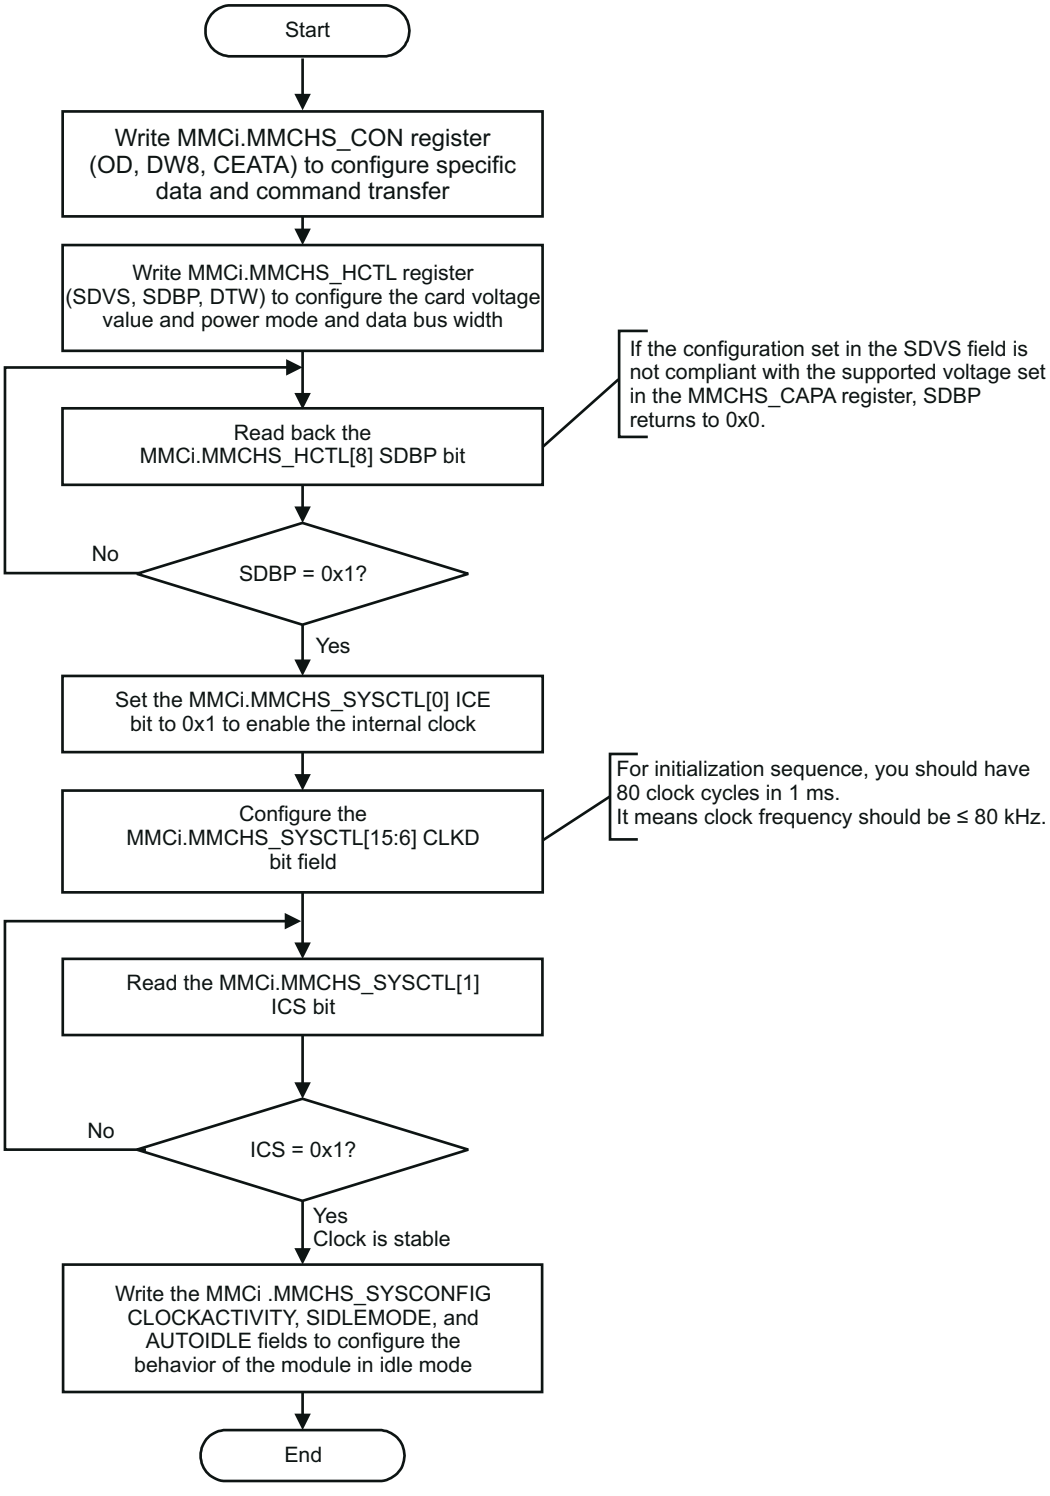

Figure 25-35. eMMC/SD/SDIO Controller Bus Configuration

Table 25-27. Register Call Summary for Main Sequence – Bus Configuration

Register Name	Register Name
MMCHS_CON	MMCHS_HCTL
MMCHS_SYSCONFIG	MMCHS_SYSCTL

25.5.1.2 Operational Modes Configuration

25.5.1.2.1 Basic Operations for eMMC/SD/SDIO Host Controller

The eMMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

25.5.1.2.1.1 Card Detection, Identification, and Selection

Figure 25-36 and Figure 25-37 show the card detection, identification and selection process.

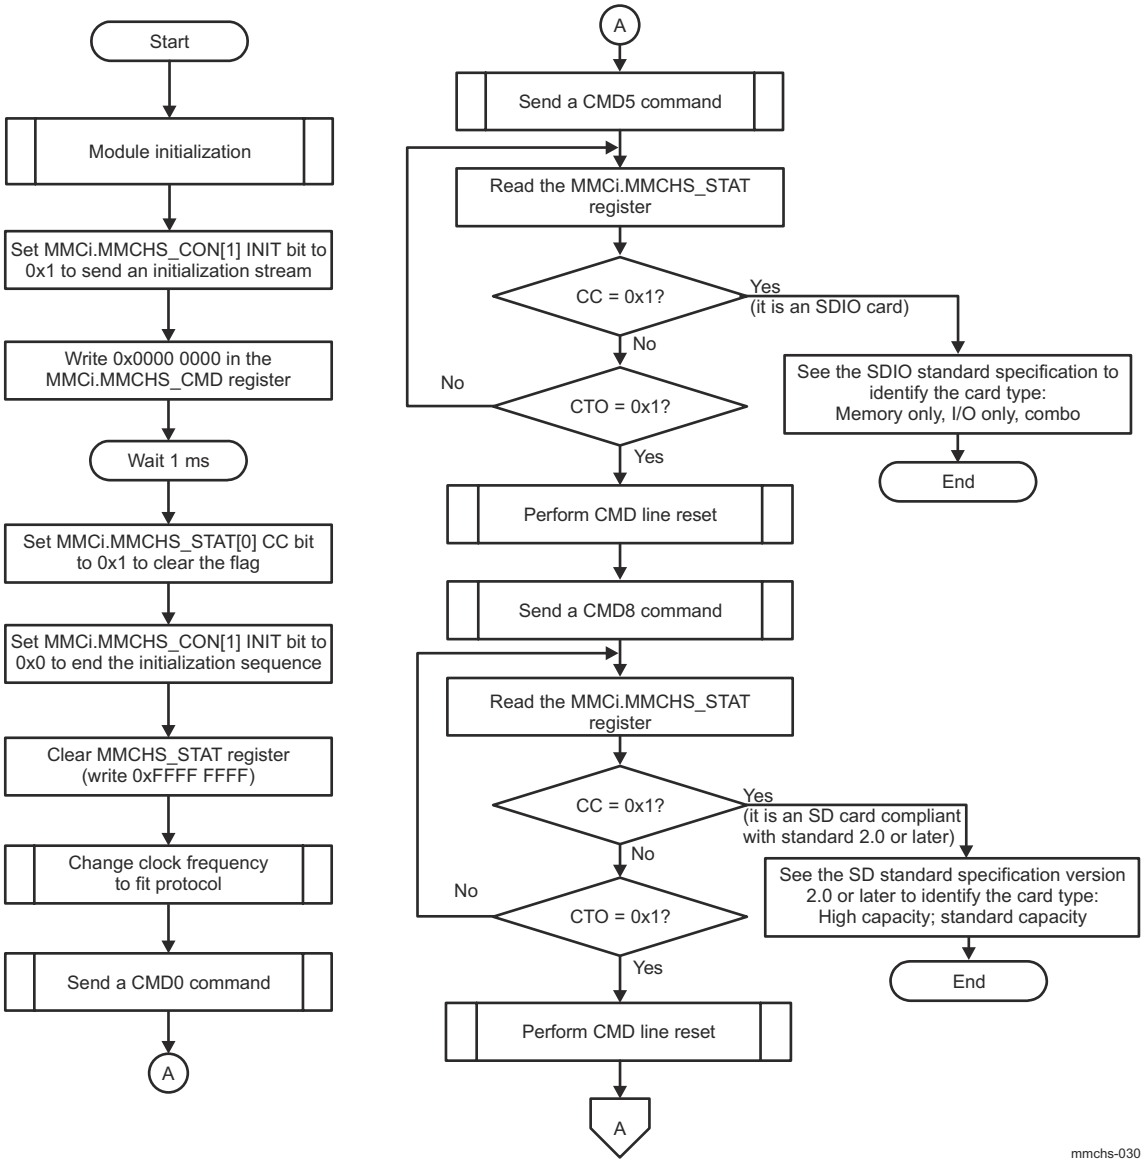

Figure 25-36. eMMC/SD/SDIO Controller Card Identification and Selection – Part 1

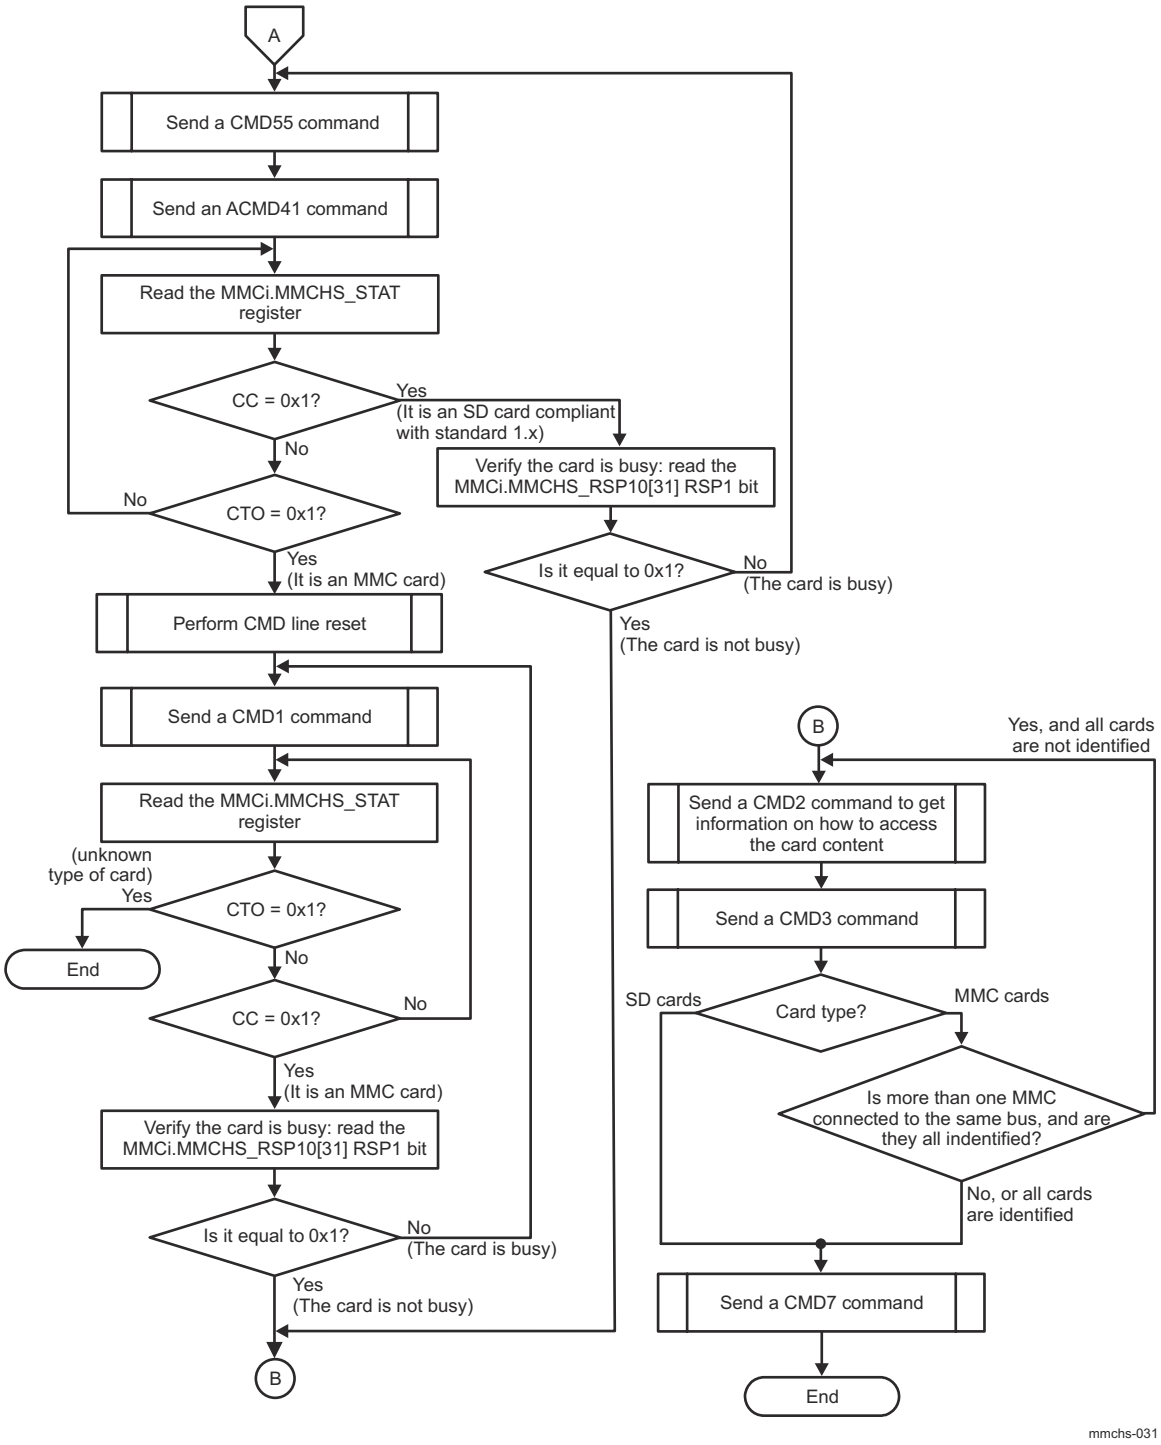

Figure 25-37. eMMC/SD/SDIO Controller Card Identification and Selection – Part 2

Perform DATA lines reset.	See Section 25.5.1.2.1.2.1, *DATA Lines Reset Procedure*.

CAUTION

CE-ATA protocol is supported only by MMC cards.

In CE-ATA mode, issuing a command during the transfer (except a CCSD command) is not allowed.

In CE-ATA mode, infinite transfers are not allowed; only finite transfers are permitted.

25.5.1.2.1.6 Suspend-Resume Flow

The suspend-and-resume feature is supported only by SDIO cards.

25.5.1.2.1.6.1 Suspend Flow

Figure 25-42 shows the suspend flow for SDIO cards.

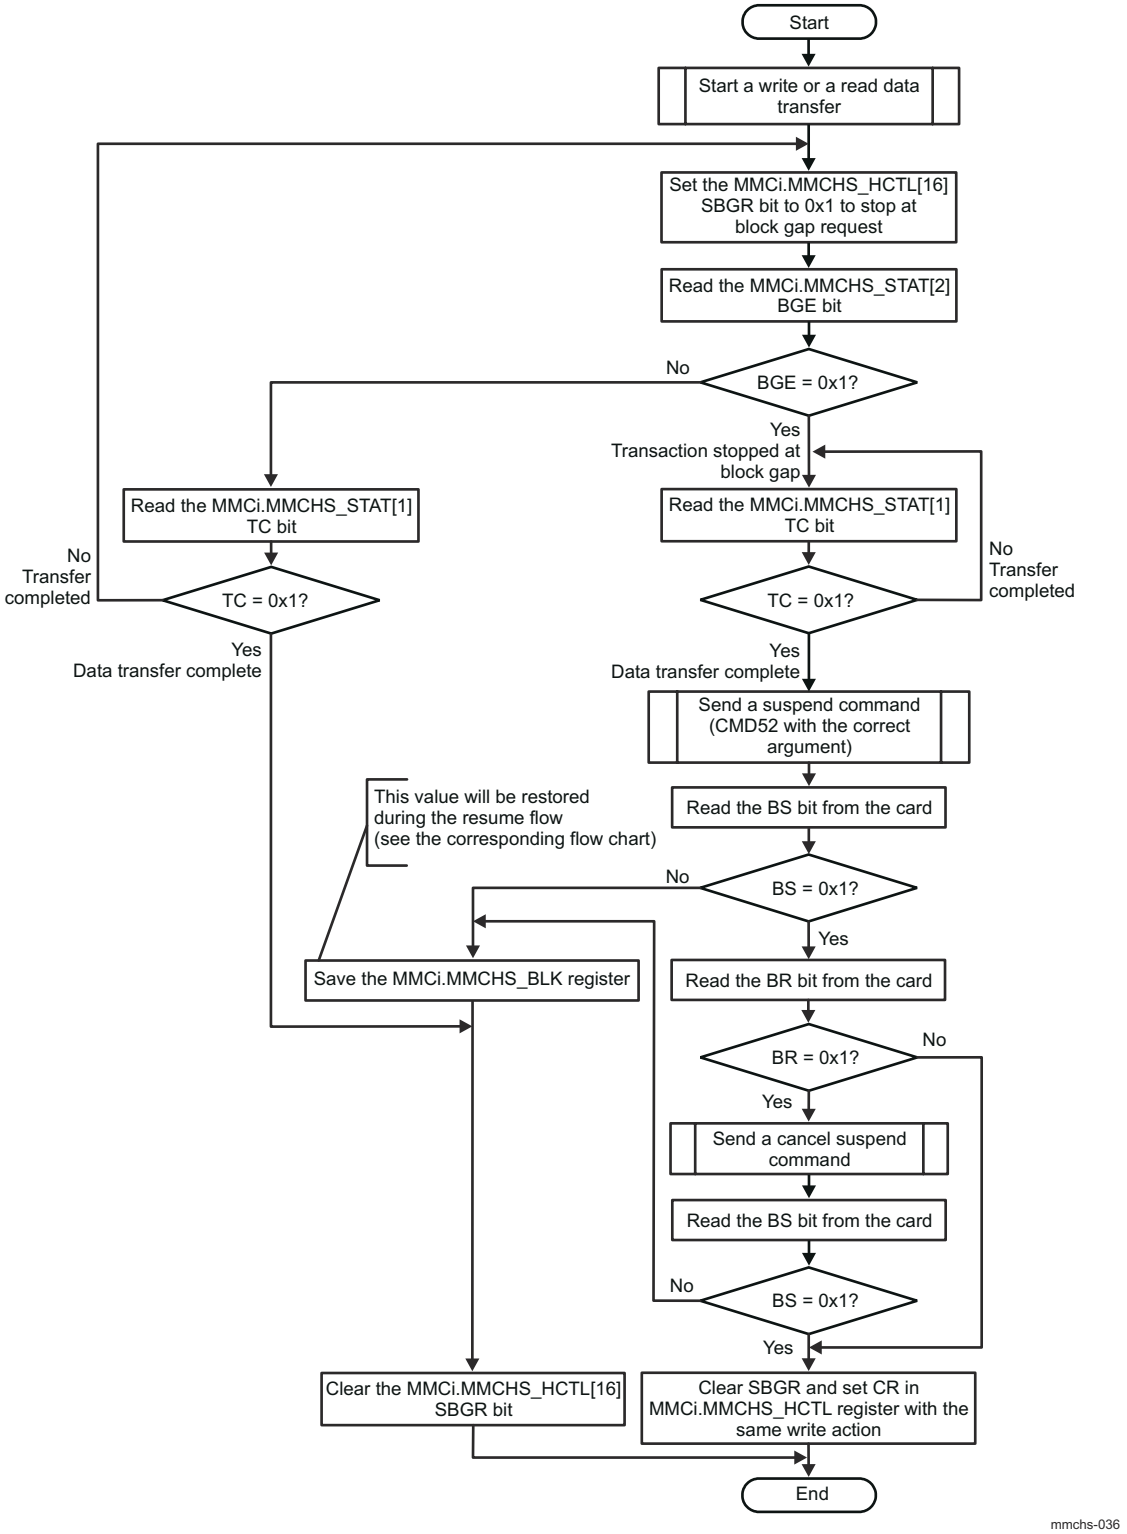

Figure 25-42. eMMC/SD/SDIO Controller Suspend Flow

Table 25-40. Register Call Summary for Main Sequence – Suspend Flow

Register Name	Register Name	Register Name
MMCHS_HCTL	MMCHS_STAT	MMCHS_BLK

Table 25-41. Subprocess Call Summary for Main Sequence – Suspend Flow

Subprocess Name	Cross-Reference
Start a write or a read data transfer.	See Section 25.5.1.2.1, *Basic Operations for eMMC/SD/SDIO Host Controller*.
Send a suspend command (CMD52 with the correct argument).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.
Send a cancel suspend command.	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.1.6.2 Resume Flow

Figure 25-43 shows the resume flow for SDIO cards.

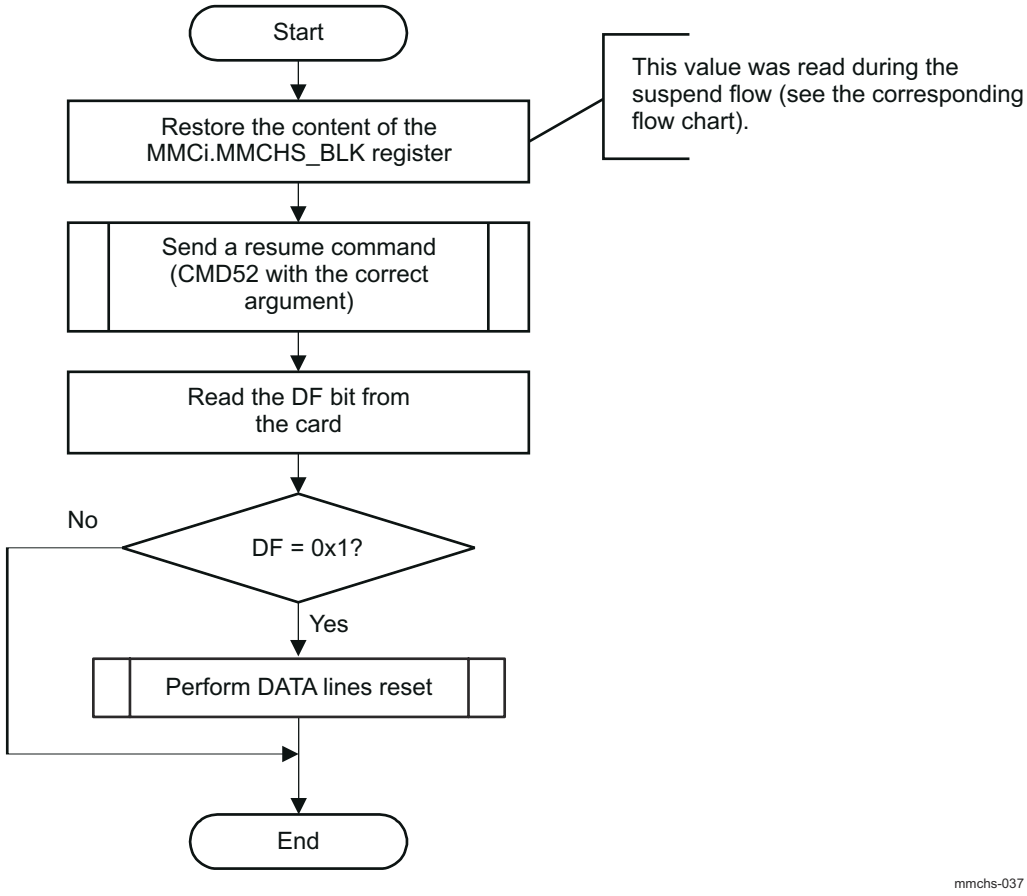

Figure 25-43. eMMC/SD/SDIO Controller Resume Flow

Table 25-42. Register Call Summary for Main Sequence - Resume Flow

Register Name	Register Name
MMCHS_BLK	MMCHS_SYSCTL

Table 25-43. Subprocess Call Summary for Main Sequence - Resume Flow

Subprocess Name	Cross-Reference
Send a resume command (CMD52 with the correct argument).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.
Perform DATA lines reset.	See Section 25.5.1.2.1.2.1, *DATA Lines Reset Procedure*.

25.5.1.2.1.7 Basic Operations – Steps Detailed

25.5.1.2.1.7.1 Command Transfer Flow

Figure 25-44 shows how to send a command to the card using polling instead of interrupts for event signaling.

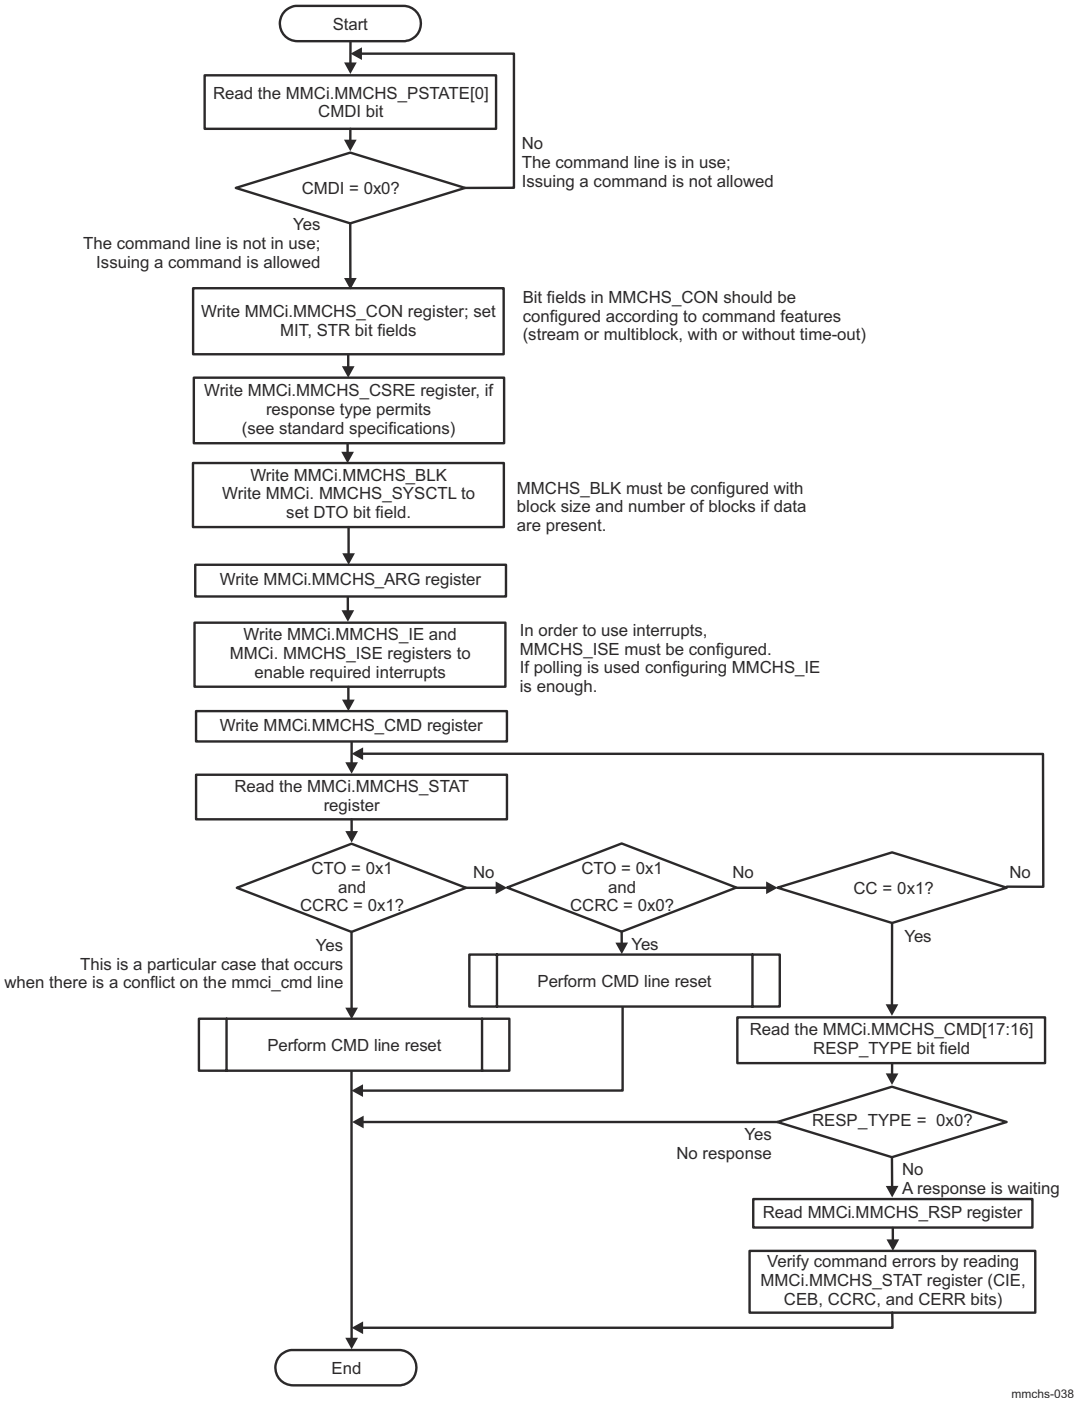

Figure 25-44. eMMC/SD/SDIO Controller Command Transfer Flow With Polling

Table 25-44. Register Call Summary for Main Sequence – Command Transfer Flow With Polling

MMCHS_RSP76	MMCHS_CON	MMCHS_HCTL

Table 25-50. Subprocess Call Summary for Main Sequence – Bus Width Configuration Flow

Subprocess Name	Cross-Reference
Initialize module and card.	See Section 25.5.1.1.2, *eMMC/SD/SDIO Host Controller Initialization Flow*. See Section 25.5.1.2.1.1, *Card Detection, Identification, and Selection*.
Send a SEND_CSD command (CMD9).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.
Send SWITCH command (CMD6).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.2 Bus Voltage Selection

The eMMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.3 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns, those pads must have an internal bias voltage reference to operate. The PBIAS module supplies this bias voltage, depending on the settings of the CTRL_CORE_CONTROL_PBIAS register.

For more information about the PBIAS cell, see *PBIAS Cell And MMC1 I/O Cells Control Registers*, in *Control Module*.

Figure 25-48 shows how to configure the MMC1 controller to fit with power switching sequence.

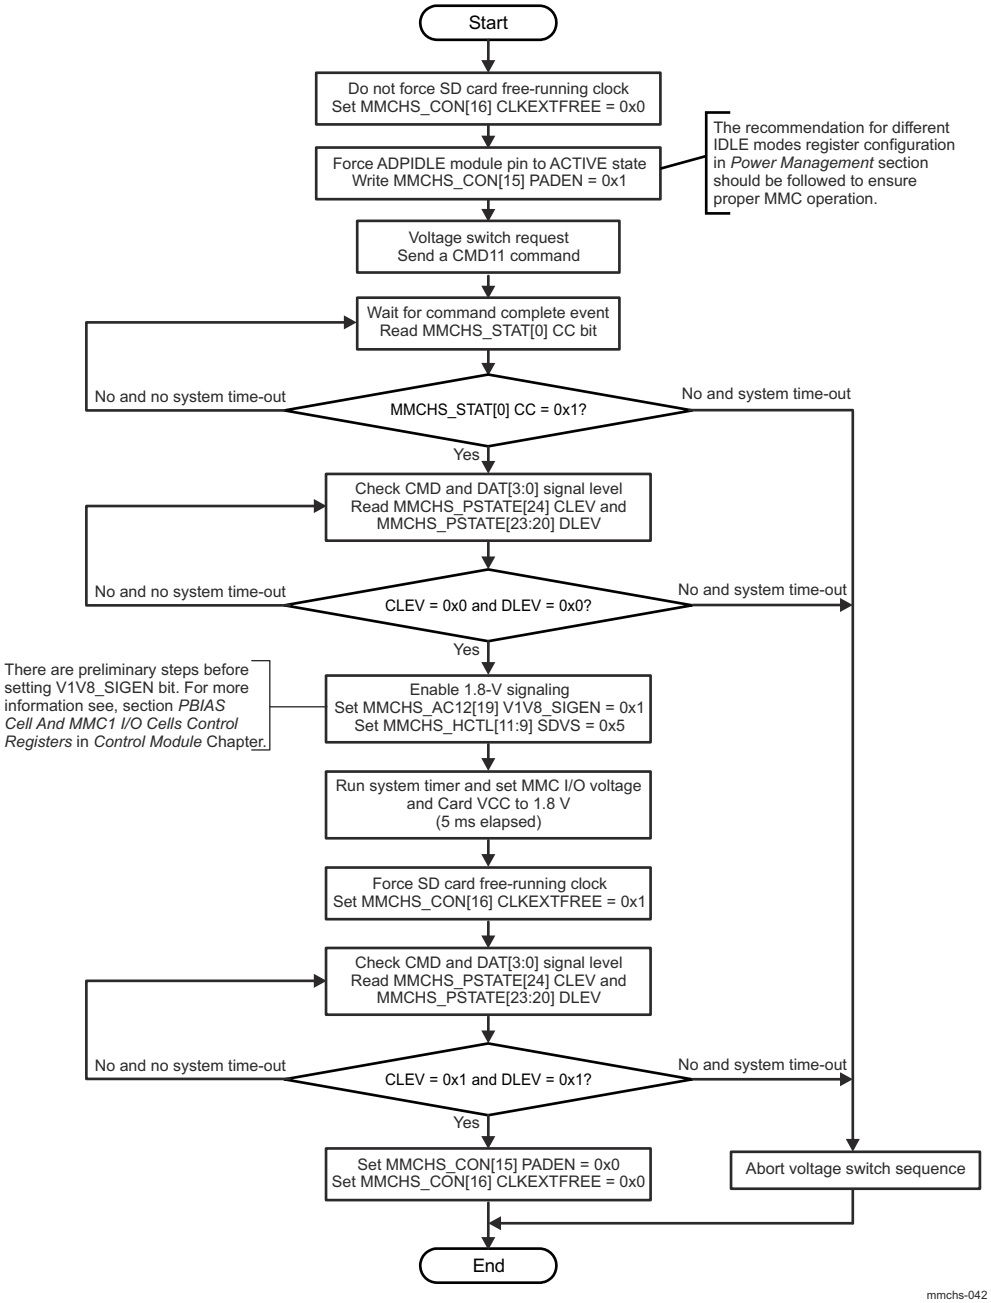

Figure 25-48. eMMC/SD/SDIO Power Switching Procedure

Table 25-51. Register Call Summary for Main Sequence – Power Switching Procedure

Register Name	Register Name
MMCHS_STAT	MMCHS_PSTATE
MMCHS_CMD	MMCHS_CON

Table 25-52. Subprocess Call Summary for Main Sequence – Power Switching Procedure

Subprocess Name	Cross-Reference
Send a READ_DAT_UNTIL_STOP command (CMD11).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.3 Boot Mode Configuration

The following sections describe the two possible ways to issue a boot command: issue a CMD0 or drive the CMD line to 0 during the whole boot phase.

25.5.1.2.3.1 Boot Using CMD0

Figure 25-49 shows the necessary steps to configure the controller boot mode using CMD0.

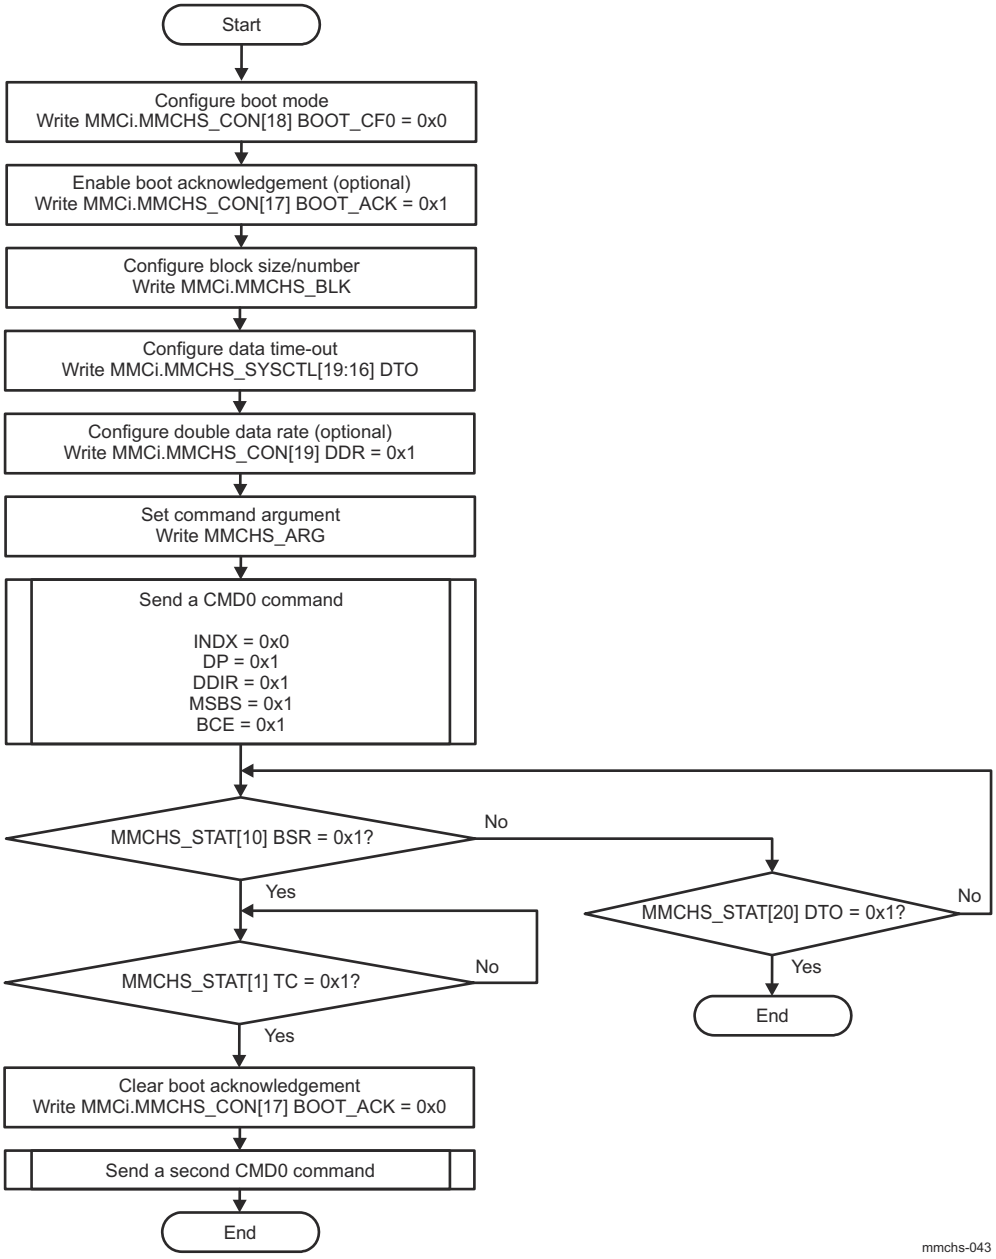

Figure 25-49. eMMC/SD/SDIO Controller Boot Using CMD0

To abort a boot sequence, the system must issue a CMD0 with the MMCHS_CMD[23:22] CMD_TYPE bit field set to 0x3 (the MMCHS_CON[17] BOOT_ACK bit previously cleared to 0x0) during the transfer to abort the transfer and enable the card to exit from boot state.

Table 25-53. Register Call Summary for Main Sequence – Boot Using CMD0

Register Name	Register Name	Register Name
MMCHS_CON	MMCHS_BLK	MMCHS_SYSCTL
MMCHS_ARG	MMCHS_STAT	

Table 25-54. Subprocess Call Summary for Main Sequence – Boot Using CMD0

Subprocess Name	Cross-Reference
Send a CMD0 command.	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.3.2 Boot With CMD Line Tied to 0

Figure 25-50 shows the necessary steps to configure the controller in this mode; the driver must follow this sequence.

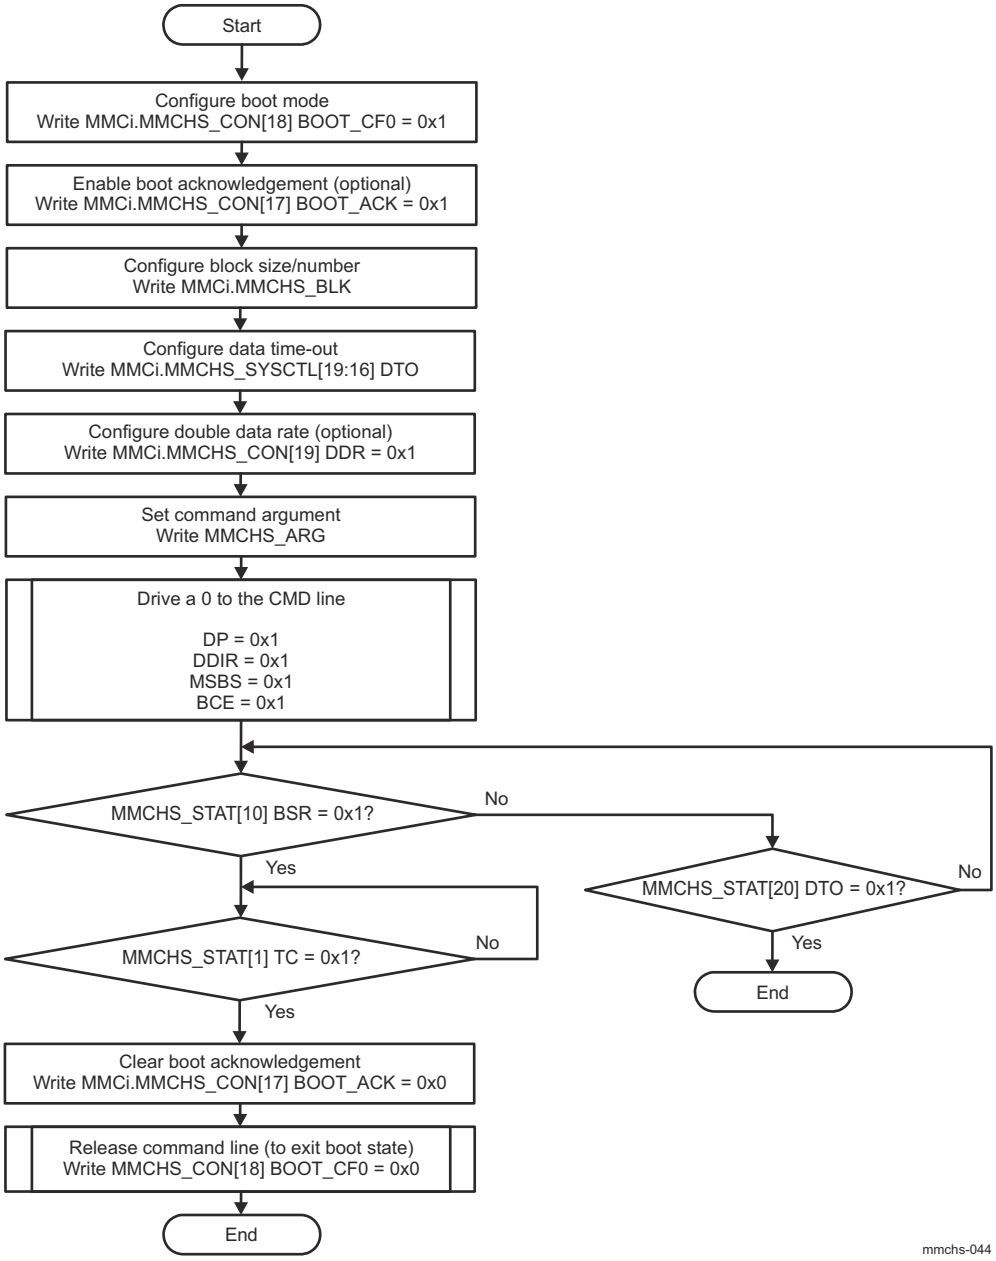

Figure 25-50. eMMC/SD/SDIO Controller Boot With CMD Line Tied to 0

To abort the boot sequence, the system must clear the MMCHS_CON[18] BOOT_CF0 bit to 0x0 during the transfer to abort the transfer and enable the card to exit from boot state.

Table 25-55. Register Call Summary for Main Sequence – Boot Using CMD0

Register Name	Register Name	Register Name
MMCHS_CON	MMCHS_BLK	MMCHS_SYSCTL
MMCHS_ARG	MMCHS_STAT	MMCHS_CMD

Table 25-56. Subprocess Call Summary for Main Sequence – Boot Using CMD0

Subprocess Name	Cross-Reference
Send a CMD0 command.	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.4 SDR104/HS200 DLL Tuning Procedure

Figure 25-51 shows the DLL tuning procedure when SDR104 and HS200 modes are used.

Note

The BRR interrupt has to be enabled during tuning for functionality to succeed. The other error flags in MMCHS_IE can also be enabled for debug purposes. The MMCHS_SYSCTL[25] SRC bit can be set for command related interrupts, but caution has to be taken such that the MMCHS_SYSCTL[26] SRD bit is not set even when DAT related errors occurred, until after tuning completion.

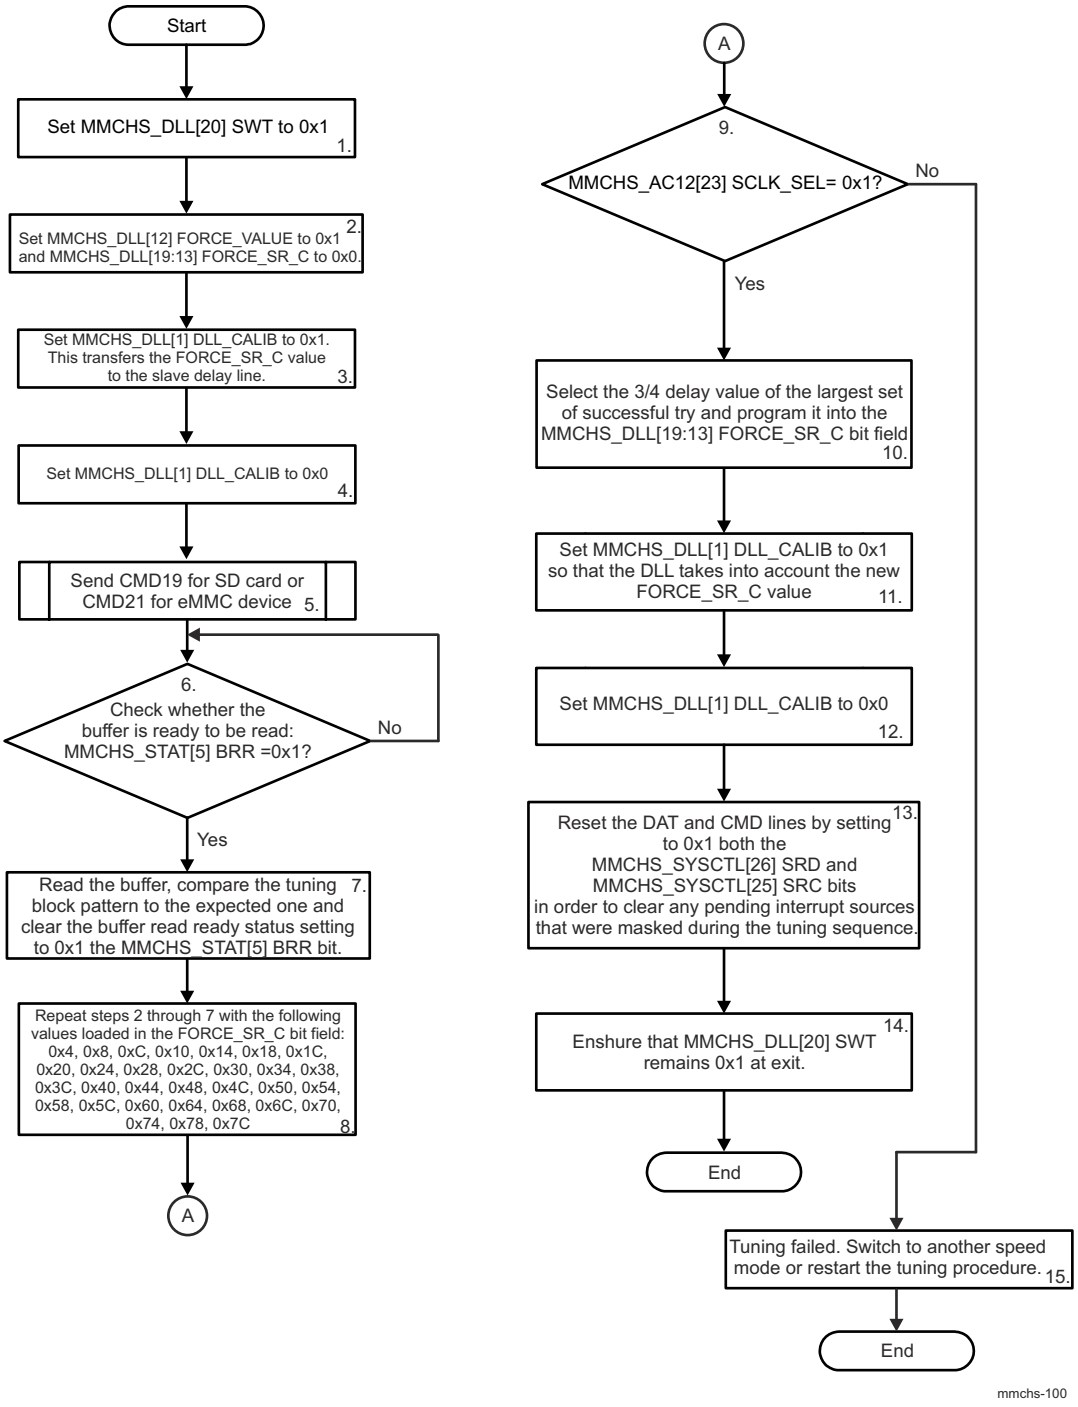

Figure 25-51. SDR104/HS200 DLL Tuning Procedure

25.6 eMMC/SD/SDIO Register Manual

25.6.1 eMMC/SD/SDIO Instance Summary

Table 25-57 lists the eMMC/SD/SDIO instances.

Table 25-57. eMMC/SD/SDIO Instance Summary

Module Name	Module Base Address	Size
MMC1	0x4809 C000	4 KiB
MMC2	0x480B 4000	4 KiB
MMC3	0x480A D000	4 KiB

RESERVED																								RETMODE	MEM_SIZE					MERGE_MEM	MADMA_EN

Bits	Field Name	Description	Type	Reset
31:7	RESERVED		R	0x-
6	RETMODE	Retention Mode generic parameter This bit field indicates whether the retention mode is supported using the pin PIRFFRET. Read 0x1: Retention mode enabled Read 0x0: Retention mode disabled	R	0x-
5:2	MEM_SIZE	Memory size for FIFO buffer: Read 0x2: Memory of 1024 bytes, max block length is 1024 bytes Read 0x1: Memory of 512 bytes, max block length is 512 bytes Read 0x8: Memory of 4096 bytes, max block length is 2048 bytes Read 0x4: Memory of 2048 bytes, max block length is 2048 bytes	R	0x-
1	MERGE_MEM	Memory merged for FIFO buffer: This register defines the configuration of FIFO buffer architecture. If the bit is set STA and DFT shall support clock multiplexing and balancing. Read 0x1: A single memory is used with multiplexed addresses, data and clocks. Read 0x0: 2 memories instantiated, one per data transfer direction.	R	0x-

Bits	Field Name	Description	Type	Reset
0	MADMA_EN	Master DMA enabled generic parameter: This register defines the configuration of the controller to know if it supports the master DMA management called ADMA. Read 0x1: Controller supports ADMA Read 0x0: No Master DMA (ADMA) management supported	R	0x-

Table 25-62. MMCHS_HL_SYSCONFIG

Address Offset	0x0000 0010

Description	Clock Management Configuration Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																										STANDBYMODE		IDLEMODE		FREEEMU	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x000 0000
5:4	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: local initiator is unconditionally placed in standby state.Backup mode, for debug only. 0x1: No-standby mode: local initiator is unconditionally placed out of standby state.Backup mode, for debug only. 0x3: Smart-Standby wakeup-capable mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator. IP module may generate (master-related) wakeup events when in standby state.Mode is only relevant if the appropriate IP module "mwakeup" output is implemented. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator.IP module shall not generate (initiator-related) wakeup events.	RW	0x2

Bits	Field Name	Description	Type	Reset
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's idle state follows (acknowledges) the system's IDLE requests unconditionally, i.e. regardless of the IP module's internal requirements.Backup mode, for debug only. 0x1: No-idle mode: local target never enters idle state.Backup mode, for debug only. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module shall not generate (IRQ- or DMA-request-related) wakeup events.	RW	0x2
1	FREEEMU	Sensitivity to emulation (debug) suspend input signal. Functionality NOT implemented in MMCHS. 0x0: IP module is sensitive to emulation suspend 0x1: IP module is not sensitive to emulation suspend	RW	0
0	SOFTRESET	Software reset. (Optional) Write 0x0: No action Write 0x1: Initiate software reset Read 0x1: Reset (software or other) ongoing Read 0x0: Reset done, no pending action	RW	0

Bits	Field Name	Description	Type	Reset
31:14	RESERVED		R	0x0 0000

Bits	Field Name	Description	Type	Reset
13:12	STANDBYMODE	Master interface power Management, standby/wait control. The bit field is only useful when generic parameter MMCHS_HL_HWINFO[0] MADMA_EN (Master ADMA enable) is set as active, otherwise it is a read only register read a '0'. 0x0: Force-standby. Mstandby is forced unconditionnaly. 0x1: No-standby. Mstandby is never asserted. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator.IP module shall not generate (initiator-related) wakeup events.	RW	0x2
11:10	RESERVED		R	0x0
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period. Bit8: Interface clock Bit9: Functional clock 0x0: Interface and Functional clock may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched-off. 0x3: Interface and Functional clocks are maintained. 0x2: Functional clock is maintained. Interface clock may be switched-off.	RW	0x0
7:5	RESERVED	This bit is initialized to zero, and writes to it are ignored. Reads return 0.	R	0x0
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the MMCHS acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally de-asserted. 0x1: If an IDLE request is detected, the request is ignored and the module keeps on behaving normally. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module shall not generate (IRQ- or DMA-request-related) wakeup events.	RW	0x2
2	ENAWAKEUP	Wakeup feature control 0x0: Wakeup capability is disabled 0x1: Wakeup capability is enabled	RW	1
1	SOFTRESET	Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0. Write 0x0: No effect. Write 0x1: Trigger a module reset. Read 0x1: The module is reset. Read 0x0: Normal mode	RW	0

Bits	Field Name	Description	Type	Reset
0	AUTOIDLE	Internal Clock gating strategy 0x0: Clocks are free-running 0x1: Automatic clock gating strategy is applied, based on the Interconnect and MMC interface activity	RW	1

Description	Card Status Response Error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCHS_CSRE[i] is set to 1, if the corresponding bit at the same position in the response MMCHS_RSP0[i] is set to 1, the host controller indicates a card error (MMCHS_STAT[CERR]) interrupt status to avoid the host driver reading the response register (MMCHS_RSP0). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCHS_RESP76) for possible card errors.

Description

System Test Register
This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification.
Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCHS_BLK[BLEN]) and the Blocks count for current transfer (MMCHS_BLK[NBLK]) are needed to generate a Buffer write ready interrupt (MMCHS_STAT[BWR]) or a Buffer read ready interrupt (MMCHS_STAT[BRR]) and DMA requests if enabled.

Description
Configuration Register
This register is used:
- to select the functional mode or the SYSTEST mode for any card.
- to send an initialization sequence to any card.
- to enable the detection on DAT[1] of a card interrupt for SDIO cards only.
and also to configure :
- specific data and command transfers for MMC cards only.
- the parameters related to the card detect and write protect input signals.

Type RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x000

Bits	Field Name	Description	Type	Reset
21	SDMA_LNE	Slave DMA Level/Edge Request: The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to MMCHS_DATA register or late de-assertion, request remains active until last allowed data written into MMCHS_DATA. 0x0: Slave DMA edge sensitive, Early DMA de-assertion 0x1: Slave DMA level sensitive, Late DMA de-assertion	RW	0
20	DMA_MNS	DMA Master or Slave selection: When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory).This option is only available if generic parameter MADMA_EN is asserted to '1'. 0x0: The controller is slave on data transfers with system. 0x1: The controller is master on data exchange with system, controller must be configured as using DMA.	RW	0
19	DDR	Dual Data Rate mode: When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of MMCHS_SYSCTL[CLKD], it is insensitive to MMCHS_HCTL[HSPE] setting. 0x0: Standard mode : data are transmitted on a single edge depending on MMCHS_HCTRL[HSPE]. 0x1: Data Bytes and CRC are transmitted on both edge.	RW	0
18	BOOT_CF0	Boot status supported: This register is set when the CMD line need to be forced to '0' for a boot sequence. CMD line is driven to '0' after writing in MMCHS_CMD. The line is released when this bit field is de-asserted and abort data transfer in case of a pending transaction. Write 0x0: CMD line is released when it was previously forced to '0' by a boot sequence. Write 0x1: CMD line forced to '0' is enabled and will be active after writing into MMCHS_CMD Read 0x1: CMD line forced to '0' is enabled Read 0x0: CMD line not forced	RW	0
17	BOOT_ACK	Boot acknowledge received: When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated. 0x0: No acknowledge to be received 0x1: A boot status will be received on DAT0 line after issuing a command.	RW	0
16	CLKEXTFREE	External clock free running: This register is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if MMCHS_SYSCTL[CEN] is set. 0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if MMCHS_SYSCTL[CEN] is set.	RW	0

Bits	Field Name	Description	Type	Reset
15	PADEN	Control Power for MMC Lines: This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control MMCHS_CON[CTPL] bit. 0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. 0x1: ADPIDLE module pin is forced to active state.	RW	0
14	OBIE	Out-of-Band Interrupt Enable MMC cards only: This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Out-of-Band interrupt detection disabled 0x1: Out-of-Band interrupt detection enabled	RW	0
13	OBIP	Out-of-Band Interrupt Polarity MMC cards only: This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Active high level 0x1: Active low level	RW	0
12	CEATA	CE-ATA control mode MMC cards compliant with CE-ATA:By default, this bit is set to 0. It is used to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. 0x0: Standard MMC/SD/SDIO mode. 0x1: CE-ATA mode next commands are considered as CE-ATA commands.	RW	0
11	CTPL	Control Power for DAT[1] line MMC and SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers. 0x0: Disable all the input buffers outside of a transaction. 0x1: Disable all the input buffers except the buffer of DAT[1] outside of a transaction.	RW	0

Bits	Field Name	Description	Type	Reset
10:9	DVAL	Debounce filter value All cards This register is used to define a debounce period to filter the card detect input signal (mmci_sdcd). The usage of the card detect input signal (mmci_sdcd) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: 33 us debounce period 0x1: 231 us debounce period 0x3: 8,4 ms debounce period 0x2: 1 ms debounce period	RW	0x3
8	WPP	Write protect polarity For SD and SDIO cards only This bit selects the active level of the write protect input signal (mmci_sdwp). The usage of the write protect input signal (mmci_sdwp) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level 0x1: Active low level	RW	0
7	CDP	Card detect polarity All cards This bit selects the active level of the card detect input signal (mmci_sdcd). The usage of the card detect input signal (mmci_sdcd) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active low level 0x1: Active high level	RW	0
6	MIT	MMC interrupt command Only for MMC cards. This bit must be set to 1, when the next write access to the command register (MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0x0: Command timeout enabled 0x1: Command timeout disabled	RW	0
5	DW8	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification 4.x (see section 3.6). 0x0: 1-bit or 4-bit Data width (DAT[0] used, MMC, SD cards) 0x1: 8-bit Data width (DAT[7:0] used, MMC cards)	RW	0

Bits	Field Name	Description	Type	Reset
4	MODE	Mode select All cards This bit select between Functional mode and SYSTEST mode. 0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the CMD register. 0x1: SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.	RW	0
3	STR	Stream command Only for MMC cards. This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer 0x1: Stream oriented data transfer	RW	0
2	HR	Broadcast host response Only for MMC cards. This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core (see section 4.3, "Interrupt Mode", in the MMC specification). In order to have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1. When MMCHS_CON[CEATA] is set to 1 and MMCHS_ARG set to 0x00000000 when writing 0x00000000 into MMCHS_CMD register, the host controller performs a 'command completion signal disable' token i.e. CMD line held to '0' during 47 cycles followed by a 1. 0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.	RW	0
1	INIT	Send initialization stream All cards. When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCHS_SYSCTL[CLKD]) should be set to ensure that 80 clock periods are greater than 1ms. (see section 9.3, "Power-Up", in the MMC card specification, or section 6.4 in the SD card specification). Note: in this mode, there is no command sent to the card and no response is expected 0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.	RW	0

Bits	Field Name	Description	Type	Reset
0	OD	Card open drain mode. Only for MMC cards. This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCHS_CON[HR]) 0x0: No Open Drain 0x1: Open Drain or Broadcast host response	RW	0

SDMA_ARG2																															

Bits	Field Name	Description	Type	Reset
31:0	SDMA_ARG2	SDMA System Address / Argument 2 This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23. (1) SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. (2) Argument 2 This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without AMDA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.	RW	0x0000 0000

Description	Transfer Length Configuration Register MMCHS_BLK[BLEN] is the block size register. MMCHS_BLK[NBLK] is the block count register. This register shall be used for any card.		

Table 25-71. MMCHS_BLK (continued)

Type RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NBLK																RESERVED				BLEN											

Bits	Field Name	Description	Type	Reset
31:16	NBLK	Blocks count for current transfer This register is enabled when Block count Enable (MMCHS_CMD[BCE]) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e, after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count. 0xFFFF: 65535 blocks 0x0: Stop count 0x1: 1 block 0x2: 2 blocks	RW	0x0000
15:12	RESERVED		R	0x0
11:0	BLEN	Transfer Block Size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (MMCHS_STAT[TC] set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched. 0x1: 1 byte block length 0x7FF: 2047 bytes block length 0x0: No data transfer 0x1FF: 511 bytes block length 0x800: 2048 bytes block length 0x2: 2 bytes block length 0x3: 3 bytes block length 0x200: 512 bytes block length	RW	0x000

Description Command Argument Register
This register contains command argument specified as bit 39-8 of Command-Format
These registers must be initialized prior to sending the command itself to the card (write action into the register MMCHS_CMD register). Only exception is for a command index specifying stuff bits in arguments, making a write unnecessary.

Description
Command and Transfer Mode Register
MMCHS_CMD[31:16] = the command register
MMCHS_CMD[15:0] = the transfer mode.
This register configures the data and command transfers. A write into the most significant byte send the command. A write into MMCHS_CMD[15:0] registers during data transfer has no effect.
This register shall be used for any card.
Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer.

23:22	CMD_TYPE	Command type This register specifies three types of special command: Suspend, Resume and Abort.	RW	0x0

Bits	Field Name	Description	Type	Reset
		These bits shall be set to 00b for all other commands. 0x0: Others Commands 0x1: CMD52 for writing "Bus Suspend" in CCCR 0x3: Abort command CMD12, CMD52 for writing " I/O Abort" in CCCR 0x2: CMD52 for writing "Function Select" in CCCR		
21	DP	Data present select This register indicates that data is present and DAT line shall be used. It must be set to 0 in the following conditions: - command using only CMD line - command with no data transfer but using busy signal on DAT[0] - Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCHS_STAT[CIE] set to1). **Note:** The register CICE cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCHS_STAT[CCRC] set to 1). **Note:** The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable	RW	0
18	RESERVED		R	0
17:16	RSP_TYPE	Response type This bits defines the response type of the command 0x0: No response 0x1: Response Length 136 bits 0x3: Response Length 48 bits with busy after response 0x2: Response Length 48 bits	RW	0x0
15:6	RESERVED		R	0x000
5	MSBS	Multi/Single block select This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0.	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: Single block. If this bit is 0, it is not necessary to set the register MMCHS_BLK[NBLK]. 0x1: Multi block. When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer.		
4	DDIR	Data transfer Direction Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host)	RW	0
3:2	ACEN	Auto CMD Enable - SD card only. This field determines use of auto command functions. There are two methods to stop Multiple-block read and write operation 1. Auto CMD12 Enable When this field is set to 01b, the Host Controller issues CMD12 automatically when last block transfer is completed. Auto CMD12 error is indicated to the Auto CMD Error Status register (MMCHS_AC12). The Host Driver shall not set this bit if the command does not require CMD12. In particular, secure commands defined in the Part 3 File Security specification do not require CMD12. 2. Auto CMD23 Enable When this bit field is set to 10b, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register. The Host Controller Version 3.00 and later shall support this function. The following conditions are required to use the Auto CMD23. – Auto CMD23 Supported (Host Controller Version is 3.00 or later) – A memory card that supports CMD23 (SCR[33]=1) – If DMA is used, it shall be ADMA. –Only when CMD18 or CMD25 is issued (**Note:** the Host Controller does not check command index.) Auto CMD23 can be used with or without ADMA. By writing the Command register, the Host Controller issues a CMD23 first and then issues a command specified by the Command Index in Command register. If response errors of CMD23 are detected, the second command is not issued. A CMD23 error is indicated in the Auto CMD Error Status register (MMCHS_AC12). 32-bit block count value for CMD23 is set to SDMA System Address / Argument 2 register (MMCHS_SDMASA). 0x0: Auto Command Disabled 0x1: Auto CMD12 enable or CCS detection enabled. 0x3: Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x2: Auto CMD23 Enable		
1	BCE	Block Count Enable Multiple block transfers only. This bit is used to enable the block count register (MMCHS_BLK[NBLK]). When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks	RW	0
0	DE	DMA Enable This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

Description	Data Register This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

23:20	DLEV	DAT[3:0] line signal level DAT[3] => bit 23 DAT[2] => bit 22 DAT[1] => bit 21 DAT[0] => bit 20 This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The value of these registers after reset depends on the DAT lines level at that time.	R	0x-
19	WP	Write protect switch pin level For SDIO cards only. This bit reflects the write protect input pin (mmci_sdwp) level. The value of this register after reset depends on the protect input pin (mmci_sdwp) level at that time. Read 0x1: If MMCHS_CON[WPP] is set to 0 (default), the card is not write protected, otherwise the card is protected. Read 0x0: If MMCHS_CON[WPP] is set to 0 (default), the card is write protected, otherwise the card is not protected.	R	-

Bits	Field Name	Description	Type	Reset
18	CDPL	Card detect pin level This bit reflects the inverse value of the card detect input pin (mmci_sdcd), debouncing is not performed on this bit and bit is valid only when Card State Stable (MMCHS_PSTAE[CSS]) is set to 1. Use of this bit is limited to testing since it must be debounced y software. The value of this register after reset depends on the card detect input pin (mmci_sdcd) level at that time. Read 0x1: The value of the card detect input pin (mmci_sdcd) is 0 Read 0x0: The value of the card detect input pin (mmci_sdcd) is 1	R	-
17	CSS	Card State Stable This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (MMCHS_PSTATE[CDPL]). Debouncing is performed on the card detect input pin (mmci_sdcd) to detect card stability. This bit is not affected by a software reset. Read 0x1: No card or card inserted Read 0x0: Reset or Debouncing	R	0
16	CINS	Card inserted This bit is the debounced value of the card detect input pin (mmci_sdcd). An inactive to active transition of the card detect input pin (mmci_sdcd) will generate a card insertion interrupt (MMCHS_STAT[CINS]). A active to inactive transition of the card detect input pin (mmci_sdcd) will generate a card removal interrupt (MMCHS_STAT[REM]). This bit is not affected by a software reset. Read 0x1: If MMCHS_CON[CDP] is set to 1, the card has been inserted from the card slot. If MMCHS_CON[CDP] is set to 0, no card is detected. The card may have been removed from the card slot. Read 0x0: If MMCHS_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot. If MMCHS_CON[CDP] is set to 0, the card has been inserted.	R	0
15:12	RESERVED		R	0x0
11	BRE	Buffer read enable This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCHS_BLK[BLEN] has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCHS_STAT[BRR]). Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer. Read 0x0: Read BLEN bytes disable	R	0
10	BWE	Buffer Write enable This status is used for non-DMA write transfers. It indicates if space is available for write data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data. Read 0x0: There is no room left in the buffer to write BLEN bytes of data.	R	0

Bits	Field Name	Description	Type	Reset
9	RTA	Read transfer active This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request. Read 0x1: read data transfer on going. Read 0x0: No valid data on the DAT lines.	R	0
8	WTA	Write transfer active This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request. Read 0x1: Write data transfer on going. Read 0x0: No valid data on the DAT lines.	R	0
7:4	RESERVED		R	0x0
3	RTR	Re-Tuning Request Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This bit is cleared when a command is issued with setting MMCHS_AC12[22] ET. This bit isn't set to 1 if MMCHS_AC12[23] SCLK_SEL is set to 0 (using fixed sampling clock). Refer to MMCHS_CAPA2[15:14] RTM for more detail. Read 0x1: Sampling clock needs re-tuning Read 0x0: Fixed or well tuned sampling clock	R	0
2	DLA	DAT line active This status bit indicates whether one of the DAT line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. Read 0x1: DAT Line active Read 0x0: DAT Line inactive	R	0

Bits	Field Name	Description	Type	Reset
1	DATI	Command inhibit(DAT) This status bit is generated if either DAT line is active (MMCHS_PSTATE[DLA]) or Read transfer is active (MMCHS_PSTATE[RTA]) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCHS_STAT[TC]). Read 0x1: Issuing of command using DAT lines is not allowed Read 0x0: Issuing of command using the DAT lines is allowed	R	0
0	CMDI	Command inhibit(CMD) This status bit indicates that the CMD line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is set to 0 in either the following cases: - After the end bit of the command response, excepted if there is a command conflict error (MMCHS_STAT[CCRC] or MMCHS_STAT[CEB] set to 1) or a Auto CMD12 is not executed (MMCHS_AC12[ACNE]). - After the end bit of the command without response (MMCHS_CMD[RSP_TYPE] set to "00") In case of a command data error is detected (MMCHS_STAT[CTO] set to 1), this register is not automatically cleared. Read 0x1: Issuing of command using CMD line is not allowed Read 0x0: Issuing of command using CMD line is allowed	R	0

Table 25-80. MMCHS_HCTL

Address Offset	0x0000 0228

Bits	Field Name	Description	Type	Reset
31:28	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
27	OBWE	Wakeup event enable for 'Out-of-Band' Interrupt. This bit enables wakeup events for 'Out-of-Band' assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). The write to this register is ignored when MMCHS_CON[OBIE] is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt 0x1: Enable wakeup on 'Out-of-Band' Interrupt	RW	0
26	REM	Wakeup event enable on SD card removal This bit enables wakeup events for card removal assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card removal 0x1: Enable wakeup on card removal	RW	0
25	INS	Wakeup event enable on SD card insertion This bit enables wakeup events for card insertion assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card insertion 0x1: Enable wakeup on card insertion	RW	0
24	IWE	Wakeup event enable on SD card interrupt This bit enables wakeup events for card interrupt assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt	RW	0
23:20	RESERVED		R	0x0
19	IBG	Interrupt block at gap This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode	RW	0
18	RWC	Read wait control The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCHS_HCTL[SBGR]) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line. 0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control	RW	0

Bits	Field Name	Description	Type	Reset
17	CR	Continue request This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCHS_HCTL[SBGR]). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e DAT line is active (MMCHS_PSTATE[DLA]) or transferring data (MMCHS_PSTATE[WTA]). The Stop at block gap request must be disabled (MMCHS_HCTL[SBGR]=0) before setting this bit. 0x0: No affect 0x1: transfer restart	RW	0
16	SBGR	Stop at block gap request This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCHS_HCTL[CR]) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCHS_STAT[TC] set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCHS_DATA). 0x0: Transfer mode 0x1: Stop at block gap	RW	0
15:12	RESERVED		R	0x0
11:9	SDVS	SD bus voltage select All cards. The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system (MMCHS_CAPA[VS18,VS30,VS33]) before starting a transfer. 0x6: 3.0V (Typical) 0x7: 3.3V (Typical) 0x5: 1.8V (Typical)	RW	0x0
8	SDBP	SD bus power Before setting this bit, the host driver shall select the SD bus voltage (MMCHS_HCTL[SDVS]). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage MMCHS_HCTL[SDVS] is not supported according to capability register (MMCHS_CAPA[VS*]). 0x0: Power off 0x1: Power on	RW	0
7	CDSS	Card Detect Signal Selection This bit selects source for the card detection.When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupts caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing. 0x0: mmci_sdcd is selected (for normal use) 0x1: MMCHS_HCTL[6] CDTL is selected (for test purpose)	RW	0

Bits	Field Name	Description	Type	Reset
6	CDTL	Card Detect Test Level: This bit is enabled while MMCHS_HCTL[7] CDSS is set to 1 and it indicates whether the card is inserted or not. 0x0: No Card 0x1: Card Inserted	RW	0
5	RESERVED		R	0
4:3	DMAS	DMA Select Mode: One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register MMCHS_CAPA . Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MADMA_EN is set to 1. When MADMA_EN is set to 0 the bit field is read only and returned value is 0. 0x0: Reserved 0x1: Reserved 0x3: Reserved 0x2: 32-bit Address ADMA2 is selected	RW	0x0
2	HSPE	Before setting this bit, the Host Driver shall check the MMCHS_CAPA[21] HSS. This bit shall not be set when dual data rate mode is activated in MMCHS_CON[DDR]. 0x0: The Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock 0x1: The Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock **NOTE: Do not set this bit to 0x1 because device was timing closed with HSPE bit set to 0x0 for all supported modes of operation.**	RW	0
1	DTW	Data transfer width For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with MMC standard specification 4.x (see section 3.6). This register has no effect when the MMC 8-bit mode is selected (register MMCHS_CON[DW8] set to1), For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (DAT[0] used) 0x1: 4-bit Data width (DAT[3:0] used)	RW	0
0	LED	Reserved bit. LED control feature is not supported This bit is initialized to zero, and writes to it are ignored.	R	0

Bits	Field Name	Description	Type	Reset
31:27	RESERVED		R	0x00
26	SRD	Software reset for DAT line This bit is set to 1 for reset and released to 0 when completed. For more information about SRD bit manipulation, see *DATA Lines Reset Procedure*. DAT finite state machine in both clock domain are also reset. Here below are the registers cleared by MMCHS_SYSCTL[SRD]: - MMCHS_DATA - MMCHS_PSTATE: BRE, BWE, RTA, WTA, DLA and DATI - MMCHS_HCTL: SBGR and CR - MMCHS_STAT: BRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. 0x0: Reset completed 0x1: Software reset for DAT line	RW	0
25	SRC	Software reset for CMD line For more information about SRC bit manipulation, see *CMD Line Reset Procedure*. This bit is set to 1 for reset and released to 0 when completed. CMD finite state machine in both clock domain are also reset. Here below the registers cleared by MMCHS_SYSCTL[SRC]: - MMCHS_PSTATE: CMDI - MMCHS_STAT: CC Interconnect and MMC command status management is reinitialized. 0x0: Reset completed 0x1: Software reset for CMD line	RW	0
24	SRA	Software reset for all This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the capabilities registers (MMCHS_CAPA and MMCHS_CUR_CAPA). 0x0: Reset completed 0x1: Software reset for all the design	RW	0
23:20	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
19:16	DTO	Data timeout counter value and busy timeout. This value determines the interval by which DAT lines timeouts are detected. The host driver needs to set this bitfield based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCHS_CAPA[TCF]). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCHS_STA[DTO]). The MMCHS_SYSCTL[DTO] register is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0xF: Reserved 0x0: TCF x 2^13 0x1: TCF x 2^14 0xE: TCF x 2^27	RW	0x0
15:6	CLKD	Clock frequency select These bits define the ratio between MMCi_FCLK and the output clock frequency on the CLK pin of either the memory card (MMC, SD or SDIO). 0x0: MMCi_FCLK bypass 0x1: MMCi_FCLK bypass 0x2: MMCi_FCLK / 2 0x3: MMCi_FCLK / 3 0x3FF: MMCi_FCLK / 1023	RW	0x000
5	CGS	Clock Generator Select - For SD cards Host Controller Version 3.00 supports this bit. This bit is used to select the clock generator mode in MMCHS_SYSCTL[15:6] CLKD. If the Programmable Clock Mode is supported (non-zero value is set to MMCHS_CAPA2[23:16] CM), this bit attribute is RW, and if not supported, this bit attribute is RO and zero is read. This bit depends on the setting of MMCHS_AC12[31] PV_ENABLE. If PV_ENABLE = 0, this bit is set by Host Driver. If PV_ENABLE = 1, this bit is automatically set to a value specified in one of Preset Value registers, see, Table 25-22.	R	0
4:3	RESERVED		R	0x0
2	CEN	Clock enable This bit controls if the clock is provided to the card or not. 0x0: The clock is not provided to the card . Clock frequency can be changed . 0x1: The clock is provided to the card and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCHS_SYSCTL[ICS]).	RW	0

Bits	Field Name	Description	Type	Reset
1	ICS	Internal clock stable (status) This bit indicates either the internal clock is stable or not. Read 0x1: The internal clock is stable after enabling the clock (MMCHS_SYSCTL[ICE]) or after changing the clock ratio (MMCHS_SYSCTL[CLKD]). Read 0x0: The internal clock is not stable.	R	0
0	ICE	Internal clock enable This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wakeup events) and the interface clock (used for reads and writes to the module register map) are not affected by this register. 0x0: The internal clock is stopped (very low power state). 0x1: The internal clock oscillates and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value) .	RW	0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED		R	0x0
29	BADA	Bad access to data space This bit is set automatically to indicate a bad access to buffer when not allowed: -This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[BRE] =0) -This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_STATE[BWE] =0) Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Bad Access Read 0x0: No Interrupt.	RW	0

Bits	Field Name	Description	Type	Reset
28	CERR	Card error This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCHS_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read MMCHS_RSP76 register to detect error bits in the command response. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card error Read 0x0: No Error	RW	0
27	RESERVED		R	0
26	TE	Tuning Error This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure (Occurrence of an error during tuning procedure is indicated by Sampling Select). By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning. To reset tuning circuit, Sampling Clock shall be set to 0 before executing tuning procedure. The Tuning Error is higher priority than the other error interrupts generated during data transfer. By detecting Tuning Error, the Host Driver should discard data transferred by a current read/write command and retry data transfer after the Host Controller retrieved from tuning circuit error. The bit is set if the lock is lost (but not during the tuning process) or if the lock counter expires without the lock being asserted. If the latter happens, the SW can decide to ignore the interrupt and wait some more for the lock to be set. 0x0: No Error 0x1: Error	RW	0
25	ADMAE	ADMA Error: This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register.In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: ADMA error Read 0x0: No Interrupt.	RW	0

Bits	Field Name	Description	Type	Reset
24	ACE	Auto CMD error Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register (MMCHS_AC12) has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Auto CMD error Read 0x0: No Error.	RW	0
23	RESERVED		R	0
22	DEB	Data End Bit error This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data end bit error Read 0x0: No Error	RW	0
21	DCRC	Data CRC Error This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data CRC error Read 0x0: No Error.	RW	0
20	DTO	Data timeout error This bit is set automatically according to the following conditions: - busy timeout for R1b, R5b response type - busy timeout after write CRC status - write CRC status timeout - read data timeout Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Time out Read 0x0: No error.	RW	0
19	CIE	Command index error This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable in MMCHS_CMD[CICE] register. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command index error Read 0x0: No error.	RW	0

Bits	Field Name	Description	Type	Reset
18	CEB	Command end bit error This bit is set automatically when detecting a 0 at the end bit position of a command response. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command end bit error Read 0x0: No error.	RW	0
17	CCRC	Command CRC Error This bit is set automatically when there is a CRC7 error in the command response depending on the enable in MMCHS_CMD[CCCE] register. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command CRC error Read 0x0: No Error.	RW	0
16	CTO	Command Timeout Error This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Time Out Read 0x0: No error	RW	0
15	ERRI	Error Interrupt If any of the bits in the Error Interrupt Status register (MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. Read 0x1: Error interrupt event(s) occurred Read 0x0: No Interrupt.	R	0
14:11	RESERVED		R	0x0
10	BSR	Boot status received interrupt This bit is set automatically when MMCHS_CON[BOOT] is set 0x1 or 0x2 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Boot status received interrupt. Read 0x0: No Interrupt.	RW	0
9	OBI	Out-Of-Band interrupt This bit is set automatically when MMCHS_CON[OBIE] is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCHS_CON[OBIP]. This interrupt is only useful for MMC card. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Interrupt Out-Of-Band occurs Read 0x0: No Out-Of-Band interrupt.	RW	0

Bits	Field Name	Description	Type	Reset
8	CIRQ	Card interrupt This bit is only used for SD and SDIO and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives CMD line to zero during one cycle after data transmission end.All modes above are fully exclusive. The controller interrupt must be clear by setting MMCHS_IE[CIRQ] to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCHS_IE[CIRQ] is set to 1. Writes to this bit are ignored. Read 0x1: Generate card interrupt Read 0x0: No card interrupt	R	0
7	CREM	Card removal This bit is set automatically when MMCHS_PSTATE[CINS] changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card removed Read 0x0: Card state stable or Debouncing	RW	0
6	CINS	Card insertion This bit is set automatically when MMCHS_PSTATE[CINS] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card inserted Read 0x0: Card state stable or debouncing	RW	0
5	BRR	Buffer read ready This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by MMCHS_BLK[BLEN] is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Ready to read buffer Read 0x0: Not Ready to read buffer	RW	0

Bits	Field Name	Description	Type	Reset
4	BWR	Buffer write ready This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCHS_BLK[BLEN]. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Ready to write buffer Read 0x0: Not Ready to write buffer	RW	0
3	DMA	DMA interrupt : This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: No dma interrupt Read 0x0: Dma interrupt detected	RW	0
2	BGE	Block gap event When a stop at block gap is requested (MMCHS_HCTL[SBGR]), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. This event does not occur when the stop at block gap is requested on the last block. In read mode, a 1-to-0 transition of the DAT Line active status (MMCHS_PSTATE[DLA]) between data blocks generates a Block gap event interrupt. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Transaction stopped at block gap Read 0x0: No block gap event	RW	0
1	TC	Transfer completed This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCHS_HCTL[SBGR]). In Read mode: This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[RTA]). In write mode: This bit is set automatically on completion of the DAT line use (MMCHS_PSTATE[DLA]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data transfer complete Read 0x0: No transfer complete	RW	0

Bits	Field Name	Description	Type	Reset
0	CC	Command complete This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[CMDI]) If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCHS_STAT[CTO]) has higher priority than command complete (MMCHS_STAT[CC]). If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command complete Read 0x0: No Command complete	RW	0

Table 25-85. MMCHS_AC12

Address Offset	0x0000 023C		
Physical Address	0x4809 C23C 0x480B 423C 0x480A D23C 0x480D 123C	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	Host Control 2 Register and Auto CMD Error Status Register This register is used to indicate CMD12 response error of Auto CMD12 and CMD23 response error of Auto CMD23. The Host driver can determine what kind of Auto CMD12 / CMD23 errors occur by this register. Auto CMD23 errors are indicated only in bits[4:1]. Bits[7:0] are valid only when the MMCHS_CMD[3:2] ACEN bitfield is configured to enable Auto CMD and the Auto CMD Error bit (MMCHS_STAT[24]ACE) is set.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PV_ENABLE	AI_ENABLE	RESERVED	SCLK_SEL	ET	DS_SEL	V18_SIGEN	UHSMS	RESERVED	CNI	RESERVED	ACIE	ACEB	ACCE	ACTO	ACNE

Bits	Field Name	Description	Type	Reset
31	PV_ENABLE	Preset Value Enable Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set, automatic SDCLK frequency generation and driver strength selection is performed without considering system specific conditions. This bit enables the functions defined in the Preset Value registers, see, Table 25-22. If this bit is set to 0, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Driver. If this bit is set to 1, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Controller as specified in the Preset Value registers, see, Table 25-22. 0x0: SDCLK and Driver Strength (DS_SEL) are controlled by Host Driver. 0x1: Automatic Selection by Preset Value are Enabled.	RW	0
30	AI_ENABLE	Asynchronous Interrupt Enable This bit can be set to 1 if a card supports asynchronous interrupts and MMCHS_CAPA[29] AIS is set to 1. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver the Card Interrupt to the host when it is asserted by the Card. 0x0: Disabled 0x1: Enabled	RW	0
29:24	RESERVED		R	0x00
23	SCLK_SEL	Sampling Clock Select Host Controller uses this bit to select sampling clock to receive CMD and DAT. This bit is set by tuning procedure and valid after the completion of tuning (when MMCHS_AC12[22] ET is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting MMCHS_AC12[22] ET. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to compete re-tuning sequence in a short time. Change of this bit is not allowed while the Host Controller is receiving response or a read data block. 0x0: Fixed clock is used to sample data 0x1: Tuned clock is used to sample data	RW	0

Bits	Field Name	Description	Type	Reset
22	ET	Execute Tuning This bit is set to 1 to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to MMCHS_AC12[23] SCLK_SEL. Tuning procedure is aborted by writing 0. This is Read-Write with automatic clear register 0x0: Not Tuned or Tuning Completed 0x1: Execute Tuning	RW	0
21:20	DS_SEL	Driver Strength Select Host Controller output driver in 1.8V signaling is selected by this bit. In 3.3V signaling, this field is not effective. This field can be set depending on Driver Type A, C and D support bits (DTA, DTC and DTD respectively) in the MMCHS_CAPA2 register. This bit depends on setting of Preset Value Enable. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set by a value specified in the one of Preset Value registers, see, Table 25-22. 0x0: Driver Type B is selected (Default) 0x1: Driver Type A is selected 0x3: Driver Type D is selected 0x2: Driver Type C is selected	RW	0x0
19	V1V8_SIGEN	1.8V Signaling Enable This bit controls voltage regulator for I/O cell. 3.3V is supplied to the card regardless of signaling voltage. Setting this bit from 0 to 1 starts changing signal voltage from 3.3V to 1.8V. 1.8V regulator output shall be stable within 5ms. Host Controller clears this bit if switching to 1.8V signaling fails. Clearing this bit from 1 to 0 starts changing signal voltage from 1.8V to 3.3V. 3.3V regulator output shall be stable within 5ms. Host Driver can set this bit to 1 when Host Controller supports 1.8V signaling (One of support bits is set to 1: SDR50, SDR104 or DDR50 in MMCHS_CAPA2 register) and the card or device supports UHS-I (S18A=1. Refer to Bus Signal Voltage Switch Sequence in the Physical Layer Specification Version 3.0x). 0x0: 3.3V Signaling 0x1: 1.8V Signaling	RW	0

Bits	Field Name	Description	Type	Reset
18:16	UHSMS	UHS Mode Select This field is used to select one of UHS-I modes or eMMC HS200 mode and is effective when 1.8V Signaling Enable is set to 1. If MMCHS_AC12[31] PV_ENABLE is set to 1, Host Controller sets MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL according to Preset Value registers, see, Table 25-22. In this case, one of preset value registers is selected by this field. Host Driver needs to reset MMCHS_SYSCTL[2] CEN before changing this field to avoid generating clock glitch. After setting this field, Host Driver sets MMCHS_SYSCTL[2] CEN again. When SDR50, SDR104 or DDR50 is selected for SDIO card, interrupt detection at the block gap shall not be used. Read Wait timing is changed for these modes. Refer to the SDIO Specification Version 3.00 for more detail. 0x0: SDR12 0x1: SDR25 0x2: SDR50 0x3: SDR104/HS200 0x4: DDR50 0x5: Reserved 0x6: Reserved 0x7: Reserved	RW	0x0
15:8	RESERVED		R	0x00
7	CNI	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. Read 0x1: Command not issued Read 0x0: No error	R	0
6:5	RESERVED		R	0x0
4	ACIE	Auto CMD Index Error - For Auto CMD12 and Auto CMD23 This bit is set if the Command Index error occurs in response to a command. Read 0x1: Error Read 0x0: No error	R	0
3	ACEB	Auto CMD End Bit Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting that the end bit of command response is 0. Read 0x1: End bit Error Generated Read 0x0: No error	R	0
2	ACCE	Auto CMD CRC Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting a CRC error in the command response. Read 0x1: CRC Error Generated Read 0x0: No error	R	0

Bits	Field Name	Description	Type	Reset
1	ACTO	Auto CMD Timeout Error - For Auto CMD12 and Auto CMD23 This bit is set if no response is returned within 64 SDCLK cycles from the end bit of command. If this bit is set to1, the other error status bits (D04-D02) are meaningless. Read 0x1: Auto CMD Time Out Read 0x0: No error	R	0
0	ACNE	Auto CMD12 Not Executed If memory multiple block data transfer is not started due to command error, this bit is not set because it is not necessary to issue Auto CMD12. Setting this bit to 1 means the Host Controller cannot issue Auto CMD12 to stop memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (D04-D01) are meaningless. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. Read 0x1: Auto CMD12 Not Executed Read 0x0: Auto CMD12 Executed	R	0

Bits	Field Name	Description	Type	Reset
26	VS18	Voltage support 1.8V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 1.8V Not supported Write 0x1: 1.8V Supported Read 0x1: 1.8V Supported Read 0x0: 1.8V Not Supported	RW	0
25	VS30	Voltage support 3.0V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 3.0V Not supported Write 0x1: 3.0V Supported Read 0x1: 3.0V Supported Read 0x0: 3.0V Not Supported	RW	0
24	VS33	Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 3.3V Not supported Write 0x1: 3.3V Supported Read 0x1: 3.3V Supported Read 0x0: 3.3V Not Supported	RW	0
23	SRS	Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/ Resume functionality. Read 0x0: The Host controller does not Suspend/ Resume functionality.	R	1
22	DS	DMA support This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x1: DMA Supported Read 0x0: DMA Not Supported	R	1
21	HSS	High speed support This bit indicates that the host controller supports high speed operations and can supply an up-to maximum card frequency. Read 0x1: High Speed Supported Read 0x0: High Speed Not Supported **NOTE: High Speed modes are supported, but MMCHS_HCTL[HSPE] bit must always be set to 0x0 because device was timing closed with HSPE bit set to 0x0 for all supported modes of operation.**	R	1
20	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
19	AD2S	ADMA2 Support This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN Read 0x1: ADMA2 Supported Read 0x0: ADMA2 not Supported	R	0
18	RESERVED		R	0
17:16	MBL	Maximum block length This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. This value depends on definition of generic parameter with a max value of 2048 bytes. The host controller supports 512 bytes and 1024 bytes block transfers. Read 0x2: 2048 bytes Read 0x1: 1024 bytes Read 0x0: 512 bytes	R	0x1
15:8	BCF	Base Clock Frequency For SD Clock This value indicates the base (maximum) clock frequency for the SD Clock. 8-bit Base Clock Frequency This mode is supported by the Host Controller Version 3.00. Unit values are 1MHz. The supported clock range is 10MHz to 255MHz. FFh : 255MHz .... : ..... 02h : 2MHz 01h : 1MHz 00h : Get information via another method If the real frequency is 16.5MHz, the lager value shall be set 0001 0001b (17MHz) because the Host Driver use this value to calculate the clock divider value (Refer to MMCHS_SYSCTL[15:6] CLKD) and it shall not exceed upper limit of the SD Clock frequency. If these bits are all 0, the Host System has to get information via another method. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method.	R	0x00
7	TCU	Timeout clock unit This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCHS_STAT[DTO]). Read 0x1: MHz Read 0x0: KHz	R	1
6	RESERVED		R	0
5:0	TCF	Timeout clock frequency The timeout clock frequency is used to detect Data Timeout Error (MMCHS_STAT[DTO]). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.	R	0x00

Bits	Field Name	Description	Type	Reset
15:14	RTM	Re-Tuning Modes This field selects re-tuning method and limits the maximum data length. Bit47-46 Re-Tuning Mode Re-Tuning Method Data Length There are two re-tuning timings: Re-Tuning Request controlled by the Host Controller and expiration of a Re-Tuning Timer controlled by the Host Driver. By receiving either timing, the Host Driver executes the re-tuning procedure just before a next command issue. The maximum data length per read/write command is restricted so that re-tuning procedures can be inserted during data transfers. (1) Re-Tuning Mode 1 The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MiB. (2) Re-Tuning Mode 2 The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MiB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. (3) Re-Tuning Mode 3 The host controller has the capability to take care of the re-tuning during data transfer (Auto Re-Tuning). Re-Tuning Request shall not be generated during data transfers and there is no limitation to data length per read/write command. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. Re-Tuning Timer Control Example for Re-Tuning Mode 1 The initial value of re-tuning timer is provided by Timer Count for Re-Tuning field in this register. The timer starts counting by loading the initial value. When the timer expires, the Host Driver marks an expiration flag. On receiving a command request, the Host driver checks the expiration flag. If the expiration flag is set, then the Host Driver should perform the re-tuning procedure before issuing a command. If the expiration flag is not set, then the Host Driver issues a command without performing the re-tuning procedure. Every time the re-tuning procedure is performed, the timer loads the new initial value and the expiration flag is cleared. Re-Tuning Timer Control Example for Re-Tuning Mode 2 and Mode 3 The timer control is almost the same as Re-Tuning Mode 1 except the timer loads the new initial value after data transfer (when receiving Transfer Complete). In case of Mode 3, Timer Count for Re-Tuning is set either smaller value: Tuning effective time after re-tuning procedure or after data transfer. If a Host System goes into power down mode, the Host Driver should stop the re-tuning timer and set the expiration flag to 1 when the Host System resumes from power down mode. Read 0x3: Reserved Read 0x2: Auto Re-Tuning (for transfer) - Timer and Re-Tuning Request Read 0x1: Timer and Re-Tuning Request - Max data length 4 MiB Read 0x0: Timer - Max data length 4 MiB	R	0x0

Description

Force Event Register for Auto CMD Error Status and Error Interrupt status
The Force Event Register is not a physically implemented register. Rather, it is an address at which the Auto CMD Error Status Register (MMCHS_AC12) can be written.
Writing 1 : set each bit of the Auto CMD Error Status Register
Writing 0 : no effect
Rather, it is an address at which the Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register if the corresponding bit of the Error Interrupt Status Enable Register is set.
Writing 1 : set each bit of the Error Interrupt Status Register
Writing 0 : no effect
Note: By setting this register, the Error Interrupt can be set in the Error Interrupt Status register. In order to generate interrupt signal, both the Error Interrupt Status Enable and Error Interrupt Signal Enable shall be set.

Table 25-91. MMCHS_ADMAES (continued)

Description	ADMA Error Status Register When ADMA Error Interrupt is occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows: ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address ST_FDS: Current location set in the ADMA System Address register is the error descriptor address ST_CADR: This sate is never set because do not generate ADMA error in this state. ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address In case of write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

Chapter 26

Shared PHY Component Subsystem

This chapter describes the shared PHY component subsystems of the device.

26.1 SATA PHY Subsystem

This chapter describes the features and functions of the serial advanced technology attachment (SATA) PHY subsystem of the device.

26.1.1 SATA PHY Subsystem Overview

Note

SATA is not supported on the AM570x family of devices.

The physical layer (PHY) is responsible for transmitting and receiving the parallel 8b/10b encoded information as a serial data stream on the wire.

The SATA host controller subsystem instantiates a single serializer (transmitter), SATA_PHY_TX, and a single deserializer (receiver), SATA_PHY_RX. Together the transmitter and receiver are also signified as SATA_PHY throughout this chapter. The role of the TX and RX components is to adapt SATA Link parallel 10-bit input/output (I/O) data stream for a serialized differential transmission and reception over SATA electrical interface, respectively.

The high speed transmission clock is generated by and integrated into the SATA host subsystem dpll (DPLL_SATA).

The DPLL_SATA is configured and controlled through a SATA dedicated PLL controller (DPLLCTRL_SATA) with associated registers, accessible over a L4_CFG interface adapter.

The components (SATA_PHY_RX, SATA_PHY_TX, DPLL_SATA, DPLLCTRL_SATA, and DPLLCTRL_SATA L4-interface adapter) build the SATA PHY subsystem. This subsystem is responsible for PHY components clock generation and physical layer transmission/reception within the device SATA subsystem.

Figure 26-1 gives an overview of the SATA PHY subsystem. As shown in Figure 26-1, at one side the SATA_PHY components directly interface the attached to host controller SATA mass storage device (over TXP/TXN transmission and RXP/RXN reception interface I/Os) and on the other side they interface the SATA controller, described in detail in Section 24.8, *SATA Controller*.

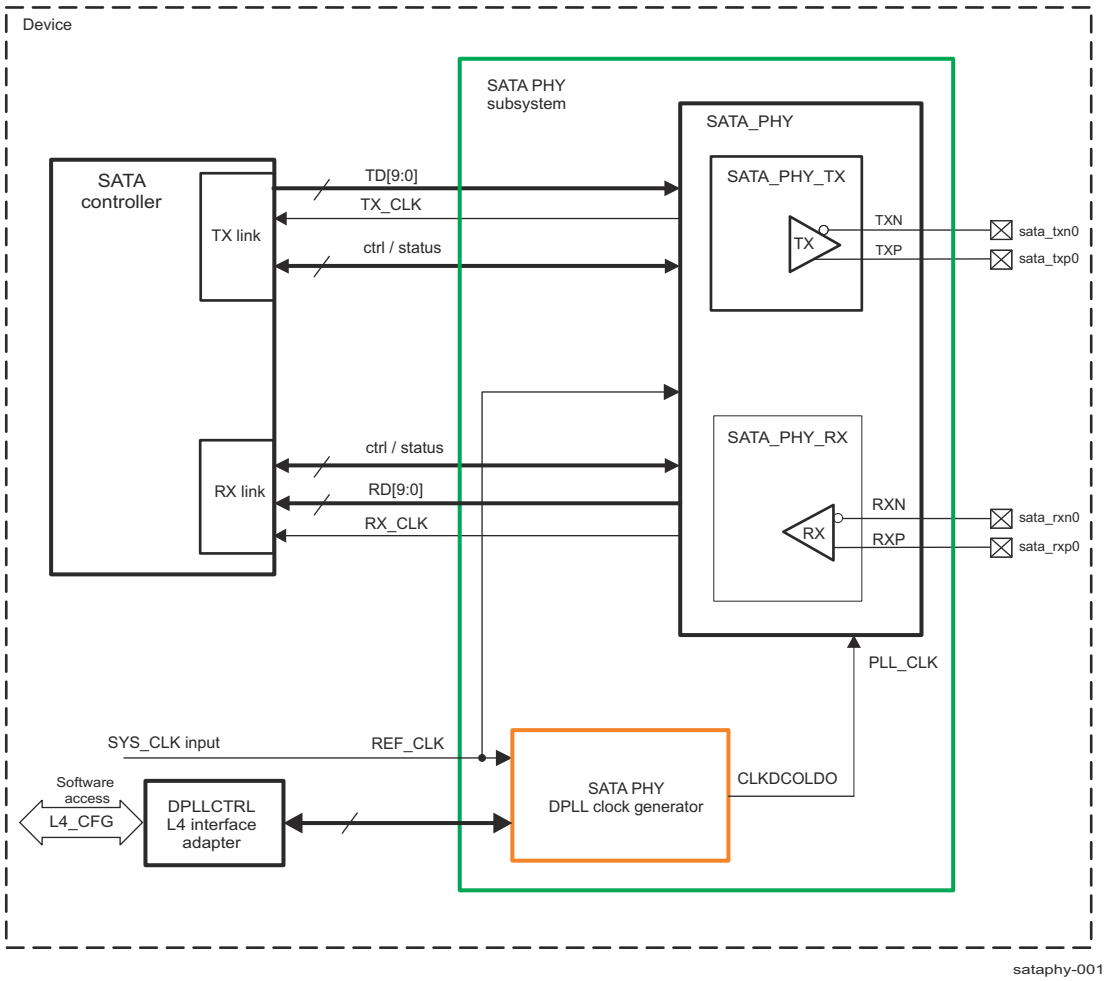

Figure 26-1. SATA PHY Subsystem Overview

26.1.2 SATA PHY Subsystem Environment

Note

SATA is not supported on the AM570x family of devices.

26.1.2.1 SATA PHY I/O Signals

Table 26-1 lists the module pins and their corresponding signal names at the device level, and also specifies their links to functions.

Table 26-1. SATA PHY I/O Signals

Module Signal	Device Pin	I/O(1)	Description	Pin Reset Value
TXP	sata_txp0	O	TXP output of the SATA PHY differential transmission lane	HiZ
TXN	sata_txn0	O	TXN output of the SATA PHY differential transmission lane	HiZ
RXP	sata_rxp0	I	RXP input of the SATA PHY differential reception lane	HiZ
RXN	sata_rxn0	I	RXN input of the SATA PHY differential reception lane	HiZ

(1) I = Input; O = Output

Figure 26-2 shows module pin signals mapping to SATA PHY I/O signals visible at device pad level.

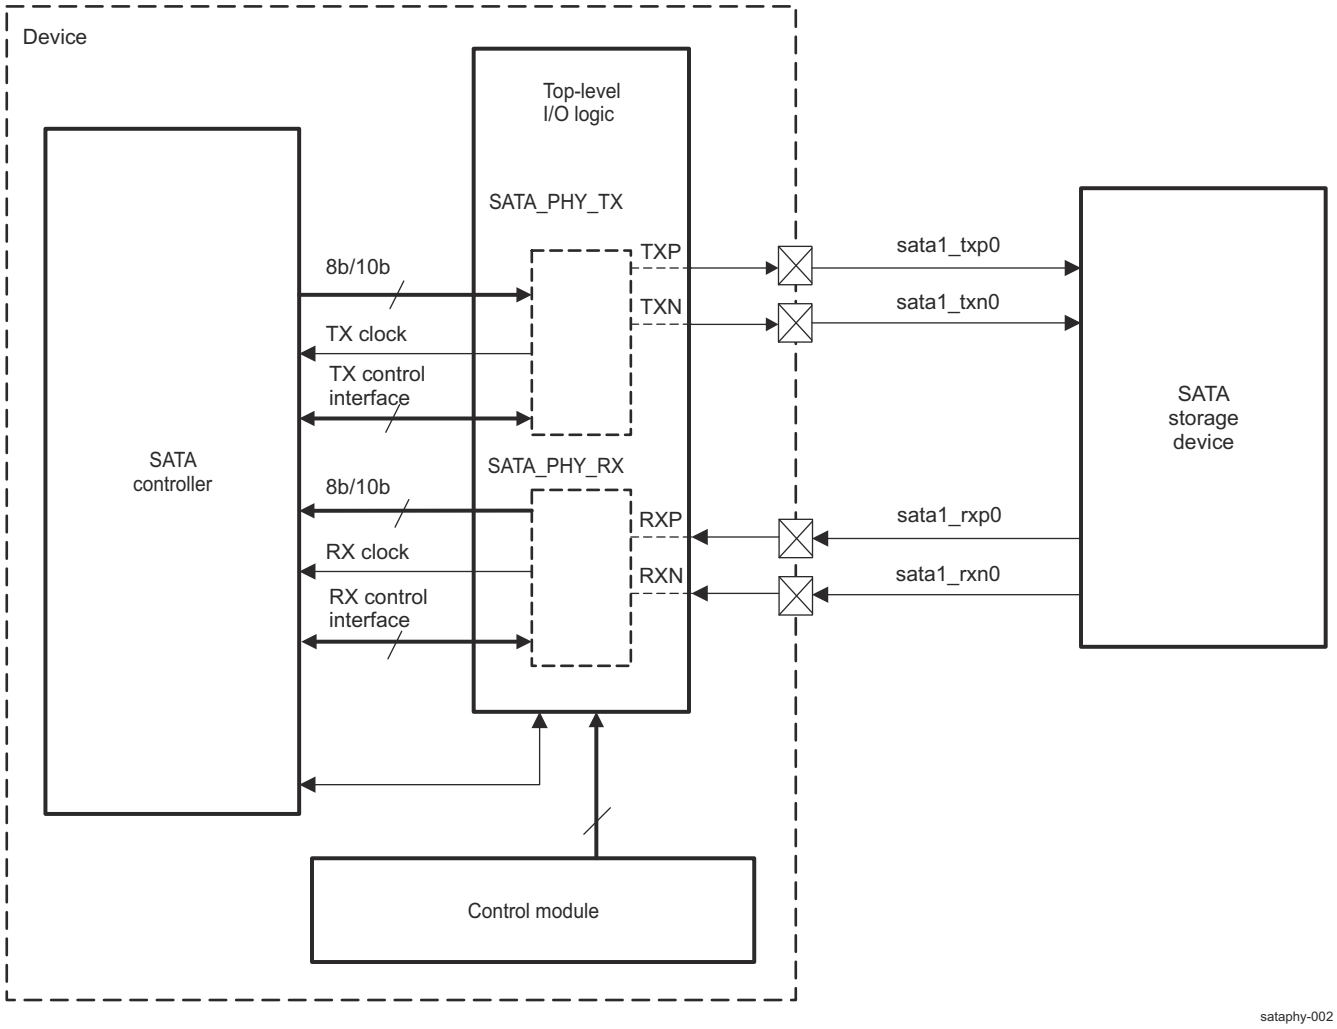

Figure 26-2. SATA PHY I/O Signals

Note

The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers. See *Control Module*, for more information.

26.1.3 SATA PHY Subsystem Integration

Note

SATA is not supported on the AM570x family of devices.

This section describes the SATA PHY subsystem-related components (SATA_PHY, DPLL_SATA, DPLLCTRL_SATA, OCP2SCP3) integration in the device, including information about clocks, resets, and hardware requests.

Figure 26-3 shows the SATA_PHY integration.

The SATA_PHY module integration features are:

- A low-power nonretention reset, L3INIT_RST
- A DPLL reference input clock, PLL_CLK
- Parallel 10-bit TD[9:0] (SATA_PHY_TX) and 10-bit RD[9:0] (SATA_PHY_RX) data interfaces to SATA controller
- TX_CLK output clock for the parallel TX data interface between SATA_PHY.SATA_PHY_TX and SATA controller
- RX_CLK output clock for the parallel RX data interface between SATA_PHY.SATA_PHY_RX and SATA controller
- REF_CLK clock input (SATA_REF_GFCLK)
- A device core control module command port to the SATA_PHY integrated power sequencer

The DPLL_SATA integration features are:

- A low-power nonretention reset, L3INIT_RST
- A power, reset, and clock management (PRCM) gated version of SYS_CLK (SATA_REF_GFCLK) supplying the DPLL_SATA.CLKINP pin
- A single high-frequency clock output (DPLL_SATA.CLKDCOLDO to the SATA_PHY TX/RX components)
- No high-speed (HS) divider integration
- Idle signaling implementation
- LDO and DCO PWRDNZ monitoring signals
- A DPLL_LOCK locked status indication output to SATA_PHY and the SATA controller

The DPLLCTRL_SATA integration features are:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SCP3) Interconnect adapter target interface
- Configuration/control programming interface to the DPLL_SATA
- No direct gate control for DPLL_SATA.CLKINP and CLKDCOLDO

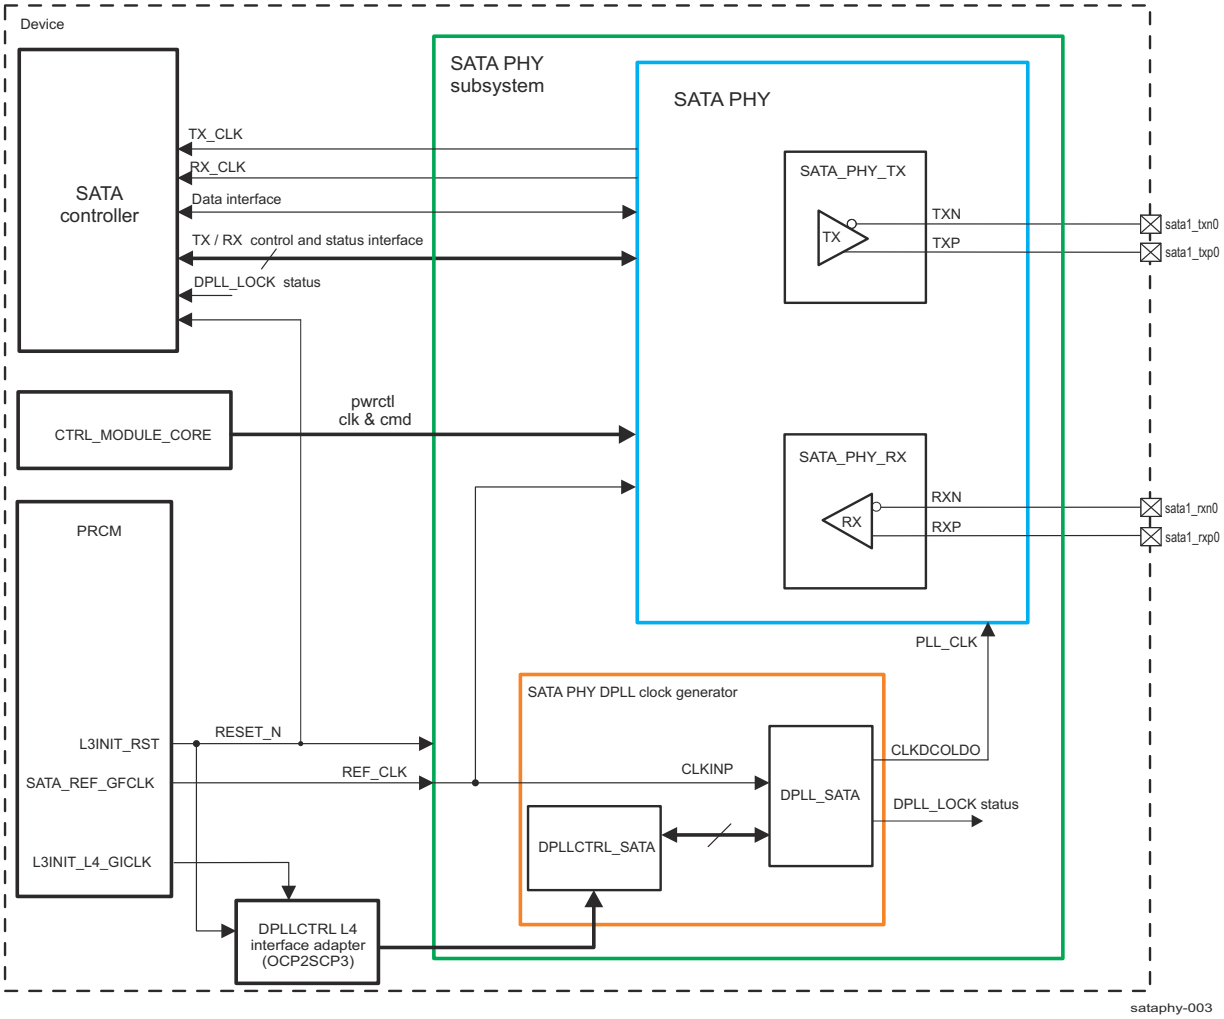

Figure 26-3. SATA PHY Subsystem Integration

Table 26-2 through Table 26-4 summarize the integration of the module in the device.

Table 26-2. SATA PHY Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect

Resets

Table 26-4. SATA PHY Resets (continued)

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SATA_PHY subsystem	RESET_N	L3INIT_RST	PRCM	A nonretention reset to all SATA_PHY subsystem components

Note

The SATA_PHY, DPLL_SATA, and DPLLCTRL_SATA modules do not generate DMA, interrupt, or wakeup hardware requests to the surrounding modules integrated in the device.

26.1.4 SATA PHY Subsystem Functional Description

Note

SATA is not supported on the AM570x family of devices.

26.1.4.1 SATA PLL Controller L4 Interface Adapter Functional Description

The L4_CFG interconnect adapter (OCP2SCP3), allows user software to configure the DPLLCTRL_SATA registers over the L4_CFG port. Hence it is expected that this adapter is configured to operate before any programming of the DPLLCTRL_SATA.

Aa value of 0x6 or more should be written to the register bitfield OCP2SCP_TIMING[3:0] SYNC2.

L4_CFG interconnect adapter software reset is performed via writing OCP2SCP_SYSCONFIG[1] SOFTRESET to 0b1. The software reset completion is observed in bit OCP2SCP_SYSSTATUS[0] RESETDONE.

By default a smart-idle power mode is selected for OCP2SCP3. The smart-idle mode supported by OCP2SCP3 is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP3 by setting the OCP2SCP_SYSCONFIG [4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

By default OCP2SCP_SYSCONFIG[0] AUTOIDLE =0x1, which defines that the PLLCTRL L4 interface adapter automaticaly gates its L4 input clock based on L4_CFG interconnect activity. To enable a free-running clock, one should set bit AUTOIDLE to 0x0.

26.1.4.2 SATA PHY Serializer and Deserializer Functional Descriptions

26.1.4.2.1 SATA PHY Reset

No software reset is applicable to SATA_PHY. L3INIT reset assertion is automatically managed by hardware.

26.1.4.2.2 SATA_PHY Clocking

26.1.4.2.2.1 SATA_PHY Input Clocks

A standard high-speed 1.5 GHz input clock of SATA_PHY is provided by the DPLL_SATA.CLKDCOLDO output. PRCM. SATA_REF_GFCLK (derived from the SYS_CLK) should be enabled, to provide the necessary DPLL_SATA and SATA_PHY clocking within the SATA subsystem.

Depending on the SATA_REF_GFCLK (SYS_CLK derived) frequency, following settings should be made in the CTRL_MODULE_CORE.CONTROL_PHY_POWER_SATA[31:22] SATA_PWRCTL_CLK_FREQ bitfield for proper operation:

- 0x26: If SYSCLK = 38.4 MHz
- 0x1A: If SYSCLK = 26.0 MHz
- 0x13: If SYSCLK = 19.2 MHz
- 0x10: If SYSCLK = 16.8 MHz
- 0x0C: If SYSCLK = 12.0 MHz

26.1.4.2.2.2 SATA_PHY Output Clocks

The 10-bit data parallelly transmitted data between SATA_PHY_TX and SATA controller link logic is sampled with respect to the TX_CLK. Frequency of this clock is obtained as the SATA_PHY.PLL_CLK clock frequency:

- Divided by 10 if a 1.5-Gbps limit is negotiated by software setting DWC_ahsata.SATA_PxSCTL[7:4] SPD = 0x1
- Divided by 5 if a 3-Gbps limit is negotiated by software setting DWC_ahsata.SATA_PxSCTL[7:4] SPD = 0x0 or 0x2

The actually negotiated between host and the attached SATA device speed is indicated in the read-only SATA controller.SATA_PxSSTS[7:4] SPD bit field. For more information, see Section 24.8.6, *SATA Controller Register Manual*, in Section 24.8, *SATA Controller*.

RX_CLK: The SATA_PHY_RX output RX_CLK is a clock that is recovered from the serial data received over the RXP/RXN lanes serial data. The RX_CLK clock supplies the SATA controller link parallel 10-bit data reception logic.

26.1.4.2.3 SATA_PHY Power Management

The SATA_PHY power sequencer receives a power-up/power-down command input from the device general core control module. The power sequencer takes care to execute different stages of the SATA_PHY_TX and SATA_PHY_RX power-up/-down processes. Besides a power-up/-down functionality, the SATA PHY accepts power transition commands/states (Ready state, Partial or Slumber states) from the SATA controller link power management port .

26.1.4.2.3.1 SATA_PHY Power-Up/-Down Sequences

Powering up/down the SATA_PHY_TX and SATA_PHY_RX modules is triggered by software writing corresponding power-up/-down commands in the CTRL_MODULE_CORE. CONTROL_PHY_POWER_SATA register of the device core control module, as follows:

- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x0 (default value), commands both SATA_PHY_TX and SATA_PHY_RX to power-down (OFF) state.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x1, powers up the SATA_PHY_RX only.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x2, powers up the SATA_PHY_TX only.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x3, simultaneously powers up the SATA_PHY_RX and the SATA_PHY_TX.

For more information, see *Control Module*.

26.1.4.2.3.2 SATA_PHY Low-Power Modes

Setting the DWC_ahsata.SATA_PxSCTL[3:0] DET bit field to 0x4 automatically puts the SATA_PHY_RX deserializer in offline mode. This software operation has no impact over the SATA_PHY_TX serializer.

Note

The SATA controller transition to partial or slumber mode has no impact over the SATA_PHY_RX deserializer.

Note

The SATA_PHY_TX.TX_CLK output clock is a free-running clock and cannot be gated, even when the transmitter is disabled by a SATA controller.

26.1.4.2.4 SATA_PHY Hardware Requests

No DMA, interrupt or wake-up requests are generated by the SATA_PHY to the surrounding SATA controller subsystem components.

26.1.4.3 SATA Clock Generator Subsystem Functional Description

The DPLL_SATA, which is located outside the PRCM boundaries and is part of the SATA host controller subsystem, directly injects a high-speed clock into the SATA_PHY serializer/deserializer input, PLL_CLK. The DPLL generator is controlled through a programmable interface from a dedicated PLL controller, DPLLCTRL_SATA.

26.1.4.3.1 SATA DPLL Clock Generator Overview

The SCP interface of the SATA PLL controller (the DPLLCTRL_SATA instance) is used to set the configuration of the digital phase-locked loop (DPLL) modules, primarily the various counter values. Figure 26-4 is an overview of the DPLL clock generator embedded into the SATA host controller subsystem.

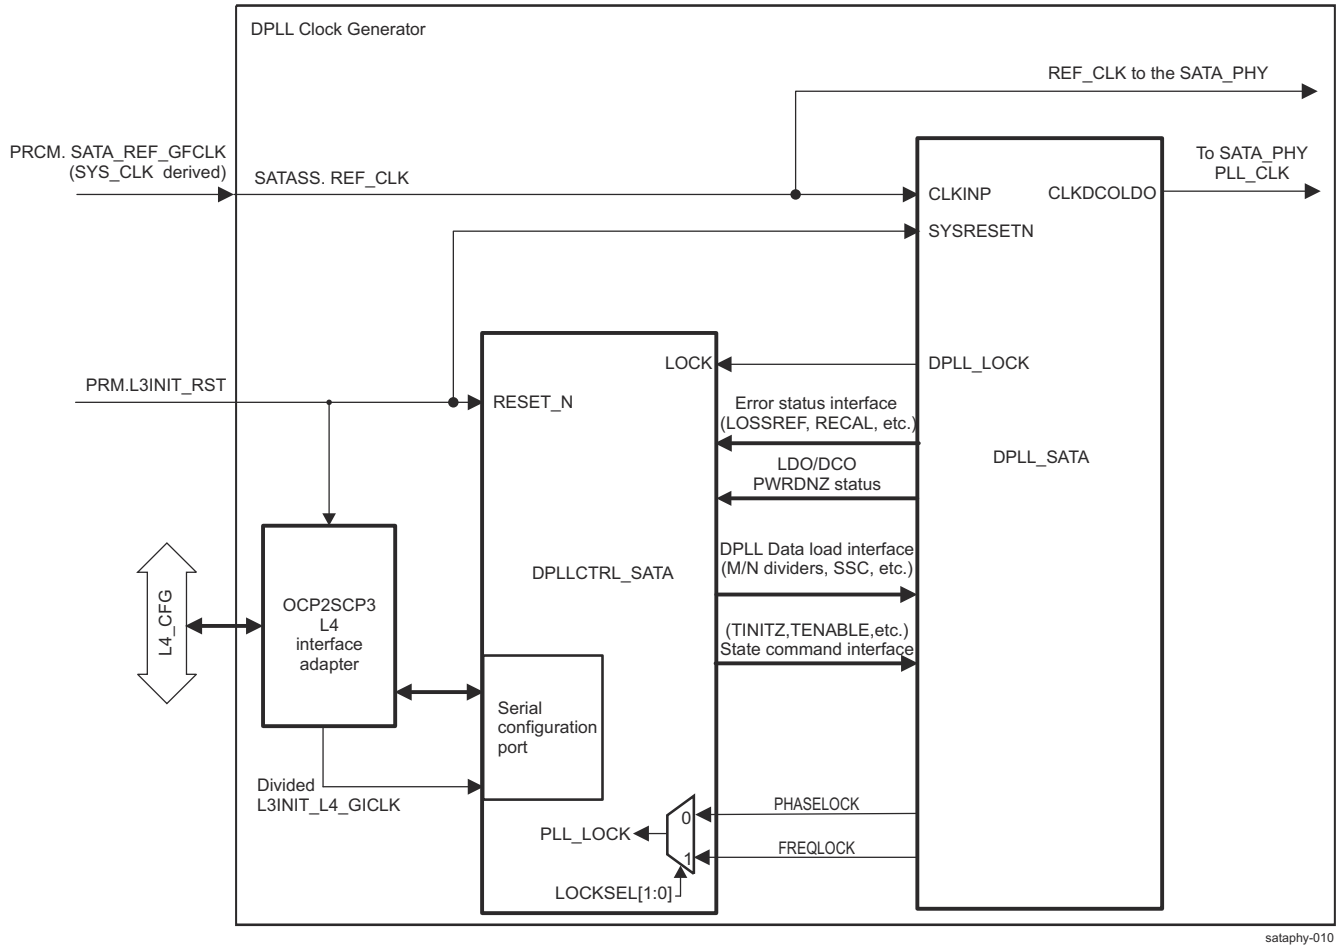

Figure 26-4. SATA DPLL Clock Generator Overview

Note

The DPLLCTRL_SATA module is user accessible on the L4_CFG interconnect. However, to make access possible, the user must configure the OCP2SCP3 instance prior to accessing the DPLLCTRL_SATA registers.

The DPLL_SATA features are:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Digital control and loop filter
- Internal oscillator output clock on internal LDO domain (CLKDCOLDO output)
- DPLL output clock spread spectrum clocking (SSC) support
- No retention capabilities
- No idle-bypass fast relock capabilities
- Idle-bypass low-power mode
- M/N bypass mode
- Relock from standby

The DPLLCTRL_SATA components features are:

- DPLL error and status notification
- DPLL initialization and configuration
- DPLL lock criteria selectable between frequency and phase lock

- Idle command implementation
- No software reset implementation

26.1.4.3.2 SATA DPLL Clock Generator Reset

The SATA PLL controller and SATA DPLL clock generator share a common hardware nonretention reset (L3INIT_RST) which comes from the device power and reset manager. When the DPLL_SATA hardware reset completes, the DPLLCTRL_SATA.PLL_STATUS[0] PLLCTRL_RESET_DONE bit is automatically updated to 1. For more information on the hardware reset source, see *Reset Domains*, in *Power, Reset, and Clock Management*.

The DPLLCTRL_SATA itself has no software reset capabilities.

The DPLLCTRL_SATA performs a software reset sequence on the DPLL_SATA in hardware (through the TINITZ signal activation).

26.1.4.3.3 SATA DPLL Low-Power Modes

The power-management port (PMP) is not integrated for DPLLCTRL_SATA. The DPLL_SATA has no retention capabilities. This means the DPLL digital power supply remains switched on during all modes of operation.

The low-power (LP) modes supported by DPLL_SATA are idle-bypass low power and MN-bypass modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKDCOLDO output pulled low

For more details on the PLL settings and conditions necessary to enter idle-bypass and MN-bypass low-power modes, see Section 26.1.4.3.6.4, *SATA DPLL Idle-Bypass Low-Power Mode*, and Section 26.1.4.3.6.5, *SATA DPLL MN-Bypass Mode*.

DPLL_SATA is held in a similar low-power state (DCO and LDO switched off, with CLKDCOLDO = 0) after POR, before the first PLL_GO command has been software-triggered on the PLL controller. See Section 26.1.4.3.6.1, *SATA Clock Generator Power Up*.

26.1.4.3.4 SATA DPLL Clocks Configuration

26.1.4.3.4.1 SATA DPLL Input Clock Control

The DPLL_SATA accepts the functional clock (SATA_REF_GFCLK) on its CLKINP pin (REF_CLK input at SATA SS level) directly from the device PRCM, without involving any DPLLCTRL_SATA interactions. The SATA_REF_GFCLK is derived from SYS_CLK1, and can be optionally software-gated by setting the PRCM.CM_L3INIT_SATA_CLKCTRL[8] OPTFCLKEN_REF_CLK bit. The status of the SATA_REF_GFCLK clock can be monitored in the PRCM.CM_L3INIT_CLKSTCTRL[19] CLKACTIVITY_SATA_REF_GFCLK bit. See *Clock Domain Module Attributes* in *Power, Reset, and Clock Management*.

If CLKINP signal is lost for some time, the LOSSREF output signal, which serves as a feedback to DPLLCTRL_SATA, is asserted high. When CLKINP resumes, the LOSSREF signal goes low (LOSSREF inactive state). The LOSSREF status signal can be monitored by software in the DPLLCTRL_SATA.PLL_STATUS[3] PLL_LOSSREF bit.

26.1.4.3.4.2 SATA DPLL Output Clock Configuration

Only the DPLL_SATA output, CLKDCOLDO, is used to provide the high-speed clock at the PLL_CLK pin of the SATA_PHY. Only the REGM, REGN, and SD divider values are used within the DPLL clock generator subsystem to adjust the CLKDCOLDO output clock frequency. This is done by programming the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM, DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN, and DPLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD bit fields, respectively. The SATA DPLL CLKOUT and CLKOUTLDO outputs are not used, and internal REGM2 and REGM1 dividers are not software controllable.

Note

At the DPLL/PLLCTRL integration level, the PLL_REGM1[3:0] and PLL_REGM2[6:0] divider control signals are tied-off by hardware to 0x0 and 0x1, respectively.

For more details on output clock settings sequence, see Section 26.1.4.3.7.2, *SATA DPLL Clock Programming Sequence*.

26.1.4.3.4.2.1 SATA DPLL Output Clock Gating

There is no direct software gate control for the DPLL_SATA.CLKDCOLDO output.

The DPLL_SATA.CLKDCOLDO clock output is automatically gated (CLKDCOLDO pulled low) in the following scenarios:

- DPLL power-up sequence. For more information on the power-up sequence, see Section 26.1.4.3.6.1, *SATA Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on the relocking sequence, see Section 26.1.4.3.6.2, *SATA DPLL Sequences*.
- DPLL entering idle-bypass low-power mode. For more information on idle-bypass mode, see Section 26.1.4.3.6.4, *SATA DPLL Idle-Bypass Mode*.
- DPLL entering MN-bypass mode. For more information on MN-bypass mode, see Section 26.1.4.3.6.5, *SATA DPLL MN Bypass Mode*.

26.1.4.3.5 SATA DPLL Subsystem Architecture

Figure 26-5 is a simplified block diagram of the DPLL_SATA instance integration in the SATA clock generator subsystem.

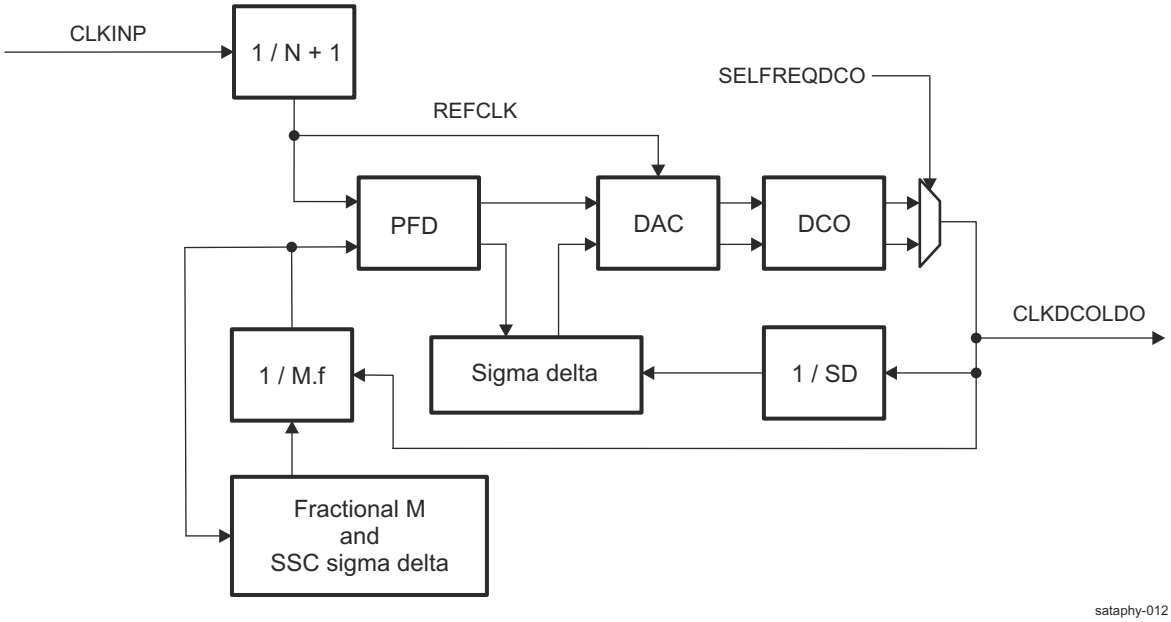

Figure 26-5. DPLL_SATA Functional Block Diagram

The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

The frequency ranges for the DPLL_SATA input clock (CLKINP) and the DPLL internal reference clock (REFCLK = CLKINP/N + 1) are:

- 0.62 to 60 MHz for CLKINP

- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKDCOLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP × M/(N + 1). For that purpose the feedback multiplier M must be configured through the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL_SATA module supports fractional synthesis (that is, the frequency multiplication factor M can be programmed as fractional). This is achieved by having a sigma delta feedback divider (M). A fractional value (Fractional M) of 18 bits is supported enabling control for a better accuracy. Programming the 18-bit Fractional M value is done by setting the DPLLCTRL_SATA.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field (similar to REGM). To enable integer only division Fractional M should be set to 000…0.

Note

Fractional synthesis is not supported for M > 4093.

26.1.4.3.6 SATA DPLL Clock Generator Modes and State Transitions

The DPLL_SATA can be set in different modes during operation. PLLCTRL triggers DPLL_SATA state transitions to different static modes by means of TINITZ and TENABLE hardware control signals.

26.1.4.3.6.1 SATA Clock Generator Power Up

After power up, the DPLL_SATA.SYSRESETN input is automatically pulled low by PRM, together with DPLLCTRL_SATA.RESET_N input. Because PRM.L3INIT_RST is an asynchronous reset, the DPLL_SATA input clock (DPLL_SATA.CLKINP) is not demanded upon reset. The LOSSREF signal, which monitors the presence of CLKINP clock, remains 1 during SYSRESETN = 0 irrespective of presence/absence on the CLKINP clock. If CLKINP is present upon reset assertion, the LOSSREF signal is deasserted to 0, a certain time after the hardware reset completion. During DPLL power-up mode, CLKDCOLDO clock is maintained inactive (pulled low). After POR, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too.

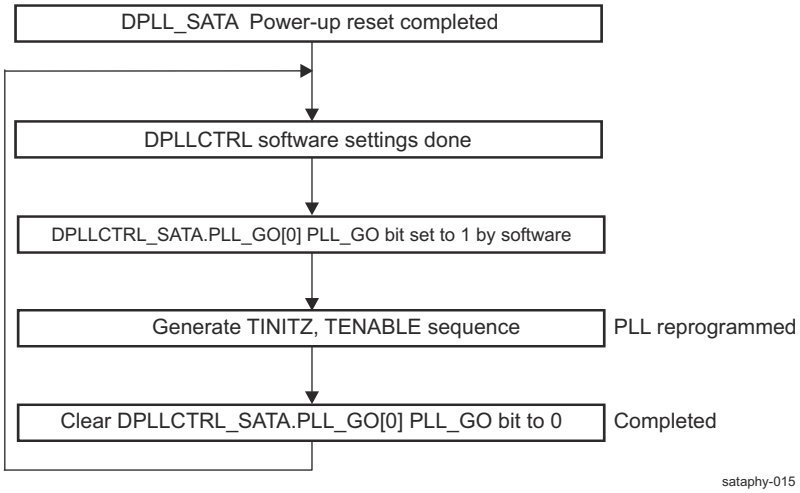
26.1.4.3.6.2 SATA DPLL Sequences

Once all the configuration values have been initially programmed into the DPLLCTRL_SATA registers (see Section 26.1.4.3.7.2, *SATA DPLL Clock Programming Sequence*), the DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit should be set to update the configuration values and start the DPLL calibration and locking sequence.

After DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit is set high in software, the DPLLCTRL_SATA state-machine takes the following action:

1. Sets TINITZ signal to 0. TINITZ acts as a soft reset to DPLL_SATA. This starts the DPLL initialization procedure. During initialization mode, the CLKDCOLDO, FREQLOCK, and PHASELOCK signals are kept at 0 and the BYPASSACK signal is kept at 1.
   VDDA power supply of DPLL should be active before DPLL_SATA initialization is performed, but it is not required to be switched on immediately after device power up.
2. The TENABLE signal is asserted high by the PLLCTRL hardware to load the user-programmed values of REGM, REGN, REGSD, and SELFREQDCO into DPLL registers.
3. After TENABLE is asserted, TINITZ is driven high (disabled) by the PLLCTRL to trigger a DPLL calibration and lock sequence after the loop control values are loaded. The module calibration-lock sequence will begin from the first CLKINP edge after TINITZ is disabled.

Figure 26-6 summarizes the software and hardware sequences flow of DPLL_SATA.



All thick-outlined blocks in Figure 26-6 show operations performed by software. Other blocks show operations performed by hardware.

Figure 26-6. SATA PLL GO Sequence

DPLL_SATA Relock Sequence: When DPLL leaves a lost clock condition (LOSSREF = 1 → 0) or idle-bypass mode it enters relock sequence from the first CLKINP edge (after bypass mode leaving). Relock sequence is the same as calibration-lock sequence already described.

A DPLL relock sequence is also software triggered by setting DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit to 0b1 for DPLL parameters update.

When DPLL_SATA enters a relock sequence, CLKDCOLDO is pulled low. FREQLOCK and PHASELOCK status signals are also low. CLKDCOLDO output clock is activated after FREQLOCK or PHASELOCK signal goes high, depending on the selected locking criteria.

The DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit can be used by software to monitor if PLLCTRL locking process is still pending (PLL_GO = 0b1).

26.1.4.3.6.3 SATA DPLL Locked Mode

When DPLL_SATA finishes calibration and lock sequences it enters the LOCKED state. During the LOCKED state, LOSSREF is deasserted, BYPASSACK is deasserted, and the FREQLOCK or PHASELOCK signals are asserted.

DPLL lock event criteria (FREQLOCK or PHASELOCK) is software selectable through the DPLLCTRL_SATA.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL bit field.

The DPLL indicates it is in the LOCKED state to the DPLLCTRL_SATA, SATA controller core controller, and SATA_PHY through assertion of the DPLL_LOCK signal, which reflects the internal lock loop status. The user software can monitor the DPLL locked event in the DPLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit, which is active high.

26.1.4.3.6.4 SATA DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_SATA.

DPLL_SATA supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the DPLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE bit to 0x1. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and DCO oscillator.

In idle-bypass low-power mode, the PHASELOCK and FREQLOCK output signals are asserted low and CLKDCOLDO goes low, respectively. Also, the internal reference clock REFCLK = CLKINP/N + 1 is gated inside the DPLL digital control logic to save power.

In the functional mode, DPLL_SATA.TICOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal DCO oscillator. The internal DCO oscillator is powered down in idle-bypass mode or during period from SYSRESETN 0 → 1 to module initialization. The DCO oscillator exits power down (TICOPWDN goes low) whenever the module internally tries to lock or relock after initialization or exiting idle-bypass mode.

In the functional mode, DPLL_SATA.LDOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal LDO. LDOPWDN goes high as soon as the internal LDO is powered down. LDOPWDN goes low after the LDO output voltage is stable. The internal LDO is powered down in period from SYSRESETN 0 → 1 to module initialization or when entering into idle-bypass mode. LDOPWDN is cleared whenever the module internally tries to lock or relock after initialization or exiting idle-bypass mode after the internal LDO output voltage has stabilized.

The DCO and LDO power ON/OFF states are reflected within the read-only DPLLCTRL_SATA.PLL_STATUS[16] PLL_TICOPWDN and DPLLCTRL_SATA.PLL_STATUS[15] LDOPWDN monitor bits.

To exit idle-bypass mode and restore clock generation, the user should set DPLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE to 0x0, which deasserts the IDLE signal and DPLL_SATA automatically enters a relock sequence. The CLKDCOLDO output clock is activated after the FREQLOCK or PHASELOCK signal goes high, depending on selected locking criteria.

26.1.4.3.6.5 SATA DPLL MN-Bypass Mode

The MN-Bypass mode will be activated if REGM = 0 or 1 is loaded into the module on the rising edge of TENABLE. TINITZ also should be pulsed to enter MN-Bypass mode. The module enters a low-power mode by gating all its internal clocks (REFCLK) and powering down the internal LDO (LDOPWDN = 1) and DCO (DCOPWDN = 1). CLKDCOLDO remains gated (low) during this mode.

Note

When the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field is updated to 0x0 or 0x1, the CLKDCOLDO output clock is gated.

26.1.4.3.6.6 SATA DPLL Error Conditions

The PLL lock and recalibration signals can be monitored to detect the loss of lock condition and the DPLL requirement to recalibrate (caused by a large temperature change since the last lock request):

- The DPLLCTRL_SATA.PLL_STATUS[2] PLL_RECAL bit informs whether the DPLL_SATA must be recalibrated.

The PLL reference clock (CLKINP) loss status and PLL-in-high-jitter condition can also be monitored:

- The DPLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit gives the SATA PLL LOCKED state.
- The DPLLCTRL_SATA.PLL_STATUS[3] PLL_LOSSREF bit informs whether the DPLLCTRL_SATA has lost the reference clock.
- The DPLLCTRL_SATA.PLL_STATUS[5] PLL_HIGHJITTER bit informs whether the PLL has entered a high-jitter condition.

26.1.4.3.7 SATA PLL Controller Functions

26.1.4.3.7.1 SATA PLL Controller Register Access

The configuration registers are accessed through the OCP2SCP3 L4 adapter register space using the SCP interface of the DPLLCTRL_SATA. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

Note

Because the SATA_PHY directly provides parallel data interface clocks RX_CLK and TX_CLK to the SATA controller, the DPLLCTRL_SATA and DPLL_SATA must be configured before any data transfer between the SATA controller and an external SATA storage device.

26.1.4.3.7.2 SATA DPLL Clock Programming Sequence

The DPLL_SATA factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

- The REGM factor is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- The fractional part of REGM factor is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field.
- The REGN factor is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- The DCO frequency range is set in the DPLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field.
  - PLL_SELFREQDCO should be set to 0x2, if 750 MHz < CLKDCOLDO [MHz] < 1500 MHz
  - PLL_SELFREQDCO should be set to 0x4, if 1250 MHz < CLKDCOLDO [MHz] < 2500 MHz
- The SD divider is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD bit field. The DPLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field should be programmed depending on the value of CLKDCOLDO = CLKINP × M/(N + 1). The formulas are shown in Figure 26-7.

Figure 26-7 shows the programming sequence.

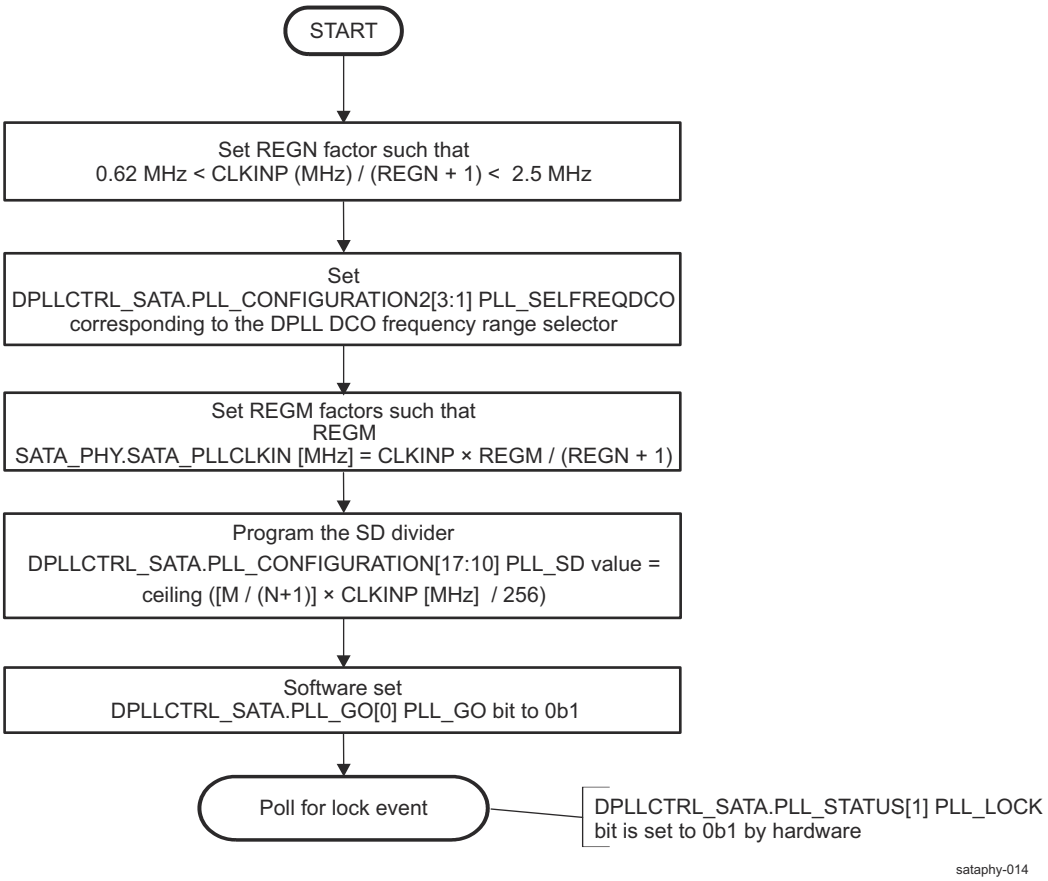


Figure 26-7. SATA PLL Programming Sequence

Note

- The equation for SATA_PHY_TX/SATA_PHY_RX (MHz) applies to the CLKDCOLDO of the DPLL_SATA.
- For normal operation CLKDCOLDO output frequency of the DPLL_SATA should be either 750 MHz (SATA-1 mode) or 1500 MHz (SATA-2 mode).

Table 26-5 summarizes the registers for the DPLLCTRL_SATA programming sequence.

Table 26-5. Register Call Summary for SATA PLL Programming Sequence

Register Name	Register Name	Register Name	Register Name
DPLLCTRL_SATA.PLL_CONFIGURATION2	DPLLCTRL_SATA.PLL_GO	DPLLCTRL_SATA.PLL_STATUS	DPLLCTRL_SATA.PLL_CONFIGURATION3

26.1.4.3.7.3 SATA DPLL Recommended Values

Table 26-6 lists the DPLL_SATA recommended values.

Table 26-6. Recommended Programming Values

Field Name	Value	Description
DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM	See (1).	Feedback clock divider
DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN	See (1).	Reference clock divider
DPLLCTRL_SATA.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL	0x-	Criteria to lock the PLL
DPLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO	See (1).	Program based on the PLL choice and lock frequency.
DPLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE	0	PLL active
DPLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD	See (1).	Ceiling { [PLL_REGM/(PLL_REGN + 1)] × CLKINP(MHz)/256 }
DPLLCTRL_SATA.PLL_GO[0] PLL_GO	0x1	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.

(1) The value of the bit field must be set according to the desired clock frequencies – 750 MHz for SATA-1 and 1.5 GHz for SATA-2 speeds.

26.1.5 SATA PHY Subsystem Low-Level Programming Model

Note

SATA is not supported on the AM570x family of devices.

Table 26-7 summarizes the low-level programming sequence to set up the SATA PHY subsystem for SATA I/O operations.

Table 26-7. SATA PHY Subsystem Low-Level Programming Sequence

Step	Description	Comment
1.	Set the startup low-performance OPP in the appropriate PRCM registers.	For more information regarding demanded OPP, see the device *Data Manual*.
2.	Enable the PRCM.SATA_REF_GFCLK.	See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
3.	Enable the PRCM.L3INIT_L4_GICLK clock to enable the OCP2SCP3 interface adapter operation.	See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
4.	Software reset the OCP2SCP3 and poll until soft reset completion is indicated in status.	See Section 26.1.4.1.
5.	Set up division ratio between the OCP clock (PRCM.L3INIT_L4_GICLK) and SCP clock to supply the serial configuration register domains of the DPLLCTRL_SATA.	See Section 26.1.4.1.
6.	Set up necessary SYNC1 and SYNC2 timings to ensure no blocking of transactions over the SCP bus.	. See Section 26.1.4.1.After this step user is ready to access DPLLCTRL_SATA .
7.	Configure DPLL_SATA to generate frequency (CLKDCOLDO) = 1.5 GHz.	See Section 26.1.4.3.7.2 and Table 26-8.
8.	Soft assert bit DPLLCTRL_SATA.PLL_GO[0] PLL_GO to 0x1.	Start the DPLL lock with desired parameters.
9.	Poll DPLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit until it is seen 1.	DPLL locked event
10.	Perform a SATA_PHY tuning required for SATA i/f operation	Follow steps described in Table 26-9, *SATA PHY Tuning Table*.
11.	Software trigger the SATA_PHY_TX power-up sequence.	For more details, see Section 26.1.4.2.3.1, *SATA_PHY Power-Up/-Down Sequences*.
12.	Software trigger the SATA_PHY_RX power-up sequence.	For more details, see Section 26.1.4.2.3.1, *SATA_PHY Power-Up/-Down Sequences*.

Table 26-8. DPLL CLKDCOLDO Recommended Settings

Parameter	Setting				
F(CLKDCOLDO) MHz	1500				
SYS_CLK (MHz)	12	16.8	19.2	26	38.4
N	4	6	7	12	15
SELFREQDCO[2:0]	100	100	100	100	100
M	625	625	625	750	625
Frac	0	0	0	0	0
SD	6	7	6	6	6

Table 26-9. SATA PHY Tuning Table

Physical address[2] [bits to modify]	Preferred value setting[1]
0x4A09 600C [31:27]	0b01000 for SATA 1.5 Gbps mode 0b00100 for SATA 3 Gbps mode
0x4A09 600C [17:14]	0b1010 for SATA-Gen1x and SATA-Gen2x[3] 0b0101 for SATA-Gen1m and SATA-Gen2m

Table 26-9. SATA PHY Tuning Table (continued)

Physical address[2] [bits to modify]	Preferred value setting[1]
0x4A09 6028 [23:19]	0b11100 if spread-spectrum is ON 0b00001 if spread-spectrum is OFF
0x4A09 6028 [18:11]	0b01100110 (regardless of spread-spectrum being ON or OFF)
0x4A09 600C [6:5]	0b00
0x4A09 601C [31:30]	0b01
0x4A09 6024 [31:30]	0b10
0x4A09 6038 [31:16]	0x0000
0x4A09 6038 [15:7]	0b111110000
0x4A09 6038 [2:1]	0b11
0x4A09 6044 [10:9]	0b00

(1) These are the preferred settings of SATA_PHY, in case that SATA PHY PLL_CLK=1.5 GHz.
(2) Accesses to these locations have to be done in 32-bits only. User must NOT modify SATA PHY bits different than those described in Table 26-9.
(3) For SATA Genx and Genm description, please refer to *Serial ATA II Electrical Specification 1.0*.

26.2 USB3_PHY Subsystem

This chapter describes the features and functions of the USB3_PHY subsystem of the device.

26.2.1 USB3_PHY Subsystem Overview

The USB3.0 physical layer (PHY) is responsible for transmitting the USB1 controller media access layer (MAC) 32-bit parallel data output as a serial data stream over a differential pair (TXP/TXN) and converting the differentially received serial data (RXP/RXN) to 32-bit parallel input data demanded by the MAC receiver logic.

The USB3_PHY component operates with a 2.5 GHz-source clock, to achieve the USB 3.0 super-speed throughput of 5 Gbps. The USB3_PHY serializer/deserializer source clock is generated by a DPLL clock generator (DPLL_USB_OTG_SS) which isintegrated into the USB1 host subsystem.

The DPLL_USB_OTG_SS is configured and controlled through the USB3_PHY dedicated PLL controller (DPLLCTRL_USB_OTG_SS) with associated serial configuration port (SCP) accessible registers.

A common interconnect adapter component, OCP2SCP1, lets the user program the USB3_PHY serializer/deserializer and DPLLCTRL_USB_OTG_SS through the L4_CFG interconnect.

Figure 26-8 gives an overview of the USB3_PHY subsystem. Figure 26-8 shows that the USB3_PHY serializer and deserializer directly interract with the attached to USB OTG SS controller USB3.0 compatible device (over TXP/TXN transmission and RXP/RXN reception interface I/Os). The PIPE port interracts with the USB1 MAC port, described in details in Section 24.7, *SuperSpeed USB DRD*.

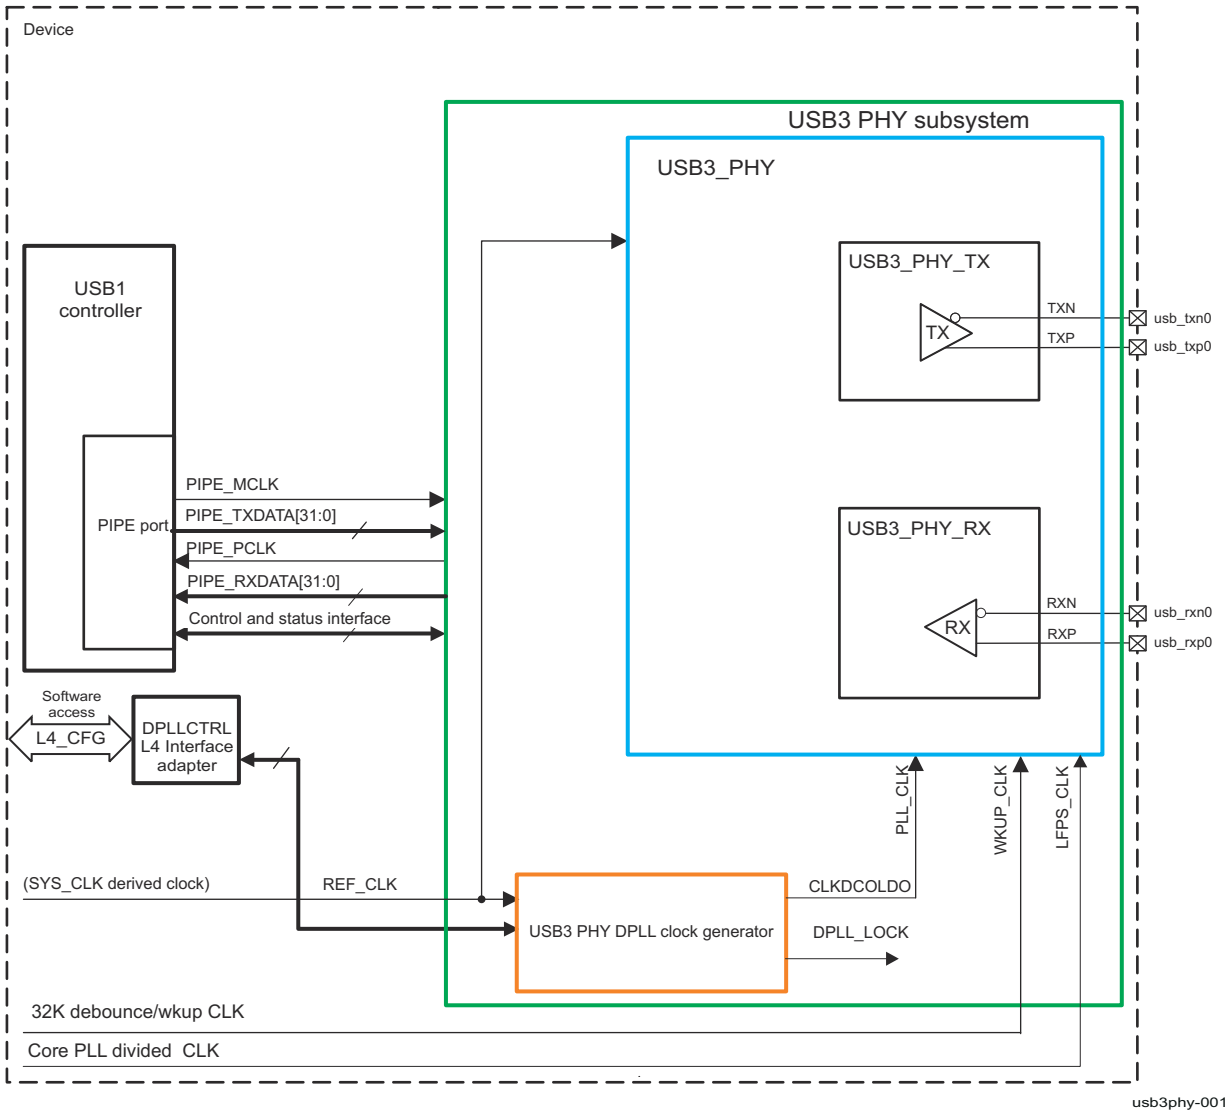

Figure 26-8. USB3_PHY Subsystem Overview

26.2.2 USB3_PHY Subsystem Environment

26.2.2.1 USB3_PHY I/O Signals

Table 26-10 represents module pins and their corresponding signal names at the device level, and also specifies their links to functions.

Table 26-10. USB3_PHY I/O Signals

Module Pin Name	Device-Level Signal Name	I/O(1)	Description	Module Pin Reset Value(2)
TXP	usb_txp0	O	TX output of the USB3_PHY differential transmission line	0
TXN	usb_txn0	O	TY output of the USB3_PHY differential transmission line	0
RXP	usb_rxp0	I	RX input of the USB3_PHY differential reception line	HiZ
RXN	usb_rxn0	I	RY input of the USB3_PHY differential reception line	HiZ

(1) I = Input; O = Output
(2) HiZ = High impedance

Figure 26-9 shows module pin signals mapping to USB3_PHY signals visible at the device pad level.

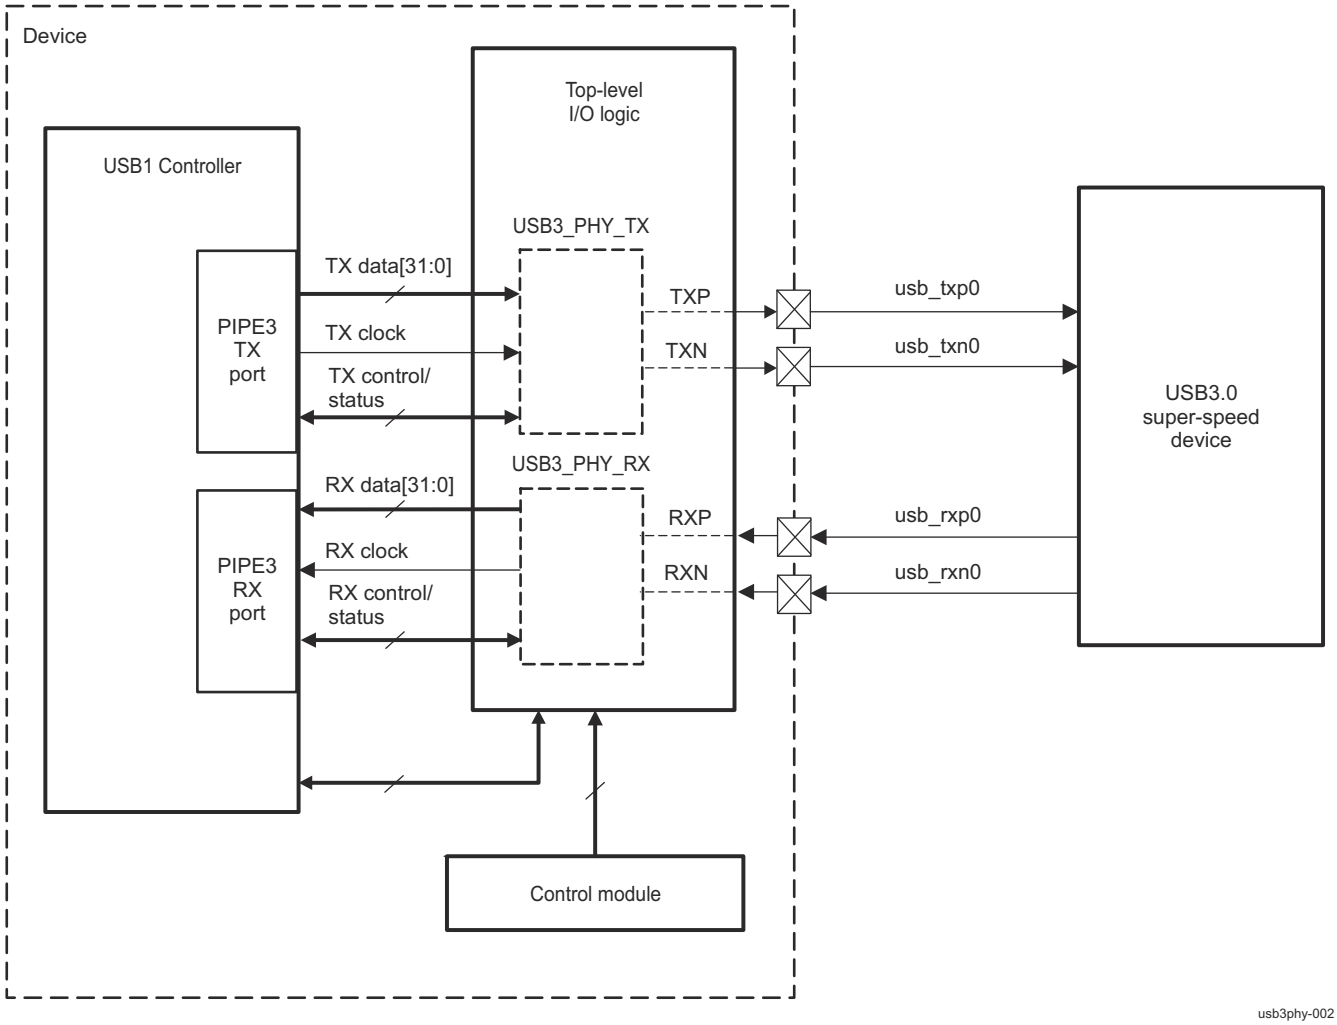

Figure 26-9. USB3_PHY I/O Signals

26.2.3 USB3_PHY Subsystem Integration

This section describes the USB3_PHY subsystem-related components (USB3_PHY module, DPLL_USB_OTG_SS, DPLLCTRL_USB_OTG_SS, and OCP2SPC1) integration in the device, including information about clocks, resets, and hardware requests.

Figure 26-10 shows the USB3_PHY integration.

The USB3_PHY module integration features:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SPC1) Interconnect adapter target interface
- A high-frequency input clock (PLL_CLK) tied to the DPLL_USB_OTG_SS.CLKDCOLDO output
- A local port connected to the USB1 MAC PIPE3 port
- A clock output (PIPE_PCLK) to the USB1 PIPE port
- A clock output (PIPE_MCLK) from the USB1 PIPE port
- A common clock from PRCM - REF_CLK, to supply DPLL and PHY RX/TX logic
- PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK clock tied to the USB3_PHY_TX
- A device CORE CONTROL MODULE command port to the power sequencer

The DPLL_USB_OTG_SS integration features:

- A low-power nonretention reset, L3INIT_RST
- A PRCM gated version of the device SYS_CLK (USB_OTG_SS_REF_CLK) supplying DPLL_USB_OTG_SS.CLKINP pin
- A single high-frequency clock output, DPLL_USB_OTG_SS.CLKDCOLDO, to the PLL_CLK input of the USB3_PHY_TX/RX components.
- No HS divider integration
- IDLE signaling implementation
- LDO and DCO PWRDNZ monitoring signals
- A DPLL_LOCK LOCKED status indication

The DPLLCTRL_USB_OTG_SS integration features:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SPC1) Interconnect adapter target interface also providing the input SCP clock to the DPLLCTRL_USB_OTG_SS
- Configuration/control programming interface to the DPLL_USB_OTG_SS
- No direct gate control for DPLL_USB_OTG_SS.CLKINP and CLKDCOLDO

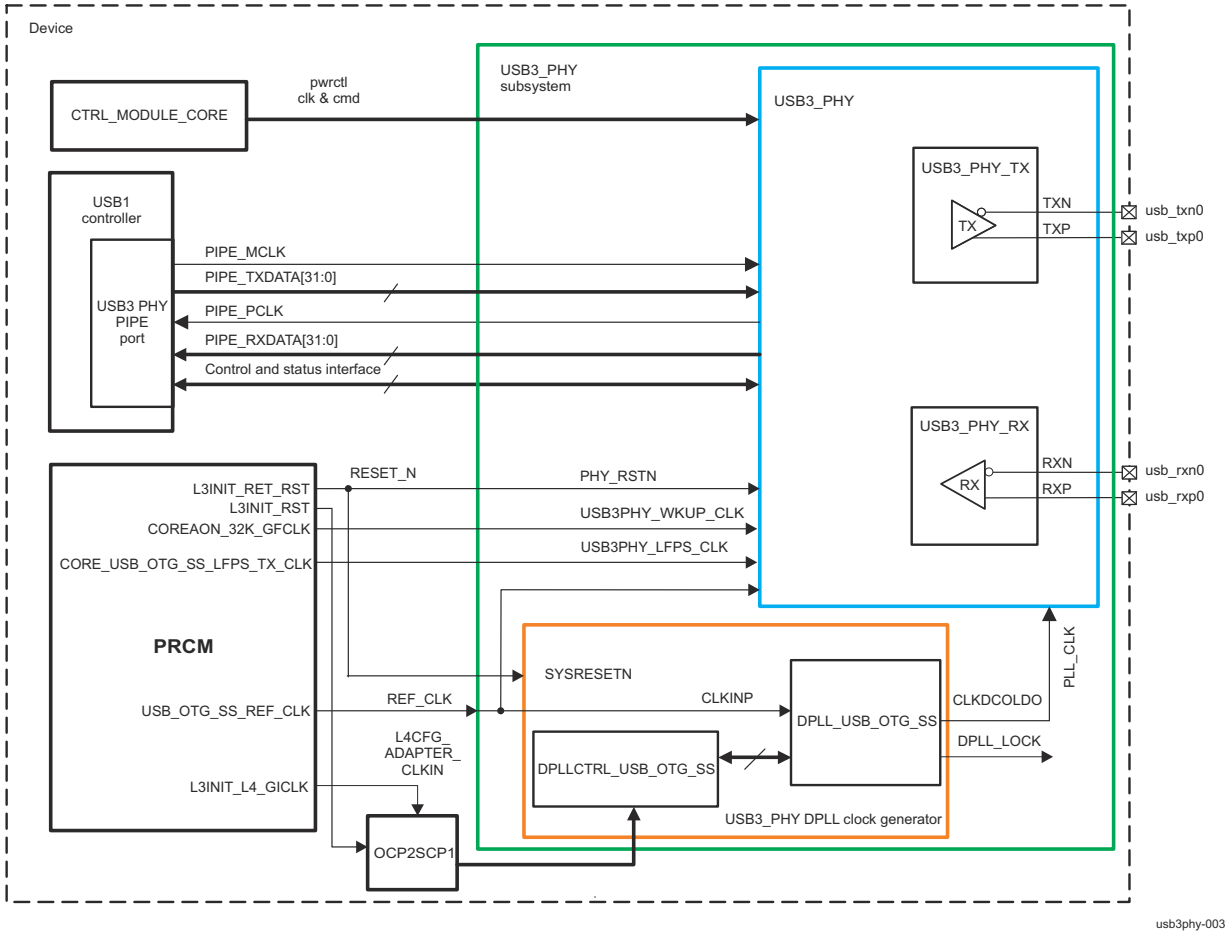

Figure 26-10. USB3_PHY Subsystem Integration

Table 26-11 through Table 26-13 summarize the integration of the module in the device.

Table 26-11. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
USB3_PHY_TX	PD_L3INIT	OCP2SCP1 SCP interconnects
USB3_PHY_RX		OCP2SCP1 SCP interconnects
USB3_PHY (wrapper)		CTRL_CORE_MODULE power control
DPLLCTRL_USB_OTG_SS		OCP2SCP1 adapter SCP interconnect
DPLL_USB_OTG_SS	PD_COREAON	
OCP2SCP1		L4_CFG

Table 26-12. Clocks

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
USB3_PHY subsystem	RESET_N	L3INIT_RST	PRCM	A nonretention reset to all USB3_PHY subsystem components

Note

The USB3_PHY_RX generates a hardware wakeup request to the PRCM module.

26.2.4 USB3_PHY Subsystem Functional Description

26.2.4.1 Super-Speed USB PLL Controller L4 Interface Adapter Functional Description

The L4_CFG interconnect adapter (OCP2SCP1), allows user software to configure the DPLLCTRL_USB_OTG_SS registers over the L4_CFG port. Hence it is expected that this adapter is configured to operate before any programming of the DPLLCTRL_USB_OTG_SS.

Before initiating any software reset to this adapter, a value >= 0x6 should be written to the register bitfield OCP2SCP_TIMING[3:0] SYNC2.

L4_CFG interconnect adapter software reset is performed via writing OCP2SCP_SYSCONFIG[1] SOFTRESET to 0b1. The software reset completion is observed in bit OCP2SCP_SYSSTATUS[0] RESETDONE.

By default a smart-idle power mode is selected for OCP2SCP1. The smart-idle mode supported by OCP2SCP1 is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP1 by setting the OCP2SCP_SYSCONFIG [4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

By default OCP2SCP_SYSCONFIG[0] AUTOIDLE =0x1, which defines that the DPLLCTRL L4 interface adapter automaticaly gates its L4 input clock based on L4_CFG interconnect activity. To enable a free-running clock, one should set bit AUTOIDLE to 0x0.

26.2.4.2 USB3_PHY Serializer and Deserializer Functional Descriptions

26.2.4.2.1 USB3_PHY Module Resets

26.2.4.2.1.1 Hardware Reset

The USB3_PHY active low reset which is sourced from PRCM module. L3INIT_RST is hardware-asserted upon power up. For more information on the hardware reset source , see *Reset Domains*, in *Power, Reset, and Clock Management*.

26.2.4.2.1.2 Software Reset

The USB3_PHY PIPE i/f logic is software reset from USB1 over PIPE port by software assertion of the USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST bit to 0x1. The user must set USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x1 before triggering the serializer and deserializer power-up sequence in the CTRL_CORE_PHY_POWER_USB register. For more information on power-up sequence, see Section 26.2.4.2.3.1, *USB3_PHY Power-Up/Down Sequences*.

The user should deassert USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x0, after the serializer and deserializer power-up sequence completes. For more information, see Section 26.2.4.2.3.1, *USB3_PHY Power-Up/Down Sequences*.

26.2.4.2.2 USB3_PHY Subsystem Clocking

26.2.4.2.2.1 USB3_PHY Subsystem Input Clocks

The USB3_PHY component receives a feedback clock, PIPE_MCLK, which is the reflected version of the PIPE_PCLK (PIPE port synchronizing clock) generated by the USB3_PHY component. The clock is turned on/off according to the PIPE power-down port states. As PIPE port works in source-synchronous mode, all data movement from the MAC layer to the PIPE interface is synchronous to PIPE_PCLK.

The USB3_PHY.PLL_CLK high-speed transmission (2.5 GHz) clock input pin is connected to the DPLL_USB_OTG_SS clock output, CLKDCOLDO. For more information on the DPLL_USB_OTG_SS.CLKDCOLDO output clock settings, see Section 26.2.4.3.4.2, *USB3_PHY DPLL Output Clock Configuration*.

As shown in Figure 26-11, the same PRCM-sourced clock (USB_OTG_SS_REF_CLK), tied at the USB3_PHY subsystem REF_CLK input, supplies the USB3_PHY RX/TX components and the DPLL_USB_OTG_SS.CLKINP inputs.

The PHY associated power sequencer receives PRCM.USB_OTG_SS_REF_CLK as a functional clock . Software must notify the PHY logic about which REF_CLK frequency is selected by writing the CTRL_CORE_PHY_POWER_USB[31:22] USB_PWRCTL_CLK_FREQ bit field, as follows:

- 0x26: If SYSCLK = 38.4 MHz
- 0x1A: If SYSCLK = 26.0 MHz
- 0x13: If SYSCLK = 19.2 MHz
- 0x10: If SYSCLK = 16.8 MHz
- 0x0C: If SYSCLK = 12.0 MHz

The USB3PHY_LFPS_CLK clock input is used to support different USB3_PHY functions, such as the low-frequency periodic signaling (LFPS) generator. This USB3_PHY_TX clock input is tied to the PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK functional clock.

The USB3_PHY_RX deserializer I/O wake-up logic is supported by the PRCM.COREAON_32K_GFCLK clock, applied at the USB3PHY_WKUP_CLK input.

26.2.4.2.2.2 USB3_PHY Subsystem Output Clocks

- PIPE_PCLK: The PIPE interface is source-synchronous. A PIPE_PCLK clock is generated by the USB3_PHY component, used to synchronize USB1 PIPE port inputs, and reflected back as the PIPE_MCLK along with the PIPE outputs. The clock is turned on/off according to the power control port. All data movement from the PIPE interface to the USB1 MAC layer is synchronous to this clock.

The PIPE_PCLK clock which drives the PIPE3 logic is sourced by the on-chip USB3_PHY. The PIPE interface is source-synchronous (that is, the clock is received from the PHY), used to synchronize USB1 PIPE inputs, and reflected back along with the PIPE outputs as the PIPE_MCLK. The PIPE_PCLK clock is turned on/off according to the USB3_PHY power control port. For more details, see Section 26.2.4.2.3, *USB3_PHY Power Management*.

26.2.4.2.3 USB3_PHY Power Management

From one side the control over power up/down states of the USB3_PHY is provided through a power sequencer module tightly integrated with the the USB3_PHY physical layer TX/RX components.

26.2.4.2.3.1 USB3_PHY Power-Up/-Down Sequences

Powering-up/-down the USB3_PHY_TX and USB3_PHY_RX modules is triggered through software writing corresponding power-up/down commands in the CTRL_CORE_PHY_POWER_USB register of the device core control module, as follows:

- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x0 (default value) commands both USB3_PHY_TX and USB3_PHY_RX to power-down (OFF) state.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x1 powers up the USB3_PHY_RX only.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x2 powers up the USB3_PHY_TX only.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x3 simultaneously powers up the USB3_PHY_RX and the USB3_PHY_TX

For more information, see *Control Module*.

26.2.4.2.3.2 USB3_PHY Low-Power Modes

An implemented powerdown control port allows USB3_PHY to support four low-power states:

- 0b00: P0, normal operation (used for all Polling, Configuration, Recovery, Loopback, and Hot_Reset states, and U0 state),
- 0b01: P1, low recovery time latency, power saving state (used for U1 state)
- 0b10: P2, longer recovery time latency, lower power state (used for U2, Rx.Detect and SS.Inactive states)
- 0b11: P2, lowest power state (used for SS.disabled and U3)

The USB3_PHY transitions from P0-active mode to low-power P1, or either of the two P2 states, is synchronized with USB1 transitions from U0 active state to U1, U2, and U3 low-power states through the input PIPE_POWERDOWN[1:0]. The PIPE port low-power behavior is configured from various bit fields inside

the USB1.USB_GUSB3PIPECTL register. For more information on PIPE port low-power (LP) configuration, see *USB Register Description* in Section 24.7, *SuperSpeed USB DRD*.

26.2.4.2.3.3 Clock Gating

The USB3_PHY component high-speed clocks, PLL_CLK and PIPE_PCLK, are gated during the P1 low-power state.

26.2.4.2.4 USB3_PHY Hardware Requests

An asynchronous wake-up request is generated to the PRCM module by the USB3_PHY_RX I/Os (RXP, RXN). When the wake-up request is acknowledged, the DPLL_USB_OTG_SS and PIPE_PCLK are restarted.

Neither interrupt nor DMA requests are generated.

26.2.4.3 USB3_PHY Clock Generator Subsystem Functional Description

The DPLL_USB_OTG_SS, which is located outside the PRCM boundaries and is part of the USB1 controller subsystem, directly injects a high-speed clock into the USB3_PHY serializer/deserializer input, PLL_CLK. The DPLL generator is controlled through a programmable interface from a dedicated PLL controller, DPLLCTRL_USB_OTG_SS.

26.2.4.3.1 USB3_PHY DPLL Clock Generator Overview

The SCP interface of the USB3_PHY PLL controller (DPLLCTRL_USB_OTG_SS instance) is used to set the configuration of the DPLL modules, primarily the various counter values. Figure 26-11 is an overview of the DPLL clock generator embedded into the USB1 controller subsystem.

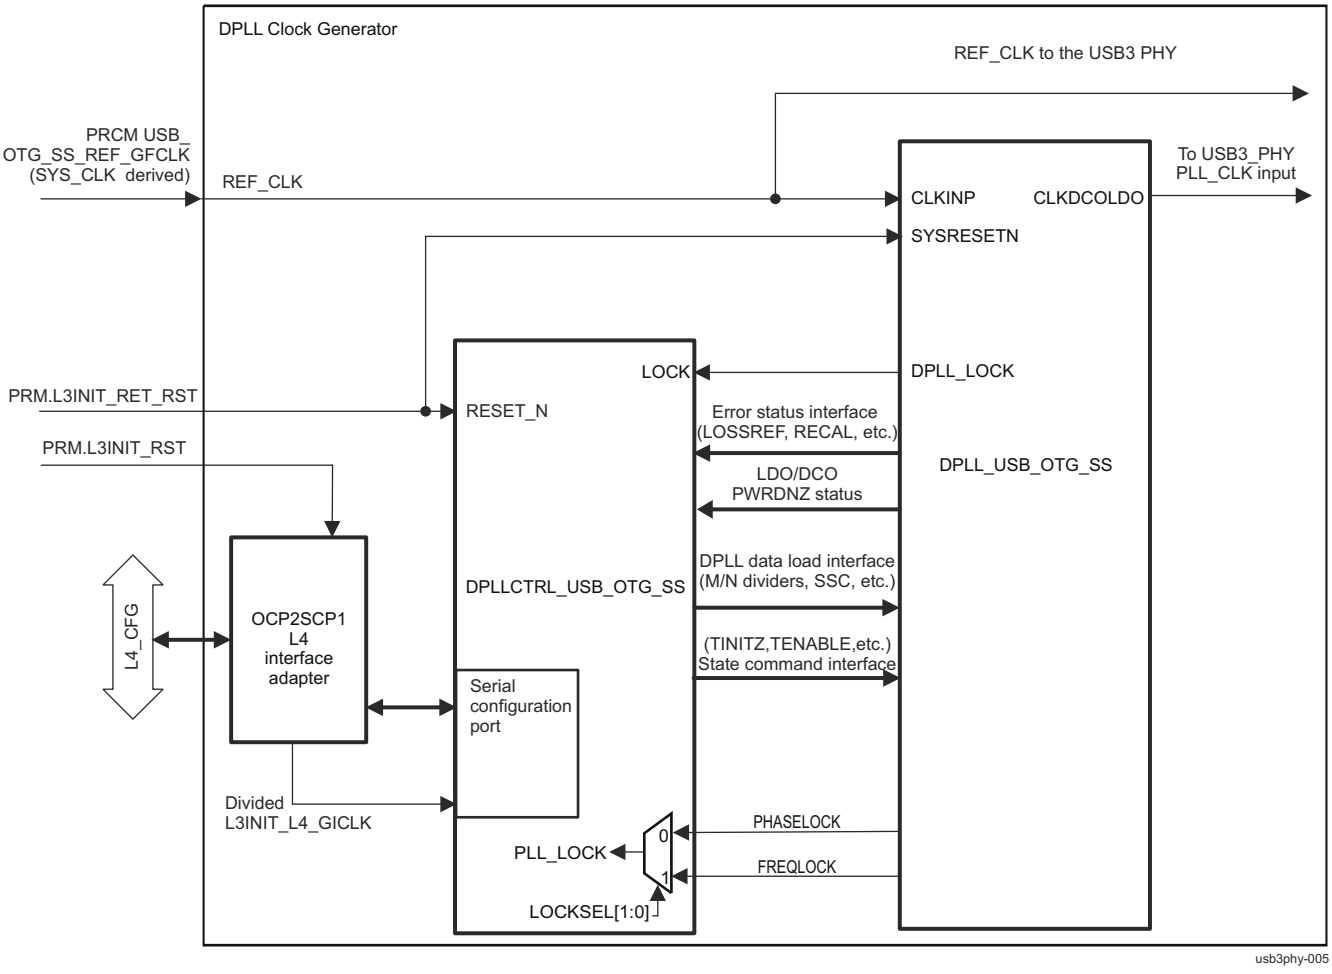

Figure 26-11. USB3_PHY DPLL Clock Generator Overview

The DPLL_USB_OTG_SS features:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Digital control and loop filter
- Internal oscillator output clock on internal LDO domain (CLKDCOLDO output)
- DPLL output clock SSC (spread spectrum clocking) support
- No retention capabilities
- No Idle-bypass fast relock capabilities
- Idle-bypass low-power mode
- M/N bypass mode
- Relock from standby

The DPLLCTRL_USB_OTG_SS components features:

- DPLL error and status notification
- DPLL initialization and configuration
- DPLL lock criteria selectable between frequency and phase lock
- Idle command implementation
- No software reset implementation
- Automatic enable/disable control, synchronized with USB1 controller PIPE port commands to set USB3_PHY to P1, P2, and P3 low-power states

26.2.4.3.2 USB3_PHY DPLL Clock Generator Reset

The USB3_PHY PLL controller and USB3_PHY DPLL clock generator share a common hardware nonretention reset, L3INIT_RST, which comes from the device power and reset manager. Upon DPLL_USB_OTG_SS hardware reset completion, the DPLLCTRL_USB_OTG_SS.PLL_STATUS[0] PLLCTRL_RESET_DONE bit is automatically updated to 1. For more information on the hardware reset source, see *Reset Domains* in *Power, Reset, and Clock Management*.

The DPLLCTRL_USB_OTG_SS itself has no software reset capabilities.

DPLLCTRL_USB_OTG_SS performs a software reset sequence on the DPLL_USB_OTG_SS in hardware (through the TINITZ signal activation).

26.2.4.3.3 USB3_PHY DPLL Low-Power Modes

The power-management port (PMP) is not integrated for DPLLCTRL_USB_OTG_SS. The DPLL_USB_OTG_SS has no retention capabilities. This means, the DPLL digital power supply remains switched on during all modes of operation.

The low-power modes supported by DPLL_USB_OTG_SS are Idle-bypass low-power and MN-bypass modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKDCOLDO output pulled low

For more details on the PLL settings and conditions necessary to enter Idle-bypass and MN-bypass low-power modes, see Section 26.2.4.3.6.4, *USB3_PHY DPLL Idle-bypass low-power Mode* , and Section 26.2.4.3.6.5, *USB3_PHY DPLL MN-Bypass Mode*.

DPLL_USB_OTG_SS is held in a similar low-power state (DCO and LDO switched off, with CLKDCOLDO = 0) after Power-up Reset, before first PLL_GO command has been software triggered on the PLL controller. See Section 26.2.4.3.6.1, *USB3_PHY Clock Generator Power Up*.

26.2.4.3.4 USB3_PHY DPLL Clocks Configuration

26.2.4.3.4.1 USB3_PHY DPLL Input Clock Control

The DPLL_USB_OTG_SS accepts the functional clock, USB_OTG_SS_REF_CLK, on its CLKINP pin (REF_CLK input at USB3_PHY subsystem level) directly from the device PRCM, without involving any DPLLCTRL_USB_OTG_SS interactions. The USB_OTG_SS_REF_CLK is derived from SYS_CLK1. See *Clock Domain Module Attributes* in *Power, Reset, and Clock Management*.

If the CLKINP signal is lost for some time, the LOSSREF output signal, which serves as a feedback to DPLLCTRL_USB_OTG_SS, is asserted high. When CLKINP resumes, LOSSREF goes low (LOSSREF inactive state). The LOSSREF status signal can be software-monitored in the DPLLCTRL_USB_OTG_SS.PLL_STATUS[3] PLL_LOSSREF bit.

Note

DPLLCTRL_USB_OTG_SS has no software or hardware mechanisms to control DPLL_USB_OTG_SS input clock (CLKINP).

26.2.4.3.4.2 USB3_PHY DPLL Output Clock Configuration

Only the DPLL_USB_OTG_SS output, CLKDCOLDO, is used to provide the high-speed clock at the PLL_CLK pin of the USB3_PHY. Only the REGM, REGN, and SD divider values are used within the DPLL clock generator subsystem to adjust the CLKDCOLDO output clock frequency. This is done through programming the DPLLCTRL_USB_OTG_SS.DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9], PLL_REGM, DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1], PLL_REGN, and DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD bit fields, respectively. The USB3_PHY DPLL CLKOUT and CLKOUTLDO outputs are not used, and internal REGM2 and REGM1 dividers are not software controllable.

Note

At DPLL/DPLLCTRL integration level the PLL_REGM1[3:0] and PLL_REGM2[6:0] divider control signals are hardware tie-off to 0x0 and 0x1, respectively.

For more details on output clock settings sequence, see Section 26.2.4.3.7.3, *USB3_PHY DPLL Clock Programming Sequence*.

26.2.4.3.4.2.1 USB3_PHY DPLL Output Clock Gating

There is no direct software gate control for the DPLL_USB_OTG_SS.CLKDCOLDO output.

DPLL_USB_OTG_SS.CLKDCOLDO clock output is automatically gated (CLKDCOLDO pulled low) in the following scenarios:

- DPLL power-up sequence. For more information on power-up sequence, see Section 26.2.4.3.6.1, *USB3_PHY Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on relocking sequence, see Section 26.2.4.3.6.2, *USB3_PHY DPLL Sequences*.
- DPLL entering Idle-bypass low-power mode. For more information on idle-bypass mode, see Section 26.2.4.3.6.4, *USB3_PHY DPLL Idle-Bypass Mode*.
- DPLL entering MN-bypass mode. For more information on MN-bypass mode, see Section 26.2.4.3.6.5, *USB3_PHY DPLL MN-Bypass Mode*.

26.2.4.3.5 USB3_PHY DPLL Subsystem Architecture

Figure 26-12 is a simplified block diagram of the DPLL_USB_OTG_SS instance integration in the USB3_PHY clock generator subsystem.

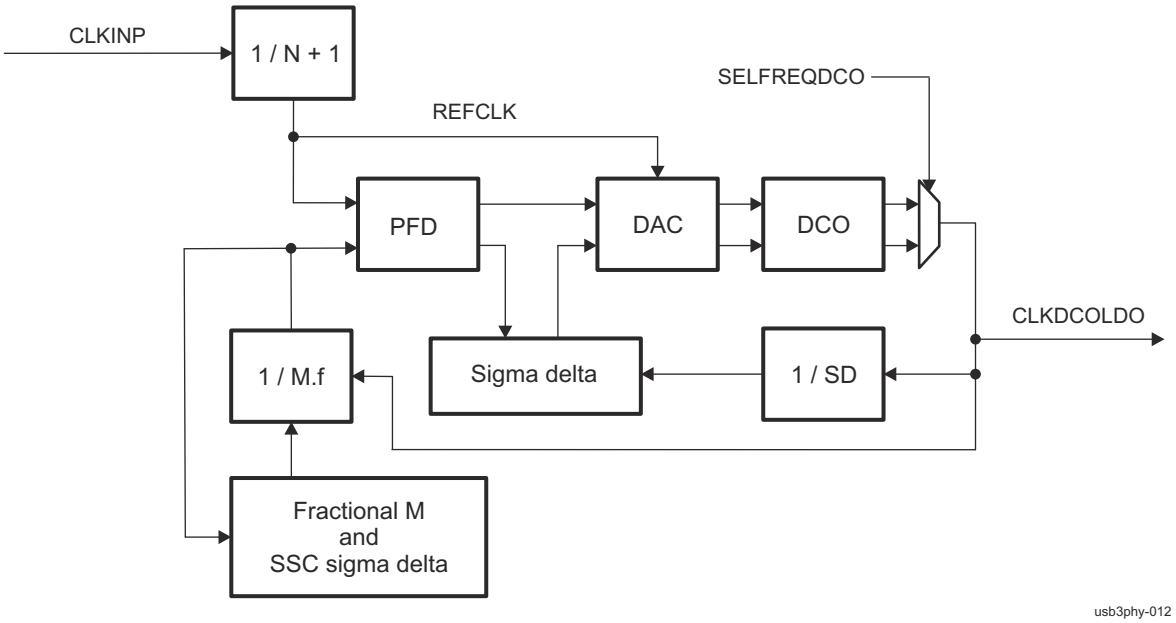

Figure 26-12. DPLL_USB_OTG_SS Functional Block Diagram

The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

The frequency ranges for the DPLL_USB_OTG_SS input clock - CLKINP and the DPLL internal reference clock, REFCLK = CLKINP/N + 1 are:

- 0.62 to 60 MHz for CLKINP
- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKDCOLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP×M/(N + 1). For that purpose the feedback multiplier M must be configured through the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL_USB_OTG_SS module supports fractional synthesis (that is, the frequency multiplication factor M can be programmed as fractional). This is achieved by having a sigma delta feedback divider (M). A fractional value (Fractional M) of 18 bits is supported, thus enabling control for a better accuracy. Programming the 18-bit Fractional M value is done by setting the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field (similar to REGM). To enable integer only division, Fractional M should be set to 000…0.

Note

Fractional synthesis is not supported for M > 4093.

The module also supports SSC on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce any electromagnetic interference (EMI). When SSC is enabled, the clock spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread (df) and the modulation frequency (fm); that is, {10×log10(df/fm)} dB.

The SSC is performed by changing the feedback divider (M) in a triangular pattern, which means the frequency of the output clock varies in a triangular pattern. The frequency of the triangular pattern is modulation frequency (fm). The peak (dM) or the amplitude of the triangular pattern as a percent of M is equal to the percent of the frequency spread (df); that is, $dM/M = df/F_{OUT}$.

Because this is in-band modulation for the DPLL_USB_OTG_SS, the modulation frequency must be within the loop bandwidth of the DPLL. A higher modulation frequency would result in less spreading in the output clock.

The SSC can be enabled and disabled by asserting the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION1[0] EN_SSC bit. The acknowledge signal SSCACK, observed by the DPLLCTRL_USB_OTG_SS.PLL_STATUS[12] SSC_EN_ACK bit, notifies the exact start and end of SSC. When EN_SSC is deasserted, SSC is disabled only after completion of one full cycle of the triangular pattern given by the modulation frequency. This is done to maintain the average frequency.

The modulation frequency (fm) can be programmed as a ratio of REFCLK/4; that is, the value programmed in the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field must be = REFCLK/(4×fm).The ModFreqDivider is split into Mantissa and 2^{Exponent} (ModFreqDivider = ModFreqDividerMantissa × $2^{\text{ModFreqDividerExponent}}$).

- The Mantissa is controlled by bits [29:23] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.
- The Exponent is controlled by bits [22:20] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.

Although the same value of ModFreqDivider could be obtained by different combinations of Mantissa and Exponent values, it is preferred to get the target ModFreqDivider by programming maximum Mantissa and minimum Exponent values.

To define the frequency spread (df), dM must be controlled as previously explained. To define dM, the step size of M for each REFCLK during the triangular pattern must be programmed.This is defined as follows:

- dM =($2^{\text{ModFreqDividerExponent}}$) × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent <= 3
- dM = 8 × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent > 3

DeltaMStep value is split into integer part and fractional part, as follows:

- The MSB of 3-bit integer part, DeltaMStepInteger, is controlled by the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[30] DELTAM2 bit and the remaining LSBs by bits [19:18] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.
- The 18-bit fractional part, DeltaMStepFraction, is controlled by bits [17:0] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.

If the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION1[2] DOWNSPREAD bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0 (except for 20 percent overshot).

26.2.4.3.6 USB3_PHY DPLL Clock Generator Modes and State Transitions

The DPLL_USB_OTG_SS can be set in different modes during operation. DPLLCTRL triggers DPLL_USB_OTG_SS state transitions to different static modes by means of the TINITZ and TENABLE hardware control signals.

26.2.4.3.6.1 USB3_PHY Clock Generator Power Up

After power up, the DPLL_USB_OTG_SS.SYSRESETN input is automatically pulled low by the PRM, together with the DPLLCTRL_USB_OTG_SS.RESET_N input. Because PRM.L3INIT_RST is an asynchronous reset, the DPLL_USB_OTG_SS input clock (DPLL_USB_OTG_SS.CLKINP) is not demanded upon reset. The LOSSREF signal, which monitors the presence of CLKINP clock, remains 1 during SYSRESETN = 0 irrespective of presence/absence of the CLKINP clock. If CLKINP is present when reset is asserted, the LOSSREF signal is deasserted to 0, a certain time after the hardware reset completes. During DPLL power-up mode, CLKDCOLDO clock is maintained inactive (pulled low). After power-up reset, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too.

26.2.4.3.6.2 USB3_PHY DPLL Sequences

Once all the configuration values have been initially programmed into the DPLLCTRL_USB_OTG_SS registers (see Section 26.2.4.3.7.3) , the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit should be set to update the configuration values and start the DPLL calibration and locking sequence.

After the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit is set high in software, the DPLLCTRL_USB_OTG_SS state-machine takes the following action:

1. Sets the TINITZ signal to 0, which acts as a soft reset to DPLL_USB_OTG_SS. This starts the DPLL initialization procedure. During initialization mode, the CLKDCOLDO, FREQLOCK, and PHASELOCK signals are kept at 0 and the BYPASSACK signal is kept at 1.
   VDDA power supply of DPLL should be active before DPLL_USB_OTG_SS Initialization is performed, but it is not required to be switched on immediately after device power up.
2. The TENABLE signal is asserted high by DPLLCTRL hardware to load the user-programmed values of REGM, REGN, REGSD, and SELFREQDCO into DPLL registers.
3. After TENABLE is asserted, TINITZ is driven high (disabled) by the DPLLCTRL to trigger a DPLL calibration and lock sequence after the loop control values are loaded. The module calibration-lock sequence will begin from the first CLKINP edge after TINITZ is disabled.

Figure 26-13 summarizes the software and hardware sequences flow of DPLL_USB_OTG_SS.

Note

All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

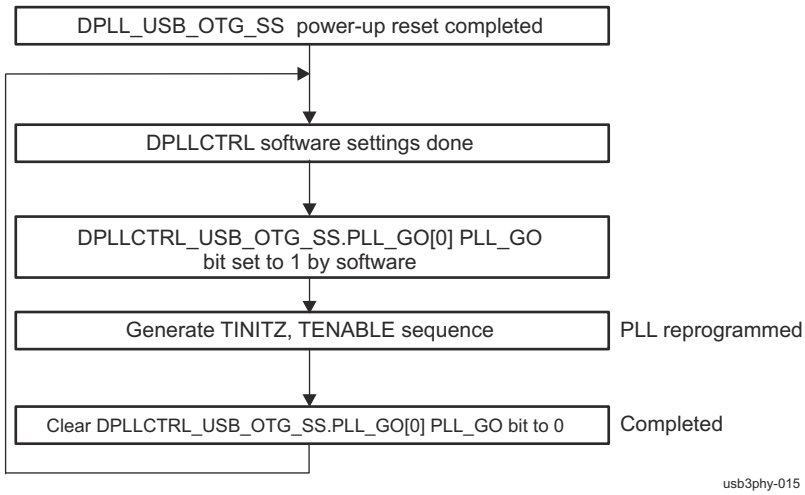

Figure 26-13. USB3_PHY PLL GO Sequence

DPLL_USB_OTG_SS relock sequence:

When the DPLL leaves a lost clock condition (LOSSREF = 1 → 0) or idle-bypass mode it enters relock sequence from the first CLKINP edge (after bypass mode leaving). Relock sequence is the same as calibration-lock sequence already described.

A DPLL relock sequence is also software triggered by setting the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit to 0b1 for DPLL parameters update.

When DPLL_USB_OTG_SS enters a relock sequence, CLKDCOLDO is pulled low. FREQLOCK and PHASELOCK status signals are also low. CLKDCOLDO output clock is activated after the FREQLOCK or PHASELOCK signal goes high, depending on the selected locking criteria.

The DPLLCTRL_USB_OTG_SS.PLL_GOUSB3PHY_PLL_GO[0] PLL_GO bit can be used by software to monitor if DPLLCTRL locking process is still pending (PLL_GO = 0b1).

26.2.4.3.6.3 USB3_PHY DPLL Locked Mode

When DPLL_USB_OTG_SS finishes calibration and lock sequences it enters a locked state. During the locked state, LOSSREF and BYPASSACK are deasserted, FREQLOCK or PHASELOCK is asserted.

DPLL lock event criteria (FREQLOCK or PHASELOCK) is software-selectable through the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL bit field.

The DPLL signalizes the locked state to DPLLCTRL_USB_OTG_SS, USB_OTG_SS core controller, and USB3_PHY through assertion of the DPLL_LOCK signal, which reflects the internal lock loop status. The user software can monitor the DPLL locked event in the DPLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit, which is active high.

26.2.4.3.6.4 USB3_PHY DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_USB_OTG_SS.

DPLL_USB_OTG_SS supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the DPLLCTRL_USB_OTG_SS.DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE bit to 0x1. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and the DCO oscillator.

In idle-bypass low-power mode, the PHASELOCK and FREQLOCK output signals are asserted low and CLKDCOLDO goes low. Also, the internal reference clock REFCLK = CLKINP/N + 1 is gated inside the DPLL digital control logic to save power.

In the functional mode, the DPLL_USB_OTG_SS.TICOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal DCO oscillator. The internal DCO oscillator is powered down in idle-bypass mode or during period from SYSRESETN 0->1 to module initialization. The DCO oscillator exits power-down (TICOPWDN goes low) whenever the module internally tries to lock/relock after initialization or exiting idle-bypass mode.

In the functional mode, DPLL_USB_OTG_SS.LDOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal LDO. LDOPWDN goes high as soon as the internal LDO is powered down. LDOPWDN goes low after the LDO output voltage is stable. The internal LDO is powered down in the period from SYSRESETN 0 → 1 to module initialization or when entering into idle-bypass mode. LDOPWDN is cleared whenever the module internally tries to lock/relock after initialization or exiting idle-bypass mode after the internal LDO output voltage has stabilized.

The DCO and LDO power ON and OFF states are reflected within the read-only DPLLCTRL_USB_OTG_SS.PLL_STATUS[16] PLL_TICOPWDN and DPLLCTRL_USB_OTG_SS.PLL_STATUS[15] LDOPWDN monitor bits.

To exit idle-bypass mode and restore clock generation, the user should write DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE to 0x0, which deasserts the IDLE signal, and DPLL_USB_OTG_SS automatically enters a relock sequence. CLKDCOLDO output clock is activated after the FREQLOCK or the PHASELOCK signal goes high, depending on selected locking criteria.

26.2.4.3.6.5 USB3_PHY DPLL MN-Bypass Mode

The MN-bypass mode will be activated if REGM = 0 or 1 is loaded into the module on the rising edge of TENABLE. TINITZ also should be pulsed to enter MN-bypass mode. The module enters a low-power mode by gating all its internal clocks (REFCLK) and powering down internal LDO (LDOPWDN = 1) and DCO (DCOPWDN = 1). CLKDCOLDO remains gated (low) during this mode.

Note

When the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field is updated to 0x0 or 0x1, the CLKDCOLDO is gated.

26.2.4.3.6.6 USB3_PHY DPLL Error Conditions

The PLL lock and recalibration signals can be monitored to detect the loss-of-lock condition and the DPLL requirement to recalibrate (caused by a large temperature change since the last lock request):

- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[2] PLL_RECAL bit informs whether the DPLL_USB_OTG_SS must be recalibrated.

The PLL reference clock (CLKINP) loss status and PLL-in-high-jitter condition can also be monitored:

- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit gives the USB3_PHY PLL lock state.
- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[3] PLL_LOSSREF bit informs whether the DPLLCTRL_USB_OTG_SS has lost the reference clock.
- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[5] PLL_HIGHJITTER bit informs whether the PLL has entered a high-jitter condition.

26.2.4.3.7 USB3_PHY PLL Controller Functions

26.2.4.3.7.1 USB3_PHY PLL Controller Register Access

The configuration registers are accessed through the OCP2SCP1 L4 adapter register space using the SCP interface of the DPLLCTRL_USB_OTG_SS. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

Note

Because the USB3_PHY directly provides parallel data interface clocks RX_CLK and TX_CLK to the USB1 MAC controller, the DPLLCTRL_USB_OTG_SS and DPLL_USB_OTG_SS must be configured before any data transfer between the USB1 controller MAC layer and an external USB3 device.

26.2.4.3.7.2

26.2.4.3.7.3 USB3_PHY DPLL Clock Programming Sequence

The DPLL_USB_OTG_SS factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

- REGM factor is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- Fractional part of REGM factor is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field.
- REGN factor is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- DCO frequency range is set in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field.
  - PLL_SELFREQDCO should be set to 0x2 if 750 MHz < CLKDCOLDO [MHz] < 1500 MHz.
  - PLL_SELFREQDCO should be set to 0x4 if 1250 MHz < CLKDCOLDO [MHz] < 2500 MHz.
- SD divider is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD bit field. The DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO register bit field should be programmed depending on the value of CLKDCOLDO = CLKINP × M/(N + 1).

Figure 26-14 shows the formulae and programming sequence.

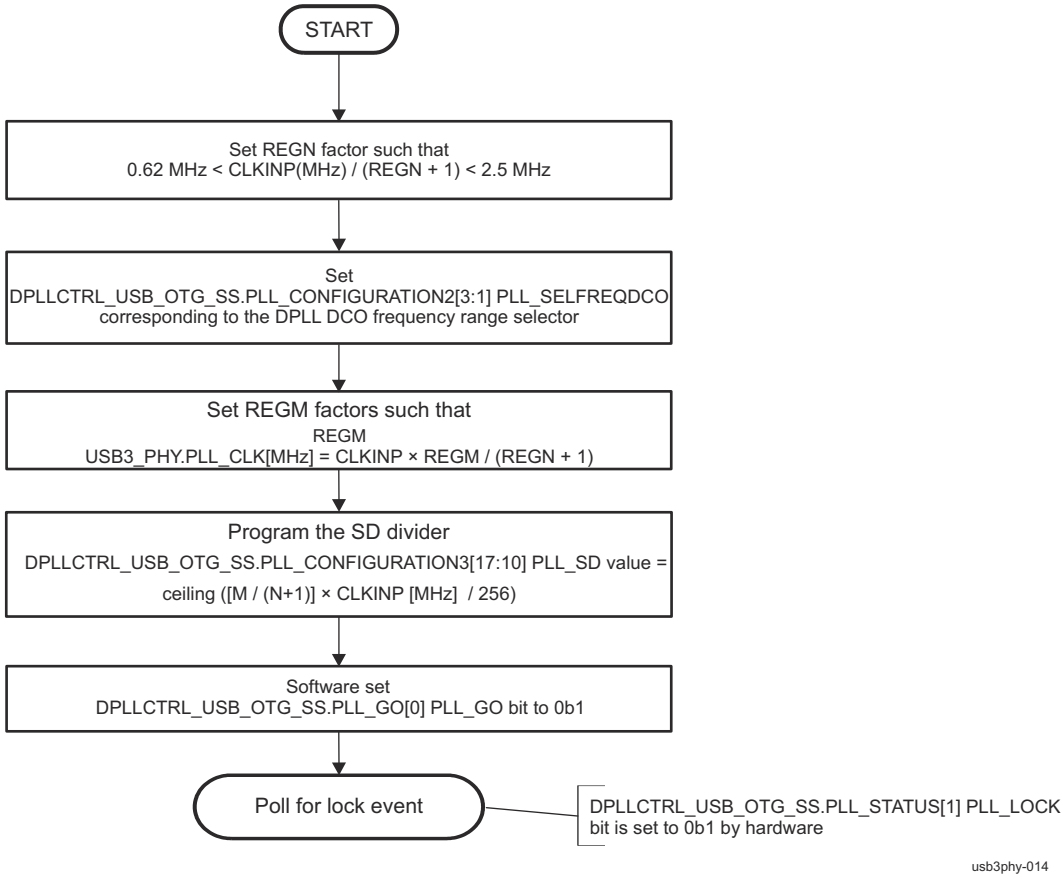

Figure 26-14. USB3_PHY PLL Programming Sequence

Note

- The equation for USB3_PHY_TX/USB3_PHY_RX (MHz) applies to the CLKDCOLDO of the DPLL_USB_OTG_SS.
- CLKDCOLDO output frequency of the DPLL_USB_OTG_SS should be programmed to 2.5 GHz, for the super-speed USB (5 Gbps) mode.

Table 26-14 summarizes the registers for the DPLLCTRL_USB_OTG_SS programming sequence.

Table 26-14. Register Call Summary for USB3_PHY PLL Programming Sequence

Register Name	Register Name	Register Name	Register Name
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2	DPLLCTRL_USB_OTG_SS.PLL_GO	DPLLCTRL_USB_OTG_SS.PLL_STATUS	DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3

26.2.4.3.7.4 USB3_PHY DPLL Recommended Values

Table 26-15 lists the DPLL_USB_OTG_SS recommended values.

Table 26-15. Recommended Programming Values

Field Name	Value	Description
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM	See (1).	Feedback clock divider
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN	See (1).	Reference clock divider

Table 26-15. Recommended Programming Values (continued)

Field Name	Value	Description
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL	0x-	Criteria to lock the PLL
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO	See (1).	Program based on the PLL choice and lock frequency.
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE	0	PLL active
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD	See (1).	Ceiling { [PLL_REGM/(PLL_REGN+1)] × CLKINP(MHz)/256 }
DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO	0x1	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.

(1) The value of the bit field must be set according to the desired clock frequency.

26.2.5 USB3_PHY Subsystem Low-Level Programming Model

The low-level programming sequence to set up the USB3_PHY subsystem for USB superspeed I/O operations is summarized in the Table 26-16

Table 26-16. USB3_PHY Subsystem Low-Level Programming Sequence

Step	Description	Comment
1.	Set the startup low performance OPP in the appropriate PRCM registers.	For more information regarding demanded OPP, see the device *Data Manual*.
2.	Enable the PRCM.USB_OTG_SS_REF_CLK.	See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
3.	Enable the PRCM.L3INIT_L4_GICLK to enable the OCP2SCP1 interface adapter operation.	See *Clock Domain Module Attributes*, in *Power, Reset, and Clock Management*.
4.	Software reset the OCP2SCP1 and poll until soft reset completion is indicated in status.	See Section 26.2.4.1.
5.	Set up division ratio between the OCP clock (PRCM.L3INIT_L4_GICLK) and SCP clock to supply the serial configuration register domains of the DPLLCTRL_USB_OTG_SS .	See Section 26.2.4.1.
6.	Set up necessary SYNC1 and SYNC2 timings to ensure no blocking of transactions over the SCP bus.	See Section 26.2.4.1. After this step, the user is ready to access the DPLLCTRL_USB_OTG_SS registers.
7.	Configure DPLL_USB_OTG_SS to generate frequency (CLKDCOLDO) = 2.5 GHz.	See Section 26.2.4.3.7.3.
8.	Software-assert the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit to 0x1	Start the DPLL lock with desired parameters.
9.	Poll the DPLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit until it reads 1.	DPLL locked event
10.	Perform a USB3_PHY tuning required for the Super-Speed OTG USB i/f operation	Follow steps described in Table 26-17, *USB3_PHY Tuning Table*.
11.	Set USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x1	Software reset the USB3_PHY over USB OTG SS controller PIPE port. Note that this reset does not impact settings made in step 10.
12.	Software-trigger the USB3_PHY_TX power-up sequence.	For more details, see Section 26.2.4.2.3.1.
13.	Software-trigger the USB3_PHY_RX power-up sequence.	For more details, see Section 26.2.4.2.3.1.
14.	Clear USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x0	Deassert the software reset bit after power-up sequence completion is indicated

Table 26-17. USB3_PHY Tuning Table

Physical address(2) [bits to modify]	Preferred value setting(1)
0x4A08 440C [31:27]	0b10000
0x4A08 440C [17:14]	0b1010

Table 26-17. USB3_PHY Tuning Table (continued)

Physical address[2] [bits to modify]	Preferred value setting[1]
0x4A08 4428 [23:11]	0b1110001100110
0x4A08 4428 [28:26]	0b001
0x4A08 440C [6:5]	0b00
0x4A08 441C [31:30]	0b10
0x4A08 4424 [31:30]	0b11
0x4A08 4438 [10:7]	0b1001
0x4A08 4438 [2]	0b0

(1) These are the preferred settings of USB3_PHY, in case that USB3_PHY PLL_CLK=2.5 GHz.
(2) Accesses to these locations have to be done in 32-bits only. User must not modify USB3_PHY bits different than those described in Table 26-17.

26.3 USB3 PHY and SATA PHY Register Manual

This chapter summarizes and describes the registers for USB3 PHY and SATA PHY subsystems.

26.3.1 USB3 PHY and SATA PHY Instance Summary

Note

For OCP2SCP1 registers, please refer to Section 26.4.6 , *PCIe PHY Subsystem Register Manual*.

Table 26-18. USB3 PHY and SATA PHY Instance Summary

Module Name	Module Base Address	Size
USB3_PHY_RX	0x4A08 4400	128 bytes
USB3_PHY_TX	0x4A08 4800	100 bytes
DPLLCTRL_USB_OTG_SS	0x4A08 4C00	64 bytes
DPLLCTRL_SATA	0x4A09 6800	64 bytes

Note

SATA is not supported on the AM570x family of devices.
